Individual Characteristics as Predictors of Verdicts

An abundance of research has been conducted on the relationship between individual juror characteristics and jurors' verdict preferences. Research generally suggests that there is no single set of personality or demographic predictors that can be used for all types of cases. Unfortunately, those characteristics that are the most visible, such as gender and race, tend to be weakly correlated with verdict across cases. Although these characteristics are not good predictors in general, race and gender may be good predictors in specific types of cases in which these racial and gender issues are salient. For example, although juror gender is important when gender is an issue in the trial, such as in rape or sexual harassment cases, gender is not a stable predictor of verdicts in other types of cases. There is also evidence that personality characteristics such as authoritarianism, liberalism, and the need for social approval affect juror decisions. For example, jurors who score high on measures of authoritarianism are more conviction prone. It is arguable that group membership and political beliefs may have a greater influence on verdict judgments than race or gender because, unlike gender and race, people choose their affiliations. Jurors are affected by their cultural backgrounds, prior

experiences, and personal affiliations. These factors influence the manner in which they understand and judge the details of the case. Social psychological research on in-group/out-group bias suggests that jurors may have an inclination to judge a witness who is similar to them as more credible and reliable than a witness who is dissimilar to them. However, research on the black sheep effect indicates that jurors may perceive in-group members more negatively than out-group members when the in-group member has committed a transgression. Therefore, the nature of the interaction between jurors' group memberships and the defendant and witnesses' group memberships will depend on the context of the particular case.

Although demographic and personality variables are not stable predictors of verdict judgments across cases, research suggests that case-relevant attitudes, such as death penalty attitudes or attitudes about business, predict verdicts. Studies on death penalty attitudes indicate that those who are pro–death penalty are more likely to render a guilty verdict than those who are against the death penalty. Finally, some research indicates that attitudes toward business and tort reform predict verdicts and awards in civil cases.

Efficacy of Jury Selection

A number of mock jury studies and field studies have been conducted to investigate the influence of jury selection strategies on jury verdict. In general, the research in this area indicates that the evidence accounts for the greatest amount of variance in juror verdicts, and that juror's individual characteristics account only for approximately 5–15% of the variance. However, in cases such as capital cases where defendants have a possibility of receiving the death penalty, it can be argued that factors influencing this small percentage of variance become very important to study. Research has also demonstrated that case-relevant attitudes, such as attitudes toward the death penalty or attitudes toward the insanity defense, are better predictors of verdicts than general attitudes or demographic characteristics.

Investigating the utility of scientific jury selection is often done using mock jury simulations. Critics of this method argue that mock jury studies provide little practical utility for real jury selection because it is virtually impossible to replicate every aspect of a trial. Because participants know that their decisions in a study have no impact on a defendant in a real case, they may find it easier to render a guilty verdict because there are no real consequences for doing so.

Jury selection research has not conclusively established the superiority of one technique over another, in part because research in this area is difficult. To demonstrate that scientific jury selection is efficacious, it is necessary to establish its superiority over traditional jury selection and the random selection of jurors. However, some research suggests that traditional jury selection may result in a jury with attitudes similar to a jury composed of the first 12 jurors to be considered for the jury or a jury that is randomly selected from the jury pool. Nevertheless, instead of trying to identify which approach is more useful, it may be possible that a combination of an attorney's experience and a trial consultant's advanced research methodology would prove to be the most effective approach. Because the role of the jury is an integral part of the legal system, the process of selecting the jury is important and needs further empirical evaluation.

Jury Size and Decision Rule

Both the size of the jury and the number of jurors who must be in agreement for a verdict to be concluded (the group's "social decision rule") have been the subject of litigation at the U.S. Supreme Court as well as

a subject of research by psychologists and other social and behavioral scientists. The number of jurors and the minimum proportion of them who must be in agreement are set by formal legal rules (e.g., state statutes, federal rules of civil procedure), and those rules are in turn subject to constitutional requirements. The Supreme Court has framed its analysis of jury size and decision rule questions in terms of the effects of those variables on jury behavior. Thus, the findings of research on group decision making as a function of group size and social decision rule are of central relevance to the Court's constitutional analysis. Yet a considerable tension exists between the Court's conclusions and the empirical findings.

Jury Size

For 600 years of common-law history and 200 years of American constitutional history, the jury was considered to have 12 members. But several states and federal districts in the United States began to use smaller juries, and in the 1970s, challenges to the use of juries with fewer than 12 members reached the U.S. Supreme Court. The Court analyzed the constitutionality of smaller juries by rejecting the guidance of history, tradition, and its own precedents. Instead, the Court reasoned that because the size of the jury was not specified in the Constitution and the framers' intentions regarding jury size could not be divined, the answer would have to be found through a "functional" analysis of the jury's purpose: If smaller juries did not behave differently from juries of 12, then they were their functional equivalent and therefore were constitutional.

In a series of cases—*Williams v. Florida* (1970) (state criminal juries of 6), *Colgrove v. Battin* (1973) (federal civil juries of less than 12), and *Ballew v. Georgia* (1978) (state criminal juries numbering 5)—the Supreme Court held smaller juries to be constitutionally permissible because it found no important differences between 6- and 12-member juries in the reliability of their fact finding, the quality or quantity of their deliberation, their cross-sectional representation of the community, the ability of jurors in the minority to resist the social pressure to conform, or their verdicts. These findings were reached through a combination of judicial intuition, misconstruing nonstudies as empirical studies, misreading the findings of actual empirical studies, and failing to see elementary flaws in actual empirical studies.

What the empirical research findings actually indicate is that smaller groups foster behavior that is beneficial in some respects, but in view of the purposes for which juries are employed, most of the advantages appear to favor keeping juries at 12. On the positive side, in smaller juries, members share more equally in the discussion, find the deliberations more satisfying, and are more cohesive.

A meta-analysis of studies specifically of juries (both simulated and actual) found that larger juries are more likely than smaller juries to contain members of minority groups, deliberate longer, hang more often, and recall trial testimony more accurately. Turning to studies of small-group behavior generally, one finds that larger groups tend to discuss and debate more vigorously, collectively recall more information, and make more consistent and predictable decisions. The latter finding means that as juries grow smaller, they will tend in criminal cases to make more errors of acquitting the guilty or convicting the innocent; and in civil cases, not only will the rate of erroneous verdicts rise, but juries will tend to render damage awards that are more variable and unpredictable. (Because such differences will be small, very large sample sizes would be necessary to detect them.) In accord with classic research on the psychology of conformity, because in larger groups there is greater likelihood that a dissenter will have at least one ally, a dissenter in larger juries will usually find an ally and therefore be better able to resist the pressure to submit to the majority.

In short, the *Williams* Court had scant support for its conclusion that "there is no discernible difference between the results reached by the two different-sized juries"; the little research evidence that existed then and most of the evidence that developed later supported the opposite conclusion: that 6-person juries did behave differently from 12-person juries and most of those differences represented less-desirable decision-making processes.

In the *Ballew* case, the Supreme Court drew the line, holding juries of 6 to be the constitutional minimum. Justice Harry Blackmun's opinion announcing the judgment of the Court extensively reviewed the empirical research on the subject, much of it having been prompted by the *Williams* decision. Curiously, although the research summarized in the opinion mostly compared 6- and 12-person juries and indicated that the former did not perform as well as the latter, the Court did not reverse its earlier holdings. Instead, it reaffirmed the earlier decisions finding

equivalence between large and small juries, but it now held that juries smaller than 6 were unconstitutional because, in Justice Blackmun's opinion, the studies raised serious concerns about the performance of juries of fewer than 6 members.

The research findings have been recognized in other legal settings. The Standing Committee on Federal Civil Rules recommended 12-person juries for federal civil trials (a recommendation not adopted by the Judicial Conference). During the administration of President Reagan, the Department of Health and Human Services promulgated a model medical malpractice statute for the states that specified 12-person juries (specifically for their greater predictability). And the New Hampshire Supreme Court—citing the factual findings of *Ballew* but rejecting its legal holding—ruled that a reduction in jury size below 12 would violate the New Hampshire State Constitution (which similarly did not specify a jury size).

Social Decision Rule

From the 14th century in England until the latter part of the 20th century, juries had been required to reach unanimous verdicts. Several American states began to permit quorum verdicts, and in the 1970s, challenges to the constitutionality of quorum verdicts came before the U.S. Supreme Court.

The principal motivation for eliminating the unanimity rule seems to have been a desire to reduce the incidence of hung juries. Without quorum verdicts, hung juries occur at a national rate of about 5% or 6%, and allowing quorum verdicts reduces that rate by a few percentage points.

In *Apodaca v. Oregon* (1972) and *Johnson v. Louisiana* (1972), the Supreme Court held verdicts split as widely as 9:3 to be constitutional, and in *Burch v. Louisiana* (1979), the Court held that the verdicts of 6-person juries had to be unanimous. The Court's reasoning was much the same as in the jury-size cases: As to the social decision rule for a jury verdict, the Constitution does not say and the intentions of the framers are unknown, so the "inquiry must focus upon the function served by the jury in contemporary society."

The main issues about group behavior that were debated in the Court's functional analysis were whether juries required to reach only quorum decisions would pay less attention to the arguments of the unneeded minority, whether the jury's verdicts would be less accurate, and whether the weight of evidence sufficient to produce a conviction would be reduced. The last of those questions is an especially interesting one. The standard or proof (preponderance, beyond a reasonable doubt) is directed at individual jurors, seemingly separate from the issue of the rules for combining individual views into a group decision. But the two together will surely have a bearing on the group's collective confidence in their verdict and on the quantum of proof needed to lift the jury over those several individual-to-group decision thresholds to a verdict.

The Supreme Court's opinions assert that jurors will not behave differently when a nonunanimous decision rule is in place—at least not when the jury numbers 12—or not differently enough to matter. Less research has been done on social decision rules than on group sizes, but what research has been conducted does not generally support the Court's majority.

Compared with unanimous rule juries, juries operating under a nonunanimous decision rule deliberate for a shorter time, do not let dissenters have sufficient say so as to change the minimum consensus once it is achieved (while in unanimous rule juries, jurors in the minority participate disproportionately in the deliberation), are more vote oriented and less evidence oriented, are less certain of the defendant's guilt when convicting, and are less likely to end in a deadlock. In research on group decision making generally, groups required to reach unanimous decisions are found to be more likely to reach correct solutions (on problems with clear right/wrong answers) than groups working with less-demanding social decision rules.

Notwithstanding the Supreme Court's rulings permitting nonunanimous verdicts under the federal Constitution, the great majority of states continue to require unanimous verdicts in felony trials, and all do in capital murder trials.

Jury Understanding of Judges' Instructions in Capital Cases

Research has shown that jurors in many types of cases frequently fail to understand the jury instructions they receive. However, this failure to understand has special implications in capital, or death penalty, cases. As in other cases, juror comprehension of instructions in death penalty cases is very low, and the difficulty of some of the terms and concepts used in the death penalty context exacerbates their confusion. But this misunderstanding carries with it an additional set of consequences in capital cases. Not only will jurors who misunderstand a judge's instructions in a death penalty case have difficulty in applying the law accurately, but these jurors may also be more easily influenced by bias or prejudice in their decision-making process and may be more likely to vote for a sentence of death.

Guided Discretion

In 1972, in *Furman v. Georgia*, when the Supreme Court held that the death penalty was unconstitutional, it based its decision in part on the fact that the jury's decision-making processes in capital cases at the time seemed "arbitrary" and "capricious." When the Supreme Court approved new death penalty laws 4 years later, in *Gregg v. Georgia* and several other cases, it was because the Court felt that the new laws provided jurors with a framework intended to guide their decision-making process, guaranteeing that the jury's discretion was controlled or channeled. Because this sort of guided discretion (communicated to the jury through jury instructions) was central to the Court's decision to bring back the death penalty in the United States, it is important that jurors in capital cases actually understand the jury instructions intended to provide that guidance.

Several components of death penalty cases make the jurors, the trials, and the jury instructions in those trials unique. During the jury selection process, for example, the death qualification process eliminates from service those potential jurors who have such strong views about the death penalty that those views might affect their ability to make an unbiased decision in an individual case. In addition, a capital trial is frequently divided into two phases: a "guilt phase," in which jurors are asked to decide if the defendant is guilty or not guilty, followed by a "penalty phase" if the defendant was found guilty during the first phase. In the penalty phase, the same jurors are asked to decide whether a defendant should be sentenced to life in prison without the possibility of parole or to death.

Penalty Phase Instructions

A significant amount of research has focused on the jury instructions used in the penalty phase of capital trials. This research has focused on several concepts that are central to the penalty phase and the structure approved by the Supreme Court. First, the term *aggravating circumstances* is used in death penalty cases to describe the evidence that suggests that the defendant should receive a death sentence. This evidence is usually presented by the prosecution. Aggravating evidence includes those aspects about the crime or the defendant that, if true, should encourage jurors to vote for the death penalty. Aggravating factors are frequently limited to those listed in state statutes and can include things such as prior felony convictions or the circumstances of the crime in question. The term *mitigating circumstances*, on the other hand, describes the evidence to be considered by jurors that weighs in favor of a life sentence. Mitigating evidence is information about the crime, the defendant, or his or her life circumstances that, if true, should encourage a life sentence. Sometimes, specific examples of mitigation are included in jury instructions (e.g., the age or mental capacity of the defendant or social history), but mitigating evidence is not limited by law. The Supreme Court has said that jurors in death penalty cases should be able to consider any and all mitigating circumstances. As a result, death penalty statues frequently include a "catch all" category to let jurors

know that mitigating evidence can include anything they believe should weigh in favor of a life sentence.

Both aggravating evidence and mitigating evidence are presented during the penalty phase of a capital trial, to inform the jury's life and death decision. Although most jury instructions refer to these terms, many instructions do not provide definitions of the terms for jurors. Similarly, some states provide a list of "factors" that can be considered in the penalty phase but do not indicate whether the individual factors should be considered as aggravating or mitigating. In most jurisdictions, jurors are instructed to "weigh" aggravating and mitigating evidence in order to decide on the appropriate punishment. However, no specific formula for this weighing process or information about how it should take place is provided to jurors.

Juror Confusion

Evidence from mock jury studies, case studies, and interviews with actual jurors in death penalty cases shows that jurors have a great amount of trouble understanding these terms and applying the concepts. In some studies, jurors understood less than half the instructions they heard. This confusion extends beyond a failure to understand the words used; it also affects the ability of jurors to identify whether particular types of evidence should be used in favor of a life sentence or a death sentence and their ability to weigh the evidence presented in a legally appropriate manner. For example, studies have shown that many jurors believe that they are required to impose a sentence of death in certain situations, when in fact a death sentence is never required by law.

Many possible explanations for this confusion have been advanced. For example, some explanations focus on the use of confusing, passive language and the excessive use of jargon in the instructions. Others have suggested that jurors may become confused because they hold incorrect assumptions about crime and punishment at the time of the trial and these assumptions prevent them from understanding the accurate legal meanings of terms and instructions.

It is significant to note that in addition to the general lack of comprehension of instructions in the penalty phase of capital cases, the confusion does not seem to be evenly distributed, or to have a neutral impact. Although jurors have trouble with all these concepts, they seem to have more trouble understanding the concept of mitigating (the evidence that should be used in support of a life sentence) than aggravating circumstances. There are several possible explanations for this confusion. For example, in cases where the terms are not defined, jurors may rely on their personal knowledge of the terms. Because *aggravating* is a term we use more often than *mitigating* in our daily lives, it may be more familiar to jurors. No matter what the reason, this confusion means that sometimes jurors may not recognize mitigating evidence as being relevant to their decision. At other times, jurors may mistake mitigating evidence as being aggravating instead and use it against the defendant (to vote for death) rather than in his or her favor (by sparing the defendant's life). This sort of error, a direct result of juror confusion, can have significant consequences for the accuracy of the decision-making process and for the defendant's future.

Jury Decision Making

This lack of comprehension affects the jury decision-making process in capital cases in both direct and indirect ways. For example, as described above, research suggests that the skewed nature of the confusion may bias jurors toward death, rather than life, sentences, although the specific impact of juror comprehension on verdict choice is currently unclear. There is also some concern that this bias toward the death penalty embedded within the jury instructions works in combination with several other aspects of the capital-sentencing structure (including the use of two phases with the same jury for both and the death qualification process) to make death verdicts even more likely.

In addition to the direct impacts of juror confusion on verdict choice, research shows that jurors who are confused by the instructions will rely instead on the things they know and understand—if jurors do not understand the judge's instructions, they are more likely to make their decisions based on their personal schemas and stereotypes. While a juror with a good understanding of the instructions is likely to base his or her decision on the relevant evidence and adhere to the weighing process in a legally appropriate way, the confused juror's reliance on stereotypes allows for bias and prejudice to enter the decision-making process. Research has shown, for example, that mock jurors with lower comprehension levels are more likely to sentence a Black defendant to death than those with higher comprehension levels. In addition,

mock jurors with lower comprehension levels find mitigating evidence to be more persuasive in the case of a White defendant than in the case of a Black defendant. Mock jurors with high comprehension levels do not exhibit the same discriminatory behaviors.

Finally, above and beyond the impact of low comprehension on juror verdict choices, it is clear that jurors—citizens who are being called away from their everyday lives and asked to make a very difficult decision—experience frustration with the instructions themselves, and many feel confused and upset during the decision-making process.

Improving Comprehension

Despite the limitations of the capital-sentencing instructions being used today, several studies have demonstrated that it is possible to improve comprehension levels using a variety of techniques. For example, several studies using psycholinguistic improvements designed to simplify and clarify the language in the penalty phase instructions have shown improved comprehension levels in jurors. Similarly, researchers have experimented with penalty phase instructions that incorporate case-specific details, instructions that include definitions of the terms *aggravating* and *mitigating*, enhancements designed to improve both the declarative and the procedural knowledge of jurors, and other innovations, all of which have been successful in improving jurors' comprehension of penalty phase instructions to some degree.

Although there is a significant body of social scientific evidence documenting the limitations of juror comprehension in capital cases, and providing techniques and suggestions for improvement, juror comprehension of capital penalty phase instructions continues to represent an area of tension between psychology and the law. The Supreme Court has consistently upheld the death sentences of defendants challenging the instructions used in their trials, reasoning that there is a presumption that the jury both uses and understands the instructions provided in any case.

Juvenile Boot Camps

Correctional programs designed to be similar to military basic training are called "boot camps." Although there are some programs for youths at risk of delinquency, these vary widely, and most juvenile boot camps are designed for children adjudicated as delinquent. This entry describes the program and operations of typical boot camps for adjudicated youths, reviews the development of correctional boot camps, and examines how they have changed over time. It then discusses controversies concerning the risks and benefits of boot camps, including the issue of net widening, and reviews research on their effectiveness.

Most boot camps for adjudicated juveniles require that they serve 3 to 6 months in a boot-camp-type facility. The programs resemble those of military boot camps; for example, staff are usually called drill instructors, and staff and juveniles wear military-type uniforms. Youths must say "Yes, sir" or "Yes, ma'am" in response to staff, and they cannot speak unless spoken

to or given permission to speak. There is a rigorous daily schedule of activities. Strict rules govern all facets of the juveniles' activities and comportment. They are required to respond immediately to staff commands. Rule violations are punished immediately, referred to as summary punishments, often with some physical activity (e.g., pushups, running laps). If they do not comply with the rules of the program, the juveniles may be required to serve a longer period of time in another type of juvenile detention facility.

A Day in a Boot Camp

On a typical day in a boot camp, participants arise before dawn, dress quickly, and march in cadence to an exercise area, where they do calisthenics and other physical exercise. They return to their dormitory for quick showers and then march to the dining hall for breakfast. After breakfast, they may practice drill and ceremony until they march to their classrooms for the required educational activities. Later in the day, they may have other classroom activities such as cognitive skills training or drug treatment. Before dinner, they may again be required to practice drill and ceremony or participate in additional physical exercise. Evenings may include additional therapeutic programming or required homework. They are not permitted to watch television unless it is an educational program, nor do they have access to radios, other musical devices, or computer games.

Strict rules exist at mealtimes. Participants are required to stand at parade rest when the serving line is not moving and execute crisp military movements and turns when the line does move. They are often required to approach the table and stand at attention until ordered to sit and eat. Frequently, they must eat without conversation.

The Development of Correctional Boot Camps

Boot camps began in the adult correctional systems of Georgia and Oklahoma in the early 1980s. By the early 1990s, there were more than 21 programs for adults in 14 state correctional systems. Juvenile boot camps developed in the late 1980s. By the mid-1990s, approximately 35 juvenile boot camps were operating. The number of camps keeps varying because some of the old camps have closed down while other new camps have opened.

Several factors account for the rapid growth of correctional boot camps. One important influence was the conservative political climate of the 1980s. Politicians felt the need to be tough on crime. Many sanctions appeared to be "soft" on the criminal. Boot camps were a different story. Boot camps appealed to the "gut instincts" of a public that wanted criminals punished swiftly and harshly in a place where they were required to respect authority and obey rules.

Another important factor influencing the rapid development of the camps was the media. Boot camps provided powerful visual images of juveniles snapping to attention in response to staff members. The tough drill sergeant yelling at the young street thug made great television for a public that wanted to get tough responses to crime. It was ideal for the 60-second feature in the evening news.

Differences in Boot Camps

Juvenile boot camps have changed dramatically over time. The biggest change was in the move away from an emphasis on the basic training model. The first boot camps emphasized the basic military training with strict rules and discipline, physical training, and hard labor. Later, the camps began to emphasize other aspects such as education, leadership training, drug treatment, or cognitive skills. In fact, many of the camps no longer referred to themselves as "boot camps." They used a variety of other names for the programs, such as leadership academy, leadership development, highly structured program for juveniles, or challenge program. While these programs still had strict rules and discipline, physical training, and drill and ceremony, they placed a greater focus on leadership, education, and other therapeutic activities.

Camps differ greatly in the amount of time devoted to different activities. Some still emphasize basic training, and the juveniles spend a great deal of time in physical training and drill and ceremony. Other camps focus on therapeutic activities such as drug treatment, cognitive skills training, vocational training, or education, and the daily schedule reflects this emphasis. Furthermore, the follow-up supervision and aftercare vary among camps. Some have a long-term aftercare program with therapeutic activities, other camps may have intensive supervision, and others may have little follow-up supervision or care. These differences depend, in part, on the philosophy of those who manage the programs or the correctional administrators

who oversee the programs. Money available for programming is also an important factor in determining the type of activities included in the boot camp; therapeutic programming and aftercare may greatly increase the cost of the program.

Controversies Over Juvenile Boot Camps

Boot camps have been controversial since they first opened. Advocates believe that the strict discipline and control in these camps is what these youths need. Many adults who have spent time in the military argue that this was a life-altering and positive experience for them, and camps can have the same impact on juvenile delinquents. Others point to the fact that the orderly environment and control help the youths focus on their problems and make positive changes in their lives. They believe that these undisciplined youths will prosper in an environment that requires them to obey and respect adults.

Critics of boot camps have other concerns. Correctional psychologists argue that the confrontational nature of the interactions do not reflect the type of supportive interpersonal interactions that are conducive to positive change. They maintain that 90 days of verbal abuse, push-ups, and marching cannot be expected to address the problems related to addiction, low educational attainment, or gang membership and other problems faced by these juveniles. In their opinion, boot camps do not include components that are associated with effective correctional treatment, such as therapeutically trained staff and individualized treatment. Furthermore, military training in the armed forces is followed up by 2 years or more of service that emphasizes the skills learned in basic training. Juvenile boot camps do not continue to give participants such long-term follow-up services and treatment.

The Problem of Net Widening

Boot camps appear to be a deceptively seductive alternative for youths with behavior problems. Thus, there is a good chance that low-risk juveniles may be sent to boot camps when they would otherwise have been given a community alternative such as probation. This essentially widens the net of control over juveniles. Net widening is viewed as a disadvantage because increased numbers of juveniles are incarcerated in facilities when there is little advantage in incarcerating them. There may be little risk that they will commit future delinquencies. Also, these low-risk youths may be negatively affected by the programs. From the perspectives of both costs and the impact on youths' lives, there may be little advantage in widening the net of control.

Dangers of the Boot Camp Environment

The rigorous physical activity, confrontational interactions, and summary punishments in boot camps carry with them the chance of abuse or injury. The environment is apt to be mentally and physically stressful for the participants. There have been several deaths in the juvenile camps, and law cases are pending regarding responsibility for the deaths. Many people question whether the dangers of the boot camp atmosphere outweigh any benefits of the programs. While physical activity can be healthy, some of the camps have been criticized for requiring activities that are beyond the health status of the participants (e.g., the required long-distance running for overweight juveniles). This is a particular concern if the staff has not had adequate training to be able to determine when juveniles are experiencing extreme mental or physical stress.

Do Juvenile Boot Camps Work?

The effectiveness of correctional programs can be measured in many ways. For example, boot camps may have an impact on the conditions of confinement. From this perspective, research may investigate whether boot camps are safer than other facilities or whether they increase positive changes such as increased educational attainment or decreased antisocial attitudes. Often the major interest of policymakers and the public is whether correctional programs reduce the recidivism or future criminal activities of participants.

There is some research examining the effectiveness of correctional boot camps in reducing recidivism. MacKenzie and her colleagues conducted a meta-analysis comparing the recidivism of boot camp participants with the recidivism of comparison groups. A meta-analysis is a statistical analysis that uses studies as the unit of analysis. The meta-analysis of boot camps included 44 different studies of adult and juvenile boot camps. The studies used different measures of recidivism, including rearrests, reconvictions, and reincarcerations. For each study, an effect size was

calculated. The effect size indicates whether recidivism was lower for the boot camp participants or the comparison group and how large this difference was. The researchers found that the recidivism rates of the participants and of the control group that did attend a boot camp were almost exactly the same. This was true for both the adult and the juvenile programs. Thus, from this research, it does not appear that juvenile boot camps are effective in reducing the later criminal activities of juvenile delinquents.

Some research has indicated that boot camps have a positive impact on participants' attitudes. In this research, the participants were found to have become less antisocial and develop better attitudes toward staff and programs. However, these results are not consistent. It may be that the results differ depending on the emphasis of the camp. Boot camps that emphasize therapeutic treatment may have a more positive impact on attitudes than camps that emphasize basic military training, consisting of physical training, drill and ceremony, and hard labor. We don't have enough research to clearly assess whether the camps have a positive impact on attitudes.

Another way the effectiveness of boot camps can be studied is to examine the cost of the programs. It is costly to build and operate facilities. If the boot camps widen the net by putting juveniles in facilities when they would otherwise have been in the community, there may be a substantial cost to the programs. On the other hand, if the camps reduce the amount of time juveniles spend in facilities, they could reduce costs. Most juvenile programs are relatively small, so the costs of the programs may not have a large impact on the jurisdictions operating them. This may be the reason why there is no research investigating the issue of the cost of juvenile boot camps.

The Future of Juvenile Boot Camps

Boot camps were a popular correctional approach that fit the philosophy of the conservative 1980s and 1990s. The programs appeared tough on crime and therefore answered politicians' needs to show that they supported tough programs. They answered the public's desire to punish juveniles instead of coddling them. The media liked them because they made good short news pieces for national television. But will they last? This is a question that many people are asking. There have been deaths of both staff and juveniles in the boot camps; as a result, people are beginning to question whether this is good correctional practice. Critics continue to advocate the elimination of the camps because they do not follow the principles of effective correctional practice. It is impossible to tell at this point whether boot camps will continue to operate. Given the disappointing results of the recidivism analyses, it appears that there is little reason to continue to operate the camps. Unless some additional justification for the camps is discovered, most likely there will be fewer and fewer juvenile boot camps in the future.

Juvenile Offenders

Interest in juvenile offenders has increased in the past few decades due to the large number of youths coming into contact with the law and the rising violent crime. Research by Howard Snyder and Melissa Sickmund provides extensive juvenile population and crime statistic data, and some of their pertinent information is summarized here to provide a rough picture of the characteristics of juvenile offenders in the United States. From 1989 to the mid-1990s, juvenile violent crime was on the rise, and it peaked in 1994. From 1994 to 2003, the juvenile crime rate decreased, with a particularly steep decline of 48% in the juvenile violent crime arrest rate. Juvenile offending remains a significant social problem, and subgroups

of juveniles engage in different levels of criminal behavior. Specifically, the arrest rate for female juveniles has increased over this 10-year period, while the juvenile male arrest rate has declined. Furthermore, while the violent crime arrest rate for Black youth has declined, it still is greater than the rate for any other racial group. Several environmental factors, social factors, and personal traits contribute to the persistence or desistance of juvenile delinquency. While different developmental trajectories for the progression of delinquency and different risk factors for male and female juveniles exist, juvenile offenders generally are at greater risk for mental health problems, less education, substance abuse problems, and low socioeconomic status.

Juvenile Population and Crime Statistics

In 2002, the juvenile population in the United States was nearing 73 million. Just over 2 million juveniles (i.e., under age 18) were arrested in 2003, but fortunately, over the 10-year period from 1994 to 2003, juvenile arrests declined by 18%. Property crimes (e.g., burglary and larceny), which accounted for 463,300 juvenile arrests in 2003, constituted the largest crime category, and violent crimes, such as murder, accounted for 92,300 juvenile arrests. The overall trend for very young offenders, but not for juvenile female offenders, mirrored that for juvenile offenders in general. In fact, the rate of offending for girls increased. Additionally, arrest rates differed by racial group but were similar to the overall pattern for juveniles.

Very Young Juvenile Offenders

Marked differences in the rate of offending across age exist, and there are also general trends in the extent to which very young people engage in antisocial conduct. Very young offenders are of particular concern because it is not expected that young children would be breaking laws. This phenomenon might also signal substantive problems with our parenting practices and broader problems with communities in that both may be less than effective in developing prosocial behavior in youth. Recent trends show that among very young juvenile offenders (10–12 years of age), the arrest rates for violent (+27%) and drug-related (+105%) crimes increased, while their overall arrest rate declined, from 1980 to 2003. Furthermore, for most offense types, more females were arrested than males in the 10- to 12-year age range. For example, the violent crime index for young juvenile female offenders increased by 135% between 1980 and 2003, while it increased only by 14% in the same time period for young juvenile male offenders. Very young juvenile offenders form a unique subgroup in that they are particularly at risk for substance use and gang affiliation.

Gender Trends

Taking into account the total number of arrests in 2003, the arrest rate for juvenile females was higher than that for juvenile males (20% vs. 15%). Additionally, from 1994 to 2003, the arrest rate for juvenile males declined by 22%, which is greater than the decrease in the juvenile female arrest rate (–3%) over this period. Additionally, the juvenile female arrest rate either increased more or decreased less than the juvenile male arrest rate for most offense types. For example, simple assault arrests increased by 1% for juvenile males and by 36% for juvenile females from 1994 to 2003. Juvenile females accounted for 29% of all juvenile arrests and were disproportionately arrested for prostitution (69%) and running away from home (59%). These findings indicate the importance of examining gender differences in juvenile offenders and that trends found with boys do not necessarily reflect what will occur with girls who are offending in the community and vice versa.

Race Trends

White juveniles accounted for 71% of all juvenile arrests in 2003, while Black youths were responsible for 27% of juvenile arrests. Sixteen percent of Black and of White arrests in 2003 were attributed to juveniles. However, Black juveniles, who represented only 16% of the juvenile population (ages 10–17), accounted for 63% of the arrests for robbery, 48% of murder arrests, and 40% of the arrests for motor vehicle theft. The proportion of juvenile arrests varied across offense type. For example, 9% of all arrests for murder involved juveniles, while 51% of all arrests for arson involved juveniles. The proportion of White and Black juvenile arrests also differed across offense types. Juveniles were responsible for a larger proportion of Black arrests than of White arrests for robbery (27%) and motor vehicle theft (33%), while the proportion of White arrests attributed to juveniles was

greater for arson (53%) and vandalism (41%). However, Black and White juveniles were both responsible for the same proportions (9%) of Black and White arrests for murder in 2003. Although there has been some discussion about the inequity in charges across race, it is difficult to determine the specific causes of these disparities.

Violent Crime Trend

As mentioned, the violent crime rate varied across years, with the late 1980s to early 1990s evidencing high rates of juvenile violent crime. The Violent Crime Index for juveniles was generally stable from 1980 to 1988, but by 1994, it had increased to 61%. By 2003, the Violent Crime Index for juvenile arrests had dropped below its level in the early 1980s. The juvenile male arrest rate, which was 8.3 times the rate for juvenile females in 1980, dropped to 4.2 times the female arrest rate in 2003. From 1988 to 1994, the increase in the arrest rate for juvenile females (98%) was larger than it was for juvenile males (56%). Additionally, the greater decline in the male than the female rate (51% vs. 32%) from 1994 to 2003 was largely responsible for the decline in the overall rate of juvenile violent crime. While some of these statistics are encouraging, there continue to be a large number of juvenile offenders.

Surprisingly, the murder arrest rate increased 110% from 1987 to 1993. For juvenile males, the arrest rate for murders increased 117% in this time period, which accounted for the overall rise in the juvenile murder arrest rate. The juvenile female arrest rate did not contribute to the overall increase because this rate increased only by 36% during this time period. In 2003, the murder arrest rate for both juvenile males (78%) and juvenile females (62%) declined the most since 1980 or earlier. The violent crime trend for several minority groups, including Black, Asian, and Native American, mirrored the trend for White juveniles, with each group's arrest rate peaking in 1994. The rate for Black juveniles declined the most, but their violent crime arrest rate was still higher than the rate for any other racial group in 2003. In 2003, the violent crime arrest rate for Black juveniles, which had decreased by 35%, was approximately four times the rate for White juveniles, which was the next highest rate (800 arrests vs. 200 arrests per 100,000 juveniles, respectively). The large number of youths who come into contact with the law, which affects their own personal mental health, ability to excel in school, and other aspects of life that could lead to well-being, has led researchers to attempt to better understand youths with conduct problems. This research has led to further efforts to understand juvenile offenders and, thus, further subtyping of juvenile offenders and of youths with conduct problems.

Developmental Pathways of Delinquent Behavior and Juvenile Offending

Childhood- Versus Adolescent-Onset Antisocial Behavior

According to Terrie Moffitt, childhood-onset or life-course-persistent antisocial behavior has a different developmental pathway from adolescent-onset antisocial behavior. Early-onset antisocial behavior is the result of a child's characteristics and a poor family and social environment. Traits increasing a child's risk of antisocial behavior include a difficult temperament, cognitive deficits, developmental motor delays, and hyperactivity. Environmental influences include weak or broken familial bonds, poverty, poor parenting, and strained relationships with teachers and peers. Childhood-onset antisocial behavior commonly persists into adulthood, and these children have much poorer prognoses than children with adolescent-onset behavior. Additionally, the life-course-persistent group of antisocial youth, which is much smaller than the adolescent-limited group, is responsible for a disproportionately large amount of crime. In contrast, adolescent-onset antisocial behavior is considered developmentally normal and occurs in otherwise healthy children. Adolescent-onset antisocial behavior is deemed normal because it is a means by which youths establish independence from their parents, and these children generally outgrow this behavior as they progress into young adulthood. However, desistance in adolescent-onset youths may be delayed if they encounter problems, such as addiction.

Triple-Pathway Model

Rolf Loeber and David Farrington identified three categories of troublesome behavior in children aged 7 to 12 years. These authors developed a triple-pathway model to explain the links between various pathways in the context of increasingly severe delinquency. First, children exhibiting disruptive behaviors, such as

aggression, should be considered at risk of becoming juvenile offenders because they frequently exhibited similar behaviors early in life. Approximately, one quarter to half of these children are at risk of progressing to delinquency. Next, low-level juvenile offenders commit less serious and generally nonviolent crimes (e.g., shoplifting), but these delinquent behaviors frequently serve as precursors to more serious crimes. Serious juvenile offenders, who have committed homicide, rape, or arson, are of greatest concern because they are responsible for 10% of all juvenile arrests. Additionally, this subset of offenders committed 2%, or 600, of the murders attributed to juveniles, and weapons were used in more than 50% of these murders. Furthermore, juveniles who had access to weapons began committing crimes at a younger age than those juveniles without access to weapons.

The development of delinquent behavior in boys has been shown to occur through three pathways—overt, covert, and authority conflict. Juveniles on the overt pathway initially engage in low levels of aggression but graduate to physical fighting and then violence. In contrast, the covert pathway is associated with the commission of minor acts of delinquency (e.g., shoplifting) before 15 years of age and progresses to property damage (e.g., fire setting) and then to moderately severe forms of delinquency (e.g., fraud). Finally, in juveniles under 12 years of age, the authority conflict pathway is characterized by defiant behavior at low levels and by avoidant behavior (e.g., running away) at the highest level. For these boys, higher levels of avoidant behaviors are associated with a greater risk of covert and overt delinquent behaviors. In all three pathways, as the severity of behaviors increases, the number of juveniles engaging in these behaviors decreases. Additionally, juvenile males with an earlier onset of delinquency are more likely to progress to the more severe behaviors within each pathway. Another trend in the development of delinquent behavior is the expansion of such behavior from the home to the community. However, normal levels of disruptive behavior are commonly seen in 2- and 3-year-old children and, therefore, must be distinguished from problematic levels. Two major indicators of future delinquency are developmentally inappropriate (i.e., elevated) levels of disruptive behaviors in terms of frequency and severity and the persistence of these behaviors beyond 3 years of age.

Gender Differences in Risk Factors for Developing Antisocial Behavior

Female and male juvenile offenders share many risk factors, including poor academic histories, living in high-crime neighborhoods, family dysfunction, and poverty. However, female juvenile offenders are more likely than male juvenile offenders to have experienced physical or sexual abuse. For girls, having at least one parent with a criminal record greatly increases the likelihood that they will be arrested by age 15.

While the overall juvenile female arrest rate exceeds the rate for juvenile males, young females are less likely than boys to possess the risk factors associated with the life-course-persistent trajectory of antisocial behavior. For example, female children exhibit fewer developmental motor delays, temperamental difficulties, and neuropsychological and cognitive problems, including learning and reading difficulties. As predicted, fewer females than males were classified as life-course-persistent, but their backgrounds were similar in that they shared several of the life-course-persistent risk factors. However, adolescence-onset antisocial girls are expected to be more numerous than their life-course-persistent counterparts because they are exposed to the same antisocial peers as are adolescent boys. Yet the opportunities to engage in antisocial behavior may be more limited for adolescent girls than for adolescent boys because girls are more likely to experience physical harm (e.g., sexual assault), which may reduce their involvement in delinquent behaviors.

Predictors of Desistance and Persistence

The initial commission of a criminal act by age 13 is associated with a 2 to 3 times greater risk of chronic, violent offending. Depending on environmental factors and personality or behavioral traits, criminal behavior in juveniles can be prolonged. The presence or absence of snares (e.g., delinquent peers) could respectively limit or promote desistance of criminal behavior in juveniles. For example, economically depressed neighborhoods have high rates of juvenile crime and violence, and they have more risk and fewer protective factors. Within neighborhoods, additional sources of influence include a youth's family and peers, and the interaction of these microsystems must be collectively considered to gain a more complete

understanding of juvenile delinquency. Additional environmental factors associated with juvenile offending include poverty, tenuous community bonds, minimal social control from other residents in the neighborhood, and low parental supervision. A consistent finding in juvenile delinquency research is that associating with a delinquent peer group is a strong predictor of serious, chronic offending. In contrast, protective factors include consistent discipline and positive, warm parental interactions.

Personality traits of juveniles also influence the frequency and severity of their committing delinquent or criminal acts. Callousness and impulsivity have both been linked to future juvenile delinquency. Low restraint (e.g., impulsivity) and high distress (e.g., anxiety) are associated with rearrest. However, high-restraint youth committed fewer but more severe crimes.

Callous and unemotional traits (e.g., lack of empathy) have consistently been linked to a subgroup of antisocial youth with particularly severe aggressive behavior. Furthermore, callous children also express a preference for arousing, dangerous stimuli and have lower levels of reactivity to threatening or emotionally upsetting stimuli.

Consequences of Juvenile Offending

Several consequences of juvenile offending exist, and they are particularly salient for juveniles with early-onset of delinquency. Early-onset juvenile offenders are more likely to continue engaging in delinquent behavior, and the repeated commission of such acts throughout childhood is also a factor in persistent delinquency. In other words, involvement in delinquency precludes juveniles from engaging in prosocial behaviors and is associated with low educational attainment, inadequate social skills, limited employment opportunities, low socioeconomic status, and, for males, early parenthood. These juveniles also have higher rates of externalizing behaviors (e.g., aggression), internalizing behaviors (e.g., depression), substance abuse, and suicide. The increased number and severity of mental health problems in juvenile offenders lead to their greater involvement with child welfare service, mental health providers, and the criminal justice system. Juvenile offenders and their victims have more psychological and occupational problems and, overall, a lower quality of life. Moreover, juvenile delinquents who develop into chronic offenders cost society $1.3 to 1.5 million. Because of the great impact juvenile offending has on the children involved in criminal activity and on society, further research into prevention and intervention needs to be conducted.

Juvenile Offenders, Risk Factors

Broadly defined, a risk factor for juvenile offending is any experience, circumstance, or personal characteristic that increases the probability that a given youth will commit a legal transgression. No single risk factor *causes* offending; many youths who have been exposed to various risk factors never commit a crime. Rather, juvenile offending typically emerges as a result of complex interactions among a wide variety of risk and protective factors that vary from child to child. Combined risk factors tend to exhibit additive effects, with the likelihood of offending increasing as the number of risk factors increases. Also, the impact of a given risk factor varies across the life course; some may have an effect only at a particular developmental stage. Attempts to mitigate possible risk factors must, therefore, take into account a youth's developmental status. The risk factors for different types of offending vary as well. Studies have found that juvenile offenders tend to

follow one of two possible patterns of offending. The majority exhibit *adolescence-limited* offending, which begins during adolescence and subsides during the transition to young adulthood. *Life-course-persistent* offenders, in contrast, tend to exhibit conduct problems early (prior to adolescence) and continue to offend into adulthood.

Risk factors for juvenile offending are numerous and wide-ranging. Some (such as gender) are unalterable. Others (such as neighborhood conditions or family dynamics), though changeable in theory, are systemic and difficult to control. Nevertheless, by understanding the wide range of risk factors for juvenile offending, prevention programs and treatments can be tailored to meet the unique needs of the various populations of youths they aim to help. The predominant factors can be grouped into three broad categories: individual characteristics, social influences, and community conditions. This entry describes well-established risk factors in these domains.

Individual Characteristics

Antisocial Behavior

One of the best predictors of future delinquency is a history of antisocial behavior in childhood. Adolescents who engage in antisocial behavior (e.g., theft, fighting, vandalism, fire setting, etc.) before puberty (prior to age 13) are more likely to be delinquent than those who have not engaged in these acts prior to puberty. Research also suggests that violent careers often begin with relatively minor forms of antisocial behavior that escalate over time. Those with an early arrest (before age 13) are more likely to become chronic offenders by age 18. Such chronic offenders make up a small percentage of the offending population but are responsible for the majority of serious violent crimes. In addition, youths whose delinquent careers begin early tend to engage in a broad range of antisocial behavior rather than specialize in a particular type of offending. Early childhood may thus be an important developmental period to target for the prevention of juvenile delinquency.

Substance Abuse

Chronic abuse of drugs and alcohol is a precursor to other dangerous behaviors, including criminal activity. Although some degree of experimentation with drugs and alcohol is not unusual during adolescence, excessive use is a risk factor for delinquency.

Cognitive Deficits

Cognitive deficits have also been implicated as a risk factor for delinquent behavior. Low intelligence quotient (IQ) scores, weak verbal abilities, learning disabilities, and difficulty with concentration or attention have all been associated with subsequent delinquent behavior. Social-cognitive development is especially important because it affects one's ability to learn social norms and expectations. For example, studies have shown that delinquent youths are more likely than their peers to think that other children's behavior is deliberately hostile, even when it is not. Though not conclusive, studies suggest that such cognitive deficits usually precede the development of delinquency and not vice versa.

Psychological Factors

Youths who are impulsive, hyperactive, and engage in risk-taking behaviors are more prone to delinquent acts than those who are not. In fact, self-control (or the lack thereof) has been suggested by some to be the root individual-level determinant of crime throughout the life course. Persons with low self-control lack diligence, find it difficult to delay gratification, have little tolerance for frustration, lack interest in long-term pursuits, and have little ability to resolve problems through verbal rather than physical means. While youths who react to new stimuli with anxiety or timidity tend to be less likely to commit antisocial acts, youths who approach new stimuli impulsively or aggressively tend to be more likely to offend. Interestingly, motor restlessness (fidgeting, or the inability to sit still) in kindergarten is a stronger predictor of delinquency between 10 and 13 years of age than low anxiety or a lack of prosocial behavior. In fact, children who become persistent offenders are more likely than their peers to suffer from attention-deficit/hyperactivity disorder (ADHD).

Brain Development

Neuropsychological deficits (often initially manifested as subtle cognitive deficits or a difficult temperament) have been linked to delinquency and chronic offending. Anatomical, chemical, and neurological

abnormalities are more prevalent among chronic criminal offenders and those exhibiting recurrent antisocial behavior than among the general population. These abnormalities may be caused by damage to a specific brain region (i.e., through injury) or by a variety of behavioral or environmental factors (e.g., poor nutrition, exposure to violence, substance abuse). For example, research has found that prenatal and perinatal complications have been associated with later antisocial behavior. Adolescence is a time of marked brain development in many regions, including areas implicated in various aspects of self-control. As such, neurological development during adolescence has a significant effect on emotion regulation. Researchers are actively investigating the complex interrelations among biological and psychological factors as correlates of conduct problems.

Social Influences

Family

Family structure, family characteristics, and family dynamics have all been connected to juvenile offending. The effect of family characteristics is most pronounced in early childhood. While some research has reported that children from single-parent households are at increased risk of delinquent behavior, these differences are often found to be negligible when differences in socioeconomic status are taken into account. Interestingly, family size has been connected to juvenile offending, with youths having more siblings being more likely to engage in delinquent behaviors. The most powerful family-level predictors of juvenile delinquency include lack of parental supervision, inconsistent discipline, and hostile or rejecting parenting styles. Also, children who witness or are victims of abuse in the home are at even greater risk of engaging in antisocial behavior. Aggressive behavior has been found to run in families: Having an antisocial sibling, especially one who is close in age, increases a child's likelihood of engaging in delinquent behavior, and youths whose parents engage in antisocial behavior are more likely to do so themselves.

Peers

The importance of peers in youths' social networks grows substantially during adolescence. It is thus not surprising that most youths commit crimes in groups and that certain characteristics of a youth's peer group increase his or her likelihood of offending. Foremost, individuals with delinquent friends are more likely to offend than individuals without delinquent friends. While peers are known to influence an individual's behavior (known as *socialization*), research also demonstrates that adolescents who are delinquent are more likely to seek out and befriend other delinquents (known as *selection*). Antisocial peer influence can thus be self-reinforcing. The age and gender of an adolescent's peers are also important factors; having older friends is associated with a greater likelihood of offending, and male peers are generally more likely to encourage antisocial behavior than female peers. Gang membership reflects the most extreme example of deviant peer influence on offending. Interestingly, aggressive children who are universally rejected by their peers are at greater risk of becoming chronic juvenile offenders than are aggressive children who are not rejected.

The negative influence of peers tends to arise as a key risk factor later in development, whereas family influences typically are most important during earlier stages. Nevertheless, the influence of peers is magnified when the family environment is not healthy.

Community Conditions

Neighborhood

Children raised in disadvantaged neighborhoods are at greater risk of becoming juvenile offenders than children from more affluent neighborhoods. This neighborhood effect remains significant even when differences in school quality and family socioeconomic status are taken into account. Since disadvantaged neighborhoods have weak social controls due to isolation and high residential turnover, delinquent behavior is more likely to go unnoticed or be ignored by others in the community. The lack of social control in poorly monitored neighborhoods not only provides more opportunities for antisocial behavior but also increases youths' exposure to criminal behavior by others in the community. Such exposure is yet another risk factor for subsequent offending.

School

Youths who experience problems at school are at increased risk of becoming delinquent. Problems at school can include a wide range of experiences, such

as poor scholastic performance, weak connections to school, and low educational aspirations. Such factors are associated with delinquent behavior even when cognitive factors (such as intelligence or attention deficits) are taken into account. Youths who drop out of high school are more likely than those who graduate to engage in delinquent activities. School policies such as suspension and expulsion have been found to exacerbate delinquent behavior among at-risk youths.

Prediction

Risk factors combine in complex ways to influence individual behavior. Although these factors can be used to predict the relative probabilities of offending in large groups with similar characteristics, they cannot be reliably used to predict the behavior of specific individuals. Even among groups with numerous risk factors, the majority of youths generally do not offend, making it extremely difficult to use such factors to identify individual future offenders with meaningful accuracy. The number of "false positives" from such predictions would exceed the number of "true positives," and the potential stigma of being labeled as a "future offender" would itself be detrimental.

Juvenile Psychopathy

Despite disagreement about its exact contours, most conceptualizations of psychopathic personality disorder emphasize traits of emotional detachment, including callousness, failure to form close emotional bonds, low anxiety proneness, remorselessness, and deceitfulness. Nevertheless, most measures of psychopathy go beyond these interpersonal and affective features to assess repeated involvement in antisocial behavior, which many scholars view as peripheral to the construct. Chiefly, this is because most measures are based on the Psychopathy Checklist–Revised (PCL–R), which weighs past violent and antisocial behavior as strongly as traits of emotional detachment. Over the past decade, researchers have extended this adult measure of psychopathy downward to adolescents and children, with the goal of assessing "juvenile psychopathy." This research has gained considerable momentum, despite ongoing controversy about the appropriateness of diagnosing psychopathy before youths' personalities have reached a period of relative developmental stability. Most contemporary research and virtually all practical interest revolve around the reliability and utility of measures of juvenile psychopathy in forecasting youthful offenders' violent and antisocial behavior. In this entry, this movement is noted, but research on the validity of extending this construct to youths is emphasized. Theoretically driven research on the potential mechanisms that underpin psychopathy reveals the importance of emotional detachment as a likely manifestation of psychopathy in youths. However, there is no compelling evidence that the purported traits of psychopathy (a) remain stable during the transition to adulthood or (b) do not respond to treatment. This limits the utility of measures of psychopathy for informing legal decisions with long-term consequences concerning youth. Although relevant measures have been developed for children as young

as 3 years, the focus of this entry is on preteens and adolescents.

Extending Psychopathy From Adults to Youths

Several factors have encouraged the extension of psychopathy from adults to youth. Foremost among them are (a) the recognition that the chief tools for diagnosing psychopathy predict violence and criminal recidivism and (b) the juvenile justice system's increasingly punitive policies, which have created a demand for identifying inalterably dangerous youths. Although researchers hoped that psychopathy assessments would be used to identify a subgroup of at-risk youths to target for intervention, recent legal reviews suggest that the youths identified are likely to be excluded from treatment and set up for harsh sanctions.

Most measures of juvenile psychopathy modify the PCL–R items and scoring criteria to reference youths' peer, family, and school experiences. They are built on the assumption that the features of psychopathy manifested by adult psychopaths will, when exhibited in youths, identify a small subgroup of offenders who are maturing into psychopaths. That is, psychopathy is manifested similarly, whether one is 13 or 33 years old. This assumption is challenged by a study of clinical psychologists' conceptions of juvenile psychopathy. Clinicians viewed some of the features of adult PCL–R psychopathy (e.g., impulsivity, the failure to accept responsibility, a parasitic lifestyle, criminal versatility) as nonprototypic of juvenile psychopathy. Although this raises the possibility that the manifestations of psychopathy differ as a function of developmental stage, no "bottom-up" measures of juvenile psychopathy have been developed.

Reliability and Predictive Utility of Juvenile Psychopathy Measures

The most widely validated measures of juvenile psychopathy were derived from the PCL–R, including the Psychopathy Checklist: Youth Version (PCL:YV), the Antisocial Process Screening Device (APSD), and the Child Psychopathy Scale (CPS). Like its parent measure, the PCL:YV is based on a clinical interview and file review; the other measures are based on self- or collateral report. Perhaps, given these method differences, the PCL:YV correlates only moderately with the remaining measures.

These measures share two general strengths. First, each has been shown to be reliable (interrater, internal consistency, and/or short-term test-retest). Second, each has demonstrated some utility in predicting youths' violent or antisocial behavior. The typical degree of association with these behavioral outcomes is similar to that observed in adults (i.e., $r \neq .25$). Although most prospective studies follow youths for only 1 to 2 years, one retrospective study indicates that youths' (mean age = 16) file-based PCL:YV scores moderately predict violent recidivism over an average 10-year follow-up period. Most of the PCL:YV's predictive utility in this study, however, was attributable to its assessment of an impulsive, antisocial lifestyle rather than traits of emotional detachment. This finding is consistent with much of the adult literature and challenges the assumption that the measure's association with violence is an indication that emotionally detached psychopaths use violence to prey on others. Instead, the measures may tap traits of aggression or externalizing features that predict violence but are not specific to psychopathy.

Construct Validity of Juvenile Psychopathy: Potential Mechanisms and Etiology

For such reasons, predictive utility (which seeks clinical utility) cannot be mistaken for construct validity (which seeks construct identification). To determine whether psychopathy is a valid construct when applied to youths, juvenile psychopathy must be (a) evaluated against a validation hierarchy dictated by a theory of the disorder and (b) shown to be a stable personality disorder that does not dissipate as youths become adults.

Despite the differences among them, most theories describe psychopathy as a largely inherited affective or cognitive processing deficit. These theories dictate a validation hierarchy that places pathophysiologic and etiologic mechanisms at the top, as they offer the greatest potential for explaining the disorder and potentially altering its course. The question is whether diagnostic criteria for juvenile psychopathy identify a homogeneous group of youths with clearly delineated deficits and largely genetic pathophysiology.

Paul Frick and his students have begun to address this question. Their work highlights the importance of features of emotional detachment, or "callous/unemotional" (C/U) traits, in defining juvenile psychopathy. Theoretically, traits of emotional detachment

are underpinned by a fearless temperament and deficient processing of emotionally distressing stimuli, which causes insensitivity to socializing agents and interferes with the typical development of conscience. At the symptomatic level, Frick and his colleagues have found that youths with traits of emotional detachment tend to be fearless, thrill and adventure seeking, and low in anxiety. At the pathophysiological level, they have found that emotionally detached traits identify—among a *pool* of youths with early and persistent antisocial behavior—those who possess information-processing and emotional deficits similar to those found among psychopathic adults. These include reduced sensitivity to cues of punishment when a reward-oriented response set is primed and diminished reactivity to threatening and emotionally distressing stimuli. Although such results might be interpreted as evidence that psychopathy is genetically influenced, caution should be exercised in drawing premature inferences because the heritability of these laboratory variables is unclear.

Only one behavioral-genetic study of psychopathy has been conducted with youths to date. In this study, psychopathy was operationalized using teachers' ratings of C/U traits on an unvalidated but internally consistent scale. Based on a selection of 661 7-year-old probands with extreme C/U traits (>1.3 *SD*), the authors found concordance rates of 39% and 73% for dizygotic and monozygotic twins, respectively, yielding an estimate of moderate heritability for C/U traits ($h = .67$). Although observational studies suggest that childhood maltreatment relates more strongly to antisocial behavior than features of emotional detachment per se, more research is needed to determine whether features of emotional detachment are more highly heritable.

In summary, existing research provides some support for the validity of emotional detachment or C/U traits in defining juvenile psychopathy. The importance of these traits is bolstered by psychometric studies. Studies that apply item response theory indicate that interpersonal and affective items convey more information about the underlying juvenile psychopathy construct than items that tap aggressive and antisocial conduct. Some of the recently developed measures of juvenile psychopathy (e.g., the Youth Psychopathic Traits Inventory; the Inventory of Callous Unemotional Traits) focus on emotional detachment, de-emphasizing antisocial behavior. It remains for future research to determine whether these measures more "cleanly" assess the construct than their predecessors.

Malleability of Juvenile Psychopathy

The fact that we can reliably assess features of emotional detachment in youths that relate in a theoretically coherent manner to cognitive and affective deficits provides some support for extending psychopathy measures downward from adults to youth. Presently, however, we lack the necessary collateral evidence that what we are assessing in youths is psychopathy, a personality disorder that will remain stable into adulthood.

Scholars have expressed two main concerns about the stability of juvenile psychopathy. First, downward translations of the PCL–R include normative and temporary features of adolescence such as impulsivity, stimulation seeking/proneness to boredom, poor behavior controls, and irresponsibility. At least one study indicates that measures of juvenile psychopathy correlate moderately with measures of psychosocial maturity. To the extent that measures of juvenile psychopathy tap construct-irrelevant variance related to psychosocial maturity, a youth's score will gradually decrease as he or she matures. It is possible that recent measures of juvenile psychopathy that focus specifically on emotional detachment may capture less construct-irrelevant variance related to psychosocial maturity. Indeed, a cross-sectional item-response theory study indicates that PCL:YV items that assess emotional detachment are more defining of psychopathy across age groups than items that tap impulsive, antisocial behavior.

The second concern is that there is no compelling evidence that youths assessed as psychopathic will mature into psychopathic adults. Because personality and identity may not be well formed until adulthood, our nosological systems generally forbid applying diagnoses of personality disorders to children and adolescents. Although psychopathic adults probably manifested similar traits when they were younger, relatively few youths with psychopathic features may mature into psychopathic adults. Reasoning by analogy, the majority of children with conduct disorder desist acting out and do not mature into adults with antisocial personality disorder.

Three relevant studies have been conducted. In the first, the APSD was repeatedly administered to 100 nonreferred fourth graders. Across a 4-year period, the stability of APSD scores and rank order was excellent

(interclass correlation [ICC] = .80), suggesting that parent ratings change little from late childhood to early adolescence. The two remaining studies focused on the transition from adolescence to adulthood. In the second study, more than 200 youths were administered the CPS at age 13 and a screening version of the PCL at age 24. Over this 10-year period, there was relatively poor stability (ICC = .27), and most of the shared variance was between the CPS and PCL's antisocial scale. Of the adolescents who obtained extremely high CPS scores (i.e., the top 5%) at age 13, less than one-third (29%) were classified as psychopathic at age 24. In the third study, PCL measures were repeatedly administered to approximately 200 adolescents and 100 adults. Over a 2-year period, the stability of adolescents' PCL:YV scores was limited (ICC = .34). Adolescents' PCL:YV scores decreased significantly more than adults' PCL–R scores, indicating that psychopathy assessed during adolescence is less stable than that assessed during adulthood.

The apparent features of psychopathy can change not only as a function of maturity but also as a function of intervention. The results of recent research challenge the long-standing therapeutic pessimism about psychopathy. Although three studies of youth have been conducted, only one is prospective and includes a control group. In this study, of approximately 150 youths with pronounced PCL:YV scores and long histories of acting out, those who participated in an intensive treatment program were 2.4 times *less* likely to recidivate violently the year after release than those who participated in treatment as usual.

Legal Implications

Although juvenile psychopathy is a promising construct, the available evidence cannot support its application to legal decisions about youth that have long-term consequences. First, given the lack of evidence that these measures identify inalterably dangerous youths who will mature into adult psychopaths, it is inappropriate to apply these measures to determine whether a youth should be tried in the adult court system. Second, these measures should not be used as an exclusion criterion for treatment programs. Indeed, juveniles with high psychopathy scores should be reframed as high-risk cases in need of intensive treatment rather than hopeless cases to incapacitate.

What legal uses of these measures might be appropriate? Given their predictive utility, one might use a measure of juvenile psychopathy as a risk assessment tool to inform short-term decisions about placement (particularly levels of security). However, risk assessment tools that have been designed and validated for youth are available. Before selecting a diagnostic measure of psychopathy over a validated risk assessment tool, one must consider the potential for stigmatizing a child or an adolescent with the unsavory label "psychopath." Studies of juvenile justice professionals and mock juries alike indicate that this label invites assumptions that the youth is inalterably dangerous. Although this assumption does not enjoy empirical support, it pushes decision makers away from rehabilitative efforts toward harsh sanctions and incapacitation. Because adolescence is a time of significant developmental change, it is imperative to learn more about the stability, nature, and manifestations of psychopathy before embracing this construct as a component in the evaluation of juvenile offenders.

Juveniles and the Death Penalty

The controversy surrounding the juvenile death penalty is not new; the courts have struggled with the issue for decades. Meanwhile, psychologists have presented research results on both the capabilities of juveniles and the public's support for the juvenile death penalty. Although the Supreme Court has not

consistently relied on psychological findings, those findings are relevant to the legal debate.

Supreme Court Rulings

In 1988, the U.S. Supreme Court in *Thompson v. Oklahoma* overturned a death sentence for a 15-year-old offender because it violated the Eighth Amendment prohibition against cruel and unusual punishment. The Court found that the community's "evolving standards of decency" were incommensurate with the execution of a juvenile. The Court considered four factors: the number of state statutes prohibiting the juvenile death penalty for 15-year-olds, jury sentencing statistics, the opinions of national and international organizations, and the Court's analysis of whether the juvenile death penalty accomplished the goals and purposes of the punishment.

A year later, the Court reexamined whether the death penalty should be available for 16- or 17-year-olds in *Stanford v. Kentucky* (1989). This time, the Court failed to find consensus in state statutes and held that the death penalty for these youths was not in violation of the Eighth Amendment. Surprisingly, the Court ignored all other measures of evolving community standards that were considered in *Thompson.*

Making matters even more confusing, the Court did an about-face in 2005, finding the juvenile death penalty unconstitutional in *Roper v. Simmons* and determining that the community's standards of decency had evolved to oppose executing juveniles of any age. Furthermore, relying on psychological research, the Court found that the juvenile death penalty did not satisfy the punishment goals of deterrence and retribution, due in part to juveniles' immaturity and their inability to make rational judgments that consider the outcomes of committing violent crimes.

Psychologists have contributed to these legal developments in two ways. First, they have conducted polls to measure community support for the juvenile death penalty. Second, they have conducted research testing the development of juveniles.

Public Opinion Research

The Supreme Court has sometimes referred to the results of public opinion polls measuring the "evolving standards" of the community. Polls have shown changing support over time. Although 28% of respondents supported the juvenile death penalty in 1936, only 19% supported the punishment in 1953, and only 11% were supportive in 1957. Surprisingly, a 1965 poll reported 21% support for juvenile executions, despite declining public support for the death penalty in general. Demonstrating even more variability, a 1988 poll showed 44% support and a 1989 poll showed 57% support for juveniles over 16. At the same time, another 1989 poll found 25% to 30% support for executing offenders as young as 14 years. More recently, a 2002 Gallup poll found 31% support for juvenile executions. Exhibiting regional differences, a 1991 poll in the southeastern United States found that 64% supported executing juveniles aged 16 or over and 35% supported executing those under 16. Still, the level of support (83%) for executing adults was much higher.

Support is not uniform, however, as Whites and conservatives are typically more supportive of the death penalty in general than their counterparts. Similarly, participants who are older, male, White, and conservative are more supportive of the juvenile death penalty.

Despite this variability among polls, the trend indicates a general disfavor among respondents especially when it comes to executing juveniles as compared with executing adults. The *Roper* ruling did not rely on polling results; nevertheless, findings from this research do agree with the Court's judgment that the juvenile death penalty now does offend the community's evolving standards of decency.

Research on Juvenile Development

A second line of psychological research argues against executing juveniles because their limited developmental judgment capacities mitigate their culpability. The American Psychological Association filed an amicus brief in the *Roper* case that referred to research demonstrating that juveniles are biologically, psychosocially, and cognitively less developed than adults. These differences suggest that the death penalty does not fulfill its purposes when the state invokes it against juveniles who commit homicide. It is not possible to deter juveniles from committing homicide if they do not engage in a rational cost-benefit analysis before engaging in violence.

As adolescents progress to adulthood, they develop capabilities, attention, information-processing skills, and memory, which makes them more reasoned decision makers. Some research suggests that older juveniles are similar to adults in their reasoning skills, at least when

tested in laboratory settings (e.g., participants imagine how they would react to hypothetical situations). However, critics argue that differences between adult and juvenile judgments are much more likely to emerge in real-world settings than in laboratories.

Some researchers concluded that juveniles' psychosocial development remains immature even in later adolescence. As a result, juveniles are more susceptible to peer influence, are ineffective in weighing the risks and rewards of their behavior, have difficulties in reasoning about the long-term consequences of behavior, and have a lower capacity for self-management (e.g., impulse control). These deficiencies affect their cost-benefit analysis, leading them to make immature decisions.

A growing body of neuropsychological research has confirmed that juveniles differ from adults in important ways. For instance, recent research has indicated that the areas of the brain that control reasoning (e.g., the prefrontal cortex) are the last to develop. As such, juveniles are less competent than adults, with less-developed capabilities for concentration, control of impulsivity, self-monitoring, and decision making. Because these areas of the brain are underdeveloped, juveniles rely more heavily on the amygdala, the area of the brain that processes emotions. Thus, juveniles are biologically different in ways that may decrease criminal culpability.

In sum, the age at which an offender is legally eligible for the death penalty is 18. At least for now, the legal debate surrounding the juvenile death penalty is settled, due in part to the work of psychologists studying public opinion and the development of cognitive, emotional, and neurological capacities.

Legal Authoritarianism

In its broadest sense, legal authoritarianism refers to the constellation of beliefs held about the legal system that is relevant to juror decision making. Because jurors enter trials with preconceived notions about evidence, criminal conduct, and the criminal justice system in general, understanding these beliefs allows researchers to better understand how jurors process information and render decisions about the case. Furthermore, because one of the goals of the jury selection process and voir dire is to assess attitudes that individuals might hold that could affect their role as jurors, the study of juror attitudes is of great relevance to judges and trial attorneys, trial consultants, and researchers of jury decision making.

Early Measures of Attitudes Relevant to Juror Decision Making

Early attempts to measure attitudes relevant to juror decision making relied on measures generally not intended for those purposes. Some commonly used measures were internal or external locus of control, just-world beliefs, and authoritarianism. Of these constructs, authoritarianism was the most frequently used in conjunction with juror decision making and had the most success in predicting juror judgments. Individuals scoring high on measures of authoritarianism express stereotyped beliefs toward out-groups, support conventional norms and authority, and advocate harsh sanctions against deviates. These beliefs have obvious implications to how one might react to evidence presented at trial. And, not surprisingly, measures of authoritarianism have been shown to have a weak but positive relation to juror verdicts. A meta-analysis revealed the average correlation between authoritarianism and verdicts to be .11.

Measures of Legal Authoritarianism

As noted, measures of authoritarianism such as the California F Scale contain items removed from a legal context. Yet these same themes present in authoritarian attitudes (e.g., the tendency to support and trust institutionalized authority, the willingness to advocate harsh sanctions against deviates) are telling features about how one views the legal system. It was noted at the outset that, broadly, any measures of legal attitudes are frequently termed legal authoritarian measures. However, in a more narrow interpretation, because authoritarian beliefs are so central to how one views the criminal justice process, any measure of legal attitudes relevant to jury decision making must address these authoritarian themes to one extent or another. As a result, each of these existing measures of juror attitudes can be reasonably characterized as legal authoritarianism measures.

Although it was not conceived as a measure of attitudes relevant to jury decision making, Herbert L. Packer's identification of the due process and crime control model provides an early example of legal authoritarianism. Packer articulated these two perspectives on the criminal justice system in the influential 1968 text *The Limits of the Criminal Sanction.* These perspectives reflect a series of attitudes one holds surrounding the legal system that have important

consequences about how one views a criminal trial. According to Packer, individuals who hold strong crime control values regard the control and reduction of criminal conduct as the primary goal of the criminal justice system. To do so, one seeks efficiency in the criminal justice process to be maintained at all costs. They, therefore, tend to have greater confidence in law enforcement and other criminal justice actors to correctly and competently carry out their duties of apprehending and convicting criminals while acquitting the innocent. These individuals see the presumption of innocence and burden of proof as unwanted obstacles and encourage the power of institutionalized authority over the rights of the accused. Conversely, those holding due process values question the ability of the criminal justice system to properly carry out their duties in apprehending and trying offenders. They stress the rights of the accused, are fearful of innocent persons wrongfully convicted, and emphasize the importance of procedural safeguards in maintaining the integrity of the process, even at the expense of releasing persons who may be factually guilty. The crime control and due process models conceptually covary with legal authoritarianism. That is, those who place trust in the system and seek to apprehend and punish wrongdoers at the expense of their liberties demonstrate authoritarian values, whereas those who question unfettered police powers and seek to maintain procedural safeguards to protect the rights of the accused demonstrate antiauthoritarian values.

In the same year, Packer published his theory of the crime control and due process models, and Virginia Boehm published the Legal Attitudes Questionnaire (LAQ). The scale measures three constructs: authoritarianism, antiauthoritarianism, and equalitarianism. This 30-item scale was grouped into 10 sets of triads, each containing a statement reflecting each construct. Participants rank ordered agreement with the statements within each triad. Authoritarian items expressed unquestioned support for authority and limits on the rights of the accused (e.g., "Evidence illegally obtained should be admissible in court if such evidence is the only way of obtaining a conviction."). Antiauthoritarian items reflected beliefs that challenged authority and expressed the need for procedural safeguards to protect the accused (e.g., "Wiretapping by anyone and for any reason should be completely illegal."). Equalitarian statements reflected neither authoritarian nor antiauthoritarian values, but instead reflected beliefs that fell somewhere within these extremes (e.g., "Citizens need to be protected against excessive police power as well as against criminals.").

Researchers later developed the Revised Legal Attitudes Questionnaire (RLAQ) in an effort to improve the psychometric properties of the scale. Ranked agreement within the 10 triads was abandoned in favor of Likert scoring for all 30 items. This led to a sizable reduction in items scored incorrectly. It also revealed some limits to the construct validity of the scale. For the RLAQ, significant negative correlations emerged for the authoritarian and equalitarian subscales, whereas the antiauthoritarian subscale failed to correlate with the others. Moreover, although the authoritarian subscale significantly positively correlated with a traditional measure of authoritarianism—the Balanced F Scale—it was scores on the equalitarian subscale and not the antiauthoritarian subscale that negatively correlated with this measure of authoritarianism. This finding suggested that equalitarian items on the scale are better conceptualized as antiauthoritarian and vice versa.

In 1983, Saul Kassin and Larry Wrightsman published the Juror Bias Scale (JBS). The goal was to create a measure of "generalized pretrial bias." They noted that typical models of jury decision making assume that verdicts reflect two judgments—the likelihood that the defendant committed the crime charged, or probability of commission (PC), and a judgment of threshold necessary to convict, or reasonable doubt (RD). The authors surmised that jurors may differ along two theoretically independent dimensions (i.e., PC and RD). The scale contains 9 PC items (e.g., "Generally, the police make an arrest only when they are sure about who committed the crime.") and 8 RD items (e.g., "If a majority of the evidence—but not all of it—suggests that the defendant committed the crime, the jury should vote *not guilty*."). Here again, these same elements of authoritarian beliefs (e.g., trust in authority) as well as antiauthoritarian beliefs (e.g., need for safeguards to protect the rights of citizens) emerge.

Researchers, in developing the most recent measure of juror attitudes—the Pretrial Juror Attitudes Questionnaire (PJAQ)—used a dual approach to item generation. Here, items were derived from a sample of participants in addition to using items present in existing scales. The initial pool of items was reduced to a manageable size based on a separate sample's consensus that the items reflected attitudes that could bias a juror's judgment in the case, along with factor analytic methods. For the final 29-item scale, the separate constructs of cynicism and confidence reemerged, along with

additional constructs labeled social justice (e.g., "Rich individuals are almost never convicted of their crimes."), racial bias (e.g., "Minority suspects are likely to be guilty more often than not."), and innate criminality (e.g., "Once a criminal, always a criminal."). Therefore, we see that even when relying on empirical means to generate items, constructs emerge that reflect these authoritarian and antiauthoritarian beliefs.

Legal Authoritarianism Measures as Predictors of Individual Verdicts in Criminal Cases

There have been multiple studies assessing the predictive validity of legal authoritarianism measures. A meta-analysis revealed that legal authoritarianism measures demonstrate an average effect size of $r = .16$. However, this correlation is somewhat reduced by the inclusion of studies that have used rape trial scenarios. Measures of legal authoritarianism appear to be poor predictors of verdicts in rape trials, and although researchers have offered some explanations as to why this might be, it has yet to be investigated. Moreover, many of the studies on which the analysis was conducted used college students and/or written transcripts and trial summaries. However, a general pattern is that as the ecological validity (in terms of sample used as well as presentation medium) of the study increases, so too does the relation between authoritarianism and verdicts.

In a recent study comparing the predictive validity of the JBS, a shortened version of the Revised Legal Attitudes Questionnaire (RLAQ–23), and the PJAQ, researchers found that the JBS and RLAQ–23 combined were able to account for approximately 4% of the variance in guilt judgments. By comparison, the PJAQ by itself accounted for approximately 7% of the variance in guilt judgments. Consequently, when we speak of the value of these scales as a predictor of guilt judgments, the relation remains relatively modest. Moreover, this relation is further weakened as the evidence against the defendant becomes less equivocal. In other words, attitudes that one carries to trial can influence final judgments, but evidence still provides the bulk of the explanation about how we decide cases.

Of course, examining the beliefs jurors hold about issues relevant to the legal system and their final verdict in a case ignores myriad ways in which these beliefs might indirectly affect verdicts. That is, the attitudes jurors hold concerning trust in law enforcement, for example, can influence the weight they assign to evidence brought to trial from these sources (e.g., police searches, confessions), or their ability to recall certain facts, or the sources of evidence at a later time when deliberating over the case. Researchers are just beginning to grapple with these issues, but it highlights the potential for the study of pretrial attitudes in general, and specifically measures of legal authoritarianism, to aid our understanding of how jurors decide cases. Because it is well accepted that jurors are not immune to the biasing role that these attitudes likely play in their decisions, no model of juror decision making can be complete without accounting for these attitudes and the role they play in the decision-making process. While researchers are probably correct in warning that these measures of legal authoritarianism can only have limited applied impact, as judges tend to place strict limits on the use of questionnaires submitted to members of the venire, their greatest impact may likely lie in their potential for researchers to better understand the decision-making process of jurors.

Legal Negotiation

Negotiation is extremely common in legal settings. In the criminal context, most cases are resolved through

the plea bargaining process rather than through trials. Similarly, many more civil disputes are resolved by private settlement than go to trial. Transactional lawyers spend much of their time negotiating deals and contracts. In practice, lawyers will negotiate with opposing parties and their counsel, with insurers, with regulators, and with their own clients. Psychologists have studied negotiation in a variety of contexts, including negotiation as it occurs in the legal system. Research indicates that negotiation outcomes may be influenced by such factors as cognitive heuristics and biases, social perceptions, emotions, social influence, and the legal background of the negotiators.

Basic negotiation theory holds that negotiation outcomes are a function of the negotiator's reservation price, or bottom line. That is, negotiators will identify a point at which they would prefer to walk away from the negotiation without an agreement rather than accept terms that fall below that point. Where negotiators set this reservation price along a continuum of possible agreements is affected by their expectations about the outcomes that would likely result in the absence of a negotiated agreement. So, for example, a civil plaintiff's reservation point (i.e., the lowest amount for which he or she would settle) is informed by his or her prediction about what would happen if the case was decided at trial. Similarly, a party negotiating a sales agreement on behalf of a buyer sets his or her reservation price (e.g., the highest price he or she would pay) in light of the availability and value of a possible agreement with an alternative contracting partner. Negotiators with more attractive predicted alternatives are likely to have higher reservation prices and to reach more favorable agreements. Negotiators have also been shown to be influenced by their aspirations, or goals, for the negotiation, with negotiators who set higher goals achieving more favorable agreements. At the same time, however, high reservation prices and aspirations have both been shown to lead to a higher likelihood of impasse (i.e., failure to reach a negotiated agreement) and to a decreased level of satisfaction with the same objective outcomes.

Within this general framework, however, it is clear that negotiators are influenced by a number of additional factors. Going beyond expected value theory, in which negotiation decisions are determined by a comparison of the expected value of forgoing a negotiated agreement with the expected value of the proposed agreement, psychological research demonstrates that negotiation decision making is also affected by negotiators' construal of and judgments about the other party or parties, the context, and themselves.

Heuristics and Biases

Legal negotiators, like other negotiators, can be influenced in their decision making by psychological heuristics or biases. For instance, legal negotiators on different sides of a dispute tend to make biased evaluations of the merits of the case such that their evaluations favor their side, overestimate their likelihood of prevailing at trial, and are more likely to believe that the fair outcome is one that favors their side. In part, this is because those who are exposed to only the information that is available to a particular side of a dispute tend to be optimistically overconfident—that is, to be more confident and less accurate in their predictions of the likelihood that they will prevail than those who have information from both sides. Similarly, when they seek out additional information, negotiators exhibit the confirmatory bias as they seek and evaluate data in ways that are consistent with their already existing views. In addition, however, even when they have access to the same objective facts, negotiators often interpret those facts and make judgments about them in ways that are consistent with their own (or their clients') interests—a manifestation of the self-serving (or egocentric) bias.

Negotiators may also be influenced by anchors. Anchoring and adjustment refer to a phenomenon by which available values provide a starting point (or "anchor") for a judgment; adjustments are then made away from the anchor, but these adjustments are often insufficient. In the legal context, anchors have been shown to influence settlement decision making in civil cases by anchoring negotiators' evaluation of the appropriate settlement amount. For example, the availability in memory of sizable verdicts that are reported in the media may anchor negotiators' perceptions of a case's potential settlement value. In addition, the first offer made in a settlement negotiation has been shown to influence the final negotiated agreement—the higher the opening offer, the higher the ultimate settlement. Similarly, research has found that disputants are more likely to agree to a particular final settlement amount when that final offer is preceded by a more extreme opening offer than they are when the offer is preceded by an opening offer that is only slightly different from the final offer. Because the initial offer anchors expectations about the appropriate settlement amount, the value of any concession is measured against those expectations.

In addition, experimental research has demonstrated that negotiators can be influenced by contrast and compromise effects as they generate and consider options

for negotiated outcomes. Contrast effects occur when the options in an initial set are evaluated differently relative to each other when an additional option is added that is similar, but inferior to one of the initial options, making that initial option appear relatively more attractive. For example, a disputant involved in a dispute over a piece of property might consider selling the property and dividing the proceeds with the other party or allowing the other party to keep the property in exchange for a particular sum of money. When a third option is introduced, for example, allowing the other party to keep the property in exchange for the same sum of money, but paid over time—an option that is similar but inferior to the option involving a lump sum payment, more people are inclined to choose the lump sum payment option and fewer are inclined to sell the property and divide the proceeds than in the absence of the additional option.

Compromise effects, on the other hand, occur when an extreme option is introduced into the set of options under consideration. The introduction of an extreme value alters the range of options that are in the middle of the choice set. Because negotiators are more likely to choose an option when it appears to be a moderate choice, this shift in range tends to increase the attractiveness of a choice that would have appeared extreme in the smaller set, but appears moderate in the presence of the additional, more extreme, option. For example, negotiators are more likely to enter into a land purchase contract when the property at issue is considered among a set of alternative properties that make it appear to be a compromise, or moderate, option. Thus, while it is useful for legal negotiators to actively generate creative options for agreement, it is also useful for them to attend to the ways in which additional options affect their evaluation of existing alternatives.

Finally, legal negotiators are also influenced by how the negotiation is framed. Prospect theory suggests that negotiators compare proposed outcomes with the status quo. When the negotiator's choices are perceived as gains, the negotiator is likely to behave in a manner that is risk averse—thus, civil plaintiffs in ordinary litigation may be more inclined to settle. In contrast, when the negotiator's choices are perceived as losses, the negotiator is likely to behave in a risk-seeking manner—thus, typical civil defendants may be more inclined to gamble on a trial.

Social Factors

Negotiations in legal settings are also influenced by a variety of social and interactional factors. For example, legal negotiation is influenced by the negotiators' perceptions of fairness. Negotiators are concerned both with the distributive fairness of a negotiated outcome and with the procedural and interactional fairness of the negotiation process itself. Importantly, negotiators resist agreeing to substantive outcomes that do not comport with their notions of substantive fairness. Similarly, fair interpersonal treatment has been shown to diminish self-serving bias, reduce the likelihood of impasse, and increase satisfaction with substantive outcomes.

Social factors can also influence the perceived fairness of a proposed settlement. For example, options that are otherwise perceived to be fair seem less so when proposed by the other side in the negotiation—a phenomenon known as reactive devaluation. Similarly, the negotiators on each side tend to value the concessions that they make (and thus are perceived as losses) more highly than they value those concessions that are made by the other side (and thus are perceived as gains). This "concession aversion" consequently influences perceptions of the relative fairness of reciprocal concessions and of proposals offered by the parties.

In some instances, legal negotiators may also be influenced by a need to restore or maintain a sense of equity between the parties or to achieve vindication. Thus, they may reject compromises that seem inequitable, even when accepting them would be economically rational. Negotiators may also seek out ways to achieve a sense of equity or the acknowledgment of a harm. Thus, for example, apologies have been shown to influence legal settlement decision making. Research has shown that when a wrongdoer apologizes (particularly if the apology accepts responsibility for having caused harm), the injured party may make more favorable attributions about the opposing party and the incident, be less likely to seek legal counsel for assistance in pursuing a claim, set lower aspirations, find lower settlement values to be fair, be less likely to desire punishment, and be more likely to accept an offer of settlement than when the wrongdoer does not apologize.

Influence

Scholars of legal negotiation have also drawn on the psychology of influence and persuasion to better inform their understanding of negotiation strategies. In particular, legal negotiators may adhere to principles of reciprocity when engaging in the back-and-forth concession making that characterizes most

negotiation. The norm of reciprocity holds that when one negotiator makes a concession to the other, the other is obliged to respond in kind. Thus, a legal negotiator may elicit a concession from the other side by offering a concession of his or her own. Moreover, a legal negotiator might make an extreme demand that is likely to be rejected, followed by a more moderate request—the moderation of the request may be perceived as a concession and, thus, may elicit a reciprocal concession. In psychology, this is known as the "rejection-then-retreat" strategy. Legal negotiators may also invoke authority, scarcity, social proof, or familiarity and liking as strategies of social influence in negotiation.

Emotion

Legal disputes can involve intense emotions, such as anger, and such emotions are known to play a central role in negotiation. Negotiators experiencing positive emotions tend to make more concessions and to be more likely to engage in problem-solving behavior. Conversely, negotiators experiencing negative emotion tend to be more likely to use hard-bargaining strategies and less likely to create joint gain.

One specific emotion that has been explored in the legal context is the role of regret in legal negotiation. Research has found that disputants may prefer to reach negotiated settlements in legal cases rather than go to trial, in part due to a desire to minimize the regret they anticipate experiencing following their decision. Disputants who choose to settle are not able to know what the outcome of their case would have been had it gone to trial and are, thus, able to avoid the regret that would attend the knowledge that a trial would have resulted in a better outcome. In contrast, disputants who choose to go to trial will ultimately be aware not only of the outcome of the trial but also of any settlement offers they had rejected. Therefore, it is possible that they will experience the regret of knowing that they could have obtained a better result through settlement—regret they would prefer to avoid.

Agents/Lawyers

One of the distinctive features of much legal negotiation is that the principal parties—the legal clients—are often represented by attorneys as agents. As agents, attorneys are likely to engage in settlement negotiations in ways that differ from those of their clients. For example, as nonparties, attorneys can be more detached from the emotions underlying the dispute. Similarly, attorneys are selected and trained to be highly analytical. Moreover, given their role as legal advisors, attorneys are likely to be more familiar with and attuned to the legal rules than are their clients. These differences give attorneys some advantages in handling legal disputes. For example, attorneys may be able to avoid the impasse that might result when the parties are too emotional to negotiate with each other. However, these differences also present attorneys with some challenges in representing clients in negotiation. For example, attorneys may need to pay special attention to clients' nonlegal psychological, emotional, and social interests to negotiate effectively on their behalf.

Legal Socialization

Legal socialization is the process of developing attitudes toward rules, laws, and the legal system. Legal socialization research studies this process and also examines why individuals choose to obey or disobey the law. In fact, the first approaches to studies of attitudes toward the law appear in the legal socialization literature. Factors that affect how these attitudes develop include cognitive developmental variables, such as legal reasoning, and social learning variables,

such as salient features of the environment. Other factors that need to be considered are resiliency, psychosocial maturity, individual difference variables (e.g., belief in a just world, authoritarianism), culture, and attitudes. Contemporary work on legal socialization has focused on the effect of legal socialization on rule-violating behavior and compliance with the rules.

Socialization itself connects individuals to society, as socialization operates through family, schools, and other institutions. The study of socialization attempts to elucidate how individuals become engaged in culture and how culture and its affiliated institutions are preserved. Legal socialization is the development of standards, attitudes, and behaviors regarding the legal system. The legal socialization literature also underscores how legal contexts influence and are influenced by citizen behaviors.

Two Theoretical Approaches

Two approaches exist in the legal socialization literature. The individual-oriented cognitive developmental perspective argues for the importance of cognitive differences in legal socialization. The environment-based social learning perspective investigates environmental influences on legal socialization.

Cognitive Development Theory

The earliest work on legal socialization was that of June Tapp and Felice Levine. In the 1970s, they approached the understanding of legal socialization from a cognitive developmental framework based on the moral reasoning work of Lawrence Kohlberg. They argued that one's level of legal reasoning varied based on one's age, with cognitive structures supporting the maturation from Levels I through III: Level I, preconventional reasoning, focuses on obeying rules based on obedience to authority and fear of punishment from authorities. Level II, conventional reasoning, emphasizes law maintenance or obeying rules to conform to the norms of society. Finally, Level III, postconventional reasoning, focuses on law creating, or obeying rules based on independent judgments of fairness.

Social Learning Theory

Other researchers expanded the original cognitive developmental notion of legal socialization to include factors in the environment that affect social learning. This view suggests that it is through an individual's interaction with the environment that legal socialization occurs. With age, individuals are exposed to increasingly expansive legal contexts. In environmental contexts (neighborhood, school, etc.), reward and punishment are doled out both formally (based on written law) and informally (peers, family, school). When punishment is fair and even, legal legitimacy is strengthened; whereas when punishment is capricious or inequitable, it contributes to legal cynicism. Legitimacy is the degree to which people feel obligated to follow the laws or rules established by legal authorities. Legal cynicism measures whether people act in ways that are outside the law and social norms.

Legal socialization researchers also have varied in their conceptualizations of environment. For example, in a study of rule following on college campuses, Ellen Cohn and Susan White manipulated the rule-following environment by including a peer community wherein residents established rules and decided on enforcement and an external authority community wherein residents had no say over rules or enforcement and instead authorities had absolute power. In an international study of legal socialization, other researchers defined environment in terms of country, focusing on seven countries that varied in the extent of time they had been democratized: Russia, Bulgaria, Poland, Hungary, Spain, France, and the United States. Similarly, James Finckenauer also used country as the environment in his comparison of Russian versus American culture for teenagers.

Research

Current research has embodied both the individualistic cognitive development and the social learning viewpoints. This work has examined the developmental aspects of legal socialization; gender, environmental, and cultural differences in legal socialization; as well as the relation between legal reasoning and delinquency.

Developmental Differences

In Felice Levine's legal socialization research, elementary and high school students answered questions about legal reasoning, moral reasoning, legal attitudes, and legal behaviors. There was a significant relation between subjects' age and their level of legal and moral reasoning; students in high school had significantly higher moral reasoning scores than elementary students. In addition, legal and moral reasoning had a direct influence on attitudes about roles and

rights and mediated the effect of age but did not influence attitudes about compliance independent of age.

Gender Differences

The one piece of research that did find gender differences in predictions of rule-violating behavior was work that used a legitimacy measure of attitudes toward the criminal legal system. The participants in this study were high school students. They answered questions about attitudes toward the criminal legal system, belief in a just world, and authoritarianism. It was found that, for boys, negative attitudes toward the legal system were the sole significant predictor of delinquent behaviors. In contrast, for girls, negative attitudes toward the legal system mediated the negative relation between belief in a just world and delinquency and partially mediated the negative relation between authoritarianism and delinquency.

Environmental Differences

Some researchers have focused on the environment or the behavioral context. In one study, researchers manipulated the legal contexts within two different university dormitories. The external authority condition allowed no input or influence on rule enforcement, whereas in the peer community condition, dorm residents participated in the making of rules and ensuing disciplinary action. Results suggested that the individuals in the external authority condition violated fewer rules than individuals in the peer community condition. Over time, however, rule-violating behavior decreased in the peer community condition and increased in the external authority condition. Furthermore, legal reasoning increased in the peer community condition and decreased in the external authority condition.

Some researchers have found that jury deliberation has an effect on people who differ in the level of legal reasoning. In a study of a highly politicized and publicized case known as the Wounded Knee Trial, June Tapp and her associates investigated the hypothesis that the jury acts as a socializing agent. The researchers tested legal reasoning levels before and after participants served as jury members in the trial. Results showed that legal reasoning levels increased for the jury participants.

In another study, people who differed in their legal reasoning level deliberated about one of three legal cases that varied in the behavioral context of the relation between norms and rules. In one case of a physical assault, the norms concerning the behavior agreed with the rules; people did not approve of the behavior and agreed with the rule against the behavior. In another case, that of a beer-bottle-throwing game, the norm and the rule did not agree; people approved of the behavior and did not agree with the rule against it. Finally, in the last case of sexual harassment, people were divided. For some, the norm and the rule agreed; for others, the norm and the rule did not agree. The findings showed that the jury deliberations affected postconventional reasoners most with the physical assault case and preconventional reasoners most with the sexual harassment case. Conventional reasoners were not affected by the jury deliberation in any of the cases.

Cultural Differences

Researchers have studied legal socialization in a number of different countries. In one study, legal socialization was studied as a mediator of rule-violating behavior. In this study, Heath Grant examined legal reasoning as a form of resilience in Mexican youth and found that legal reasoning mediated the relation between risk factors (such as negative peer influence) and delinquency. In another study, juveniles in Russia were compared with juveniles in the United States to understand different legal contexts. Overall, there were no differences between Russian and American youth in legal reasoning.

Furthermore, differences in legal socialization have been measured in seven countries, three older democracies (the United States, France, and Spain) and four countries more recently democratized (Russia, Bulgaria, Poland, and Hungary). The countries did not differ in the level of legal reasoning. They did differ on other legal measures such as procedural and distributive justice, with procedural justice being more important in the older democracies and distributive justice more important in the newer democracies.

Legal Reasoning and Delinquency

A few studies have investigated the relation between legal reasoning and delinquency. In a comparison of

Russian and U.S. youth, delinquents reported lower levels of legal reasoning than nondelinquents. This finding was replicated in an American study of college students.

In a study of serious juvenile offenders, Alex Piquero and colleagues investigated the developmental course of two aspects of legal socialization: legitimacy and legal cynicism. They found that both factors remained relatively stable for more than 18 months. The researchers also found that older adolescents viewed the law as less legitimate than younger adolescents and that a greater number of prior arrests was associated with greater legal cynicism. Conversely, Tom Tyler and Jeffrey Fagan's cross-sectional research on children aged 10 to 16 years did find age differences, with legal cynicism increasing with age and legitimacy dissipating with age.

Measures of Legal Socialization

Researchers have measured legal socialization differently. Early researchers developed open-ended questions about legal reasoning that are coded into the three levels. More recently, investigators have developed a closed-ended version of the legal reasoning measure. In addition, some researchers have included measures of legitimacy and legal cynicism as measures of legal socialization or have asked about specific attitudes toward the legal system.

Leniency Bias

It is well established that if a verdict option is favored by a substantial (e.g., two-thirds) majority of jurors prior to deliberation, the jury is very likely to ultimately reach that verdict. A number of studies have suggested the following qualification to this simple rule—in criminal juries, pro-acquittal factions tend to be more influential than proconviction factions of comparable size. The net effect of this asymmetry is a tendency for juries to be more lenient than individual jurors, except for cases that produce a large majority of jurors for conviction. This tendency constitutes the *leniency bias.*

Evidence for the Leniency Bias

The initial and strongest evidence for this bias comes from a number of jury simulation studies. Robert MacCoun and Norbert Kerr meta-analytically combined the results of 13 such studies and reported that (a) on average, acquittal was about four times as likely as conviction for mock juries that began deliberation evenly split (e.g., 6 G vs. 6 NG); (b) an initial two-thirds majority favoring acquittal was more likely to ultimately prevail (94% of the time, on average) than a two-thirds majority favoring conviction (67% of the time); and (c) the stronger the evidence against a defendant, the weaker was this bias. On the other hand, a handful of surveys of ex-jurors from actual criminal jury trials (e.g., by Dennis Devine and his colleagues) have suggested either no such asymmetry or even the reverse effect (i.e., a harshness bias), but at present it remains unclear whether or not actual criminal juries do exhibit a leniency bias. This is because there are a number of potentially important methodological ambiguities clouding the comparisons of the mock versus actual juries. For example, the surveys of actual jurors all appear to have treated jurors who say that they are undecided at the first jury vote as advocates for acquittal, which is likely to overestimate the true size of the pro-acquittal faction in the jury. In summary, there is good evidence of a leniency bias in mock juries where

estimates of pro- and anticonviction faction sizes are based on direct assessment of mock jurors' predeliberation verdict preferences in relatively close cases. There is currently no strong evidence of such a bias (and some evidence to the contrary) where these estimates are based on ex-jurors' retrospective recollections of the number of proconviction votes at their actual jury's first ballot, in convenience samples of diverse cases.

Explaining the Leniency Bias

One explanation for the leniency bias is the existence of a prodefendant norm among jurors. Research on group decision making and polarization suggests that one effect of group deliberation is to increase commitment to shared norms. The more consistent evidence for a leniency bias among mock jurors, who are usually college students, than among actual jurors could be interpreted as reflecting different norms in the student and nonstudent populations. A direct comparison of the leniency bias for a student versus a nonstudent sample has shown that nonstudents exhibit a somewhat weaker leniency effect, but the difference was not statistically significant.

Another, related explanation is based on the common law's aversion to false conviction. Such values are reflected in several elements of the law, including the presumption of innocence, the prosecution's burden of proof, and particularly the reasonable-doubt standard of proof. The law prescribes that juries must give a criminal defendant the benefit of any reasonable doubt. This should give advocates of acquittal an advantage over advocates of conviction during jury deliberation. For example, jurors favoring acquittal need only raise a single reasonable doubt in the minds of proconviction jurors, whereas jurors arguing for conviction must refute all reasonable doubts in the minds of pro-acquittal jurors. This explanation predicts that there should be no leniency bias when jurors apply a standard of proof that is not slanted to favor the defendant, such as the "preponderance of evidence" standard used in civil trials; this prediction has been confirmed experimentally. A model presented by Norbert Kerr, Robert MacCoun, and Geoffrey Kramer generalizes the asymmetry effect, demonstrating how any shared local norm can create disproportionate influence for one side of an issue.

Implications of the Leniency Bias

The leniency bias has a number of interesting implications, both for the development of psychological theory and for legal application. Asymmetries in the power of opposing factions, such as the leniency bias, have been used to analyze the group decision-making process and thereby, to better understand exceptions to the "majority-wins" rule and to predict when and why groups differ from individuals in their susceptibility to a variety of judgmental biases. The most direct applied implication of the leniency bias is that, except for cases with very strong evidence against the defendant, deliberating juries should be more likely to acquit than individual triers of fact (e.g., a judge in a bench trial). Thus, the leniency bias provides an alternative explanation for a classic finding from the landmark product of the Chicago Jury Project, *The American Jury*—most verdict disagreements between juries and judges were instances in which the jury was more lenient (i.e., more likely to acquit) than the judge. Harry Kalven and Hans Zeisel attributed this to differences in what judges and jurors value or know (e.g., knowledge of prior convictions). But the leniency bias suggests that this effect may stem not from who makes the decision (judges vs. jurors) but from how the decision is made (i.e., individual vs. group decision making). This interpretation suggests that if panels of judges were the triers of fact, they would likewise tend to be overall more lenient than individual judges. The fact that, in *The American Jury,* there was no such asymmetry in the disagreements of judges and juries for *civil* cases (where a symmetric standard of proof is applied) further supports this interpretation.

Lineup Filler Selection

Lineup fillers prevent unreliable witnesses from guessing the identity of the police suspect and should allow for a fair recognition test for those witnesses who do remember the culprit. The primary strategies for selecting fillers for criminal identification lineups are presented in this entry. The suspect-matched and perpetrator-description-matched strategies are two methods of constructing lineups that have been compared by researchers. Additionally, care should be taken to ensure that the structure of the lineup is uniform across members. To assess the fairness of a lineup, several indices that measure lineup bias and lineup size have been developed.

The Function of Lineup Fillers

Lineup fillers, also known as *foils* (an innocent person in a police lineup), serve the major purpose of testing an eyewitness's recognition memory for a criminal perpetrator so as to establish evidence that the suspect is guilty of the crime. Fillers also serve to screen out unreliable witnesses: Witnesses who identify foils may have a weak memory for the perpetrator or may be guessing. With respect to the problem of guessing, the probability that a witness will select the suspect from a lineup based on chance alone equals $1/k$, where k equals the number of foils in the lineup. Having more options during the identification test decreases the probability that witnesses will identify the suspect by guessing alone. Additionally, presenting foils that resemble the suspect works toward preventing the witness from being able to deduce who the suspect is simply by eliminating improbable choices from the lineup.

Filler Selection Strategies

There are two primary filler selection strategies that have been investigated by researchers. First, foils may be selected for the lineup on the basis of their similarity to the physical appearance of the suspect, a procedure that is known as the *suspect-matched* strategy. Second, foils may be selected based on their resemblance to a physical description of the perpetrator given by the eyewitness, a procedure that is termed the *perpetrator-description-matched* strategy.

Two main concerns arise when foils are selected for the lineup on the basis of the suspect-matched strategy. First, if the suspect is not the culprit and is in fact innocent, then selecting the foils based on their match to the innocent suspect may result in a lineup in which the similarity of the foils to the perpetrator is low. This is a concern in cases in which the suspect is apprehended because he or she is physically similar to the description of the culprit given by an eyewitness. In such cases, the suspect may be the only one in the lineup that resembles the perpetrator. As a result, the innocent suspect might be frequently identified from lineups in which the foils are chosen on the basis of their match to the innocent suspect's appearance, a consequence that is known as the *backfire effect.* Another concern that arises when the foils are chosen for the lineup using the suspect-matched strategy is that if the suspect is in fact the culprit, then the foils could potentially be too similar to the suspect, and thereby decrease the odds that a witness who remembers the perpetrator can distinguish the guilty suspect from the foils.

In view of these concerns, the perpetrator-description-matched strategy has been proposed. In the event that an innocent suspect is in the lineup, the perpetrator-description-matched strategy is thought to ensure that the innocent suspect and the foils have the same probability of being chosen. The rationale is that if investigators select the foils and the suspect for the lineup using the same criteria (i.e., their match to the witness's description), then the foils should look no more like the perpetrator than does the innocent suspect. Additionally, for a witness who remembers the perpetrator, the perpetrator-description-matched strategy allows for *propitious heterogeneity*, a term that refers to having sufficient variability across lineup members to allow the witness to recognize a guilty suspect.

Some researchers studying lineup identification in the laboratory employ a hybrid of the suspect-matched and perpetrator-description-matched strategies. A pool of potential foils that fit the modal description of the target (i.e., the "perpetrator") is obtained. Participant raters then judge the similarity of each face in the pool to the target. The faces that are rated as being the most similar to the target are selected as fillers. An additional method on the horizon for the selection of fillers for lineups is the use of principal components analysis (PCA). PCA represents

the similarity of faces on multiple dimensions using Euclidean distances. Results derived from PCA have been shown to relate to lineup identification performance and to measures of lineup fairness.

Special Considerations in Selecting Fillers

In employing the perpetrator-description-matched strategy to select fillers, a number of issues may arise. One difficulty is that the witness may provide an inadequate number of details regarding the perpetrator's appearance for selecting fillers for the lineup. Selecting foils when there is little information regarding the culprit's appearance may result in a lineup in which the members are highly dissimilar in relation to one another and to the suspect. As a consequence, the perpetrator-description-matched strategy might in some cases increase the rate at which innocent suspects are identified. Additionally, the degree to which the lineup members are similar can affect the eyewitness's decision standard. If the foils in the lineup are relatively low in their similarity to the culprit, then witnesses may be less cautious in identifying a face compared to when there is a higher degree of similarity across lineup members. Finally, research comparing the suspect-matched and perpetrator-description-matched strategies has produced findings that are mixed, thereby leading some researchers to maintain that it is premature to recommend one strategy over the other at this time.

Nevertheless, additional procedural safeguards have been suggested for selecting fillers when using the perpetrator-description-matched strategy. For example, if the witness does not mention a characteristic, such as facial hair, the police might assume the perpetrator has the default value of the characteristic, and assume that the perpetrator was clean shaven. Though placing the clean-shaven suspect among foils with facial hair would not violate the witness's description, doing so would draw attention toward the suspect and perhaps bias the witness to choose the suspect only because the suspect's appearance is different from the others. Therefore, to avoid this possibility, if the suspect is clean shaven, then he should be placed among clean-shaven foils. Additionally, when the suspect does not fit the description given by the eyewitness on some level, it has been recommended that investigators select foils based on their match to the appearance of the suspect on the features in which the description of the culprit does not match the suspect. Along these same lines, if there are multiple witnesses involved in a case, a recommendation that has been made is to create a separate lineup for each eyewitness. In laboratory studies in which researchers feel that it is not feasible to create lineups for each participant, the foils can be selected based on their match to the typical or modal description given by research participants viewing the suspect.

Finally, care should be taken to ensure that the arrangement of the lineup is uniform. The photographs themselves should be similar and presented to witnesses in a standardized fashion. For example, if one photograph is slightly tilted away, or the focal length is greater, or the facial expression differs from the others, responses may be biased toward that photograph simply because it stands apart from the others in its presentation. Additionally, uniformity across members with respect to clothing should also be achieved. Moreover, if the eyewitness describes the perpetrator as wearing a particular type of clothing, the suspect should not be the only one wearing that type of clothing in the lineup.

Assessing Lineup Fairness

Researchers use the mock-witness procedure to determine lineup fairness, or the adequacy of lineup fillers. In the mock-witness procedure, participants who have not seen the perpetrator are given a description of the perpetrator along with a lineup. They are asked to pick the member of the lineup that most closely resembles the perpetrator's description. If the lineup is fair, then mock witnesses should not select the suspect at a rate significantly above chance.

Mock-witness choices can also be used to determine whether the fillers that have been selected for the lineup bias choices toward or away from the suspect. Bias measures include functional size and defendant bias. Mock-witness choices are also used to determine lineup size, which refers to the extent to which identification responses are distributed evenly across lineup members. Measures designed to examine lineup size include effective size, number of acceptable foils, and Tredoux's *E*.

Lineup bias and size can vary depending on how the members of the lineup are arranged. For instance, if the suspect is placed between two foils that are low in similarity relative to the suspect, the suspect may "pop out" and hence be chosen significantly more

often than when the suspect is placed between two other lineup members that have a greater resemblance to the suspect. This problem may arise even when the average pairwise similarity rating across the lineup members is high. Therefore, it is important that the foils are selected for the lineup using the same criteria. Another method for circumventing possible popout effects is for researchers to systematically rotate, or *counterbalance*, the position of the suspect in the lineup across participants.

Counterbalancing the position of the suspect in the lineup also controls for the possibility that the decision standard varies along with the number of faces that are viewed. This may be problematic especially in sequential lineups, in which the witness views each face one at a time. In particular, there is some evidence that the decision standard that witnesses use in making a positive identification may be lowered as they progress through the series of faces in a sequential lineup. As such, innocent suspects might have a higher probability of being chosen if they are positioned later in the sequence, as opposed to earlier.

Lineup Size and Bias

A lineup is constructed by placing a person suspected of committing a crime (the suspect) among a collection of innocent people (fillers). An eyewitness is asked to identify the offender from this collection, with a suitable admonition that the offender may not be present. A properly conducted lineup can provide evidence that the suspect is (or is not) the offender or that the eyewitness does not have a reliable memory of the offender's identity. For this to be the case the lineup must not be biased and it must be of sufficient effective size. A lineup is biased when a witness with a poor (or absent) memory is able to guess the identity of the suspect at a rate greater than chance expectation (one per lineup size). A lineup has a certain number of members, including the suspect, and this is called the *nominal size.* A lineup is unfair to the extent that it contains fillers who are not plausible choice alternatives to the suspect for a witness choosing randomly or a witness with a poor (or absent) memory. The suspect plus the number of persons who are alternative-choice alternatives is called the lineup's *effective size.*

Two basic rules govern the construction of eyewitness identification lineups. First, the suspect in the lineup should not "stand out" (be inappropriately distinct) from the other lineup members. Second, fillers should resemble the suspect in important attributes and should be appropriate-choice alternatives (i.e., witnesses who have a poor memory of the offender should not be able to reject them).

Lineup Fairness Evaluation

To determine whether the two basic rules have been adhered to, lineup evaluation research participants who have not seen the offender are asked to guess which lineup member is the suspect on the basis of a brief physical description (e.g., the description originally given by the witness to the police) or with no information at all about the appearance of the offender.

Lineup Bias

Bias is bidirectional—it can make the suspect more likely, or less likely, to be chosen by a witness who has no or very little specific memory of the offender. It is defined as a statistically reliable tendency for a

suspect to be chosen from a lineup at a rate different from that expected if the choice were made by chance alone (i.e., a random pick of a lineup member). The proportion of lineup evaluation research participants able to pick the suspect from the lineup is a measure of lineup bias.

Lineup Size

Nominal size is the number of persons presented in a lineup. Effective size, as noted earlier, is the number of persons in the lineup who are effective choice alternatives for a witness who has little information or memory about the actual offender or for a witness viewing a lineup in which the suspect is actually innocent (i.e., is not the offender). It is thought of as a reduction of the nominal size to a value that better represents the "true" number of plausible foils, or innocent persons in a police lineup (i.e., nominal size ≥ effective size). The index E, is a measure of the effective size of a lineup.

Role of Lineups in the Criminal Justice System

One purpose of having fillers in a lineup is to provide alternative choices for witnesses who feel that they must choose someone from the lineup but who may have little memory for the offender's actual appearance. When the witness feels compelled to make a choice, the presence of the fillers provides a safeguard against false identification by reducing the chance of false identification of an innocent suspect from 100% to 20% (for live lineups, which often have five members) or 16.67% (photo spreads, which often have six members).

Another purpose of having fillers in a lineup is to test the witness's memory for the perpetrator, although it must be said that the interpretation of this test is confounded. To see this, consider that a witness can make several choices when faced with a lineup. The witness can identify the suspect, identify a foil, say that the offender is not in the lineup, or say that he or she does not know whether the offender is in the lineup. If the witness identifies the suspect, we are likely to strengthen our belief that the suspect is the offender. If the witness identifies a foil, we are likely to either strengthen our belief that the witness has a poor memory or weaken our belief that the suspect is the offender. If the witness rejects the lineup, we may weaken our belief that the suspect is the offender, but if the witness does this with little confidence we will not know whether to weaken our belief that the suspect is the offender or to weaken our belief in the witness's memory. In all these cases, the inference(s) made are conditional on the fairness (size and bias) of the lineup. For example, a witness with no memory of the offender could choose the suspect from a biased or low-effective-size lineup with comparative ease.

Good and Bad Lineups

To fulfill their purpose, eyewitness identification lineups must not contain cues to the identity of the police suspect. For example, in one criminal case a (White) witness described the (Black) offender as possessing, among other attributes, "long hair in some kind of braids, a single row of braids that were coming loose." The lineup contained one person whose thin braids were visible, coming loose, behind his head. This person was the police suspect. It is not surprising that the witness identified him, as did 95% of lineup evaluation research participants. Since it remains ambiguous whether the basis for the identification was a genuine memory for the suspect from the criminal event or the fact that his photograph in the lineup contained a feature found in the witness's previous verbal description, it is not possible to reach a clear conclusion about whether or not the suspect is the offender.

There are two difficulties with this lineup. First, the suspect photograph stood out from the remaining photographs of the lineup because it was the only photograph that displayed thin braids that were coming loose, so that the lineup was biased against the suspect. Second, the fillers were chosen without regard to this highly distinctive feature. For this reason, the lineup had an effective size of only one, because without "braids, coming loose," none of the fillers in the lineup were a useful alternative-choice option for the suspect. The fillers might as well not have been present at all.

In another criminal case, a witness gave a description that included the phrase "small, squinted eyes." The photograph of the suspect used in the lineup showed him blinking. When the lineup was evaluated it was found that the suspect stood out dramatically in the lineup and that three of the fillers were hardly choice alternatives at all. The police had two alternative photographs of the suspect in which he had not blinked while being photographed. When one of these was substituted, the lineup was not biased against him. In addition, two other lineup members were

more likely to be identified by mock witnesses. The choice of photograph of the suspect, as well as the choice of filler photographs, is important when constructing a lineup.

Constructing Good Lineups

The general qualities of a good lineup are noted above: The suspect should not stand out, and the fillers should be effective choice alternatives to the suspect. Achieving this ideal requires careful attention to details.

- If the witness(s) has provided a description of the offender that has a reasonable amount of detail, a lineup can be formed using this description, provided that the description matches that of the suspect.
- If the witness's description of the offender is either impoverished or does not fit the suspect, then the lineup must be constructed to match the suspect's appearance.

Normally, the investigator would begin with the photo of the suspect that will appear in the lineup and, using whatever photographic archive available, find filler photographs that are sufficiently similar to the suspect for them to serve as effective choice alternatives. There are, however, some cautions to be observed.

First, if the suspect and investigator are of different racial groups, an investigator of the same racial group as the suspect should be asked to construct the lineup.

Second, the procedure of attempting to find five fillers who resemble the suspect can lead to a lineup in which the suspect stands out because he is the one person in the lineup who shares the most with each of its members: He becomes the prototype of the lineup and is more likely to be chosen by witnesses with little memory for the offender, witnesses who make a choice even when the offender is absent from the lineup. Alternate lineup construction procedures decenter the filler selection process in a number of ways. One procedure is to choose filler #1 to be an effective alternative to the suspect, and then to choose the others so that they are similar to both the suspect and filler #1. Another procedure is to choose filler #1 based on similarity to the suspect, filler #2 based on similarity to #1, and so on, until all 5 fillers have been chosen. Irrespective of the filler selection process, however, the same overall principles must be observed: The suspect should not stand out, and the fillers should be effective choice alternatives.

Evaluating Lineups

To evaluate whether a lineup is fair, we estimate its size and bias. This is done with a lineup evaluation task, as described above. Calculations over the total set of lineup evaluation participant decisions are used to determine bias (the proportion of participants choosing the suspect), and effective size (the extent to which participant choices are not equally distributed across lineup members). Thus, when the lineup has 6 members, and significantly more than 1 in 6 of the evaluation participants choose the suspect, the lineup is biased against the suspect. If significantly fewer than 1 in 6 choose the suspect, it is biased in favor of the suspect. A similar rationale is applied to lineup foils: To the extent that a foil is chosen by fewer than 1 in 6 evaluation participants, he or she is implausible as a foil. This determination can be made for each foil in the lineup, allowing one to arrive at a summary measure of the number of plausible foils. The degree to which this summary measure is less than the nominal size of the lineup represents the extent to which the safeguard against false identification afforded by the fillers has been diminished.

It is advisable to apply inferential statistics to each of these indices, especially when the number of participants is relatively small. One may test whether lineup bias is greater or less than that expected by chance (one per nominal size) and/or construct 95% confidence intervals around both bias and size indices.

All-Suspect and Multiple-Suspect Lineups

The police sometimes construct lineups in which all members are suspects. This practice entails several problems. In a single-suspect lineup, the choice of someone other than the suspect is diagnostic of a witness's unreliability because all other lineup members are known to be innocent. But in an all-suspect lineup, it is not possible for the witness to identify a person known to be innocent, because the investigator views all lineup members as potentially guilty. As a result, the safeguard against false identification is diminished. Thus, the identification of any lineup member at all becomes the suspect after the fact. For this reason, there is no way to evaluate the witness's memory

about the identified person, and there is no way to detect a witness who chooses completely at random, or on the basis of a poor or faulty memory. Lineups composed of multiple, but not all, suspects degrade the safeguard somewhat less.

Litigation Stress

Litigation stress is best understood as consisting of negative physical and psychological reactions to being involved in a legal action. Indeed, litigation itself is mentioned specifically as a stressor in the multiaxial *Diagnostic and Statistical Manual of Mental Disorders–Text Revised* (fourth edition), in Axis IV (Psychosocial and Environmental Problems). A variety of physical and emotional responses to litigation have been found. Litigation is an uncertain process and one with which most people are not familiar. It can affect one's identity, causing feelings of guilt and shame, and can lead to isolation from family and peers. The problem is particularly acute for health professionals, who face professional sanctions in addition to the other consequences of a lawsuit.

The earliest work on litigation stress was done by a physician, Sara Charles, who herself was the subject of a medical malpractice suit. In her work, she found that more than 95% of sued mental health professionals acknowledge some physical and/or emotional reaction.

Physical responses typically include the onset or exacerbation of a physical illness, such as myocardial infarction or peptic ulcer disease. Headaches, sleep disturbance, chest pain, and gastrointestinal symptoms may also be reported. An exacerbation of any preexisting physical health problems can be expected. Even cases of cardiac arrest in the first months after initiation of an investigation have been reported.

Emotional responses are more common and may range from anger to profound depression or even suicide. Cognitive disruptions such as problems with concentration and attention are common. Irrational thoughts associated with "catastrophizing" and "awfulizing" are common, along with rumination about potential disastrous outcome. Marital and family conflicts are very common consequences of litigation stress. Preexisting strains in these relationships are magnified. As one would expect, it is not uncommon for the use of alcohol, tobacco, and caffeine to increase during this time of stress. The risk for abuse of these substances increases, along with various prescription medications, especially pain medications, anti-anxiety drugs, and sleep medication.

Why do litigation and complaints cause such stress? First, the operations of the legal and complaints systems are unpredictable, particularly for those who do not work in the system or are not familiar with the rules, terminology, and processes. This unpredictability is a significant factor contributing to the practitioner's sense of a lack of control over the process they are facing. Second, this unpredictability is compounded by a lack of knowledge about the process in which they are engaged, and the fact that in many instances, others may make decisions that could significantly influence the outcome of their case. Third, a lawsuit is a direct assault on an individual's personal identity and engenders feelings of shame and guilt. Finally, it is often the case that a person who is

sued feels alone and isolated from his or her peers, family, and friends because of allegations of having done something inappropriate or wrong.

Among health care professionals, the threat of a malpractice lawsuit is particularly serious. For mental health professionals, being named in a malpractice suit can have particular professional consequences beyond what usually happens to other defendants. Since 1986, any entity making payments in settlement of a malpractice claim (unless the payment is made by the mental health professional on his or her own behalf) must report the provider and case details to the National Practitioner Data Bank (NPDB). Furthermore, credentialing bodies (e.g., hospitals, group practices, licensing authorities) are required by law to query the NPDB when considering the qualifications of a mental health professional applicant.

Surveys such as that done in 1979 by Mawardi in the *Journal of the American Medical Association* have found a high rate of concern over the threat of malpractice litigation among physicians; some respondents actually contemplated giving up the practice of medicine. These surveys have also indicated that over half of all physicians practice "defensive medicine" so as to avoid or minimize the risk of legal action. Defensive practices include limiting practice by not performing certain high-risk procedures, ordering medically unnecessary tests to document clinical judgments, and even turning away patients seen as potentially litigious. Williams, in a 1981 article in the *Journal of the Arkansas Medical Society*, termed physicians' fear of malpractice litigation "paranoia malpracticum." A similar term "litigaphobia" was later coined by Stan Brodsky.

Being sued for malpractice has indeed been shown to be an emotionally traumatic experience for physicians and for mental health professionals as well. The initial reaction to being named in a malpractice suit is often a high level of anxiety, accompanied by feelings of righteous indignation, anger, and vindictiveness. Self-esteem may also be affected. Such stressful effects may be heightened by a loss of social support similar to that often experienced in divorce, as well as the uncertainty engendered by the possible impact that the legal action may have on the professional's life and career.

In addition to the significant physical and psychological responses to malpractice litigation, mental health professionals are more likely to stop seeing patients who seem to have a greater risk of experiencing a bad outcome or of propensity to initiate a suit. These mental health professionals are more likely to consider early retirement and to discourage their own children from entering the medical profession. In a 1988 survey of psychologists, fear of litigation was an acknowledged reason for the use of sound risk-management techniques. After being sued, many mental health professionals begin to keep more meticulous records, order more tests and consultations, and stop performing procedures that may result in risk even when they are appropriate and performed competently.

MacArthur Competence Assessment Tool for Clinical Research (MacCAT–CR)

The MacArthur Competence Assessment Tool for Clinical Research (MacCAT–CR) provides a semi-structured assessment format for evaluating abilities related to the decisional capacity of subjects in clinical research. Four component abilities of a decisional capacity standard are assessed: understanding, appreciation, reasoning, and choice. Administration of the instrument begins with the disclosure of selected information about a given research project, on the basis of which these abilities are measured. The MacCAT–CR, which takes 15 to 20 minutes to administer, has demonstrated good reliability and validity and has been used both to explore the relative abilities of different subject groups and to assess the capacities of particular research subjects prior to entry into studies.

Informed consent of research subjects is a nearly universal requirement of ethical codes, federal regulations, and common law. For subjects' consent to be valid, they must be competent (i.e., they must have adequate decisional capacity—the terms are used interchangeably in this entry) to offer consent. Because persons are generally presumed to be competent to make decisions of all sorts, barring evidence to the contrary, the question of whether subjects are competent does not arise for most research subjects; the casual interactions between subjects and researchers are sufficient to sustain the presumption of subjects' capacity. However, some subject groups may have an elevated probability of incapacity, making it desirable, particularly in higher-risk studies, to perform an explicit assessment of their capacity. The demonstrated variability in clinical judgments of competence has encouraged the development of competence assessment instruments for this purpose.

The MacCAT–CR grows out of the four-part conceptualization of decisional capacity that underlay the MacArthur Competence Assessment Study and that is based on existing case law; statutes; and bioethical, psychological, and medical literature. *Understanding* is the first of these four components of competence. Research subjects, at a minimum, must have the ability to understand the basic elements of disclosure required by the U.S. Federal Common Rule, including the purpose of the research project, the procedures involved, material risks, possible benefits, and alternatives to research participation. The second component, *Appreciation,* reflects the importance of subjects' abilities to apply the disclosed information to their own situations, including their recognition that the research project is aimed at generalizable knowledge, not at optimizing the treatment they receive, and that they are truly free to decline to participate without penalty. *Reasoning,* the third component, focuses on subjects' abilities to manipulate the information disclosed to them, comparing and weighing the consequences of the alternatives before them. The final component is *Choice,* the ability to select the desired option and to sustain a consistent decision.

Because the information that subjects must understand will differ across research projects, the MacCAT–CR provides a format for disclosure of study-specific information that is standardized for all

subjects in a given research study. Following disclosure of discrete informational elements, subjects' understanding is queried by asking them to paraphrase the disclosure about specific items. Appreciation questions can be modified, if necessary, according to the nature of a given project but reasoning and choice questions are fixed. There is no effort to provide the kind of comprehensive disclosure typically embodied in informed consent forms or to measure understanding and appreciation of, or reasoning about, all aspects of the study. Rather, the MacCAT–CR offers a virtual "biopsy" of subjects' abilities related to competence, on the assumption that the sampled data will be typical of their abilities in dealing with a complete disclosure.

Subjects' responses to the MacCAT–CR items are scored in a structured fashion, with scores aggregated on scales for each of the four abilities being assessed. However, composite scores across all four scales are not generated, because poor performance on any one of the relevant abilities may indicate significantly impaired capacity, rendering a composite score meaningless. Nor does the MacCAT–CR provide a fixed cutoff above which subjects are deemed competent to consent. The degree of capacity required for participation in a given study should reflect the characteristics of that study, including its complexity and risks. Moreover, the capacity demanded of subjects at risk for decisional impairment (e.g., persons with mental illnesses, developmental disabilities, dementia, and serious medical disorders) ought not to exceed the abilities demonstrated by the general population. Finally, decisions about capacity should take into account clinical data that may not be reflected in assessment scores. Although investigators or institutional review boards can set MacCAT–CR cutoffs for particular studies, the instrument is designed to be used as an aid to clinical judgment, with investigators retaining the discretion to determine whether subjects are capable of consenting.

Use of the MacCAT–CR for research on decisional capacity and to screen subjects for entry to research projects has demonstrated that the instrument can be scored reliably, and that it shows good construct and convergent validity. Studies have been performed to date with samples of persons with depression, schizophrenia and related psychotic disorders, Alzheimer's disease, mental retardation, and HIV infection and with prisoners, forensic patients, and parents of neonatal research subjects. Impairments in the abilities measured by the MacCAT–CR correlate strongly with cognitive impairments on neuropsychological tests and correlate more variably with psychotic symptoms. Thus, increasing levels of decisional abilities are found as one moves from subjects with Alzheimer's disease to those with schizophrenia, depression, and general medical illnesses. Further research is required to determine the impairments associated with varying levels of depression and with medical conditions in which the disorder itself or its treatment may affect mentation.

Screening of potential research subjects with the MacCAT–CR has demonstrated that subjects, especially those with mental illnesses, who score poorly on initial administration can often experience improved decisional capacities with remedial educational efforts. As might be expected, levels of understanding show the greatest response to additional education, with lesser impact seen on appreciation and reasoning. Nonetheless, these studies have suggested that many research subjects can learn the information required to give a competent consent if afforded extra assistance for doing so. Thus, screening for decisional capacity accompanied by remedial education may result in better informed subjects capable of giving consent on their own rather than in the exclusion of large numbers of subjects or in a resort to substituted consent.

MacArthur Competence Assessment Tool for Criminal Adjudication (MacCAT–CA)

Mental health professionals often conduct evaluations to assist courts in determining whether a criminal

defendant is competent to participate in the adjudicatory process. A variety of instruments have been developed to help structure these forensic assessments; this entry describes one of the more contemporary competence assessment instruments, the MacArthur Competence Assessment Tool–Criminal Adjudication (MacCAT–CA).

In the United States, people accused of crimes have certain rights with respect to the adjudicatory process that are guaranteed by the Constitution. In particular, they have the Fifth Amendment protection against self-incrimination and rights articulated in the Sixth Amendment, which include the assistance of legal counsel, the right to confront their accusers, and the right to trial by a jury of their peers.

To benefit from these rights, defendants must be mentally competent to assert them. In *Dusky v. United States* (1960), the U.S. Supreme Court articulated specific functional abilities that defendants must have to participate competently in the adjudicatory process: They must be able to assist counsel, and they must have both a rational and a factual understanding of the proceedings against them.

Most, if not all, jurisdictions recognize only mental impairment—often characterized as "mental disease or defect"—as a basis for incompetence to proceed to adjudication. When questions about a defendant's mental capacities arise, the courts almost invariably solicit the assistance of mental health professionals (primarily psychiatrists and psychologists) in resolving the issue. These forensic evaluators attempt to inform the court whether, and the extent to which, the defendant's functional abilities required by *Dusky* are compromised by psychiatric problems.

Historically, the primary tool available to forensic examiners for assessing competence was the unstructured or semistructured interview. Although interview approaches can provide valuable information, they are vulnerable to a variety of sources of potential bias. For example, interview-based results from evaluations of the same defendant may be inconsistent because different examiners (a) asked questions that varied in content and/or difficulty, (b) had different subjective criteria for judging the adequacy of a defendant's responses to various questions, or (c) used different reference groups or subjective algorithms for aggregating the information to formulate more focused conclusions about the defendant's capacities.

The MacCAT–CA was designed to enable forensic examiners to collect information relevant to a defendant's competence in a way that minimizes the influence of clinical subjectivity. The MacCAT–CA comprises three measures, each of which relates conceptually to one of the *Dusky* criteria. Each of these measures is described briefly below.

The Understanding measure includes 8 items that query issues such as the general roles and responsibility of the prosecuting attorney and defense attorney, the elements of a criminal offense, the responsibilities of a judge and those of a jury, the nature of criminal sentencing, and a defendant's rights at trial. Thus, it relates to the *Dusky* requirement that a defendant have a "factual understanding" of legal proceedings.

The Appreciation measure includes 6 items that query the respondent about expectations regarding his or her pending case. These items relate to issues such as expectations about disclosing information to, and receiving assistance from, the attorney; the likelihood of being convicted; the likely severity of punishment if convicted; and expectations that one will be treated fairly by the courts. The respondent is asked to state his or her expectations and then explain the reasons for these beliefs. Scoring of these items involves a judgment of the plausibility of the defendant's reasons for his or her beliefs—thus Appreciation relates to the *Dusky* requirement of a "rational understanding" of proceedings.

Finally, the Reasoning measure includes 8 items that require a defendant to exercise logical and reasoning skills in relation to legal information. Each of 5 items presents the respondent with two pieces of hypothetical information. These pieces of information are embedded in a hypothetical vignette (i.e., a man is arrested after getting into a fight at a bar) and the respondent is challenged to determine which piece of information has the greatest legal relevance for the hypothetical actor and to explain the basis for its greater legal relevance. Three other Reasoning items describe alternative dispositional choices for the hypothetical actor, proceeding to trial or accepting a plea agreement. The respondent's task is to articulate comparisons and contrasts (e.g., conduct a risks-and-benefits analysis) between these choices, thus demonstrating the capacity to reason about legal alternatives. This measure is conceptually related to the *Dusky* requirement of "capacity to assist counsel."

Three structural features of the MacCAT–CA limit the extent of interviewer subjectivity in the assessment. First, the administration is highly structured. The same 22 items are presented to each defendant, with

instructions for both initial presentation and follow-up queries/probes to minimize examiner-related differences in the presentation. Second, explicit instructions and criteria are written for scoring each item, which minimizes differences in examiners' judgment as to what is a correct or incorrect answer. Third, the total score for each measure (sum of item scores for Understanding, Reasoning, and Appreciation) is interpreted in light of norms based on a large, multistate sample of offenders recruited in jails and forensic psychiatric hospitals. Thus, statistical norms exist to guide clinical interpretation as to whether, and to what extent, a particular respondent manifests impairment in the functional legal abilities articulated in *Dusky.*

Research with adult offenders has demonstrated that the MacCAT–CA measures are reliable, with internal consistency estimates (Cronbach's alpha) of .85, .81, and .88 for Understanding, Reasoning, and Appreciation, respectively. Interscorer reliability of .90, .85, and .75 for Understanding, Reasoning, and Appreciation, respectively, were reported in the MacCAT–CA manual. Evidence for the validity of the instrument includes that each measure correlates in expected ways with measures of intellectual capacity (positively) and with measures of psychotic symptomatology (negatively). Furthermore, poorer scores are obtained on MacCAT–CA measures by defendants who have been adjudicated incompetent to stand trial than by comparison groups of jail inmates awaiting trial. Finally, MacCAT–CA scores help to discriminate competent from incompetent defendants after controlling for measures of other constructs including demographic features, criminal history, and psychopathology variables.

Although the MacCAT–CA offers some advantages in terms of structuring and standardizing certain competence-related inquiries, it was designed to supplement, rather than to replace, the clinical interview in assessing adjudicative competence. It does not assess directly all the factors that might affect a defendant's competence—for example, poor memory for events at or near the time of the alleged crime or incoherence of thoughts or speech that might make assisting counsel difficult. Furthermore, the clinician using the MacCAT–CA must still make judgments regarding symptoms of mental disorder and their contribution, if any, to poor performance on the MacCAT–CA. Thus, the MacCAT–CA is not a stand-alone measure of competence. It is best conceived as its name indicates—a "tool" to assist mental health professionals in their assessment of defendants' competence-related abilities.

MacArthur Competence Assessment Tool for Treatment (MacCAT–T)

The MacArthur Competence Assessment Tool for Treatment (MacCAT–T) is an instrument designed to assess decision-making capacity. Designed as part of the MacArthur Competence Treatment Competence Study, a multiyear, multisite effort named for the well-known philanthropic foundation, the tool operationalizes established elements of competent decisions. The semistructured instrument, which can be completed within 20 to 30 minutes, guides clinicians through the discussion of a specific treatment decision and scores responses on four separate scales.

Structured disclosures assess patients' understanding, reasoning, appreciation, and choice, the four elements of decision making established in reviews of the established legal and ethical literature. For understanding, patients are tested on their comprehension of the nature of their illness, recommended treatment, alternatives, and risks and benefits. Reasoning evaluates patients' problem-solving ability when faced with a specific treatment choice. Appreciation assesses

acknowledgment of illness and the potential value of treatment, while choice determines whether patients make a selection consistent with their reasoning.

Intended for the comparison of patient groups, the MacCAT–T has been tested in a variety of populations, including patients diagnosed with schizophrenia, psychosis, dementia, and depression. It has shown strong interrater reliability and good agreement with the assessment of clinicians.

The MacCAT–T has been instrumental in demonstrating important correlations between symptoms, cognitive variables, and decision-making capacity. In a number of studies, it has underscored the relevance of specific variables such as thought disorganization and attention while demonstrating that patients with mental illness nonetheless overlap with control populations in many of their abilities.

Criticized for its reliance on a cognitive-based assessment of capacity, the instrument does in fact go beyond cognition in its assessment. The appreciation standard, for example, is more than a simple cognitive standard, including, as it does, the treatment's significance and relevance to the patient. Moreover, even emotional capacity relies on cognition to assess the meaningfulness of a situation. Indeed, in one direct comparison of capacity assessment tools, the MacCAT–T was clearly found to address the common construct underlying different competence standards.

One of a number of semistructured interviews to come out of the MacArthur studies, the MacCAT–T is now part of an entire generation of commonly used tools assessing specific decision-making capacities.

MacArthur Violence Risk Assessment Study

Violence risk assessment is now widely assumed by policy makers and the public to be a core skill of the mental health professions and plays a pivotal role in mental health law throughout the world. *Dangerousness to others* is a principal standard for inpatient commitment, outpatient commitment, and commitment to a forensic hospital. The imposition of tort liability on mental health professionals who negligently fail to anticipate and avert a patient's violence to others has become commonplace. Despite the pervasiveness of violence risk assessment in mental health law, research continues to indicate that the unaided abilities of mental health professionals to perform this task are modest at best. Many have suggested that making available to clinicians statistical information on the relationships between various risk factors and subsequent violent behavior is the only way to reduce the disconnect between what the law demands and what clinicians are able to provide. The MacArthur Violence Risk Assessment Study was one attempt to generate the necessary empirical information to improve clinical practice in the area of violence risk assessment. The approach to risk assessment developed in this project appears to be highly accurate when compared with other approaches to assessing risk among people hospitalized in acute-care psychiatric facilities. But it is also much more computationally complex than other approaches. Therefore, software has been developed to ease the administration of the MacArthur procedures in clinical practice.

The MacArthur Study's General Research Strategy

The MacArthur Violence Risk Assessment Study had two core goals: to do the best "science" on violence risk assessment possible and to produce an actuarial violence risk assessment "tool" that clinicians in the world of managed mental health services could actually use.

From these initial intellectual commitments, the Study evolved in six stages over the decade it took to plan, execute, and analyze the research.

Identifying Gaps in Methodology

Almost all existing studies of violence risk assessment suffer from one or more methodological problems: They considered a constricted range of risk factors, often a few demographic variables or scores on a psychological test; they employed weak criterion measures of violence, usually relying solely on arrest; they studied a narrow segment of the patient population, typically males with a history of prior violence; and they were conducted at a single site. Based on this critical examination of existing work, the MacArthur researchers designed a piece of research that could, to the greatest extent possible, overcome the methodological obstacles that had been identified. They studied a large and diverse array of risk factors. They triangulated the outcome measurement of violence, adding patient self-report and the report of a collateral informant to data from official police and hospital records. They studied both men and women, regardless of whether they had a history of violence. And they conducted the study at several sites rather than at a single site.

Selecting Promising Risk Factors

Although the MacArthur researchers lacked any comprehensive theory of violence by people with mental disorder from which they could derive hypothesized risk factors, recent studies suggested that a number of variables might be potent risk factors for violence among people with a mental disorder. The researchers assessed personal factors (e.g., demographic and personality variables), historical factors (e.g., past violence and mental disorder), contextual factors (e.g., social support and social networks), and clinical factors (e.g., diagnosis and specific symptoms). They chose what they believed to be the best of the existing measures of these variables, and where no instrument was available to adequately measure a variable, they commissioned the development of the necessary measure.

Using Tree-Based Methods

The MacArthur researchers developed violence risk assessment models based on the "classification tree" method rather than the usual linear regression method. A classification tree approach reflects an interactive and contingent model of violence, one that allows many different combinations of risk factors to classify a person at a given level of risk. The particular questions to be asked in any assessment grounded in this approach depend on the answers given to prior questions. Factors that are relevant to the risk assessment of one person may not be relevant to the risk assessment of another person. This contrasts with a regression approach in which a common set of questions is asked of everyone being assessed, and every answer is weighted to produce a score that can be used for purposes of categorization.

Creating Different Cutoffs for High and Low Risk

Rather than relying on the standard single threshold for distinguishing among cases, the MacArthur researchers decided to employ two thresholds—one for identifying higher risk cases and one for identifying lower risk cases. They assumed that inevitably there will be cases that fall between these two thresholds, cases for which any actuarial prediction scheme is incapable of making an adequate assessment of high or low risk. The degree of risk presented by these intermediate cases cannot be statistically distinguished from the base rate of the sample as a whole (therefore, they referred to these cases as constituting an *average risk group*).

Repeating the Classification Tree

To increase the predictive accuracy of a classification tree, the MacArthur researchers reanalyzed the cases that had been designated as "average risk." That is, all people not classified into groups designated either as high risk or as low risk in the standard classification tree model were pooled together and reanalyzed. The logic here was that the people who were not classified in the first iteration of the analysis might be different in some significant ways from the people who were classified and that the full set of risk factors should be available to generate a new classification tree specifically for these people who were not already classified as high risk or as low risk. They referred to the resulting classification tree model as an *iterative* classification tree.

Combining Multiple Risk Estimates

Finally, the MacArthur researchers estimated several different risk assessment models in an attempt to obtain multiple risk assessments for each case. That is, they chose a number of different risk factors to be the lead variable on which a classification tree was constructed. In attempting to combine these multiple risk estimates, they began to conceive of each separate risk estimate as an indicator of the underlying construct of interest—violence risk. The basic idea was that patients who scored in the high-risk category on many classification trees were more likely to be violent than patients who scored in the high-risk category on fewer classification trees. (And analogously, patients who scored in the low-risk category on many classification trees were less likely to be violent than patients who scored in the low-risk category on fewer classification trees.)

Specific Research Methods in the MacArthur Study

More than 1,000 admissions were sampled from acute civil inpatient facilities in Pittsburgh, Pennsylvania, Kansas City, Missouri, and Worcester, Massachusetts. The MacArthur researchers selected English-speaking patients between the ages of 18 and 40, who were of White, Black, or Hispanic ethnicity, and who had a chart diagnosis of thought or affective disorder, substance abuse, or personality disorder. The median length of stay was 9 days. After giving informed consent to participate in the research, the patient was interviewed in the hospital by both a research interviewer and a research clinician to assess him or her on each of the risk factors.

Three sources of information were used in the MacArthur Study to ascertain the occurrence and details of a violent incident in the community. Interviews with patients, interviews with collateral individuals (i.e., persons named by the patient as someone who would know what was going on in his or her life), and official sources of information (arrest and hospital records) were all coded and compared. Patients and collaterals were interviewed twice over the first 20 weeks—approximately 4 to 5 months—from the date of hospital discharge.

Violence to others was defined to include acts of battery that resulted in physical injury, sexual assaults, assaultive acts that involved the use of a weapon, or threats made with a weapon in hand.

Results of the MacArthur Study

At least one violent act during the first 20 weeks after discharge from the hospital was committed by 18.7% of the patients in the MacArthur Study. Of the 134 risk factors measured in the hospital, approximately half had a statistically significant bivariate relationship with later violence in the community ($p < .05$). Some examples of specific risk factors that were—or were not—significantly related to violence are as follows:

Gender: Men were somewhat more likely than women to be violent, but the difference was not large. Violence by women was more likely than violence by men to be directed against family members and to occur at home and less likely to result in medical treatment or arrest.

Prior violence: All measures of prior violence—self-report, arrest records, and hospital records—were strongly related to future violence.

Childhood experiences: The seriousness and frequency of having been physically abused as a child predicted subsequent violent behavior, as did having a parent—particularly a father—who was a substance abuser or a criminal.

Diagnosis: A diagnosis of a major mental disorder—especially a diagnosis of schizophrenia—was associated with a *lower* rate of violence than a diagnosis of a personality or adjustment disorder. A co-occurring diagnosis of substance abuse was strongly predictive of violence.

Psychopathy: Psychopathy, as measured by a screening version of the Hare Psychopathy Checklist, was more strongly associated with violence than any other risk factor. The "antisocial behavior" component of psychopathy, rather than the "emotional detachment" component, accounted for most of this relationship.

Delusions: The presence of delusions—or the type of delusions or the content of delusions—was not associated with violence. A generally "suspicious" attitude toward others was related to later violence.

Hallucinations: Neither hallucinations in general nor "command" hallucinations per se elevated the risk of violence. If voices specifically commanded a violent act, however, the likelihood of violence was increased.

Violent thoughts: Thinking or daydreaming about harming others was associated with violence, particularly if the thoughts or daydreams were persistent.

Anger: The higher a patient scored on the Novaco Anger Scale in the hospital, the more likely he or she was to be violent later in the community.

These are only bivariate relationships between single risk factors measured in the hospital and violence during the first 20 weeks after discharge into the community, however. The more important question is how the risk factors performed when combined as described above. The MacArthur researchers ultimately combined the results of five prediction models generated by the iterative classification tree methodology. This combination of models produced results not only superior to those of any of its constituent models but also superior to many other actuarial violence risk assessment procedures reported in the literature. Using only those risk factors commonly available in hospital records or capable of being routinely assessed in clinical practice, the researchers were able to place all patients into one of five risk classes for which the prevalence of violence during the first 20 weeks following discharge into the community was 1%, 8%, 26%, 56%, and 76%.

Violence Risk Assessment Software

To operationalize the risk assessment procedures developed in the MacArthur Violence Risk Assessment Study, five tree-based prediction models need to be constructed, each involving the assessment of many risk factors. It would clearly be impossible for a clinician to commit the multiple models and their scoring to memory, since different risk factors are to be assessed for different patients, and using a paper-and-pencil protocol would be very unwieldy. Fortunately, however, the administration and scoring of multiple tree-based models lends itself to software. In clinical use, the risk assessment instrument developed in the MacArthur Study consists simply of a series of questions that flow one to the next on a computer screen—through the various iterations of each of the models as necessary—depending on the answer to each prior question. Under a grant from the National Institute of Mental Health, the MacArthur researchers developed such a "violence risk assessment software," the Classification of Violence Risk™.

Malingering

Forensic assessments must evaluate systematically the accuracy and forthrightness of individuals referred for evaluation of psycholegal issues. Among different response styles that should be considered, malingering is a cornerstone issue for forensic consultations. *Malingering* is defined by the *Diagnostic and Statistical Manual of Mental Disorders* (fourth edition; *DSM-IV*) of the American Psychiatric Association as a deliberate fabrication or gross exaggeration of symptoms for an external goal. Feigned symptoms and associated features may be psychological, medical, or a combination of both. Forensic psychologists and psychiatrists should note that minor or even substantive exaggerations do not warrant the classification of malingering; only *grossly exaggerated* symptoms qualify for malingering. An example of gross exaggeration would be the deliberate misrepresentation of an occasional thought about one's demise (e.g., "I wish I was dead") as a current suicidal ideation that includes planning and possible preparation. Because court reports require precision, forensic psychologists may wish to operationalize "gross exaggeration." For such purposes, the Schedule of Affective Disorders and Schizophrenia (SADS) provides a criterion-based standard for rating the severity of reported symptoms. Many symptoms on the SADS are rated on six levels of severity: 1 = *absent,* 2 = *slight or subclinical,*

3 = *mild,* 4 = *moderate,* 5 = *severe,* and 6 = *extreme.* According to Richard Rogers, *gross exaggeration* should be defined as a minimum of three levels of amplification. To qualify as grossly exaggerated, (a) slight symptoms would need to be severe or extreme and (b) mild symptoms would need to be extreme.

Malingering is a *DSM-IV* classification and not a formal diagnosis. This distinction is critical to forensic evaluations. Malingering is categorized as a "V code," which signifies an undiagnosed condition that may be the focus of clinical attention. Note that the operative word is "may," suggesting that malingering is not always a focal point for clinical attention. More important, V codes do not provide inclusion criteria for clearly establishing a clinical condition. The screening indicators provided in *DSM-IV* are merely meant to raise suspicions of malingering. Misuse of these screening indicators as inclusion criteria is a very serious breach of professional practice with ethical implications. To underscore this crucial issue, forensic clinicians should draw no conclusions, however tentative, regarding the presence or absence of malingering on the basis of *DSM-IV* screening indicators.

A careful analysis of *DSM-IV* screening indicators suggests that they should not be used for any purpose, because of their inaccuracies and lack of discriminability. Based on available research, *DSM-IV* screening indicators are likely to lead to false positives approximately 80% of the time. Consider for the moment the perils of applying these indicators to criminal-forensic cases. Two of the four indicators (e.g., forensic context and antisocial personality) occur in a high proportion of cases, rendering them ineffective at distinguishing malingering from genuine disorders. The remaining two indicators (lack of cooperation and marked discrepancies) also lack discriminability.

Domains of Malingering

Malingering is almost never a pervasive response style. Instead, malingerers are typically selective about what types of symptoms are feigned and what specific goals can be achieved. Three general domains of malingering have been identified: mental disorders, cognitive abilities, and medical complaints. Each domain places specific demands of malingerers, who are attempting a successful performance (i.e., the avoidance of detection). In the next three paragraphs, each domain is explored.

Feigned Mental Disorders. Malingerers in this domain must create a plausible set of symptoms with a credible description of their onset and course. Importantly, they must decide how much insight to have regarding these symptoms and their effects on daily functioning. For truly sophisticated presentations, feigning must take into account negative symptoms (e.g., the absence of spontaneous speech) as well as positive symptoms (e.g., the presence of auditory hallucinations). If provided treatment, they must decide what changes, if any, occur with their symptoms and their insights into these symptoms.

Feigned Cognitive Impairment. Malingerers in this domain must exhibit "effortful failures." In other words, they must portray seemingly genuine effort while making plausible mistakes on neuropsychological and intelligence testing. While the immediate task of feigning appears comparatively easy (i.e., "try hard but get it wrong"), malingerers face an additional hurdle of feigning believable deficits in light of past documentation. In most instances, for example, the feigning of mental retardation poses a daunting challenge because academic records (e.g., school performance and aptitude tests) provide relevant data about intellectual abilities.

Feigned Medical Complaints. Malingerers in this domain can be categorized as feigning either nonspecific complaints or a specific diagnosis. Nonspecific complaints (e.g., headaches, fatigue, and pain) are relatively easy to generate and difficult to disprove, especially when described as intermittent or sporadic. However, malingerers must decide whether such complaints will be sufficient to meet their goals (e.g., unwarranted compensation in a personal injury case). Far more complex is the feigning of specific medical disorders that may involve the deliberate contamination of laboratory tests. Health care staff may be alerted to malingering by anomalies in test results. In addition, malingerers may evidence an unlikely level of sophistication in their knowledge of test findings that is uncharacteristic of genuine patients.

Different detection strategies are required for each domain. For example, assessment methods for identifying bogus hallucinations are likely to be ineffective with individuals claiming memory loss secondary to a traumatic injury. In this instance, persons with purported amnesia have no reasons to fabricate psychotic

symptoms. In the next section, detection strategies for feigned mental disorders and feigned cognitive impairment will be addressed. The third domain, feigned medical complaints, is beyond the scope of this contribution.

Detection Strategies

In the assessment of malingering, a crucial distinction must be made between common and discriminating characteristics. As part of the external motivation, many malingerers are involved in forensic evaluations. However, this is a common but not discriminating characteristic that is unhelpful in the evaluation of potential malingering. Naive practitioners have mistakenly assumed that the obverse is true: "If the majority of malingerers are involved in forensic referrals, then the majority of forensic referrals are malingerers." This logic is fundamentally flawed and can lead to tragic errors. To illustrate this logical fallacy, consider the proposition "Most murderers are men; therefore, most men are murderers." However, its persistence among naive practitioners may stem in part from their fundamental misunderstanding of the *DSM-IV* screening indicators.

Discriminating characteristics of malingering require that specific variables differentiate between genuine and feigned protocols. For example, individuals with genuine memory problems will conform to certain learning principles (e.g., recognition is easier than recall), whereas some malingerers will fail equally on recognition and recall tasks. Therefore, the violation of a learning principle is a discriminating characteristic and has the potential to be useful in the evaluation of feigned cognitive impairment. Discriminating characteristics form the bases for detection strategies.

What is a detection strategy for malingering? According to Richard Rogers, detection strategies represent a standardized method for differentiating between malingered and genuine conditions. Detection strategies must be conceptually based and empirically validated. For instance, the violation of a learning principle has a sound conceptual basis. For empirical validation, detection strategies should not only produce substantial effect sizes (i.e., large group differences) but also facilitate via utility estimates in the individual classification of malingered versus genuinely impaired cases.

Detection Strategies for Feigned Mental Disorders

Persons with malingering mental disorders are often unaware of characteristic patterns commonly found with bona fide patients. As a result, they often have *unlikely presentations,* characterized by atypical symptoms and symptom patterns, not usually found in genuine populations. In addition, malingerers often miscalculate the typical intensity of common symptoms and associated features. Therefore, detection strategies can also capitalize on *amplified presentations,* for which the symptoms may appear genuine, but the reported frequency and intensity is highly uncharacteristic of genuine populations. Outlined below are detection strategies based on unlikely and amplified presentations.

Unlikely Presentations

Rare Symptoms. Malingerers are unlikely to recognize which symptoms occur very infrequently among genuine patients. Reporting a large number of rare symptoms is strongly indicative of feigning.

Symptom Combinations. Malingerers are likely to recognize common psychological symptoms that are experienced by genuine patients. They are unlikely, however, to recognize that some psychological symptoms do not typically occur together. Reporting a large number of uncommon symptom combinations is indicative of feigning.

Improbable Symptoms. Improbable symptoms are extreme and fantastic in quality. These symptoms can be thought of as extreme variants of rare symptoms due to their preposterous and seemingly ridiculous content. Frequent report of improbable symptoms indicates feigning.

Unlikely Patterns of Psychopathology. This strategy relies on the idea that there are general patterns of psychopathology that are unlikely to be experienced by psychiatric patients. As the symptom combination strategy relies on unlikely patterns at a symptom level, the unlikely patterns of psychopathology strategy relies on more collective and complex patterns that are improbable in genuine populations. Owing to the complexity of this strategy, it has been primarily employed on multiscale inventories.

Amplified Presentations

Indiscriminate Symptom Endorsement. This strategy relies on the finding that malingerers will report a large array of psychological symptoms, larger than that of even the most impaired clinical patients. Endorsement of a very large number of symptoms may indicate feigning.

Symptom Severity. This strategy relies on the finding that malingerers will report a large number of symptoms as extreme or unbearable. This strategy should not be confused with indiscriminate symptom endorsement. Symptom severity relies on the amplified "depth" of symptoms as opposed to the atypical "breadth" assessed by indiscriminant symptom endorsement.

Obvious Symptoms. This strategy relies on the endorsement of very blatant symptoms of mental illness by malingerers. Obvious symptoms are different from rare symptoms due to the typicality of obvious symptom content. These symptoms are not defined by their rarity in clinical populations but by their obvious relationship with severe psychological disorders. Comparison between an individual's report of obvious versus more subtle symptoms has also been useful in the detection of feigning. Endorsement of a large number of obvious symptoms may be indicative of feigning.

Erroneous Stereotypes. The erroneous stereotype strategy relies on common misperceptions about psychological symptom experiences. These symptoms describe lay nonprofessional general perceptions about persons with mental disorders. Individuals who agree with many of these erroneous stereotypes are likely to be feigning.

Reported Versus Observed Symptoms. This strategy relies on the observation of individuals' clinical presentation and their report of psychological symptoms. Reporting of symptoms that are more impaired than what is observed may be an indication of feigning. The reported versus observed strategy is not a simple comparison of consistency. Only reports of symptoms that are "worse" than observed should be considered as possible feigning.

Many psychological measures possess scales designed to assess a patient's likelihood of feigning mental disorders. Currently, the Minnesota Multiphasic Personality Inventory–2 (MMPI–2) and Structured Interview of Reported Symptoms (SIRS) are the most widely used tests for the detection of feigned mental disorders. The MMPI–2 possesses an impressive research base demonstrating its support for the detection of feigning. The SIRS has been considered by many to be the gold standard psychological test for the detection of feigned mental disorders. Both measures contain multiple scales that employ a variety of different detection strategies. For both the MMPI–2 and the SIRS, research has demonstrated large to very large effect sizes that demonstrate marked differences between genuinely disordered and feigned groups. The basic distinction between the two measures involves individual classification via utility analysis. The MMPI–2 is generally ineffective at individual classifications because (a) cut scores range widely and (b) substantial overlaps on validity scales between genuine and feigned protocols reduce accuracy. In contrast, the SIRS has established effective cut scores that minimize false positives and overall errors. Thus, the SIRS provides accurate clinical data for individual classifications.

Detection Strategies for Feigned Cognitive Disorders

The assessment of feigned cognitive impairment has largely been limited to evaluations of memory impairment and general intellectual functioning. Detection strategies for feigned cognitive impairment have generally relied on *excessive impairment,* which is based on either unexpectedly poor performance on cognitive tasks or *unexpected patterns* that are characterized by unlikely endorsement patterns of items assessing cognitive abilities.

The following are detection strategies based on excessive impairment and unexpected patterns.

Excessive Impairment

Floor Effect. This strategy relies on the failure of malingerers to answer accurately very simple test items. Even the most cognitively impaired individuals are able to answer floor-effect items correctly. Individuals who fail to endorse floor-effect items are likely to be indicative of feigning.

Symptom Validity Testing. This strategy relies on the probability that a genuine person without any ability

would obtain a proportion of correct responses, based on chance alone, when presented with a multiple-choice format. Performance markedly below this chance level is strong evidence of purposeful failure (i.e., malingering). For this strategy to be effective, each alternative must have a similar likelihood of being chosen.

Forced Choice Testing. This strategy relies on the accurate establishment of normative data for cognitively impaired individuals. Individuals who perform far worse than the normative data on a multiple-choice test of cognitive abilities are suspected to be feigning. This strategy is vulnerable to errors because normative data do not take into account multiple cognitive conditions and complications by mental disorders and ineffective coping.

Unexpected Patterns

Magnitude of Error. This strategy relies on the identification of patterns of failure on cognitive tasks that are atypically incorrect. As the name denotes, it is the magnitude of incorrect endorsements, not simply the presence of an incorrect response, that indicates feigning based on this strategy. The magnitude of error specifically relies on a malingerer's tendency to report blatantly incorrect answers as opposed to "plausibly" incorrect answers.

Performance Curve. This strategy compares performance on easier tasks with performance on more difficult tasks. If individuals perform worse on easy tasks than on difficult tasks, feigning impairment can be suspected. This strategy can be very effective, especially with measures that represent (a) a wide range of item difficulty and (b) the absence of an obvious progression from simple to difficult items.

Violation of Learning Principles (VLP). This strategy relies on established learning principles to identify atypical performance of feigners that is incompatible with our knowledge of learning. When a person does not conform to the expected pattern of results based on a learning principle, he or she is suspected to be feigning cognitive deficits. As a good example, impaired individuals are consistently more successful at recognition than recall because the latter places a greater demand on memory abilities. When recall equals or even surpasses recognition, an important learning principle has been violated. This violation is indicative of feigned cognitive impairment.

Dozens of measures for feigned cognitive impairment have been developed in the past decade. Many measures are based on a single detection strategy (e.g., floor effect) and are vulnerable to coaching (e.g., put forth a good effort). Forensic practitioners should look for well-validated measures that have been tested with multiple groups representing different cognitive conditions. An example is the Test of Malingered Memory. In addition, practitioners may wish to include a measure that relies on symptom validity testing, such as the Portland Digit Recognition Test. Although such measures identify only a minority of malingerers, they are accurate in these classifications with very small false-positive rates.

Conclusion

Malingering is a superordinate issue in forensic evaluations. Conclusions about malingering are likely to trump all other diagnostic and forensic considerations. Because of its importance, forensic clinicians must take special care to ensure the accuracy of their determinations. Whenever feasible, these determinations should use multiple detection strategies and several validated malingering measures. Further corroboration should be sought via clinical interviews and collateral sources (e.g., informant interviews and mental health records). Finally, the classification of malingering does not truncate the assessment process. Many malingerers also have genuine disorders that may be relevant to the forensic referral.

Malingering Probability Scale

The Malingering Probability Scale (MPS) was developed in the mid-1990s as a self-report instrument to estimate the probability of malingering, taking account of base rates in underlying populations. The instrument was based on three premises: (1) that psychopathology expresses itself in clearly defined syndromes for which certain symptoms, though perhaps plausibly related, have very low likelihoods of occurrence; (2) that patients will vary in the type of symptoms they feign depending on the context; and (3) that the identification of probabilities of any given individual of malingering should be adjusted according to the base rate of malingering in the population from which he or she was drawn. The MPS was developed by Leigh Silverton, who also designed and conducted many studies; analyzed much of the data; and, in collaboration with Chris Gruber, wrote the MPS manual.

At the time the MPS was developed, there were no other instruments of malingering that provided sensitivity or specificity studies or gave probabilities of malingering predicated on estimates of base rates in the population from which the patient was drawn. The F scale of the Minnesota Multiphasic Personality Inventory (MMPI), which was most widely used, did not distinguish a true-focused response set or random responding. In constructing the MPS, Silverton also tried to address a different type of feigned psychopathology than had been traditionally covered. Past instruments in wide usage had focused on bizarre and psychotic symptoms. Psychotic symptoms tend to be feigned in criminal contexts in which punishment for mentally competent persons judged responsible for their crimes is more aversive than incarceration in a mental hospital. The focus of the MPS is broader, comprising both psychotic symptoms and nonpsychotic symptoms of the type that might be feigned in civil contexts.

Civil litigants should be more apt to feign trauma-related symptoms such as those associated with posttraumatic stress disorder, depression, and dissociation. In civil cases, where money damages are the remedy for a psychological injury, an experienced attorney understands that certain disorders are most likely to stem from trauma and thus yield the highest rewards. Whether through honest questioning by a personal injury attorney attempting to explore damages, through outright coaching, or by self-study of diagnostic material, a litigant may obtain an impression, if not a textbook definition, of the trauma-related syndrome that he or she should emulate to maximize rewards. In such a case, a patient may avoid endorsing bizarre delusional or hallucinatory symptoms represented by the F scale of MMPI–2 or the M test but may endorse posttraumatic stress-like symptoms.

The pseudoclinical items of the MPS cover symptoms related to trauma as well as those related to psychotic phenomena as might be feigned in a criminal context. The symptoms might appear, to the sophisticated faker, to reflect depression, dissociation, posttraumatic disorder, and schizophrenia. Silverton wrote items that seemed, based on the literature and her clinical experience, to reflect genuine psychopathology and those that would appear to reflect genuine psychopathology but did not. One such pair of items for the depression scale is as follows: "I am rarely awakened by sad dreams" F (pseudoitem) and "I sleep well" F (actual item). Depressed people tend to have trouble sleeping and may have sad dreams but are rarely awakened by them. Items such as these were derived rationally and then validated to arrive at a 139-item instrument to detect malingering.

A standardization sample of 1,016 adults, aged 17 and above, was selected from four regions of the United States and tested between 1995 and 1996. The sample was large, contemporary, and nationally representative. Although the sample matched the 1994 U.S. census data adequately in ethnic distribution, the actual number of ethnic minority participants was small, a fact that suggests caution in interpreting results from minorities. Reading level was measured at third to fourth grade, which should be adequate for most populations.

There are reasonably good levels of reliability, using measures of internal consistency, test-retest reliability, and temporal stability and using samples of individuals from the general population in which the malingering base rate is relatively high (prison and

civil forensically referred samples) and individuals referred for clinical but nonforensic evaluations. The reliability compares favorably with the MMPI clinical scales, which were in the .70 to .90 range.

Validation studies were performed in a number of contexts. Paradigms were employed to detect dissimulation (for college students and prison inmates) and guided dissimulation in which the subjects were given the *Diagnostic and Statistical Manual of Mental Disorders* of the American Psychiatric Association criteria for the disorders. Scores were also obtained from samples of inpatients and referred forensic and clinical outpatients. These procedures yielded Malingering (MAL), the scale used to detect malingering.

Test interpretation starts with the Inconsistency (INC) scale. A high INC score indicates that the subject was so inconsistent that the test should not be interpreted. This could be due to a poor reading level or conscious resistance to test taking. If the INC elevation is less than a *T*-score of 70, it is possible to interpret the MAL scale. In the discussion of MAL or the malingering scale of the MPS in the manual, the authors tried to convey the notion that the conclusion that a person is malingering is a probability statement. The probability relates directly to the base rate of the underlying construct and would be expected to vary from sample to sample. For instance, if a person obtains a MAL *T*-score of 73 where the base rate of malingering is assumed to be 50%, 20%, or 10%, the concluded probability of malingering is 72%, 38%, or 22%, respectively. An assessor interpreting the test report should, therefore, be able to explain his or her assumptions about base rates in the population he or she tests.

One great advantage of the instrument is also one of its greatest disadvantages: The scoring of the individual items has been protected. The item scoring has not been printed in any publication and has been further protected by providing the test in computer-scored form only. (The Western Psychological Services does, however, make available the individual items and their scoring to qualified persons who apply.) An advantage of this feature is that it is impossible for a prospective subject to study for and, therefore, foil the exam. A disadvantage of this feature is that the test cannot be easily and quickly scored by clinicians and researchers. This may discourage research on this instrument, a particularly important problem for validating the experimental clinical scales.

One advance of this instrument is that it broadened the realm of feigned psychopathology covered in malingering instruments, particularly to include those symptoms related to trauma to capture the more sophisticated feigner. But perhaps the best advance in the construction and presentation of this instrument is the conceptualization of malingering as a probability statement, which depends on the assumptions the diagnostician makes about the base rates of malingering in his or her clinical sample. These are assumptions that are all too often ignored by the forensic clinician, are rarely questioned by even the skilled cross-examiner, and yet are critical to the trier of fact where mental state is at issue.

Mandated Community Treatment

Treating people with a mental disorder without their consent always has been the defining human rights issue in mental health law. For centuries, unwanted treatment took place in a closed institution—a mental hospital. What has changed is that in recent years the locus of involuntary treatment has shifted from the closed institution to the open community. Much of the strident policy debate on outpatient commitment—a civil court order requiring a person to adhere to mental health treatment in the community—treats it as if it were simply an extension of inpatient commitment, viewing it within the same conceptual and legal framework historically used to analyze commitment to a mental hospital. Increasingly, however, it is becoming apparent that concepts developed within a closed institutional context do not translate well to the much more open-textured context of the community. It was for a good reason that mental hospitals have been described as "total institutions"—a single source supplied an individual's lodging, delivered benefits, maintained order, and provided treatment. In the community, however,

one source supplies an individual's lodging (a housing agency), another delivers benefits (a welfare agency), a third maintains order (the criminal justice system), and a fourth provides treatment (the mental health system). Outpatient commitment is better seen as only one of a growing array of legal tools from the social welfare and judicial systems now being used as "leverage" to ensure treatment adherence in the community.

Leverage From the Social Welfare System

People with serious mental disorders may qualify under current law to receive certain social welfare benefits. Two benefits to which some people are entitled under current laws are disability benefits and subsidized housing.

Money as Leverage

Recipients of federal benefits typically receive checks made in their own names. The Social Security Act, however, provides for the appointment of a "representative payee" to receive the checks if it is determined to be in the beneficiary's best interests to do so. Some patients who have a representative payee (or a more informal "money manager") believe that there is a quid pro quo relationship between their adherence to treatment and their receipt of funds.

Housing as Leverage

Recent surveys have found that there is not a single city or county in the United States in which a person with a mental disorder living solely on disability benefits can afford the fair market rent for an efficiency apartment. To avoid widespread homelessness, the government provides a number of housing options in the community for people with a mental disorder. No one questions that landlords can impose generally applicable requirements—such as not disturbing neighbors—on their tenants. However, landlords sometimes impose the additional requirement on a tenant with mental disorder that he or she be actively engaged in treatment.

Leverage From the Judicial System

People with severe mental disorders are sometimes required to comply with treatment as ordered by judges or by other officials acting in the shadow of judicial authority (e.g., probation officers). Even without a formal judicial order, patients may agree to adhere to treatment in the hope of avoiding an unfavorable resolution of their case, such as being sentenced to jail or being committed to a hospital.

Jail as Leverage

Making the acceptance of mental health treatment in the community a condition of sentencing a defendant to probation rather than to jail has long been an accepted judicial practice. In addition, a new type of criminal court—called, appropriately, a "mental health court"—has been developed that makes even more explicit the link between criminal sanctions and treatment in the community. Adapted from the drug court model, a mental health court offers the defendant intensely supervised treatment in the community as an alternative to jail.

Hospitalization as Leverage

Outpatient commitment, as described above, refers to a court order directing a person with a serious mental disorder to comply with a prescribed plan of treatment in the community, under pain of being hospitalized for failure to do so if the person meets the statutory criteria. Outpatient commitment, in this view, is properly seen as only one of several forms of "leverage" used to ensure treatment adherence and not as the sum and substance of "involuntary treatment" in the community.

Psychiatric Advance Directives

One way to establish a person's preferences regarding future treatment, should the person become unable to make or to communicate those preferences in the future, is for the person to "mandate" the preferred treatment himself or herself. Usually, advance directives pertain to medical care at the end of life. But a federal law has given impetus to mental health advocates to promote the creation of advance directives for psychiatric treatment. These directives allow competent persons to declare their preferences for mental health treatment, or to appoint a surrogate decision maker, in advance of a crisis during which they may lose capacity to make reliable health care decisions themselves.

Massachusetts Youth Screening Instrument–Version 2 (MAYSI–2)

The Massachusetts Youth Screening Instrument–Version 2 (MAYSI–2) is a brief, self-report screening tool designed to identify youths with special mental health needs in the juvenile justice system. It is not a diagnostic tool. Instead, it identifies emergent risks of youths in need of a comprehensive psychological assessment. The developers of the MAYSI–2 designed it for administration by nonclinicians and normed it for use with youths aged 12 to 17 years on entry into one of three different settings in the juvenile justice system—intake probation, pretrial detention, and postsentencing correctional facilities. It is one of the only true mental health "screening" tools (as opposed to assessment tools) developed for juvenile justice settings. As such, the MAYSI–2 is important for juvenile justice administrators who have an obligation to manage the serious mental health needs of youths in their care by, among other procedures, implementing mental health screening. At the time of writing this entry, the MAYSI–2 was being used statewide by juvenile justice agencies in more than 35 states.

Description and Administration

The MAYSI–2 is a 52-item, "yes/no" screening tool on which youths report the presence or absence of symptoms or behaviors related to several areas of emotional, behavioral, and psychological disturbances experienced "within the past few months." The test can be completed in 10 to 15 minutes and is generally administered by frontline, nonclinical staff via a voice computer program (MAYSIWARE) or a paper-and-pencil test, both of which are available in English and Spanish. The MAYSI–2 is self-administered (youths read the questions and circle their answers) unless youths have reading difficulties and the voice computer program is not an option. In these cases, staff should read questions to the youths and allow them to circle their own answers. The pencil-and-paper and voice computer modes of administration appear to yield comparable MAYSI–2 scores.

The 52 items produce scores on six clinical scales—Alcohol/Drug Use (ADU), Angry/Irritable (AI), Depressed/Anxious (DA), Somatic Complaints (SC), Suicide Ideation (SI), and Thought Disturbance (TD; for boys only)—and one nonclinical scale—Traumatic Experiences (TE), which screens for reported exposure to potentially traumatic events. Scale scores are generated from simple sums of the items, which range from 5 to 9 items depending on the scale. The TD scale is for boys only because factor analyses could not derive a coherent TD scale for girls, and the item content of the TE scale differs for boys and girls.

Each of the six clinical scales has a "Caution" cutoff to signal a "clinically significant" elevation and a "Warning" cutoff, which was based on the scores separating the upper 10% of youths in the development sample. The constellation of Caution and Warning cutoffs, which should signal a response for a particular youth (i.e., decision-making rules), was not prescribed by the MAYSI–2 developers. Instead, these decisions are left to the discretion of the juvenile justice site based on their resources and needs to respond to youths in their care.

Development and Factor Structure

The MAYSI–2 was created by Thomas Grisso and Richard Barnum, who selected a pool of items related to mental disorders, emotional disturbances, and behavioral problems common to adolescents. The final 52 items were generated from pilot testing on a small sample of youths. The developers identified the seven MAYSI–2 scales from factor analyses performed on data from 1,279 juvenile-justice-involved youths in Massachusetts. They derived Caution cutoff

scores based on the optimal balance between sensitivity and specificity in identifying youths in this sample with clinical elevations on the Millon Adolescent Clinical Inventory and the Youth Self-Report. Researchers cross-validated the MAYSI–2 factor structure and indices of internal consistency using a sample of more than 4,000 juveniles from California. Recent studies reported almost identical factor structures using confirmatory factor analytic techniques.

Reliability and Validity

MAYSI–2 scales have acceptable internal consistency, with Cronbach's alpha coefficients ranging from .61 (TD scale) to .86 (ADU scale). Alpha coefficients are comparable between genders and racial groups (with a few exceptions) and have been replicated across studies. Test-retest reliability estimates (intraclass correlation coefficients), based on comparisons of MAYSI–2 scores soon after admission to a detention facility to scores 5 to 8 days, later range from .53 (SC scale) to .89 (AI scale).

The national norm study for the MAYSI–2 found that girls were 1.5 to 2.3 times as likely as boys to score above the Caution on every scale except the ADU scale. This finding was consistent across more than 200 juvenile justice settings from around the United States regardless of youths' age, race, or legal status. Also consistent was that Whites had higher odds of meeting Caution on the SI, SC, and ADU scales than Blacks or Hispanics.

Concurrent validity studies show that MAYSI–2 scales correlate with other adolescent mental health scales in the expected direction. However, most MAYSI–2 scales do not map directly onto diagnostic scales of other measures. This is likely because MAYSI–2 scales are primarily heterotypic and measure symptoms that would span multiple diagnoses (e.g., anger). Predictive validity studies indicate that MAYSI–2 scores predict several institutional outcomes such as institutional violence, lengthier sentences, staff interventions, and service provision. Pre-post studies indicate that adoption of the MAYSI–2 in detention facilities can significantly decrease violent incidents, suicide attempts, and other areas of maladjustment.

Future Research

Some issues could benefit from further research. First, it is unknown how long MAYSI–2 scores can be considered valid. MAYSI–2 scores were not intended to have long-term stability given the items measure acute symptoms, which are expected to fluctuate. Second, it is unclear how the timing of MAYSI–2 administration may affect scores. Evidence suggests that youths receiving it within the first few hours of admission have lower scores than those taking it a day or two later. Finally, the developers should report on the psychometric properties of the Spanish-language version as data become available.

Master's Programs in Psychology and Law

The field of psychology and law (i.e., forensic psychology) has witnessed tremendous growth in the past 40 years in both academic and professional realms. While many of the early clinicians engaged in forensic practice did not receive specialized training prior to assuming their role within a forensic setting, graduate training in forensic psychology, or psychology and law, has attempted to address this need. The number of programs offering graduate-level forensic psychology training has exponentially increased in the past 30 years, such that future generations of forensic practitioners will have received specialized course work and practical/research experiences that will only

augment their effectiveness in conducting sound research, promoting relevant policy, and delivering competent clinical forensic services.

Although scholars have expressed a need for a more comprehensive look at specialized graduate training in forensic psychology since the 1970s, it was not until the Villanova conference in 1995 that models of training were evaluated. The invited conference participants provided recommendations for psychology and law training through proposed models but offered no core curriculum. As such, graduate programs have been given enormous latitude to offer a sequence of courses and practical/research experiences that jointly meet their training goals and the needs of their students.

Much has been written on graduate-level training in forensic psychology, with scant emphasis on master's level training. Yet a substantial number of students are graduating with master's degrees in forensic psychology. Currently, there are more than seven programs in the United States and Canada that offer a terminal master's degree in psychology and law.

Relevant Components for Training

Although, by definition, master's level graduate training does not offer the same breadth or depth of experience as one would receive in a doctoral-level psychology and law program or a joint degree (Ph.D./J.D. or Psy.D./J.D.) program, aspects of such training remain critical to the development of a competent master's level graduate. Broadly, master's level training should include education in law and the legal aspects (e.g., statutes, case law, and legal theory) affecting professional forensic psychology practice, knowledge of the relevant literature and ways of assessing the legal questions posed to clinicians/researchers, familiarity with broad and specialty area ethics and guidelines, and field placements in forensic settings. As the population of the United States is changing and becoming increasingly diverse, it is imperative that psycholegal researchers, scholars, and clinicians become competent to address the multiple and varied needs of a diverse forensic community.

The curriculum for master's level training in forensic psychology will vary depending on the program's orientation, with greater emphasis on research, clinical skills, or public policy to fulfill the requirements for completion of the degree. At minimum, forensic psychology curricula should include one or two law courses, including one in mental health law. Students should receive coursework that will provide them with the technical knowledge and practical skills to facilitate their clinical work in the forensic psychology field, such as clinical interviewing and psychotherapy and psychopathology and diagnosis. In addition, students should receive sufficient grounding in research design and methodology and statistical analysis. For more clinically focused programs, curriculum may include coursework in the historical basis of assessment and measurement of different variables in forensic settings and a sequence of traditional and/or specialized assessment courses. To prepare students for a wide range of possible careers, coursework may include specialty topics, such as understanding and treatment of offenders (male/female, sexual, juvenile), trauma and crisis intervention, substance abuse, and group therapy. As mentioned above, each course should reflect the diversity inherent in the United States, such that sociocultural issues should be infused within the curriculum as well as offered as a distinct course.

Because many people considering entry into forensic psychology through a master's degree program may have been influenced by media portrayal of the field, it is critical that students gain some exposure to the reality of the work through field placement/practicum experiences. Such experiences could include practical training within the criminal justice system (jails, prisons, forensic hospitals), within the law enforcement system (police departments, investigative departments, probation/parole, etc.), within the legal system (e.g., court clinics, district attorney's office, litigation consulting firms), and within the mental health system (offender and/or victim treatment programs, community mental health, etc.). Programs may wish to consider providing coursework that serves as an adjunct to the field placement experience, such that students would be able to obtain additional support and supervision as well as receive an added didactic component.

In addition to coursework and practical training, program designers may also want to consider a capstone requirement, such as a competency exam and/or completion of a thesis. The competency exam requirement is designed to provide a comprehensive learning experience in helping students consolidate their academic, clinical, and research training in a meaningful, coherent manner. Similarly, a thesis provides students with an opportunity to pursue an area of research

interest in more depth than would otherwise be available through regular coursework; the research may allow students to directly impact the systems and clients with which they interface through their field placements and potentially build on this area of research throughout their career.

Students pursue master's level training for a variety of reasons. Professionals working within law enforcement, legal, or mental health systems may attend master's programs in an effort to enhance their training and/or opportunities for promotion. Undergraduate students may want to explore a specialized field of study, such as law and psychology, without having to commit to the time required to complete a doctoral degree. Similarly, undergraduate students may postpone an eventual goal of obtaining a specialized doctoral degree by first gaining clinical and/or research experience through a master's level program. Finally, because many states allow master's level clinicians to practice independently, many graduates of these programs will have lengthy careers in the forensic field.

Considerations for Students Pursuing a Master's Degree

The decision to attend a master's program in forensic psychology is a major commitment that warrants much research. Current master's programs in this field vary greatly in program orientation, curriculum, opportunities for practical experience, faculty interests and experience, as well as student requirements. Each of these is an aspect prospective graduate students may find helpful to consider. Students need to choose a path that best fits their individual needs, encompassing their current interests as well as their future plans.

One of the fundamental questions prospective graduate students in forensic psychology should consider when faced with the often daunting task of choosing a master's program is how the program's orientation matches their own. For example, while some students may seek a clinically oriented program, others may find their interests rooted in research. Therefore, the student should thoroughly review each program's orientation. Such a consideration will prevent students from embarking on graduate study at programs with an orientation different from their own.

Exploration of requirements for graduation may also prove useful for students. Although the majority of master's programs in this field are clinically based, those students interested in research may find themselves given the opportunity to pursue this interest in a clinically based program in lieu of competency exams to fulfill a graduation requirement. Therefore, one should not discount a program solely based on orientation but, rather, should explore each option within an individual program.

Additional consideration should be given to how a student's educational and professional goals align with those of each program. Whereas some programs aim to prepare students for their respective state's professional licensing exams or a career in the public sector, others focus on preparation for doctoral programs. Thus, it is important for prospective students to inquire and consider the educational and professional paths of previous graduates, as well as consider their own intentions. Furthermore, a student may find it helpful to explore the experience and formal education requirements for occupations in their areas of interest.

The educational framework and organization of each program should be closely examined by applicants. Prospective students should critically evaluate the curriculum of each program to ensure a solid foundation is provided and their specific interests addressed. Introductory courses aimed at the integration and applicability of psychology within the legal system should be a standard at each program, which should include criminal and civil aspects. At the same time, students should consider whether they have the flexibility to take electives or seminars in which their specific interests are addressed. After careful consideration of these elements, students can then begin selecting programs that offer a solid but broad curriculum and at the same time allow exploration of specific areas of interest through electives and seminars.

Although most clinical programs address professional ethics, a comprehensive curriculum in forensic psychology will not only address general ethical issues but also attend to and integrate the Forensic Specialty Guidelines set forth by the American Psychological Association. The issues addressed include exclusions in confidentiality when treating convicted offenders, conflicts of interest in child custody cases, and licensing requirements. These guidelines are vital in adhering to standards pertinent to forensic psychology and in offering the best services possible.

Students and professionals in forensic psychology programs are often faced with a variety of clients from backgrounds with which they are not familiar. Forensic clients vary greatly in race, ethnicity, sexual orientation,

age, gender, socioeconomic status, education level, as well as religious affiliations and beliefs. Therefore, a multicultural or diversity component within the master's program will prepare students for serving a wide range of clients. A comprehensive program will also stress a multicultural component in the available internship or field placement options, which will provide students with familiarity of a wide range of cultures through hands-on experience.

In addition to formal coursework, perhaps one of the most important considerations for prospective graduate students in forensic psychology should be the opportunities for practical application of learned materials in the form of field placements or internships. When considering each program, applicants may be well served by exploring the opportunities associated with attendance at each program. For those students with specific careers in mind, a placement at a related site may be the cornerstone of their graduate school experience. Such a placement may serve either to further their commitment to an intended career path or dissuade them from such a career. In addition, field placements and internships often open the door to new, previously unconsidered avenues, as well as assist in developing beneficial professional relationships.

Although it should not be the only factor considered, prospective students may find it beneficial to research the core faculty at each program. Research interests, professional affiliations, publications, alma maters, professional reputation, and length of time at the program of interest may be helpful when considering faculty members with whom a prospective student may want to work. In addition, inquiring as to whether or not faculty members are willing to collaborate with graduate students on current research and publications also warrant consideration. Faculty areas of interest may be of particular value for those students with a bent for research. In this case, it is particularly important not only that the program provide research opportunities but also that the faculty share similar interests and are able to assist in student research endeavors.

Program structure, specifically regarding time requirements, also warrants consideration. Although most programs require full-time attendance in a 2-year program, there are exceptions. Prospective students with families and those planning on maintaining full-time employment while pursuing graduate education may find their choice of programs limited owing to time constraints. On the other hand, there are several master's programs in forensic psychology that are composed of part-time students, but these programs may require a prospective student to relocate if in a different state. Therefore, to critically evaluate each program, and choose that which best suits their needs, availability, and current commitments, such students should inquire as to whether part-time attendance is possible, as well as the expected schedules, average amount of independent work, and number of field placement or internship hours required per week.

Media Violence and Behavior

In contemporary society, a wide variety of violent content is reaching children through a variety of media including television, movies, and video games. Often, exposure to violence occurs with little adult or parental supervision. Several content analyses have examined the amount and content of violence on television. These analyses have shown that as of the late 1990s nearly two-thirds of the programs on television contained some amount of violence. There are no comparable figures for movies or video games because there is no central source or collection of programming; however, a variety of content analyses investigations examining the most popular video games, for example, appear to point to the same findings—violence is prevalent in these formats.

Research on the effects of exposure to violence in the media has included examinations of the effects of violence in films, television, video games, and music videos on aggressive behavior, thoughts, attitudes, and emotions following exposure. The research has consistently revealed a substantial, statistically significant association between exposure to violence in the media

and violent behavior measured in the laboratory, in the field, and across substantial time spans. A set of well-articulated theories explain why aggression generally increases after exposure to violence in the media. Additional research on viewer characteristics has refined notions of who is most likely to be influenced by media violence and under what circumstances they are likely to be affected. More recent research has focused on the effects of interactive media such as video games. This research demonstrates effects that are equivalent for this form of media to older media use.

Effects of Television and Movie Violence on Aggressive Behavior

Most research on media violence and viewer aggression has focused on viewers who are passively exposed to movies and television portrayals. A relatively large number of laboratory experiments in which subjects are randomly assigned to view film or television violence and compared with control groups have been conducted over the past 50 years. Several types of aggression toward others have been assessed in these studies, including verbal and physical aggression. These experiments have consistently found that young people who watched violent scenes subsequently displayed more aggressive thoughts, emotions, and behaviors than those who did not. Usually, these laboratory studies measure the immediate impact of violence exposure on aggression. Results from these studies have shown that, for example, children who watched television violence were more likely to be rated as high on physical assault (hurting other children, wrestling, as well as other types of aggression) by observers who did not know which type of film the children had seen. Field experiments in which boys at a summer camp had been assigned to view violent or nonviolent films and then observed revealed that boys who had been assigned to the violent film conditions engaged in significantly more physical assaults on fellow campers. This effect was particularly pronounced for boys who were individually higher on trait aggression. Other research has demonstrated that combining violent stimuli with other arousing activities or portrayals can enhance the aggression effect following exposure. For example, college students who have been provoked by others or who have seen sexually arousing films that portray sex and violence exhibit pronounced increases in retaliatory behavior as indexed by their willingness to deliver what they believe are electric shocks to other subjects.

Randomized laboratory experiments have also demonstrated desensitization effects, whereby children subjects exposed for prolonged periods to media violence were slower to call an adult to intervene when they saw two younger children fighting. Adults exhibit similar desensitization effects including acceptance of physical aggression toward females and hostile behavior after prolonged exposure to violent movies compared with adults in control conditions.

Meta-analyses that have computed the overall effect sizes for randomized experiments have generally concluded that the size of the effect for the media violence aggressive behavior effect is moderate to large ranging from $r = .3$ to $r = .4$ for aggression; effect sizes for criminal violence are smaller.

Survey research in which cross sections of elementary school children and adolescents have been surveyed regarding their exposure to violence in the media and measured on various indexes of general aggression have yielded results similar to those in laboratory and field experiments. These surveys show that children and adolescents who report violence viewing also exhibit higher levels of aggressive behavior. Longitudinal studies designed to study the effects of television violence on behavior over time and thus are able to measure exposure to violence in television before aggressive behavior is assessed provide evidence of a media violence aggression causal link over time. Studies that have measured assault or physical fights resulting in injury have found that exposure to violence in television at age 14 significantly predicted assault and fighting at later ages including at 22 and 30 years.

Less well-known are the effects of exposure to news violence, such as news of executions or assassinations, on violent behavior. Likewise, a few experimental studies of music videos and behavior have been conducted, but the research is rather sparse. Several studies of music videos have shown that adolescents assigned to view violent rap music videos increased endorsement of violent behavior.

Studies that have examined the introduction of television into communities that have not had it have also been undertaken. This work has tended to reinforce findings from laboratory experiments and surveys. One study, for example, found an increase in children's level of aggression in a Canadian community after the

introduction of television. However, caution must be taken in the interpretation of these studies, which often measures total television viewing and not the amount of violent programming to which children have been exposed.

Violent Video Games and Aggression

Randomized experiments involving violent video games have also been conducted. Children spend much time with these games and the process of playing them involves repetition and deep involvement. These characteristics should theoretically increase the influence of violent video games on aggressive behavior. Laboratory studies have demonstrated that college students who played violent video games were more likely to deliver high-intensity punishments than those who played a nonviolent video game. There are fewer cross-sectional surveys of video game use and aggressive behavior and little information that would allow for strong longitudinal conclusions to be drawn. Meta-analyses of violent video game effects have revealed that for studies that have the soundest methodological designs, the effect size for exposure to violent video games on aggressive behavior, aggressive attitudes, and decreases in prosocial or helping behavior is comparable with that for televised and movie violence.

Theoretical Mechanisms

Researchers in psychology, communications, and sociology have developed theoretical models that account well for the relationship between media violence and aggression. These theories are best described as social cognitive in nature and focus on how people learn, think, and behave in their social world—a world that contains interactions with humans such as parents and peers and a virtual world created by the media. Psychologists have generally distinguished between theoretical mechanisms that create short-term effects and those responsible for longer-term outcomes. Short-term effects are thought to be due to cognitive priming, temporary imitation, arousal, and excitation.

Priming explanations rely on the concept of an associative neural network in which ideas are activated (primed) by stimuli in the social environment. Exposure to violent scenes may activate related thoughts, feelings, and scripts involving aggression. These aggressive thoughts, once activated, become an interpretational filter so that ambiguous events are more likely to be interpreted as aggressive and thus stimulate aggressive behavioral tendencies.

Arousal explanations focus on the fact that violent media are arousing and exciting for children and adolescents. The residual excitement left from media violence viewing may serve to fuel dominant response tendencies after exposure to violence. Placed in a situation whereby an aggressive response is possible, the aroused individual may be more likely to be aggressive. Video games may be especially likely to provoke this form of arousal and the nature of video game playing, involving repeated and long-term use, may facilitate aggressive responding.

Both short-term and long-term effects are also thought to be the result of observational learning. Learning aggression from media portrayals of violence is facilitated by several factors. Violent models performing behavior that is similar to or attractive to the viewer are likely to increase aggression in viewers. Aggressive behavior following exposure to media violence is also more likely when there is high viewer identification with the model, the context in which the violence is presented is realistic, and the violent behavior portrayed in the media is followed by rewarding rather than punishing consequences. For the effect to become a long-term outcome, the social environment must reinforce the behaviors learned in the media. Furthermore, learning need not be limited to the specifics of the violent media portrayals. General scripts for behavior and social interaction that later guide perceptions and attitude formation may be learned from violent media.

Priming effects are usually thought of as short-term effects, but social cognitive research has shown that such effects can have lasting influences. Frequently primed aggressive thoughts and emotions may become chronically accessible in a media-violence-saturated environment. The impact of this chronic accessibility of violent thoughts and scripts for action may be that neutral social interactions are interpreted in an aggression-biased way.

Long-term exposure to violence in the media may also result in an emotional desensitization effect that appears to operate much like the habituation that occurs through therapeutic processes such as systematic desensitization—a procedure successful in treating phobias. Exposure to violence in the media appears to reduce the anxiety or fear associated with violence and causes viewers to be less physiologically aroused by violence later presented in real-life situations. The

relationship between desensitization to violence and aggressive behavior is unknown.

Viewer Characteristics

Not all media presentations of violence have the same effect. Several stable individual differences have been identified by researchers who moderate the impact of violent media on aggressive behavior. Viewer age appears to make a difference, at least under some circumstances, but the relationship between age and effects of media violence is not resolved at this time. Gender of viewer also appears to interact with exposure to violence in the media in complicated ways. Initial research found greater effects for boys than for girls; however, more recent research did not confirm this difference. It is more likely that males and females display differing aggression patterns in general, with boys exhibiting greater tendencies toward direct physical aggression and girls displaying tendencies toward indirect forms of aggression. Early exposure to violence in the media may increase indirect aggression tendencies in females (telling lies, taking other people's things out of anger) but not in males. Aggressiveness of the viewer also appears to interact with media exposure. Children who are especially aggressive may be both likely to seek out violent media and later, when exposed to it, more likely to learn aggressive scripts or be cognitively stimulated by violent depictions. Viewer intelligence appears not to be related to media violence effects. However, children with certain perceptual tendencies such as greater identification with violent actors and the perception that the media violence is realistic appear to display aggressive tendencies well after media exposure.

Media Characteristics

Some media portrayals carry more risk than others for increasing aggressive behavior in viewers. There is evidence that viewers are influenced by aggressive characters who appear to be similar to themselves. Other research has demonstrated that violent perpetrators who are charismatic or generally attractive are more likely to be imitated. The consequences portrayed for the violent behavior in the media may also be important for predicting imitation effects. Findings from experiments that manipulated whether violence was justified increased the likelihood that angered subjects would later exhibit increased aggression. Media violence perpetrators who are rewarded are also more likely to be imitated. On the other hand, showing negative consequences for violent behavior portrayed in the media appears to reduce later aggression. Media portrayals that are especially bloody or gory while increasing desensitization to violence in viewers do not necessarily appear to reduce violence as a result of the portrayal of negative consequences to the victim.

Demographic Variables and Media Violence

Children from families of lower socioeconomic status (SES) watch more television and thus are exposed to more media violence than others. There is not much evidence that low SES itself is causally related to increases in aggressive behavior following media exposure. Parental involvement may be important in moderating the effects of media violence. Children of parents who discuss the appropriateness of aggressive behavior following exposure to violence in the media show fewer aggressive tendencies. However, parental tendencies such as aggressiveness and coldness, other parental personality variables, and parental television viewing habits appear to be unrelated to children's aggressive tendencies following exposure to violence in the media.

Policy Implications

The effects of media violence on aggressive behavior are sufficiently robust for media violence to have been considered a significant public health problem. Because of the large number of children and youths exposed to media violence, the overall effect of the media on behavior may be quite significant. A correlation of .2 between viewing media violence and aggressive behavior may translate into millions of additional aggressive acts, many of them lethal, across the nation. Furthermore, there are few other variables in the violence prediction area that account for substantially more variability. The size of the media violence effect is equal to or even larger than many public health effects we as a society deem large, such as the effects of condom use on HIV transmission or the effects of passive smoking on lung cancer. Public health policy has taken two directions: the development of antiviolence interventions and the creation of media industry policies that are designed either to warn parents about violent media content or permit parents to limit violence viewing.

Few studies have been conducted on effective media violence intervention techniques. Interventions that appear to be the most promising are those that stress children and adolescents engaging in active antiviolence message construction and being able to observe themselves and others in social situations that advocate antiviolence problem solving. Strategies that emphasize parent–child coviewing of television and movies may also be effective in reducing media violence/aggression effects.

An extensive ratings system that includes warnings about both violence and sex has been developed by the television industry in response to political pressure partly generated by the large and consistent body of data developed by researchers. The introduction of the "V-chip," a device in every new television now sold in the United States, permits parents to bypass programs whose ratings indicate violent content. However, overwhelmingly, most parents in most households report not using the device.

Legal Implications

Despite overwhelming scientific evidence of a link between media violence and aggressive behavior, criminal and civil legal actions against the producers of violent content have been extremely limited by the "incitement" standard articulated in *Brandenburg v. Ohio* (1969). In this case, the U.S. Supreme Court stated that the government has a right to regulate any expression that is "directed to inciting or producing imminent lawless action and is likely to incite or produce such action" (p. 1829). Thus, for violent media content to pass the incitement test, it would need to be shown that viewing the depiction (e.g., via television, movies, or playing violent video games) is likely to lead to imminent lawless action. Furthermore, the Supreme Court said in *Brandenburg* that the expression falling into this category must be specifically intended to bring about the lawlessness.

The most prominent legal case involving the idea that media violence incites violence involved Florida resident Ronny Zamora, whose lawyer unsuccessfully argued in 1977 that "television intoxication" led him to murder an elderly neighbor at the age of 15. Mr. Zamora's lawyer tried to portray him as a youngster driven criminally insane by years of watching violent television.

Since the tragedy at Columbine in 1999, there has been a great deal of interest among state legislatures in regulating the access minors have to violent video games. Illinois, Washington, and Michigan have passed limits on what types of games minors can rent or buy. This legislative interest is partly the result of a belief that social scientists have convincingly demonstrated that exposure of minors to such games produces effects such as increased aggressive attitudes and emotions and aggressive behavior. Although still in the early stages of litigation, nearly all federal courts have blocked or struck down these state and local laws that would ban the sale of violent video games to minors, and no court has upheld such statutes. The courts have also questioned whether there is evidence that violent video games cause aggressive behavior and thus need to be regulated by the government.

Mens Rea and Actus Reus

To obtain a criminal conviction, the prosecution must establish the presence of two elements at the time of the crime—namely, *actus reus* ("guilty act") and *mens rea* ("guilty mind"). A failure to show the presence of these elements will lead to an unconditional acquittal of the charged crime. Because both must be proven with evidence beyond a reasonable doubt by the prosecution at trial, the argument that there was no actus reus or mens rea is not a defense per se. They are unlike various affirmative defenses, such as the insanity defense or self-defense, which are viewed as excuses or justifications for otherwise disfavored conduct.

Actus Reus

Actus reus is the conduct requirement for a crime. The actus reus requirement excludes from criminal liability mere thoughts, a person's condition or status (e.g., being an alcoholic as opposed to criminal behavior committed while intoxicated), and involuntary acts. Voluntary acts that satisfy this requirement include positive conduct, omissions of required or reasonably expected conduct, and possessions of criminally proscribed objects. The definition of a voluntary act is construed broadly to include any exercise of will; for example, an individual acting under threats or pressure is still considered to be acting voluntarily (although this may constitute an affirmative defense of duress).

Acts that might be considered involuntary can be divided into two categories: involuntary conduct and impaired consciousness. The first category includes physically coerced movements (e.g., someone pushes an individual into a third individual, causing harm to the third individual), reflex movements (e.g., the reaction of a person suddenly stung by a swarm of bees), muscular contractions caused by disease, and unconscious acts. Medical conditions that may cause involuntary conduct include strokes, epilepsy, and narcolepsy. These behaviors are all characterized by a break in the mind–body connection that leaves the person's actions undirected by a conscious mental process. Behaviors that fall within this category are more widely accepted as lacking the actus reus component than those in the second category.

The second category, impaired consciousness, includes behaviors where there has been a sufficient diminishment of the link between mind and body so that the person is not consciously aware of the actions being taken but can engage in goal-directed conduct based on prior learned responses. Behavior during such periods may be referred to as "automatic" and the individual may be described as an "automaton." Temporary brain damage from a concussion and sleep disorders such as night terrors are two common examples of impaired consciousness. Speculation has centered on whether symptoms resulting from hypoglycemia should be included within this category.

Evidence of a mental disorder is almost never permitted in conjunction with an assertion that the defendant lacked actus reus. Instead, this evidence can be used to support an insanity defense in those states that allow volitional arguments (e.g., the defendant's behavior was the result of an irresistible impulse that resulted from a mental disorder). Under the insanity defense, if the individual's inability to conform his or her behavior with the law is the result of a mental disorder, the defendant can be acquitted and subsequently committed for treatment, a result that cannot be imposed on those acquitted due to a lack of actus reus.

Mens Rea

Mens rea, or guilty mind, is the requirement that a defendant possess a particular state of mind at the time the crime is committed. The mens rea requirement for a crime is usually represented in the relevant criminal statute by one of the following terms: *intent, purpose, knowledge, recklessness,* or *negligence.* Most criminal statutes impose only a general or objective mens rea requirement, where the inquiry focuses on whether a reasonable person would have known that the act would cause harm. To be convicted of a so-called general-intent crime, the defendant must have known that he or she was acting but not that any particular criminal consequences would result from his or her act; this is usually captured by the rubrics of "recklessness" or "negligence." To meet this requirement, the prosecution does not have to explore the mental state of the defendant. Other crimes require a showing of specific or subjective mens rea, in which the prosecution must establish that the defendant did actually know or intend that a particular harm would result from his or her act. Because this can be difficult to prove, specific or subjective mens rea is usually reserved for more serious crimes with more severe punishments.

Evidence of a mental disorder is rarely allowed in cases involving general or objective mens rea, because

an individual's mental state is irrelevant to this inquiry. In contrast, some states permit the introduction of evidence of mental disorder whenever it is logically relevant to rebut the specific or subjective mens rea requirement (i.e., the state of mind associated with a specific-intent crime). If this argument (sometimes called *diminished capacity*) is successful, the usual result is that the defendant will only face conviction of a lesser included offense that merely requires a showing of general or objective intent. Prosecutors who charge a defendant with a specific-intent crime will frequently also charge the defendant with a general-intent crime as a means to enable them to impose some criminal sanction on the defendant should they be unable to convince the judge or jury that the requisite specific intent was present at the time of the crime. The use of evidence of a mental disorder discounting the presence of specific intent differs from the use of evidence of mental disorder for an insanity defense in that the former can result in an unconditional acquittal that does not lead to the civil commitment and treatment typically associated with the latter. This result is the same as that which results from a lack of actus reus because, as noted above, both mens rea and actus reus are elements of the crime that must be proven beyond a reasonable doubt, and if they cannot be proven the defendant will be exonerated of the charged crime. The insanity defense, in contrast, can excuse a defendant from punishment but does not exonerate him or her.

Courts and legislatures have often restricted the use of expert testimony concerning mental disorders. For example, some jurisdictions do not permit testimony regarding any evidence of a mental disorder except when it is being used to support an insanity defense. This position was upheld in *Clark v. Arizona* (2006), in which the Supreme Court ruled that Arizona's decision to restrict evidence of a mental disorder to insanity claims only, thus not admitting such evidence when it could be used to address mens rea, does not violate due process. Nevertheless, even in those states where expert testimony relating to mens rea cannot be admitted in court, the information about a defendant's mental state could still be used in plea negotiations and at sentencing.

Mental Health Courts

Mental health courts are specialty criminal courts with a separate docket to deal with mentally ill persons, who are disproportionately arrested and incarcerated. Established by local court and criminal justice officials who recognized that traditional prosecution and punishment were not effective deterrents with this population, these courts divert mentally ill defendants into community treatment with services to reduce repeat offending, jail and prison crowding, court workload, and criminal justice costs. To participate, defendants must voluntarily agree to follow a treatment regimen and to be monitored. Proceedings are nonadversarial with participants—including judges, defense and prosecuting attorneys, criminal justice officers, mental health practitioners, and other service providers—functioning as a team to provide direction, encouragement, rewards, and sanctions to defendants.

Origins of Mental Health Courts

In the 1960s, shortly after state mental hospitals began abandoning their role of providing long-term placement for persons with mental illness, criminalization accompanying this change was reported—large numbers of deinstitutionalized persons were being arrested and jailed. This process has continued to the point that some metropolitan jails house more persons with mental illness than any state mental hospital on any given day.

Most charges against persons with mental illness are not serious, being predominantly nuisance and survival offenses and offenses deriving from misuse of alcohol and illegal drugs. Although only a small proportion of their offenses are propelled by psychiatric symptoms, mental illness indirectly affects offending because it generates disadvantages in the ability to function and cope with difficult situations, which lead to offending. Mental health treatment and services can improve functioning and coping to

counteract those disadvantages, but mentally ill offenders typically have never been in treatment, do not stay in treatment, or do not adhere to a treatment regimen. Lack of appropriate mental health care and social supports for these offenders has led to their revolving through jails, hospitals, and the streets.

Because arrest and incarceration were not stopping repeat offenses among this population, various jurisdictions have developed new programs to divert them from the criminal justice system into treatment. Following the drug court model, more than 100 jurisdictions since the late 1990s have established mental health courts to address the root problem (mental illness and its disadvantages) with treatment, support services, and court monitoring.

Court Structure

Mental health courts follow the drug court model in structure, having (a) a separate docket; (b) one or two dedicated judges who preside at all hearings; (c) dedicated prosecution and defense attorneys; (d) a nonadversarial team approach involving consensus decisions by criminal justice and mental health professionals; (e) voluntary participation of defendants; and (f) dismissed charges or avoidance of incarceration, depending on whether the defendant enters pre- or postadjudication, after successful completion of the mandated treatment plan.

Some mental health courts limit eligibility to misdemeanors, some to felonies, and some take both levels of offenses. Some take only nonviolent cases; but others are willing to take violent cases, depending on the circumstances and approval of the victims. Some take only defendants with severe mental illness, with or without comorbid substance abuse, while others also accept those with less serious disorders. Referrals come most often from court officers or defense attorneys who become aware of defendants' mental disorders in the course of usual criminal processing, although some courts have systematic screening after arrest. Acceptance of defendants into mental health court requires approval by the mental health court team with heavy reliance on mental health practitioners for clinical screening and on the prosecutor for public safety screening. Acceptance also requires defendants' voluntary consent to participate in the court and willingness to comply with their individual treatment plans and to be monitored by the court with regularly scheduled court appearances, varying in duration and frequency among jurisdictions. Explanation to defendants of court operation is given by their assigned attorneys and commonly repeated by the mental health liaison during screening and by the judge in open court, each time obtaining reaffirmation of defendants' consent.

The Mental Health Court Team

In most jurisdictions, the mental health court team, consisting of the dedicated judge; designated prosecutor and defense attorneys; mental health liaison; and providers involved directly in defendants' care, such as mental health care managers and clinicians, social workers, substance abuse counselors, and probation officers, meets to review cases on the docket prior to every court session. They discuss each defendant's progress, cooperation with treatment, behavioral changes, and any needed modifications in treatment or services, then decide what the judge should say to the defendant in open court to ensure compliance, such as give encouragement and praise, offer a reward, issue a reprimand or warning, or apply sanctions. Team members anticipate failure in this population and offer multiple second chances. They stand ready to help defendants try again but employ a variety of sanctions, such as increased frequency of court appearances or reporting, curfews, and even overnights in jail, to enforce compliance and maximize motivation to change.

Mental health team clinicians take primary responsibility for designing treatment plans, which may include medication, group and individual therapy, anger management, substance abuse counseling, Alcoholics Anonymous, Narcotics Anonymous, social services such as housing and employment assistance, and vocational training; but all members of the mental health court team work in unity to provide structure, supervision, and encouragement for each defendant.

Hearings

In open court as each case is called, the prosecution or defense briefly summarizes a defendant's interim report; however, it is the judge speaking to each defendant directly about required treatment cooperation and behavioral change who is the central player. The judge attempts to engage the defendant in solving practical problems that may impede compliance and changes, encouraging an exchange by asking direct questions about their well-being and progress toward treatment and personal goals. Following the mental health court team's recommendations, the judge uses praise, encouragement, stern lecture, warnings, or

punishment, depending on compliance, while delivering the message of defendant's accountability in the agreement to participate. Unlike in the traditional criminal court, the judge makes a special effort to ensure noncompliant defendants understand the reasons for and their responsibility in receiving sanctions.

At the end of a successful required treatment/monitoring period, the defendant graduates from mental health court, at which point charges are dismissed, probation ended, or sentence dropped. In cases of repeated noncompliance, a mental health court may return the defendant to traditional criminal court for processing in preadjudication cases or for sentencing in postadjudication cases or to jail/prison for serving a prior sentence.

Evaluation

Descriptive articles on mental health courts tend to praise their diversion success. Proposing the mechanisms of change to be structure, monitoring, support, and encouragement, as well as individualized mental health treatment and services, they warn that inadequate community treatment and services limit a court's impact. Empirical studies report positive results: Defendants obtain more treatment and offend less while participating in the courts than in a comparable prior period; and, compared with mentally ill defendants in traditional criminal courts, they receive more treatment and are no more likely to re-offend. Evidence of reducing criminal recidivism more than traditional criminal courts is unclear. Little research exists about long-term effects and other effects such as functioning and quality of life.

Mental Health Law

This entry traces the origins of mental health law, discussing its transition from a medical model to a legal model and considering recent trends. It examines several of the major topics in the field, including civil and criminal commitment, patients' rights, and criminal justice issues. It then discusses how therapeutic jurisprudence, an emerging paradigm, has begun to transform the field.

Mental health law was first conceived as a separate field of law in the late 1960s and early 1970s. Before then, laws certainly existed on various topics later subsumed within mental health law. These included the law governing civil commitment, guardianship, the legal insanity defense, and incompetency to stand trial, among others. The common law had clarified some of the legal issues raised by mental illness, and there had been some statutory developments, but it was not until the U.S. Supreme Court began to constitutionalize the issues that these disparate strands of legal doctrine began to be thought of as a separate area of law. The civil rights struggle of the 1950s and 1960s produced a new breed of lawyers who championed the rights of disadvantaged populations—racial minorities, criminal defendants, prisoners, and those with mental illness as well. The Supreme Court expanded constitutional rights in the criminal justice system, in the prison, and ultimately in the mental hospital. The Court overcame its traditional reluctance to intervene in state processes and brought the Constitution to state institutions that previously had been beyond judicial scrutiny.

Transition From a Medical Model to a Legal Model

The Court's expansion of the rights of criminal defendants and prisoners led civil liberties lawyers to argue

that those involuntarily institutionalized because of mental illness should enjoy no fewer rights. Before this, the courts had taken essentially a hands-off approach to the plight of mental patients. Indeed, the law can be seen as having applied a medical model to civil commitment and other issues involving people with mental illness. These issues were seen as medical in nature and beyond the ken of the courts.

After the 1960s, this medical model was replaced by a constitutionally based legal model that focused on expanding and protecting patients' rights. Modern mental health law has been transformed by this legal model. For many, this was a welcome change indeed. The medical model granted excessive deference to physicians, which produced arbitrary and sometimes unnecessary deprivations of liberty. Mental hospitals at this time often were little more than human warehouses in which treatment was scant or nonexistent.

The legal model of mental health law ushered in significant reforms. The court severely restricted the standards for civil and criminal commitment, expanded procedural due process hearing rights, and recognized new constitutional rights for patients involved in various aspects of the mental health and criminal justice systems.

Limits on Civil and Criminal Commitment

In a 1972 case, the Court found unconstitutional the indefinite commitment of a mentally retarded criminal defendant who was incompetent to stand trial. The Court held that, at a minimum, due process requires that the nature and duration of an individual's confinement to a mental hospital must bear a reasonable relation to the purposes of such commitment. When it is clear that a criminal defendant committed on the basis of his incompetence to stand trial will not regain competence in the foreseeable future, his continued commitment on this basis would be impermissible. The Court also found that the defendant was denied equal protection because he was subjected to a more lenient commitment standard and to a more stringent standard of release than civil patients. Soon thereafter, the Court extended these rights to those committed following an adjudication of not guilty by reason of insanity and then to patients subjected to civil commitment. Courts soon used substantive due process to limit the standards that would justify commitment—and procedural due process to require greater hearing rights—including the right to counsel and the requirement that the state bear the burden of proof by clear and convincing evidence.

Rights Following Commitment

Because mental hospitals were chronically understaffed and underfunded, mental health lawyers challenged these institutions as denying patients a constitutional right to treatment. Some lower courts recognized such a right to treatment and specified detailed standards and conditions that hospitals must comply with. The Supreme Court, however, avoided deciding the issue, instead recognizing that a patient committed for many years without treatment was deprived of his constitutional right to liberty. The Court subsequently held that an individual committed to a mental retardation facility has a constitutional right to safe conditions of confinement, freedom from unreasonable physical restraint, and minimally adequate habilitation.

The Right to Refuse Treatment

A frequently litigated issue has been the asserted right of mental patients and prisoners to refuse medication and other forms of intrusive mental health treatment. In 1990, the Supreme Court upheld the involuntary administration of antipsychotic medication to a mentally ill prisoner who is dangerous to other inmates and staff. The Court recognized that the prisoner had a significant liberty interest in refusing forced medication but recognized that the prison's interest in its administration outweighed this liberty interest. The right to refuse intrusive treatment was given wider scope in contexts not involving the prison. In cases involving pretrial detainees rather than sentenced prisoners, the Court applied a more stringent standard, requiring that unwanted medication must be justified as medically appropriate and the least restrictive alternative way of achieving a compelling governmental interest, such as the protection of other inmates or staff and the need to restore a criminal defendant to competence for trial.

Constitutional Limits in the Criminal Process

The Supreme Court has determined that a criminal defendant may not waive counsel, plead guilty, or be tried, while incompetent due process requires determination of the competence question and places

limits on the nature and duration of incompetency commitment. In addition, the Eighth Amendment ban on cruel and unusual punishment was held to preclude the execution of a capital defendant who becomes incompetent by reason of mental illness or one suffering from mental retardation.

The availability of the insanity defense and how it should be defined is largely a matter of state law. Most jurisdictions recognize the defense but limit it to cognitive impairment that prevents the defendant from understanding the wrongfulness of his or her conduct. Defendants acquitted by reason of insanity typically are committed to mental hospitals as long as they continue to be mentally ill and dangerous. In the special context of sex offender civil commitment, the Court has recognized that pedophilia can justify a special sexually violent predator commitment scheme, as long as it significantly impairs the individual's ability to control his conduct.

Other Mental Health Law Issues

These constitutional developments drove much of mental health law, requiring statutory changes to reflect constitutional limits on how people with mental illness could be dealt with in both the civil mental health system and the criminal justice process. Mental health law, of course, deals with other issues that had been subject to statutory and common law developments. These include the regulation of mental health professionals and clinical practice; clinical expert witness testimony; clinical malpractice; informed consent for treatment; confidentiality and patient privacy and access to records; guardianship, housing, and zoning issues; discrimination in employment and in governmental benefits; and education of the mentally handicapped.

Benefits and Limits of the Legal Model

The legal model of mental health law that supplanted the previous medical model brought needed reforms and curtailed many abuses to which those with mental illness had been subjected in the mental hospital, the criminal justice process, and the community. Although a significant improvement over the medical model, the legal model of mental health law itself produced problems. It removed power from clinicians who may have abused it but entrusted it to judges and lawyers who often fail to understand the clinical needs of the patient. By placing primary emphasis on legal rights, the legal model may sometimes have neglected therapeutic needs. Ironically, despite its focus on those with mental illness and the clinical professionals who deal with them, the field of mental health law was not as interdisciplinary in its orientation and scholarship as one might suppose. The legal model, with its origins in and emphasis on constitutional rights, thus seemed in need of a new direction. This became particularly evident as the Supreme Court became more conservative and less inclined to extend constitutional rights further.

The Emerging Therapeutic Jurisprudence Paradigm

As a result, a new model of mental health law has been emerging in the past 20 years, supplanting the legal model with a new therapeutic orientation that focuses not only on legal rights but also on the well-being of those with mental illness. Therapeutic jurisprudence is an explicitly interdisciplinary approach to legal scholarship and law reform that emphasizes law's impact on psychiatric and psychological well-being. This approach brings insights from psychology and the mental health disciplines into the formulation and application of law in an effort to reduce unintended antitherapeutic effects and maximize law's therapeutic potential.

The therapeutic jurisprudence paradigm suggests that the law itself can be seen to function as a therapeutic agent. Legal rules, legal practices, and the way various legal actors (such as judges, lawyers, expert witnesses, and therapists) play their roles all are social forces that often produce therapeutic or antitherapeutic consequences. The therapeutic jurisprudence orientation focuses attention on these consequences and seeks creatively to reshape law and legal practices so as to increase mental health consistent with legal rights and values. The therapeutic jurisprudence approach also identifies issues for empirical exploration, generating research on the mental health system that can significantly enhance our understanding of how law functions in this area and how it can be recast to better achieve its therapeutic aims.

Therapeutic jurisprudence is thus an approach to mental health law that goes beyond the legal model that prevailed since the 1960s and that seeks to apply legal rights and legal roles in ways that are more consonant with the therapeutic needs of those suffering from mental illness. It brings interdisciplinary insights to the field and seeks to more effectively balance legal

and therapeutic considerations. Unlike the medical model of mental health law that prevailed in an earlier time, it does not privilege therapeutic values over others. Instead, it seeks to determine whether law's antitherapeutic effects can be reduced and its potential to bring about mental health can be enhanced without subordinating due process and other justice values.

Therapeutic jurisprudence scholarship and law reform have had an important impact on mental health law, particularly in the areas of civil commitment, outpatient commitment, the right to refuse treatment, incompetency to stand trial and be executed, the legal insanity defense, the psychotherapist-patient privilege and its exceptions, guardianship, hearing rights, discrimination, the avoidance of stigmatization, and sex offender law. It has functioned to reinforce patient rights by identifying the therapeutic value of their recognition and to pioneer new rights, such as the right of people with mental illness to engage in future planning through the use of advance directive instruments. It has enlarged the dialogue and debate within mental health law, making it more interdisciplinary, and refocusing its attention on achieving therapeutic ends as well as protecting legal rights. In short, it has put mental health back into mental health law.

Moreover, it has expanded the field of mental health law, addressing issues in other areas of law that have a significant impact on the mental health of those affected. It has spread across the legal landscape, emerging as a mental health approach to law generally. It thus has had a transformative effect not only on the core areas of mental health law but also on related fields such as health law, juvenile law, family law, correctional law, discrimination law, tort law, and others.

It also has had an important impact on reconceptualizing the role of judges and the courts. Modern courts often deal with a variety of psychosocial problems involving individuals in need of treatment and rehabilitation. Thus, problems of substance abuse, domestic violence, child abuse and neglect, juvenile delinquency, and family disintegration increasingly have come to the attention of the courts. The approach of therapeutic jurisprudence has helped to pioneer new judicial models for dealing with these issues, including specialized treatment or problem-solving courts such as drug treatment court, domestic violence court, mental health court, and unified family court. These new judicial models, inspired by and applying principles of therapeutic jurisprudence, represent an expansion of traditional mental health law to additional contexts in which the law seeks to improve the mental health and psychological functioning of the individual and the society.

Mental Health Needs of Juvenile Offenders

Recently, researchers and juvenile justice administrators have recognized that rates of mental health disorders are remarkably high among adolescent offenders. This finding carries significant implications for policy and practice. Youth justice facilities are mandated to provide necessary mental health treatment to detained adolescent offenders with mental health needs. Furthermore, mental disorders may interfere with youths' capacities to stand trial and/or culpability. This entry discusses some recent advances that have been made in our understanding of mental health issues among juvenile offenders and points out key gaps in knowledge.

Rates and Types of Mental Disorders Among Juvenile Offenders

The mental health of adolescent offenders has been identified as one of the single most important issues

currently faced by the youth justice system. Reported rates of mental disorders among youths vary depending on how mental disorders are measured and at what point in the system youths are assessed. However, it is apparent that rates of mental disorders among juvenile offenders are much higher than those of general community samples of youths.

Recent studies have indicated that approximately 60% to 70% of youths in juvenile detention facilities meet the criteria for at least one mental disorder. The types of disorders found in adolescent offenders are diverse. Not surprisingly, many adolescent offenders meet the criteria for conduct disorder, a disorder that is characterized by illegal and antisocial behaviors, such as violence and stealing. However, even after conduct disorder is excluded from definitions of mental disorder, estimated rates of mental disorders remain extremely high among adolescent offenders; as many as 60% of detained male youths and 70% of detained female youths meet the criteria for a disorder other than conduct disorder.

Besides conduct disorder, a number of other mental disorders are very common among adolescent offenders, including major depression, which includes symptoms such as depressed or irritable mood; posttraumatic stress disorder, which is characterized by symptoms such as flashbacks and avoidance of experiences that are reminiscent of the earlier trauma; attention deficit/hyperactivity disorder, which includes symptoms such as difficulties attending to information, hyperactivity, and impulsivity; and substance use disorders, which involve inappropriate use and overuse of substances such as alcohol and drugs in a manner that has detrimental effects on a youth's functioning. Many detained youths meet the criteria for multiple disorders.

The rates and types of mental disorders exhibited by mentally ill youths differ depending on the demographic characteristics of the youth. Female offenders experience some disorders, such as posttraumatic stress disorder and major depression, at considerably higher rates than male offenders. In addition, preliminary research has reported that many types of mental disorders are more common among detained non-Hispanic White youths than among detained Black or Hispanic youths. However, it may be that the tools that are used to detect mental disorders are less accurate when used with minority populations. For instance, individuals from ethnic minority groups may be less likely to reveal mental disorders.

Future research on mental disorders in detained youths could benefit from international perspectives. Most existing research has focused on mental disorders among detained American youths, although there is some preliminary evidence that young offenders in other countries, including Canada and the United Kingdom, may also have high rates of mental illnesses. International research could help us develop a better understanding of variations in rates of mental disorders within different youth justice systems, as well as the different types of efforts that countries have taken to respond to these mental health issues.

In addition, Thomas Grisso, the leading expert in this field, has offered a number of useful concepts to guide research on the mental health of juvenile offenders from the perspective of developmental psychopathology. A key point of this perspective is that mental disorders must be understood within a developmental context. Some characteristics that are often interpreted as symptoms of a mental disorder (e.g., impulsivity, egocentricity) could possibly reflect normal adolescent development. Thus, if we are to understand mental disorders among detained youths, it is necessary to also understand adolescent development. Also, as noted by a developmental psychopathology perspective, psychopathology may take multiple paths and lead to multiple outcomes. This principle emphasizes the importance of examining various possible outcomes of mental disorders on adolescent offenders' functioning within the youth justice system and the community, as well as reassessing psychopathology at different points, as symptoms may change and fluctuate.

Implications for Service Delivery

Grisso has noted three primary reasons to be concerned about mental disorders among juvenile offenders. First, the youth justice system has a legal responsibility to provide mental health services to youths who are in their custody. Just as youth detention and correctional centers must provide medical services to youths with conditions such as diabetes or heart disease, so too must they provide mental health services to mentally ill adolescents who are in need of treatment.

Second, the youth justice system has due process obligations to youths with mental disorders. Specifically, jurisdictions have increasingly required that juvenile defendants be competent to stand trial (also called competent to proceed to adjudication or fit to

stand trial). Mental disorders may lead to impairments in competence-related legal capacities for some youths. For instance, a youth with a thought disorder may have a paranoid delusion that her or his attorney is conspiring against her or him and thus refuse to tell her or his attorney critical information regarding her or his case, or a youth with a depressive disorder may be unmotivated to adequately defend herself or himself due to feelings of worthlessness. In some jurisdictions, youths with mental disorders may also raise the insanity defense and can be found "not guilty by reason of insanity" (not guilty by reason of mental disorder) if mental disorders interfered with their ability to understand that their illegal behavior was wrong and/or rendered them unable to control their behavior.

Finally, the justice system has a responsibility to protect the public to the extent possible. While mental disorders are not the primary cause of most youth violence, there is some preliminary evidence that violent behaviors perpetrated by youths with mental disorders may sometimes relate to mental health issues, such as attention deficit/hyperactivity disorder, substance use disorders, and possibly even some internalizing types of disorders. To the extent that mental health issues contribute to youth violence, the youth justice system has a responsibility to treat and manage psychopathology so as to help prevent violence.

Assessment of Mental Health Issues in Juvenile Offenders

In 2003, an expert panel including Gail Wasserman and colleagues developed a consensus statement with best practice recommendations for assessing mental health issues among adolescent offenders. The panel recommended that the assessment process involve multiple steps. The first step is to screen all adolescent offenders who are admitted to detention and custody centers using an evidence-based tool. Ideally, this screening should occur within 24 hours of the youth being admitted to the facility and should focus on issues such as short-term risk of harm to self and others, active substance abuse, current medications, and mental health history.

If a youth is identified as having mental health needs through this screening process, a more comprehensive assessment may be necessary. This comprehensive mental health assessment should cover a broad range of mental health issues, including Axis I disorders and suicidality, and ideally should be conducted prior to the determination of disposition so as to guide dispositions and service delivery. Those youths who are identified as having significant mental health needs should continue to be reassessed periodically throughout their detention, as youths' mental health needs may change considerably over the course of detention. Also, to help facilitate youths' transition back to the community, Wasserman and colleagues recommend that secure facilities assess all youths who are preparing to return to their communities.

A number of jurisdictions have recently made significant efforts to implement a mental health screening process for detained youths. These efforts have been advanced by the development of the Massachusetts Youth Screening Instrument–Version 2 (MAYSI–2) by Thomas Grisso and Richard Barnum. The MAYSI–2 is a brief self-report mental health screening tool that has received empirical support. In 2006, this tool was routinely administered in more than 35 states. A number of other tools may also be useful in assessing adolescent offenders' mental health needs, including more comprehensive instruments, such as the Diagnostic Interview Schedule for Children–IV (Voice Version).

Despite the progress in the screening process for adolescent offenders, there are a number of issues that still need to be addressed. Most jurisdictions do not routinely reassess youths who are being reintegrated into the community to ensure that service continues. In addition, many youth justice staff who screen adolescent offenders are frontline staff, who do not necessarily have adequate training in this area.

Treating and Managing the Mental Health Needs of Juvenile Offenders

Due to the high cost of providing treatment services for offenders, the primary focus of research and interventions in the juvenile justice system has traditionally been on reducing recidivism rather than improving mental health outcomes. Research regarding treatment that is specifically aimed at addressing the mental health needs of juvenile offenders is scarce. However, it is clear that juvenile offenders do not receive adequate treatment services for their mental disorders, particularly in the case of minority youths. Less than a quarter of offenders with mental disorders in the juvenile justice system receive the services they need.

Recognizing that the juvenile justice system may not be the optimal setting for youths with mental

health needs, some jurisdictions strive to divert mentally ill youths from the youth justice system. At various stages after arrest, youths may be referred out to community-based agencies for counseling or intervention services. Though the focus of diversion programs has also tended to be on reducing recidivism, some recent research has examined the impact of diversion programs as well as other types of programs on mental health outcomes.

Treatment programs using a "wraparound" approach, which focuses on strong interagency collaboration to address youths' individualized treatment needs, have shown reduced emotional problems and mental health symptoms in referred youths, in addition to improved social and school functioning, and reduced rearrest rates. Some preliminary research has also reported that postrelease treatment services contributed to improved outcomes. Finally, researchers have found that multisystematic treatment, a leading treatment for high-risk youths, is associated with reduced psychiatric symptomatology as well as decreased recidivism.

As another alternative to the juvenile justice system, some jurisdictions have developed specialized mental health courts and drug courts. While there is preliminary evidence that juvenile drug courts are sometimes associated with reduced substance abuse among adolescent offenders, there is an absence of research on juvenile mental health courts. Like many of the treatment options for juvenile offenders, mental health courts and drug courts are downward extensions of adult treatment strategies. It is important for these treatment strategies to be empirically investigated for youths as juvenile offenders may experience unique barriers to treatment not faced by adults.

Furthermore, approaches that have been found to be effective with youths in community mental health settings may not easily generalize to youths in juvenile justice settings. For instance, adolescent offenders have high rates of cognitive deficits, which may interfere with their ability to engage in complex cognitive processes that are central to some therapeutic modalities. Also, the youth justice system is not an ideal treatment environment. Interventions administered within the youth justice system are often ordered by the court, and youths who receive interventions may experience considerable stigma. As such, adolescent offenders may be resistant to comply with interventions.

Though research is finally moving from evaluating criminal outcomes to mental health outcomes, there is still a dearth of evidence supporting mental health treatment services for juvenile offenders. Given the significant mental health needs of adolescent offenders, it is critical that future research continue to investigate effective strategies to manage and treat mentally ill adolescent offenders.

Mental Illness and the Death Penalty

Executing mentally ill prisoners has been a controversial topic for decades. The U.S. Supreme Court has found that such executions are unconstitutional. Although public opinion is somewhat mixed and understudied, national societies such as the American Psychological Association oppose executing the mentally ill. The legal system asks mental health professionals to determine a prisoner's competency for execution. Incompetent prisoners can be medicated so that they can become competent and thus be executed. Many professionals find this practice unethical.

In 1986, the U.S. Supreme Court in *Ford v. Wainwright* determined that it was unconstitutional to execute a prisoner who became mentally incompetent after his conviction. Such an execution was said to "offend humanity" and violate the country's "evolving standards of decency." Thus, the execution was a violation of the Eighth Amendment's prohibition of cruel and unusual punishment. The "evolving standards" guideline, set forth by *Trop v. Dulles* (1958), is generally measured by factors including the public's opinion and existing state legislation. For instance, the Court considered it relevant that, at the time of the *Ford* ruling, no state permitted the execution of the mentally ill. The Court then detailed the common law and historical evidence indicating that executing the mentally ill has long been rejected in American society. Finally, the Court determined that executing the mentally ill serves no state interest and is not a deterrent to crime. As such, it is cruel and unusual punishment. More recent Supreme Court rulings require that defense attorneys investigate and present evidence that would explain the defendant's conduct (e.g., if his or her crime was related to mental illness) or lead the jury to reject a death penalty. Thus, the Supreme Court has taken several measures to protect mentally ill defendants.

Social science researchers and mental health professionals have two main roles associated with the execution of the mentally ill. First, social science researchers have conducted research and public opinion polls concerning the execution of mentally ill prisoners. Second, mental health professionals conduct evaluations to determine a prisoner's competency for execution.

Social Science Research

Public opinion polls have been used to measure the community's evolving standards of decency. Community support for execution of the mentally ill has not been well studied. Generally, support for the execution of the mentally ill is lower than the level of support for the death penalty in general. For instance, a survey published in 2003 revealed that 13% of respondents favored executing the mentally ill. However, a 2004 study revealed that 57% of respondents favored executing prisoners who had become ill while in prison. This discrepancy may be due to the timing of the illness: The first study could be interpreted to measure support for executing prisoners who were ill at the time of the crime, while the second clearly indicated support for executing prisoners who became ill after the crime. This latter finding seemingly contrasts the notion that executing the mentally ill violates the community's standards of decency.

Research has also indicated that jurors do not properly consider mental illness when determining whether or not a defendant deserves the death penalty. Although many sentencing statutes list mental illness as a mitigator (i.e., a factor that suggests that the defendant is not deserving of death), research shows that evidence of mental illness instead often leads jurors to sentence the defendant to death. Furthermore, jurors who support the death penalty are more likely than opponents to find a mentally ill defendant guilty and are less likely to believe that the crime was caused by mental illness. Thus, jurors (and the public as a whole) express some disfavor toward mentally ill defendants.

The Role of Mental Health Professionals

The legal system relies on mental health professionals to evaluate defendants for a variety of reasons, including making determinations concerning a prisoner's suitability for execution. The Supreme Court in *Ford* was not specific about the criteria that should be used in this determination. *Incompetency* is a legal term that does not directly translate into psychiatric diagnoses. Legal incompetency is often interpreted to mean that the prisoner suffers from severe mental illness and does not understand the nature of the punishment or why he should suffer it. In general, mental illnesses that affect competency are schizophrenia, bipolar disorders, and delusional disorders. Mental illness, as defined for competency purposes, does not generally refer to personality disorders.

The execution of mentally ill prisoners presents mental health professionals with ethical dilemmas. *Ford v. Wainwright* prohibits the execution of mentally ill prisoners; however, it is allowable to medicate prisoners so that they become mentally competent. Many mental health professionals and mental health associations do not promote treating mentally ill prisoners so that they may be put to death.

In sum, it is currently unconstitutional to execute mentally ill prisoners, although it is generally acceptable to medicate them so that they become competent to be executed. The Supreme Court has found that the public's standards of decency forbid such an execution, though some public opinion research contradicts

this finding. Despite the finality of the Supreme Court ruling, controversy and ethical dilemmas remain.

Mental Retardation and the Death Penalty

The execution of mentally retarded prisoners has been a controversial topic for decades. The U.S. Supreme Court has found, in *Atkins v. Virginia* (2002), that such executions are unconstitutional; this decision was partially based on the community's evolving standards of decency. The legal system requires mental health professionals to determine whether a prisoner is mentally retarded, which is a difficult and controversial task.

In 1989, the Supreme Court in *Penry v. Lynaugh* had determined that the mentally retarded, as a class, should not be protected from receiving the death penalty. Instead, defendants' mental status should be considered on a case-by-case basis, with individual factors determining whether each defendant is eligible for the death penalty. The Court found that individuals with mental retardation vary greatly in their capacity and culpability; thus, a blanket exclusion was not appropriate. After the *Penry* decision, many states enacted new statutes or adapted their existing death penalty statutes to exempt the mentally retarded.

In 2002, the Supreme Court reversed itself in *Atkins v. Virginia.* The Court determined that the execution of mentally retarded prisoners was a violation of the Eighth Amendment's prohibition of cruel and unusual punishment. They relied heavily on evidence that the majority of states' statutes forbid the execution of the mentally retarded. Even those states that still permitted such executions had not carried out an execution of a mentally retarded prisoner in the preceding years.

In addition, the *Atkins* court found it significant that the execution of the mentally retarded was opposed by professional organizations, including the American Psychological Association and the American Association on Mental Retardation (AAMR). The AAMR's amicus brief presented the results of 27 opinion polls; results of these polls varied but revealed that 56% to 84% of respondents indicated disfavor with the executions of the mentally retarded. No poll found more than 32% support for execution, no matter how the question was worded. This accumulation of data indicated that the execution of mentally retarded prisoners violated the community's "evolving standards of decency" as set forth in *Trop v. Dulles* (1958).

Since the *Atkins* decision, state courts have struggled with defining mental retardation and determining what burden of proof (e.g., clear and convincing evidence) is needed to prove that a defendant is mentally retarded. Courts have also disagreed on whether the burden of proving mental retardation should fall on the defendant or the state.

Psychologists and researchers have two main roles associated with the execution of the mentally retarded. First, social science researchers have conducted public opinion polls concerning the execution of mentally retarded prisoners. Second, mental health professionals regularly conduct evaluations to determine a defendant's level of mental retardation.

Public Opinion Research

The *Atkins* court found that public opinion opposed executing the mentally retarded. Psychologists confirmed this conclusion both before and after the punishment was determined to be unconstitutional. In the years after the *Penry* decision many polls were conducted, with most finding that the level of support for

executing the mentally retarded was in the 20% to 30% range. More recently, surveys published in 2003 and 2004 found that the rates of support for execution of the mentally retarded were 12.5% and 29%, respectively. In general, these polls confirm the Court's finding that such executions violate the community's "evolving standards."

The Role of Mental Health Professionals

The *Atkins* court determined that the mentally retarded suffer from cognitive, behavioral, and volitional impairments that affect their impulse control. As a result, the death penalty is less likely to be a deterrent. Furthermore, mentally retarded individuals are less culpable and thus do not deserve harsh treatment. The Court relied on clinical definitions of mental retardation when identifying three criteria that determine the existence of mental retardation: subaverage IQ, poor adaptive skills, and onset of symptoms before the age of 18.

The legal system requires mental health professionals to conduct evaluations to determine a defendant's level of impairment and mental retardation. This is not an easy task, as mental retardation is difficult to identify. Mental health professionals generally measure IQ, processing ability, decision-making ability, impulse control, and adaptive functioning. Critics question whether such tests should be used to make life-or-death decisions because of their inherent limitations. For instance, a defendant's score on an IQ test is considered a major factor in determining whether he is mentally retarded. However, "intelligence" is a subjective, multifaceted construct without a standard test. Instead, an examiner constructs a unique test for each defendant. Thus, two examiners would likely create two different tests that could produce two different scores. IQ tests have been criticized for many reasons, including their lack of test-retest reliability. Because mental retardation is such an elusive construct, some trials become battles of the experts to determine whether or not a person is mentally retarded.

To complicate things further, there is no uniform legal definition for mental retardation. Each state can determine its own standard, which can be a subjective endeavor. For example, states differ on the IQ score that indicates mental retardation. Some critics note that, because of varying standards, a defendant who fits the criteria for mental retardation in one state would not do so in another state.

In sum, the Supreme Court has found that the public's standards of decency forbid the execution of mentally retarded prisoners, an assertion supported by a great deal of research. Despite the Supreme Court ruling, the assessment of the mentally retarded comes with controversy.

Mild Traumatic Brain Injury, Assessment of

An uncomplicated mild traumatic brain injury (mTBI) is traumatic brain injury in which there is a brief loss of consciousness, brief posttraumatic amnesia, or an alteration of mental status (e.g., feeling dazed) without evidence of neurological damage. Physical, cognitive, and psychological symptoms are common in the days and weeks immediately following the injury, but these resolve naturally within a few months in the vast majority of patients. A relatively small number of patients show continued symptoms, which can be due to a range of other issues besides the mTBI. Psychological evaluation of these patients should

include an assessment of cognitive and emotional functioning, as well as effort or motivation. Because these patients are commonly seen in forensic evaluations, where malingering is more likely, specific cognitive tests of effort should be administered. Symptom exaggeration or suboptimal performance can also be assessed on measures of emotional functioning.

Nature, Symptoms, and Outcomes From mTBI

Mild traumatic brain injury is a trauma to the brain that results in a brief loss of consciousness; a loss of memory for events immediately before or after the event, but not greater than 24 hours; or an alteration in mental status (e.g., feeling dazed, disoriented, or confused). When evaluated immediately postinjury, mTBIs are characterized by a high Glasgow Coma Scale score (between 13 and 15), which is a measure of the ability to follow eye-opening, motor-response, and verbal-response commands. When these injury characteristics are present, and there is no evidence of neurological damage, such as hemorrhage or contusion on neuroimaging (e.g., CT or MRI scan) of the brain, the mTBI is considered to be uncomplicated. A mild complicated TBI has not only a similarly short loss of consciousness and posttraumatic amnesia but also evidence of brain damage on neuroimaging (e.g., skull fracture), thus making it a more severe injury. Uncomplicated mTBIs can be contrasted with moderate or severe TBIs in which loss of consciousness and posttraumatic amnesia are significantly longer, typically measured in days or weeks, and are often accompanied by neuroimaging evidence of brain damage.

Common causes of mTBIs include the head being struck by an object, the head striking an object, or the brain undergoing an acceleration/deceleration movement, or whiplash, without direct external trauma to the head. The latter injury is common in motor vehicle accidents. The term *mTBI* is synonymous with *concussion,* with the latter term often used to describe the injury in athletics. These can be graded on their level of severity and are most common in contact sports such as football and hockey. Of the different levels of brain injury severity, mTBIs are by far the most common, accounting for more than 75% of all TBIs.

Common symptoms in the initial days and weeks post-mTBI can include a range of physical, cognitive, and psychological changes. Common physical symptoms include headache, nausea, vomiting, dizziness, blurred vision, and sleep disturbance; common cognitive deficits include attention and memory deficits. Psychologically, symptoms such as anxiety, irritability, or depression may be present. Depending on severity, these symptoms can interfere with an individual's ability to function effectively. These acute symptoms are due to temporary dysfunction of the brain, such as metabolic changes, diminished cerebral blood flow, and impaired neurotransmission secondary to the injury. Although most neurons recover, a small number of neurons may degenerate and die. Nevertheless, the brain tends to recover quite quickly and naturally in an uncomplicated mTBI and there is typically significant improvement in symptoms within the first few days postinjury. Moreover, research has demonstrated that the vast majority of individuals are essentially symptom free and return to baseline levels of functioning within a few days to weeks, and sometimes a few months, after their injury. Recovery in athletes tends to be even more rapid, as these individuals are often highly motivated to recover and return to play. Nevertheless, a small number of individuals, fewer than approximately 5%, have prolonged and, at times, disabling symptoms postinjury that present a more complex clinical picture. Historically, various terms have been used to describe these patients, but today they are typically diagnosed with postconcussion syndrome. Not surprisingly, these individuals tend to seek continued psychological and medical treatment and may seek legal redress for their injury.

There is controversy about individuals with poor outcomes after uncomplicated mTBI and the cause of their persisting symptoms. While some have argued that these symptoms may be due to undetected and persisting brain abnormalities, most clinicians and researchers argue that other factors besides mTBI must be considered. For instance, many of these patients are in litigation and thus have external incentives to complain of persisting symptoms, even years after injury. Research has also demonstrated that those individuals who have had previous psychological or neurological problems or other life stressors tend to recover more poorly. Older age does not appear to be a risk factor for poor outcome after a single mTBI, although this is controversial, and the impact of repeated mTBIs and age (i.e., NFL players or boxers) may increase the chances of developing dementia in later life. Clearly, ongoing psychological or substance abuse postinjury, medical or pain complications from other injuries sustained in the accident (e.g., orthopedic), or additional

mTBIs (more likely in an athlete) can prolong and complicate recovery. It should be noted that recovery is slower after more severe TBIs, including complicated mTBIs, and some individuals may suffer persisting symptoms that impair social and occupational functioning. What is expected, however, is that the vast majority of individuals who suffer mTBI will completely recover and have no persistent difficulties attributable to the injury.

Psychological Evaluation of mTBI

For an individual who has sustained an mTBI, the purpose of a psychological evaluation varies. Some evaluations may be within days or a few weeks after an accident, in the context of seeking assistance with management of cognitive and behavioral symptoms, whereas others may be years later in the context of a personal injury lawsuit seeking recompense for the injury. In these latter cases, it is unlikely that any observed deficits would be due to the direct effects of the mTBI, and other causes for these should be explored. In athletics, a series of brief evaluations, with cognitive testing typically done via computerized assessment, may be performed to assist in return-to-play decisions.

The clinical evaluation of the individual who has suffered an mTBI typically includes the following: review of available psychological and/or medical records, clinical interview with the patient, neuropsychological or cognitive testing, and psychological testing. Each of these is briefly described below. When reviewing medical records, psychologists seek to obtain as much information as possible about the nature and extent of the injury, such as how the individual behaved immediately after injury, whether there is any documented loss of consciousness, and whether there is any posttraumatic amnesia. In addition, it is useful to know if the individual suffered other injuries in the accident, such as orthopedic injuries, which might affect outcome. If possible, medical records predating the injury can be obtained to determine if the individual had preexisting medical or psychological problems, such as learning disabilities or perhaps a seizure disorder that might affect recovery. The clinical interview with the patient should focus on the nature and extent of the injury, as well as the symptoms, including cognitive, behavioral, and psychological, that the patient is currently experiencing. How such symptoms are interfering with the patient's daily life is important. In addition to such injury information, the clinical interview should address the following: medical and psychiatric history, prescribed medications, neurological history such as previous TBIs or learning disabilities, substance abuse, current stressors in addition to the injury, occupation and social functioning, and litigation status. In such an interview, it is important to attempt to rule out alternative causes for the symptoms the person is experiencing. For instance, complaints for difficulty concentrating post-mTBI may not be due to the injury per se but to a preexisting anxiety disorder.

Because of the symptoms described above, evaluation of the mTBI patient typically includes both neuropsychological and psychological testing. Neuropsychological testing should include use of well-normed and psychometrically sound tests with established reliability and validity. A battery of tests should evaluate, at minimum, intelligence (e.g., Wechsler Adult Intelligence Test–III), learning and memory (e.g., California Verbal Learning Test–II), attention (e.g., Conners' Continuous Performance Test), visuospatial processing (e.g., Judgment of Line Orientation), and executive functioning (e.g., Wisconsin Card Sorting Test). Other cognitive domains may need to be assessed, including academic (e.g., Wide Range Achievement Test) and sensory-motor functioning (e.g., Finger Tapping Test), depending on the nature of the referral and patient complaints.

In addition to evaluating specific areas of cognitive functioning, it is important to evaluate the patient's effort or motivation, which may be suspect, particularly in a forensic setting where there may be motive for performing poorly (e.g., getting a larger monetary settlement in a personal injury case or evading responsibility in a criminal trial). If this is not done, impaired cognitive performances may erroneously be attributed to the mTBI and not to a patient's poor effort. When patients exert poor effort consciously for external reward, this is termed *malingering.* Psychologists have recently developed multiple cognitive tests to detect malingering or poor effort that are efficient and accurate. For instance, one commonly used test requires patients to learn multiple word pairs (which appears difficult) and then to recognize each of the words on separate trials when a distractor word is presented. Because the word pairs are so obvious (e.g., grass-green), this test is actually quiet easy, and individuals with serious neurological disorder or mental retardation perform well on it. A poor performance in an individual with mTBI is suspicious for poor effort, and performance on other cognitive testing is thus of

questionable validity. In addition to other tests designed to detect poor effort only, it can be detected on cognitive tests for which built-in validity detectors have been developed. Poor effort or malingering is also suspect when a patient does not cooperate with testing, performs inconsistently across similar tests (e.g., verbal memory), endorses symptoms inconsistent with the alleged injury, and presents during the interview in a manner inconsistent with testing (e.g., demonstrates good recall when queried about recent personal events, but poor performance on memory testing).

In addition to cognitive testing, psychological testing is also recommended in mTBI to evaluate the nature and severity of psychological involvement. Commonly used tests include the Minnesota Multiphasic Personality Inventory–2 and the Personality Assessment Inventory. These lengthy self-report tests evaluate a range of clinical complaints, such as mood, personality, and behavioral disturbance, as well as patient response variables. These latter variables evaluate whether a patient responded honestly and consistently to the items or whether he overreported symptoms (i.e., presented himself negatively) or underreported symptoms (i.e., presented himself positively). Within the forensic evaluation, overreporting symptoms are much more common in mTBI, as patients seek to emphasize experienced symptoms. It is thus important that whatever measure of personality is used, it includes a measure of patient response style. Unfortunately, the existing measures of postconcussive symptoms, which might be ideal for evaluation of an mTBI patient, typically do not include such measures.

Miller Forensic Assessment of Symptoms Test (M–FAST)

The Miller Forensic Assessment of Symptoms Test (M–FAST) is a screening measure for the detection of feigned, or malingered, mental illness. The M–FAST may be used in psychological evaluations of an adult who might be attempting to fake a psychiatric disorder. Because of the reported prevalence of malingering and difficulty of accurate detection through clinical judgment, many researchers and clinicians have suggested routine formal assessment of malingering in most evaluations. Although there are other, more lengthy, assessment measures for malingering detection, the M–FAST was developed to provide the evaluator with a brief screening tool.

Psychologists are often asked to provide an evaluation of criminal defendants to determine if they are competent to stand trial (CST) or to evaluate defendants pleading not guilty by reason of insanity (NGRI). Although most individuals who are found not CST or NGRI do have a severe mental illness, a percentage will attempt to fake mental illness for trial postponement or to be sent to a hospital rather than prison. There are other evaluations, such as disability assessments or psychological evaluations with correctional inmates, where malingering is routinely assessed. In these types of evaluations, malingering is often formally assessed with an instrument developed specifically to detect the faking of mental illness. The M–FAST is often used in these evaluations to screen the individual being evaluated for malingering. If malingering is suggested by the M–FAST results, further evaluation of feigning is carried out.

Description and Structure

The M–FAST is a 25-item structured interview that can be administered in approximately 5 to 10 minutes. The measure may be more viable than other instruments in several situations because of its interview format (e.g., reading level of the test taker is irrelevant) and its brief

administration time. The M–FAST items were developed to represent the following response styles/strategies that have been validated for identifying malingered psychiatric symptoms: Reported versus Observed Symptoms, Extreme Symptoms, Rare Combinations, Unusual Hallucinations, Unusual Symptom Course, Negative Image, and Suggestibility. The M–FAST includes items that represent these detection strategies along with items that reflect actual symptoms of mental illness.

Since the M–FAST items were developed to operationally measure several strategies for malingering detection, the factor structure has been examined. Two principal component analyses were performed on the nonclinical and clinical M–FAST development samples. Examination of the scree plots suggested one primary "malingering" factor in both samples accounting for 55% (nonclinical) and 49% (clinical) of the variance. The factor structure of the M–FAST has been tested independently from the development samples by exploratory and confirmatory factor analysis. Similar to the initial factor findings, the latest analyses indicate that the M–FAST is found best to represent a single, dominant factor.

Reliability

The M–FAST was developed at a forensic hospital with patients who were either found NGRI or incompetent to stand trial. The initial reliability (or consistency) of the M–FAST was assessed in several ways. The test-retest reliability, given an average of 2 weeks apart, and the internal consistency of M–FAST items were both reported to be high at .92. A third analysis assessed interrater reliability by comparing scores of different M–FAST interview raters. An interclass correlation coefficient, using two-way random effects model with consistency reported, was calculated and found to be high at 99.6. Several independent studies since the development of the M–FAST have indicated that the M–FAST is highly reliability; M–FAST internal consistency ranging from .90 to .92, scale (or strategy) internal consistency ranging from .53 to .82, and interrater reliability found to be 1.0.

Validity

The primary goal for M–FAST validation was to demonstrate criterion, convergent, and discriminant validity of the instrument. The diagnostic efficacy of the M–FAST for identifying malingered mental illness was also examined. Initial validation of the measure was demonstrated by significant, positive relationships found between the M–FAST and other validated instruments and scales designed to assess for response style and/or malingered mental illness. These initial studies included forensic patients who were incompetent to stand trial or NGRI and a group of civil outpatients being evaluated for mental illness disability status. In all the samples the M–FAST effectively discriminated between bona fide psychiatric patients and those who were found to be faking mental illness for secondary gain.

Since its development, the M–FAST has been examined for validity and diagnostic efficacy with several different samples including civil psychiatric inpatients, imprisoned offenders being assessed for psychiatric services, and additional samples of forensic inpatients being assessed for CST. In all these samples, the M–FAST was found to be valid and to effectively differentiate those individuals who were malingering from those who were bona fide psychiatric patients. The use of the M–FAST to detect diagnostic-specific malingering has also been examined. In these studies, the M–FAST has been found to be an effective screen when an individual is attempting to malinger the specific disorders of posttraumatic stress disorder, schizophrenia, major depressive disorder, and bipolar disorder.

Millon Clinical Multiaxial Inventory–III (MCMI–III)

The Millon Clinical Multiaxial Inventory–III (MCMI–III) is a 175-item self-report inventory designed to assess personality characteristic and psychopathology. It has 4 validity scales, 11 clinical personality pattern scales, and 3 severe clinical syndrome scales. Although not originally validated in forensic populations, and in spite of limited research with forensic subjects, it is increasingly being used in forensic practice. Extensive changes were made in the development of the MCMI–III, limiting the applicability of the research results from prior MCMI versions.

Detection of malingering, denial, and random responding and diagnostic accuracy are critical issues that are relevant to the forensic applicability of the MCMI–III. A number of issues have implications for use of the MCMI–III in forensic assessment, including poor detection of malingering and denial, interpretation of potentially random protocols, and a significant controversy regarding diagnostic accuracy. The existence of all these issues is likely to result in vigorous challenges to expert testimony based on the MCMI–III because the instrument does not meet the criteria established in *Daubert v. Merrell Dow Pharmaceuticals* (1993), which require an evaluation of the error rate of assessment methods on which experts rely.

Malingering, Denial, Random Responding, and the MCMI–III

More research is needed before firm conclusions can be drawn regarding the ability of the MCMI–III to detect malingering and denial. The extant research suggests only moderate accuracy, and there are no studies that use known groups designs with forensic populations. Mike Schoenberg and colleagues in 2003 compared students simulating psychiatric disorder with psychiatric patients and found a sensitivity of 58.5% and 51.9% for a Scale Z and Scale X, respectively. Positive predictive power was 55.6% and 66.3% for X and Z, respectively. They concluded that "the MCMI–III modifier indices were of minimal clinical utility in distinguishing college student malingerers from bona fide psychiatric patients." Somewhat better results, with higher accuracy in detecting malingering, were reported by Scott Daubert and April Metzler, who compared two groups of psychiatric patients, one instructed to malinger and one instructed to respond honestly. In a separate study by Schoenberg and colleagues, an attempt was made to develop a discriminant equation to detect malingering. They found some improvement in detecting malingering. However, research with other instruments by Richard Rogers's group and Kucharski and colleagues has shown that the accuracy of discriminant equations developed via simulation designs decreases to near-chance levels when applied to actual forensic populations. The results of a study by Richard Charter and Michael Lopez demonstrated that more than 50% of those responding randomly, using the VI > 1 criterion recommended in the MCMI–III manual, would be viewed as interpretable protocols. Failing to exclude random protocols potentially confounds the research on malingering and diagnostic accuracy and in clinical practice is likely to inappropriately characterize random responders as pathological.

Diagnostic Accuracy of the MCMI–III

Probably the most difficult issue confronting the MCMI–III is the current controversy regarding diagnostic accuracy. Two validity studies conducted by the test author in 1994 and 1997 and reanalyses of the data from these studies make up the findings on diagnostic accuracy. A reanalysis of the 1994 database, by Richard Rogers and colleagues, demonstrated that the convergent validities of the personality scales was "disconcertingly low ranging from .07 to .31" and that the "discriminant correlations were *higher* than the convergent validities." These findings are consistent with other studies conducted by Paul Retzlaff. Frank Dyer and Joseph McCann argued that the Rogers and colleagues study was flawed due to selection of poor criterion measures and use of data from the 1994 validation study, where there were obvious deficiencies in the diagnostic criterion. The 1997 validation study attempted to address this limitation by including a *Diagnostic and Statistical Manual of Mental Disorders* (fourth edition; *DSM-IV*) of the American Psychiatric Association criterion guide for diagnosis. Louis Hsu reanalyzed both the 1994 and 1997 data and found marked improvement in the diagnostic accuracy for the 1997 data. However, serious methodological flaws including criterion contamination, confirmatory bias, and availability heuristics led him to conclude that the results potentially overpredict the

diagnostic accuracy of the MCMI–III. Noteworthy in the discussion of the diagnostic accuracy is the lack of any information regarding the accuracy of the Thought Disorder scale, a scale particularly relevant to criminal forensic practice.

Applicability and Admissibility of the MCMI–III

The research to date suggests that the MCMI–III has significant limitations for forensic practice in terms of its ability to detect malingering and denial. Use of the recommended VI > 1 criterion is likely to result in inappropriate inclusion of random protocols in past research studies and clinical interpretation of protocols of questionable validity. The diagnostic accuracy controversy remains an issue owing to methodological flaws in the validation studies. The diagnostic accuracy of the MCMI–III in the identification of Axis I disorders is particularly underresearched. These are important issues that must be considered in selecting an assessment instrument not only from the perspective of the best measure for the forensic task but also for the effect it will have on court proceedings, including *Daubert* challenges to admissibility. One would be wise to heed Robert Craig's advice that a thorough knowledge of the research supporting the test's applicability and limitations will best serve the interests of the client. In this regard, the paucity of studies involving forensic populations; poor detection of malingering, denial, and random responding; and the diagnostic accuracy controversy are important issues to be aware of. Experts are in agreement that the use of the computer-generated report for the MCMI–III is inappropriate because the sensitivity for detecting pathology was artificially increased, resulting in overpathologizing of the respondent. All these issues need to be resolved before the MCMI–III can be considered a useful measure in forensic practice.

Minnesota Multiphasic Personality Inventory–2 (MMPI–2)

The original Minnesota Multiphasic Personality Inventory (MMPI) and its successor have been recognized as the most widely used and researched objective clinical personality inventories. Using 567 true-false items, the MMPI–2 assesses a diverse range of personality characteristics; symptoms of psychopathology; and patterns of behavior, attitudes, and concerns. First published in 1942 and revised in 1989, the instrument yields a wealth of clinical data and is used across multiple clinical and medical settings, for employment screening and selection, and in a variety of forensic situations.

The test includes multiple validity indices, assessing test-taking attitudes and approach; 10 basic, numbered clinical scales (1 = *Hypochondriasis,* 2 = *Depression,* 3 = *Hysteria,* 4 = *Psychopathic Deviate,* 5 = *Masculinity-Femininity,* 6 = *Paranoia,* 7 = *Psychasthenia,* 8 = *Schizophrenia,* 9 = *Hypomania,* 0 = *Social Introversion,* with all but scales 5 and 0 considered core clinical scales) and their subscales; as well as more than five dozen content scales (e.g., Antisocial Practices, Anxiety), content component scales (e.g., Negative Treatment Indicators: Low Motivation), personality psychopathology trait scales (e.g., Aggressiveness, Negative Emotionality/Neuroticism), and supplementary scales (e.g., Addiction Potential, Overcontrolled-Hostility).

Raw scores on these scales are transformed to norm-based *T*-scores (mean = 50, standard deviation = 10) to enhance the interpretability of results. Scales with a *T*-score of 65 or greater are considered clinically significant. In addition to interpretive

material linked with individual scale and subscale scores, considerable research has identified and supported descriptions associated with particular patterns of elevations, known as code types, reflecting the 1 to 3 most elevated clinical scales and their combinations. As Roger Greene emphasizes, these descriptions are probabilistic statements based on modal patterns and, as such, do not necessarily describe individuals obtaining a specific code. Nevertheless, they provide potentially useful information about problem areas, personality types and correlates, and treatment implications.

History and Development

The MMPI is an empirically derived test. Through a multistep process, Starke Hathaway and J. C. McKinley developed the original MMPI by selecting items for inclusion that discriminated a criterion group (i.e., those with a given clinical diagnosis) and comparison groups (i.e., nonpatient normative groups and those with other diagnoses). After decades of use, the need for restandardization became clear. As James Butcher and colleagues, Greene, and others have described, several factors underscored the need to revise the MMPI, including the need for current norms, a larger and more nationally representative normative sample that appropriately included ethnic and racial minorities, and updated item content. Those involved in the restandardization took steps to maintain continuity between the MMPI and its revision so that the extant research would not be made obsolete. As Gary Groth-Marnat notes, although some differences have been detected, research has largely supported comparability in findings for the two versions; the MMPI–2 seems to describe the same types of characteristics and behaviors as the MMPI.

Psychometric Properties

In light of the complex issues involving the MMPI–2's reliability (many relating to the initial version's construction), the reader is referred to the readings below for discussions of the test's development and psychometrics. A substantial body of research has supported the conclusion that, with some exceptions, its scales evidence moderate levels of internal consistency and stability over time. Thousands of studies have attested to the test's validity and the meanings of scale and code type descriptions, as well as the incremental validity obtained when using the MMPI–2 in an assessment.

Recent Refinements

In an attempt to address issues related to item overlap across the clinical scales and conceptual heterogeneity (i.e., multidimensionality) within them, Auke Tellegen and colleagues published the *Restructured Clinical* (*RC*) *Scales* in 2003. First, they developed a Demoralization scale, thought to represent much of the common "affective" variance shared across the core clinical scales. Subsequent steps were designed to yield scales assessing distinct constructs and resulted in the following: Somatic Complaints, Low Positive Emotions, Cynicism, Antisocial Behavior, Ideas of Persecution, Dysfunctional Negative Emotions, Aberrant Experiences, and Hypomanic Activation. Tellegen and colleagues reported that the RC scales have comparable or greater internal consistencies than the clinical scales, improved discriminant validity, and equivalent or improved convergent validity. They concluded that the RC scales predicted variables linked conceptually to the scales' core constructs at least as well as and, in some cases, better than the original clinical scales. Leonard Simms and colleagues further documented the increased measurement efficiency of the RC scales, reporting that they were less intercorrelated, related more clearly to measures of personality and psychopathology, and had greater incremental utility than the clinical scales.

Assets and Limitations

Groth-Marnat cogently summarizes the MMPI–2's limitations as well as its assets. As he details, issues related to scale construction (i.e., item overlap; high intercorrelations among scales; clinical scale content reflecting multidimensional variables that, in some cases, lack clear definition) are frequently highlighted shortcomings that impact psychometrics and raise interpretive challenges. Numerous authors have also pointed out that the clinical scale names are misleading or confusing because they reflect traditional diagnostic categories (e.g., Schizophrenia) or outdated terms (e.g., Hysteria), and their content does not translate directly to current disorder classification systems. In that vein, he points out that although the test was initially intended as a means of differential diagnoses, it does not provide diagnoses, and research has not

supported its utility as a direct diagnostic tool; rather, it contributes information to assist diagnostic formulations and allows for enhanced understanding of symptoms. Other limitations include the test's length and the fact that although multiple demographic variables (e.g., age, ethnicity, education) may impact interpretation, the onus is on the test user to take such factors into account. Finally, research suggests that moderate scale elevations must be interpreted with caution.

Despite these limitations, numerous advantages lend credence to the MMPI–2's wide use. Indeed, Groth-Marnat deems its popularity and familiarity assets. In fact, the test has been translated into more than 50 languages and has multiple studies supporting its use in other cultures. The MMPI–2's extensive research base, detailing the validity of profile descriptors and scale correlates, contributes to this popularity and has been labeled by Groth-Marnat and others as the test's strongest asset. Furthermore, the test's multiple validity indices aid the detection of response sets or attempts to over- or underreport psychological difficulties. Consequently, in addition to its standard clinical use, the MMPI–2 can play a role in "gatekeeping" assessments, such as required psychiatric evaluations, employment screenings, or court proceedings.

The MMPI–2 offers substantive value for professionals. Administration is straightforward and may be done via pencil and paper or computer software, and computer scoring and interpretation options are also available. If stamina or time is a concern, the MMPI–2 offers the option of a shorter version that still allows for interpretation of clinical scales and code types. With its revision and restandardization, the introduction of new scales and indices, and the development of the RC scales, the test also continues to evolve to meet practical needs.

Minnesota Multiphasic Personality Inventory–2 (MMPI–2) Validity Scales

A strength of the Minnesota Multiphasic Personality Inventory–2 (MMPI–2) is its multiple indicators regarding an examinee's approach to the test. Ideally, examinees answer all questions, respond consistently, and do not distort test findings by overreporting or underreporting experienced psychopathology. However, some individuals may approach the test in a manner that deviates from this optimal scenario, and MMPI–2 profiles can be interpreted with confidence only when these issues have been addressed. Overall, the MMPI–2's measures of test-taking approach and validity may qualify clinical findings or lend credence to interpretations yielded by the test in multiple situations, particularly in forensic situations such as criminal proceedings as well as in gatekeeping evaluations (e.g., child custody assessments), in which examinees may have motivation to modify their clinical presentation. The most commonly used validity measures include the L (Lie), K (Correction), and F (Infrequency) scales.

A first step in assessing response validity involves evaluating the Cannot Say scale, which indicates the number of unanswered items or items answered both true and false. A high number of such items renders a profile invalid and may suggest that the examinee perceived the items as irrelevant, was uncooperative, was defensive or indecisive, or could not understand the items. Second, to assess response consistency, the Variable Response Inconsistency (VRIN) and True Response Inconsistency (TRIN) scales are evaluated. VRIN measures the degree to which the examinee responded consistently to items similar in content,

with logically inconsistent responses of particular note. Though some inconsistent responding is not unusual, high levels suggest that the examinee may have responded randomly or had reading comprehension difficulties or had been confused, careless, uncooperative, or overtly psychotic. TRIN offers additional information about response sets or styles that may affect the profile, measuring the degree to which the examinee responded inconsistently by endorsing items similar in content, but phrased as opposites, as both true or as both false. High scores indicate a tendency to yea-say (i.e., endorse many items as true), and low scores indicate a tendency to nay-say (i.e., endorse many items as false).

Third, the extent to which the examinee accurately self-described symptoms and did not over- or underreport psychopathology is evaluated. Underreporting is more common in personnel, presurgical, or child custody evaluations, whereas overreporting is more common in personal injury or criminal evaluations. Several scales provide information about possible overreporting or symptom exaggeration. The F (Infrequency) scale includes items selected to detect unusual or atypical responses. Reflecting bizarre sensations, strange thoughts, and peculiar experiences, they were answered in the deviant direction by no more than 10% of an early subsample of the normative sample. There are several possible interpretations for elevations on this scale including malingering, random responding, or expressing a "cry for help." Though different in content relative to F, the F*b* (Infrequency-Back) scale is similar in purpose and format, consisting of items at the end of the test, so that response style can be evaluated throughout the entire administration. The F(*p*) (Infrequency-Psychopathology) scale consists of items that no more than 20% of two samples of psychiatric inpatients, as well as a normative sample, was endorsed in a deviant direction; it was developed to detect malingering in settings with high base rates of serious psychopathology. The FBS (Fake Bad Scale) consists of items infrequently endorsed by personal injury litigants that tap somatic rather than psychiatric symptoms. High elevations of these scales invalidate an MMPI–2 profile and may indicate confusion or reading problems, random responding, severe psychopathology, symptom exaggeration, or malingering. In all, if an overreporting scale is elevated, it is likely the examinee responded in a manner that exaggerated impressions of experienced psychopathology.

The two primary scales designed to detect underreporting of psychopathology are the L (Lie) and K (Correction) scales. The L scale includes items selected to identify examinees who are trying to avoid answering items honestly so as to create an overly positive impression. Because many L scale items are obvious, elevations indicate that the examinee is engaging in a psychologically unsophisticated and naive attempt to portray himself or herself as possessing high moral value, without even minor personal flaws or shortcomings that most individuals would endorse on a self-report test. Poor insight and denial of problems are likely in these individuals. K scale items were selected to assist in identifying individuals who displayed significant psychopathology yet had profiles within the normal range. Because such defensive responding masks experienced symptoms, several clinical scales (e.g., Schizophrenia) are corrected for K scale scores. K scale elevations may indicate that an examinee was being defensive, has poor insight, and may be seeking to maintain a façade of adequacy and control without admitting to problems or weaknesses. As compared with L, the K scale assesses more sophisticated and subtle defensive responding. In addition to the L and K scales, the Wiggins' Social Desirability Scale, with items assessing self-confidence, social skills, and effective decision making, evaluates the degree to which examinees present themselves in a positive and socially desirable fashion. A similar scale, the Superlative scale, evaluates the degree to which individuals present themselves in a superlative or highly virtuous fashion, while denying problems. As with L and K, elevations on these scales may represent defensiveness, impression management, or poor insight or awareness into one's behavior. Overall, if an underreporting scale is elevated, it is likely the examinee approached other items in a manner that attempted to present the most favorable self-image and deny psychological difficulties.

In addition to specific measures of over- and underreporting, test users can examine various configurations and interrelations of the L, F, and K scales. An example of this is the F-K Index, also known as the Gough Dissimulation Index, for which the raw score on the K (Correction) scale is subtracted from the raw F (Infrequency) scale. Specific interpretive cut scores points are available but, generally, high scores (i.e., a significantly higher F than K) indicate overreporting of psychopathology, low scores (i.e., a significantly higher K than F) indicate underreporting of

psychopathology, and intermediate scores indicate accurate item endorsement.

Minnesota Sex Offender Screening Tool–Revised (MnSOST–R)

The Minnesota Sex Offender Screening Tool–Revised (MnSOST–R) is a 16-item, "actuarial" risk assessment tool initially developed for the Minnesota Department of Corrections (MDOC) to provide empirically based estimates of risk for sexual recidivism for incarcerated male sex offenders. Indices of reliability have ranged from .76 to .86 across four studies and have generally been .80 or greater. The MnSOST–R has been successfully validated in Minnesota; North Dakota; and Ontario, Canada; however, it failed to predict significantly better than chance in an Arizona study.

Description and Development

The MnSOST–R was developed in response to a 1991 MDOC report calling for a more formal and uniform process to identify predatory and violent sex offenders. An actuarial approach was used in an attempt to bring greater accuracy and utility to sex offender risk assessments, enabling the MDOC to more effectively use limited resources.

The development sample for the MnSOST–R included 256 incarcerated sex offenders in Minnesota who were released primarily in 1988 or 1990. This sample excluded only those offenders whose offenses consisted *exclusively* of "fondling" offenses against family members that did *not* involve vaginal or anal penetration of a child aged 13 or younger or the rape of an older family member. Research on an earlier version of the instrument indicated that this group was substantially different from other sex offenders and generally presented fewer concerns regarding release decisions (e.g., level of supervision, level of community notification, and potential referral for civil commitment).

Sex offenders were sampled from each relevant Minnesota correctional facility, and the offenders were 32–42 years, on average, with a range from 17 to 70 years. Sixty-six percent of the sample was White, 24% was Black, 5% was Hispanic, 4% was Native American, and 2% were from other ethnic groups. There was some oversampling of sexual recidivists in the development sample to provide more stability in any observed relationships between sexual recidivism and potential predictor variables.

Potential predictors were drawn from research on an earlier version of the tool and from an updated review of the literature. Only variables based on information routinely available in correctional records were considered as predictors to ensure that the resulting tool could be scored for the majority of sex offenders based on a file review. Sexual recidivism, the criterion variable, was defined as a formal charge for a new sex offense within 6 years of release from prison.

Empirically based item selection and scoring procedures identified 16 items as the optimal predictors of sexual recidivism, including 12 historical/static items and 4 institutional/dynamic variables. The 12 historical variables included the number of convictions for sex offenses, length of sex offending history, commission of a sex offense while under court supervision, commission of a sex offense in a public place, use or threat of force in any sex offense, perpetration of multiple sex acts in a single event contact, offending against victims from multiple age groups, offending against a 13- to 15-year-old victim with more than a 5-year age difference between the offender and the victim, victimization of a stranger, persistent pattern of adolescent antisocial behavior, recent pattern of substantial substance abuse, and recent employment history. The four institutional variables included discipline history, chemical dependency treatment recommendations and outcomes, sex offender treatment recommendations and outcomes, and age of the offender at the time of release.

Total MnSOST–R scores were significantly predictive of sexual recidivism in the development sample, as reflected by an area under the receiver operator characteristics (ROC) curve of .77 (95% confidence interval [CI] of .71 to .83). Total MnSOST–R scores were equally predictive of sexual recidivism in the development sample for rapists (ROC = .79) and molesters (ROC = .75) and for minorities (ROC = .75) and nonminorities (ROC = .77).

Reliability

Reliability studies have yielded positive results across a variety of settings with varying degrees of training. A Minnesota study involving a minimal 2-hour training session for 10 participants, who then scored the same 11 cases by the end of the day, produced intraclass correlation coefficients (ICCs) of .80 for relative agreement and .76 for absolute agreement. A Florida study involving an optimal 1.5-day training session for 27 participants, who then scored the same 10 cases over the next 3 months, yielded ICCs of .87 for relative agreement and .86 for absolute agreement. Two Canadian studies produced interrater reliability coefficients of .80 and .83.

Validity

The MnSOST–R was validated in Minnesota with an exhaustive sample of 220 sex offenders released from prison in 1992 who met the same inclusion criteria used in the development study. This sample was very similar demographically to the development sample, and sexual recidivism was defined in the same way. Total MnSOST–R scores were significantly predictive of sexual recidivism in this sample (ROC=.73, 95% CI of .65 to .82).

Two validation studies were conducted in North Dakota. The first sample included 182 incarcerated sex offenders with an average time at risk of 8 years, and the second sample included 271 probated sex offenders with an average time at risk of 10 years. No sex offenders were excluded in either of these samples. The MnSOST–R significantly predicted sexual recidivism in the incarceration sample (ROC = .76, 95% CI of .66 to .85) and in the probation sample (ROC = .75, 95% CI of .63 to .88).

Howard Barbaree, Calvin Langton, and their associates conducted a validation study of the MnSOST–R with two Canadian samples. Because the second, bigger sample largely subsumed the first sample, the results of the second study are summarized here. That sample of 354 sex offenders who were at risk for an average of 5.9 years yielded a significant ROC = .70 for the MnSOST–R (95% CI of .62 to .77).

Darci Bartosh and her colleagues conducted a validation of several risk assessment tools, including the MnSOST–R, with a sample of 186 sex offenders in the state of Arizona who were at risk for approximately 5 years. The resulting ROC = .58 missed the threshold for statistical significance in this study, though it was only slightly lower than the ROC values for the other instruments assessed.

The North Dakota, Canadian, and Arizona studies also assessed the Rapid Risk Assessment for Sexual Offense Recidivism (RRASOR) and the STATIC–99, and none of these studies identified significant differences between the tools. In fact, the scores were clustered fairly tightly within each of these studies. The respective ROC values for the MnSOST–R, STATIC–99, and RRASOR were, respectively, .76, .75, and .73 in the North Dakota prison study; .75, .78, and .77 in the North Dakota probation study; .70, .64, and .68 in the Canadian study; and .58, .64, and .63 in the Arizona study.

M'Naghten Standard

The M'Naghten Standard is a legal test to guide juries and courts in their determination of whether a defendant should be found not guilty by reason of insanity. Although defendants were acquitted for crimes they committed while they were legally insane for centuries before the M'Naghten Standard was established, no uniform legal test was adopted by the courts until the middle of the 19th century following the case of Daniel M'Naghten (*Regina v. M'Naghten,* 1843).

Daniel M'Naghten was acquitted for killing the private secretary of the Prime Minister of England, Sir Robert Peel. Mr. M'Naghten had a mental illness that was most likely a form of paranoid schizophrenia. His mental illness was characterized by the belief that he was the victim of an international conspiracy. He believed that if he killed the prime minister, it would lead to the second coming of Christ and the salvation of humanity. Rather than shooting the prime minister, though, he mistakenly shot his private secretary, Edward Drummond, who died a few days later. After he shot Mr. Drummond, he attempted to fire a second shot, but he was apprehended and arrested.

Daniel M'Naghten's father was able to secure a well-financed defense led by a leading barrister of the day. The central issue in M'Naghten's case was the proper standard for establishing a legal defense of insanity. M'Naghten was apparently only "partly insane," and purportedly suffered from delusions concerning politics. Apart from his specific paranoid beliefs, he was able to make plans and was able to live in the society. At the trial, his barristers argued that he should be found not guilty by reason of insanity. The jury acquitted Daniel M'Naghten because of his insanity. M'Naghten was committed to Bethlem and, later, Broadmoor Mental Institution, where he died approximately at the age 50 on May 3, 1865, some 20 years following his trial.

As soon as the verdict in the *M'Naghten* case was announced, the public became alarmed that insane people could kill without fear of punishment. In addition to the concern the public showed, Queen Victoria (who herself had been the target of would-be assassins on several occasions) and members of the House of Lords also made their disapproval of the verdict known.

Just over 2 months after the decision in *M'Naghten* was made public, 15 common law judges in Great Britain were summoned to the House of Lords to help determine the proper standard for criminal responsibility of the criminally insane. Fourteen of the judges agreed that essentially the same standard employed in *M'Naghten* was the correct legal standard. The opinion delivered included the language pertaining to the legal test of insanity, known as the M'Naghten Standard:

> A person is presumed sane unless it can be clearly proven that, at the time of the committing of the act, the party accused was labouring under such a defect of reason, from disease of the mind, as not to know the nature and quality of the act he was doing; or, if he did know it, that he did not know he was doing what was wrong. The mode of putting the latter part of the question to the jury . . . had generally been, *whether the accused at the time of doing the act knew the difference between right and wrong.* (*Regina v. M'Naghten,* 1843, 10 Cl. & Fin. At 203, 8 Eng. Rep. at 720)

> A person labouring under a "partial delusion only, and [who] is not in other respects insane . . . must be considered in the same situation, as to responsibility, as if the facts, in respect to which the delusion exists, were real." (*Regina v. M'Naghten,* 1843, 10 Cl. & Fin. At 203, 8 Eng. Rep. at 723)

There are three significant substantive elements of the M'Naghten Standard. First, the decision maker must determine that the defendant was suffering from "a defect of reason, from disease of the mind." Today, these words are interpreted to mean that the defendant is suffering from a mental disorder. Next, the decision maker must decide whether the evidence shows that the defendant did not "know" the "nature and quality of the act he was doing." Thus, the defendant must not have *understood* exactly what he or she did. Finally, the M'Naghten Standard also requires an inquiry to determine whether the defendant knew "what he was doing was wrong." Therefore, the defendant who understands his or her act, yet does not have the capability of knowing that the act was wrong, may also be acquitted under the M'Naghten test. Because the final two elements require a subjective exploration of the defendant's thinking, the M'Naghten test is referred to as a "cognitive" test of insanity. It is also known as the "Right/Wrong Test" since it focuses on an enquiry of the defendant's capacity, at the time of the offense, to be able to know right from wrong.

Almost immediately, the M'Naghten Standard was employed in cases throughout England, the United States, Canada, Australia, and other common law countries. The substantive requirements of the M'Naghten rule are still being used by numerous jurisdictions around the world, including 26 of the United States. Despite its widespread acceptance, the M'Naghten Standard has been strongly criticized, and it has long been abandoned in England, the country in which it originated so long ago. A number of competing tests for legal insanity have been adopted and some jurisdictions have abandoned the defense of insanity.

Mood Disorders

Mood disorders are among the most common mental disorders in the Western world. Formerly called *affective disorders,* these disorders involve a predominant disturbance in mood. In each case, the mood disturbance leads to other problems, which frequently include physical symptoms (such as fatigue), behavioral symptoms (such as social withdrawal), and cognitive symptoms (such as self-critical thoughts). The various mood disorders differ based on the type and duration of symptoms. Severe mood disorders develop from a combination of biological, stressful experiences and personality types or interpersonal factors. Treatment options usually include a combination of medication and psychotherapy.

The various mood disorders can be distinguished based on the nature of the mood disturbance, the severity of symptoms, and their duration. The depressive disorders (sometimes known as unipolar disorders) are primarily characterized by a sad mood or a profound loss of enjoyment in most activities. In younger persons, the mood may be irritable rather than despondent. The depressed mood is often experienced as sadness, tearfulness, discouragement, and feeling "down in the dumps." In some cases, the person may complain of feeling emotionless. The loss of enjoyment or loss of pleasure, called *anhedonia,* is virtually always present to some extent in the depressive disorders; it is often experienced as a loss of interest in one's hobbies and usual activities. A reduction in sex drive is another common experience.

Other common symptoms of depressive disorders include sleep problems, low energy, and changes in appetite. Common sleep problems include insomnia in the form of nighttime waking and difficulty returning to sleep or early morning waking. Because of low energy and fatigue, the smallest tasks may seem overwhelming. Changes in appetite may be so profound as to cause extreme unintended changes in weight, usually weight loss, over a short period of time. During periods of depressed mood, cognitions frequently involve a sense of worthlessness and excessive guilt. Trivial events may be misinterpreted as proof of one's inadequacy, consistent with the negative mood. Decision making and concentration are compromised. Thoughts about death and suicide are common.

The disturbance in bipolar disorders involves periods of depressed mood and separate periods in which the mood is abnormally elevated. The signs of a manic mood include feelings of euphoria, a "high," or an abnormally cheerful mood. The mood may rapidly turn to irritability if others are perceived as interfering with the individual's plans. Inflated self-esteem occurs invariably; it may range from boastful self-confidence to grandiose delusions, such as having the firm belief that one has supernatural powers.

Many symptoms of the manic phases of bipolar disorders are opposite to those experienced in the depressive disorders. In a manic phase, the individual may demonstrate an uninhibited enthusiasm for pleasurable activities, which could include irresponsible spending sprees and indiscriminate sexual pursuits. The need for sleep is markedly reduced and surplus energy abounds. In a manic phase of bipolar disorder, a person may speak in an incessant, rapid, and loud manner. Thoughts may flow at such a rapid pace that the person may seem unable to keep up with them, a phenomenon known as *flight of ideas.* Excess energy, combined with unbridled enthusiasm and a euphoric mood, often lead unknowing observers to conclude

that the individual is under the influence of a stimulant drug, such as cocaine. Indeed, many of the symptoms of bipolar disorder seem excessive and uncontained.

Types of Mood Disorders

The most prevalent depressive disorder, known as *major depressive disorder*, corresponds loosely to the popular concept of a *clinical depression.* At the very minimum, major depressive disorder involves experiencing one episode of deep depression characterized by a sad mood or loss of enjoyment in life. Other common symptoms include sleep problems, fatigue, feelings of worthlessness, and suicidal thoughts. The depressive episode will typically last for months, during which the person experiences these problems most of the time. The symptoms usually remit 6 to 12 months after the onset. There is, however, a significant chance of future depressive episodes. A significant number of people who have recovered from major depressive disorder will have recurrent episodes although these can occur years apart. Major depressive disorder is usually first experienced in late adolescent or early adulthood. Nearly 17% of the U.S. population is likely to experience major depressive disorder, and the rates are twice as high for women as for men.

Major depressive disorder can take many varied forms. The variant with psychotic features involves an unusually severe form of depression accompanied by auditory hallucinations (such as hearing accusing or insulting voices), delusional beliefs, and overwhelming feelings of guilt. The melancholic form, which is more common in older adults, is characterized by early morning waking, weight loss, and anhedonia. The seasonal pattern describes a cyclical form of depression that recurs every fall or winter and involves weight gain and excessive sleep. The seasonal mood disturbance typically lifts in the spring.

Dysthymic disorder is a mild but long-lasting depressive disorder. Whereas the duration of major depressive disorder is measured in months, dysthymic disorder is evident over several years (the minimum is 2 years). Low self-esteem, loss of pleasure, social avoidance, and poor concentration are typical symptoms. The onset of dysthymic disorder is gradual and occurs at an early age.

The types of bipolar disorders are mostly distinguished on the basis of the manic symptoms. The most well-known is Bipolar Disorder Type 1, which was formerly called *manic depression.* It involves multiple recurrent episodes of depression and mania. The manic episodes, which are shorter, usually either precede or follow a severe depressive spell. Mood may temporarily return to normal between episodes. Bipolar Disorder Type 1 is less prevalent than major depressive disorder, affecting fewer than 2% of the population; the gender ratio is equal. Bipolar Disorder Type 2 is similar with the exception that it does not involve full-blown manic symptoms. The mild manic episodes, or *hypomania,* evidence bursts of energy, elevated or irritable mood, and poor judgment, but without the extremes of a full-blown manic episode. Cyclothymic disorder, the mildest bipolar disorder, involves chronic and fluctuating mood changes. The severity and duration of these mild mood changes are less than those witnessed in major depressive disorder or Bipolar Disorder Type 1, yet they are serious enough to cause disruptions in important areas of life and to cause significant unhappiness. To an outsider, the person with cyclothymic disorder may come across as abnormally moody.

Suicide

Suicide is the conscious and deliberate taking of one's own life. Worldwide, it is one of the top 10 leading causes of death. More than 31,000 individuals die by suicide in the United States annually, and an additional 600,000 people attempt suicide each year. The fatality figures are probably underestimates because some suicidal deaths are mistaken for accidents and surviving family members are often reluctant to label the deaths as intentional because of stigma or guilt.

The rates of suicide vary significantly according to age, gender, occupation, life situation, and health. Many young adults, as many as 1 in 10, have seriously contemplated suicide. However, the highest rates of completed suicides occur in older adults above the age of 65. Women are more likely than men to attempt suicide, but men are more likely to die of suicide because they tend to use more lethal methods. Whereas suicidal women often rely on overdosing or cutting their wrists, men tend to use firearms or hanging. People in the midst of relationship problems, such as separation or divorce, have higher suicide rates, as do people with terminal illnesses. As many as 15% of persons with mood disorders will commit suicide, and the risk is particularly high during or following an episode of severe depression.

Suicide rates also vary across ethnic and racial groups in the United States. For example, Native Americans have the highest rates of suicide, while White men have the second highest rates. The risk is relatively lower for Black women. Creative or successful scientists, artists, and professionals have a higher-than-average lifetime suicide risk.

Suicide is best understood as a desperate act designed to end seemingly inescapable emotional, physical, or interpersonal suffering. Some suicidal gestures are also intended to convey to others the depth of one's despair, as a "cry for help." Most persons who have suicidal thoughts experience some ambivalence; this is often reflected in the chosen method and in prior communications of intentions. The majority of people who commit suicide have previously communicated their suicidal intent with others, often in explicit terms. However, highly distressed persons who are determined to die will use highly lethal methods and are unlikely to have shared their intentions with others. Using a very deadly method without sharing the plan with others nearly guarantees that it will be successful.

Suicide notes can be useful for understanding the motives and desperation that drive suicidal gestures. Approximately one-third of individuals who commit suicide do leave behind a note, usually for the benefit of surviving relatives and friends. Many notes are brief and to the point, and they betray profound distress. Suicide notes may be designed to explain the act or relieve surviving relatives' feelings of guilt.

Causes of Mood Disorders

Biological Factors

It has long been known that severe mood disorders run in families, which suggests that heredity plays a role in their development. The rates of mood disorders are nearly three times higher than average among the blood relatives of persons with depressive disorders. Studies of twins, of which one has a mood disorder, show a higher rate of mood disorders among identical twins than among fraternal twins. Heredity plays a greater role in the causation of bipolar disorders. Twin studies reveal that approximately two-thirds of identical twins who have bipolar disorder have a co-twin who shares a mood disorder. In fact, the best predictor of a person's risk of developing a Bipolar Disorder is having a family history. Biological factors, however, play a smaller role in the onset of minor mood disorders.

A growing body of research reveals that severe mood disorders are related to abnormalities in the brain areas that regulate emotions and basic biological needs, such as hunger and sleep. Problems with the brain's internal biological clock are related to inefficiencies in the brain's chemistry. There is evidence that the brain's own chemical signals, known as *neurotransmitters,* are not functioning properly in persons with severe depression. It is believed that imbalances in the brain's chemical signals, combined with disruptions in the sequencing of the brain's biological clock, may account for most of the common symptoms of mood disorders. Specifically, the disruptions in the internal clock could lead to problems with sleep, energy, and loss of enjoyment. Some people may be especially vulnerable to these problems, either because of their family history or because of other nongenetic risk factors.

Life Experiences

The link between stressful life experiences and depression is well established. Several specific stressful events seem to be especially troubling for persons who are prone to mood disorders. Major losses, such as the death of a loved one or financial losses, often precede significant depression. Losses that are ego threatening (such as a divorce or job termination) are usually difficult for persons who are at risk for mood disorders, especially if they feel personally responsible for the event. In other words, being fired from a job for poor performance will be more threatening than losing a job to downsizing. Chronic and ongoing stressors also increase the risk of becoming depressed, in contrast to an abrupt and isolated source of stress.

Personality and Interpersonal Factors

Certain personality traits, such as *negative affectivity,* may help predict a person's risk of developing a depressive disorder in the face of stressful life events. Negative affectivity is a personality type that is prone to negative emotions, including worry, anxiety, and sadness. Because of this proneness to negative emotions, the individual is ill equipped to deal with major losses or threats to the ego. From another perspective, it is suggested that some people are prone to depression because of distorted beliefs about themselves, the world, and the future. Rigid and distorted beliefs

become activated by stressful experiences, causing the person to blow events out of proportion and feel personally responsible for failure and disappointment. According to this viewpoint, negative and self-critical thoughts are directly related to the onset of depression following a stressful life event.

Additionally, a number of interpersonal problems are linked with the risk for depressive disorders. Individuals who are socially isolated and those who lack the social skills for maintaining rewarding relationships are at high risk for depression. Once depressed, pessimism and negative thinking may further isolate the individual from other people who are trying to avoid the negativity, setting up a self-perpetuating cycle. The importance of interpersonal factors in the causation of depressive disorders is further highlighted by the strong association between marital distress and depression. Separation and divorce are common antecedents of depression, as is ongoing marital conflict. The direction of cause, however, is not always obvious—relationship problems could cause depression or the reverse could occur. Alternatively, a separate factor, such as negative affectivity, could be responsible for both depression and relationship problems.

Treatment

The two major approaches to treatment of the mood disorders include medication and therapy. For bipolar disorders, medication is the first line of treatment. It usually consists of a mood stabilizer, which reduces the frequency and intensity of manic episodes, often in combination with an antidepressant. Approximately 75% of individuals with a bipolar disorder who comply with medication will experience some improvement. The amount of improvement, however, is variable, ranging from mild to dramatic. Supportive therapy and family therapy may be helpful supplements for patients with severe bipolar disorder. The unpleasant side effects of mood stabilizers, such as drowsiness, upset stomach, and impaired coordination, along with the stigma of taking medication for a mental disorder, cause problems with medication compliance in many cases of bipolar disorder.

The depressive disorders are often treated with a combination of antidepressant medication and psychotherapy. Approximately two-thirds of patients will benefit from antidepressant medications such as Prozac (fluoxetine is the generic name), although it may take several weeks before any improvement is noticed. The newer antidepressant medications produce relatively few side effects; however, it is not uncommon to experience a decline in sex drive and feelings of restlessness.

Cognitive therapy for depression is one of the best documented treatments. Several large-scale studies show that its effectiveness rivals medication in the long term. Additionally, unlike medication, cognitive therapy can reduce a person's risk for future depressive episodes. As a brief and structured form of treatment, cognitive therapy is designed to help the patient identify and modify distorted thinking. Marital and family therapy may be useful for severe mood disorders that are related to conflict at home.

Moral Disengagement and Execution

People ordinarily refrain from behaving in ways that violate their core moral standards because such conduct will bring self-censure. In some institutional role functions, however, such as military combat and state executions, the taking of human life presents a grave moral predicament. Intentional infliction of death and destruction can, therefore, exact a heavy emotional toll and leave a troubled and haunted life for those who have to do it. The challenge is to explain how

individuals who are caring and compassionate in other aspects of their lives can perform roles that require them to take a human life.

In the course of socialization, people adopt standards of right and wrong that serve as guides and deterrents for conduct. They do things that give them satisfaction and a sense of self-worth and refrain from behaving in ways that violate their moral standards because such conduct will bring self-condemnation. However, moral standards do not function as fixed internal regulators of conduct. Moral self-sanctions do not come into play unless they are activated, and there are a variety of psychosocial mechanisms by which such sanctions can be selectively disengaged from lethal conduct. This enables individuals to carry out lethal functions without the restraint and personal costs of self-censure. This entry examines the critical role of selective moral disengagement in state executions.

Mechanisms of Moral Disengagement

Figure 1 presents the eight psychological mechanisms by which moral self-sanctions are suspended and the four sites in the moral control process where this can occur. At the behavioral locus, worthy ends are used to vindicate lethal means. This is achieved by moral and utilitarian justifications. They include biblical imperatives that murder must be avenged and the necessity to execute murderers to maintain societal order, deter others from homicidal crimes, and to spare societies the costs of life imprisonment. Euphemistic language sanitizes the taking of human life as simply a legal penalty and clothes executions in pallid legalese. Advantageous comparison renders executions merciful by contrasting them with the heinous homicides committed by the condemned inmates.

At the agency locus, one's role in the lethal activity is obscured or minimized by displacement and diffusion of responsibility. The path to death of a condemned inmate involves fragmentation of the execution process across jurisdictional systems and subfunctions of the lethal procedure so that no one feels that he or she is the actual agent of the death penalty. At the outcome locus, the experience suffered during the execution is minimized or disputed. At the inmate locus, the condemned are dehumanized, bestialized, and blamed for bringing the execution on themselves by their heinous crimes.

Among the various mechanisms of moral disengagement, moral justification is especially influential because it serves a dual function. Investing lethal means with moral and humanitarian purposes both enlists moral engagement in the service of the enterprise and disengages self-censure for those who have to implement the deathly means. The mechanisms usually work in concert. Moreover, they operate at the social systems level as well as at the individual level.

Moral disengagement is enlisted at each of the three levels in the application of the death penalty—at the

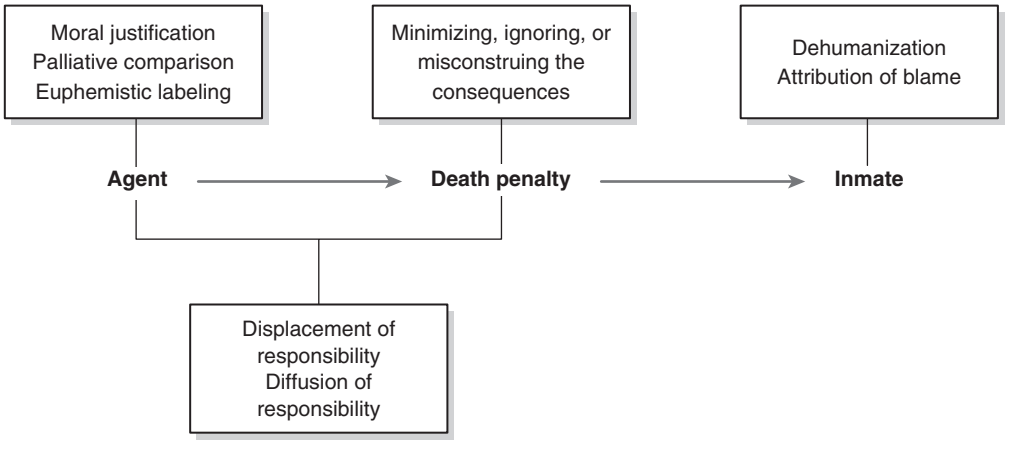

Figure 1 Mechanisms Through Which Moral Self-Sanctions Are Selectively Disengaged From Detrimental Conduct at Different Points in the Self-Control Process

Source: Osofsky, Bandura, and Zimbardo (2005). Reprinted with kind permission of Springer Science and Business Media.

societal, judicial, and execution levels. At the societal level, moral disengagement eases the public's qualms about the use of executions for capital offenses. The higher the moral disengagement, the stronger the public support for the death penalty. Moral concerns are mitigated when state executions are viewed in the abstract under the sanitized label of "capital punishment."

Jurors and Capital Sentencing

Those who favor the death penalty are far removed from its implementation in the execution chamber. It is a graver moral predicament for jurors who make decisions that sentence a person to death. Craig Haney identified the unique conditions built into the sentencing process that enable jurors to sentence a person to death. These conditions reflect the various modes of moral disengagement. Because of the widespread public support for state executions, most jury members are already favorably disposed to the death penalty through repeated societal justifications. Politicians trade on it. Individuals who unalterably oppose the death penalty are eliminated when the jury is impaneled. Attorneys battle over the personalization and dehumanization of defendants. As previously noted, displacement and diffusion of responsibility for the execution also figure prominently in the sentencing process. Jurors view their decisions as compelled by the sentencing instructions rather than as a personal decision. This displacement of responsibility is aided by prosecutors who often present them with misleading and forced choices on capital sentencing.

Jurors not only minimize their personal responsibility for their collective decision but play down its consequences as well. They contend that appellate judges will ultimately decide the question. They also believe that even if the death sentence is upheld, the execution is unlikely to happen. "They don't put you to death. You sit on death row and get old." The weakening of moral engagement by the distal role in the execution process is captured by journalist Sara Rimer in the remarks of a retiring warden: "If jurors had to draw straws to see who was going to pull the switch or start the lethal injection, there wouldn't be as many executions."

Executioners and Moral Disengagement

The gravest moral predicament is faced by executioners who have to kill a human up close and by their own hand. If they did not suspend moral self-sanctions for the intentional taking of a human life, they would have difficulty doing it and would be burdened by a troublesome legacy were they to do so. In a 2005 study, Michael Osofsky, Albert Bandura, and Philip Zimbardo examined, in three penitentiaries, the pattern of moral disengagement in three subgroups of prison personnel depending on the type and degree of their involvement in the execution process. Prison guards who had no involvement in the execution process and were thus spared a grave moral predicament exhibited little moral disengagement. Members of the support team, who provide solace to the families of the victim and the inmate, disavowed moral disengagement. Members of the execution team, who perform key roles in the execution itself, enlisted all the modes of moral disengagement. They adopted biblical, economic, and societal security justifications for the death penalty, ascribed subhuman qualities to condemned inmates, and disavowed a sense of personal agency in the taking of life. In the course of providing ameliorative aid, the support personnel hear the families of the victims recount the brutal ways in which their loved ones were murdered. As a consequence, members of the support team change from moral engagers to moral disengagers with increasing participation in executions.

The study also showed that the members of the execution team see themselves as doing society's work as in any other job in an institutional service facility. Their focus is on performing the subfunctions proficiently. To negate moral self-sanctions, executioners seek solace in the dignity of the process and in the view that condemned killers have a degraded aspect to their nature and executing them will protect the public. The executioners described the desensitization through routinization as follows: "No matter what it is, it gets easier over time. The job just gets easier." The routinization is fostered by a sense of duty and professionalism in carrying out the executions. However, some were distressed by the fact that they no longer were perturbed by their deadly activity: "The hardest thing for me is that the first one really affected me and the next two to three didn't. It affected me that it didn't affect me."

Executions are achieved through the collective effort of many people, each efficiently performing a small part. Responsibility for the executions is displaced to societal policies, the dictate of the law, and jurors' decisions. As one of the guards put it, his job is simply to carry out the order of the state. "It's not up

to me to say yea or nay. That's for the judges and juries. I'm not a part of the deal-making process. I'm here to do the job."

The study indicated that the institutional arrangement diffuses the agentic subfunctions across a variety of individuals, each performing only a small bit in the division of labor. The strap-down is accomplished by highly fractionated, diffused responsibility. Each member straps a particular part of the body: left leg, right leg, left arm and torso, right arm and torso, head. They approach their task with a strong sense of technical responsibility: "We each have a small role on the team. We carry out a job for the state." Fragmentation structurally builds a low sense of personal responsibility into the death penalty system. The moral disengagement power of diffusion of responsibility through task fractionalization is reflected in the remarks of a guard in San Quentin who strapped down the offenders' legs to the death chair in 126 executions: "I never pulled the trigger," he said. "I wasn't the executioner."

The executioners relied on a variety of strategies to manage the emotional aspects of a work life that requires them to put a person to death. Construing executions as serving high moral and societal purposes spared them a heavy emotional toll. "I wouldn't do it at all if it didn't feel right. I'd stop if I felt it were against my morals and the Bible." Societal legal sanctions had similar effects: "According to the law this was justified. I never felt pain or sorrow." Depersonalization of the relationship with condemned inmates was another ameliorative strategy: "It makes it really stressful getting to know the inmates. By not knowing them, you can do your job. Getting to know them makes it tough." Inmates' expressed attitudes of cruelty also made it easier to execute them: "Some of the inmates talk about killing people like eating a bag of potato chips. That makes it easier."

Selective control of one's own consciousness is still another emotion-regulation strategy for lessening perturbing ruminations. Members of the execution team adopted a firm compartmentalization of their work life and home life: "My life is like a switch. I turn it on when I get here and turn it off when I leave. I won't let myself take my job home."

As shown by Samuel Gross and Phoebe Ellsworth, the American public is experiencing a conflicting view regarding state executions. People voice substantial support for the death penalty while doubting its deterrent value and acknowledging that the judicial system is often administered unfairly and cannot fully protect innocent defendants from being put to death. Erosion of public support leaves executioners with the ghastly task of executing individuals stripped of moral justifications for it. "Having the whole country concerned about the death penalty creates more stress for us than the actual execution."

Motions to Suppress Eyewitness Identification

Serving as an important safeguard against wrongful convictions, motions to suppress help keep evidence that was gathered improperly or unfairly from consideration at trial. Psychological research has examined the validity of several assumptions underlying the effectiveness of motions to suppress lineup identifications. These studies have examined judges' and attorneys' knowledge about eyewitness memory in general and lineup procedures in particular. Research using an experimental paradigm raises some questions on the effectiveness of the motions to suppress lineup identification safeguard. Moreover, judges are applying the criteria outlined by *Manson v. Brathwaite* (1977),

which indicates that the suggestive aspects of the identification procedure should be weighed against the likelihood that the identification is accurate. The two prongs that constitute the *Manson* test are not independent of each other because suggestive lineup procedures can readily infect the criteria that judges must consider when evaluating the probability that the identification is accurate. Moreover, the identification accuracy criteria that are to be considered have little to do with eyewitness memory or lineup identification accuracy. In summary, there are several reasons to question the effectiveness of motions to suppress lineup identifications as a safeguard against wrongful convictions.

A motion to suppress is a request to the court to exclude evidence on the grounds that it was obtained unfairly or illegally. These motions are typically filed by criminal defense lawyers in an attempt to keep the evidence in question from consideration at a hearing or at trial. A motion to suppress must be accompanied by supporting arguments or facts that speak of the reliability of the evidence or violations of due process under the Fourteenth Amendment. For example, a lawyer may file a motion to suppress evidence that the police obtained during a search and seizure that was conducted without a warrant or without consent. Lawyers may also file a motion to suppress hearsay testimony, confession evidence, or information gleaned during the course of an interrogation. Finally, lawyers may file motions to suppress eyewitness testimony that stems from a police lineup on the grounds that the lineup identification procedure was conducted unfairly.

There is psychological research that bears on issues surrounding motions to suppress lineup identification evidence. A defense lawyer who believes that a witness erred in the lineup identification because the lineup procedure was conducted unfairly or in a biased manner may (and probably should) file a motion to suppress this evidence from relevant hearings and from trial. Such motions are designed to safeguard against wrongful convictions that are the product of mistaken eyewitness identifications produced by suggestive lineup procedures.

Judges' Sensitivity to Suggestive Lineup Procedures

Psychological research has raised some serious questions about the effectiveness of motions to suppress lineup identifications by challenging the validity of assumptions that form the backbone of this safeguard. One assumption underlying the effectiveness of motions to suppress the lineup identification as a safeguard is that judges are sensitive to unfair lineups and that their rulings on motions to suppress lineup identifications are a function of their evaluations of lineup suggestiveness and fairness. In an effort to determine what judges know about eyewitness memory and the factors that affect lineup identification accuracy, a few surveys of judges in the United States have shown that judges are aware of some factors that affect eyewitness memory and lineup identification accuracy but not others.

Judges' knowledge about eyewitness testimony probably plays an important role in their motion rulings. Richard Wise and Martin Safer surveyed 160 judges and found that familiarity with eyewitness memory issues was related to their tendency to permit the use of legal safeguards such as jury instructions on memory issues and expert testimony. The Wise and Safer research did not examine the link between education and motions to suppress, however.

Taking an experimental approach, Stinson and colleagues presented Florida criminal judges with a description of a simulated crime and eyewitness's description of the perpetrator as well as a photo lineup that varied in terms of the suggestiveness of the lineup instructions, lineup composition (i.e., the extent to which the photos in the lineup matched the eyewitness's description of the perpetrator), and lineup presentation (sequential or simultaneous). Judges recognized the unfairness of suggestive lineup composition and instructions, and they ruled on the simulated motion accordingly. Interestingly, some judges indicated that they very rarely see these types of motions. Neither the reason for this finding nor the extent to which results generalize to other areas is clear. Until fairly recently, the only record of a lineup procedure was a photograph of the array or the lineup members, so defense lawyers would not be able to evaluate the fairness of the lineup procedure nor obtain much evidence to support a motion to suppress. Additionally, some judges indicated that their general practice was to deny these types of motion; their justification typically revolved around the notion that jurors ought to evaluate and weigh the lineup identification evidence and that judges should not be gatekeepers of this type of evidence.

Defense Lawyers' Sensitivity to Suggestive Lineup Procedures

Another assumption impinging on the motion to suppress safeguard is that lawyers are sensitive to

suggestive lineup procedures and file motions to suppress lineup evidence in these situations. Several survey studies have reported that lawyers recognize some biased lineup procedures such as lineup composition and instructions but not others (e.g., lineup presentation). One experiment tested the effects of biased lineup procedures on defense attorneys' reactions to the lineup. These data showed that lawyers were sensitive to some unfair lineup procedures. Compared with lawyers who saw a fair lineup procedure, those who saw lineups that were unfair with respect to the composition were more likely to express their intention to file a motion to suppress the lineup identification evidence and predict that a judge would grant such a motion.

Having direct implications for the motion to suppress safeguard, defense lawyers reported that they rarely attend their clients' lineups. Most lineups are pre-indictment photo arrays during which there is no right to counsel (*Kirby v. Illinois,* 1972; *United States v. Ash,* 1973). Thus, it is difficult for defense lawyers to observe and record biased lineup procedures and to substantiate a motion to suppress the lineup identification. In 1999, the U.S. Department of Justice produced guidelines for law enforcement that included a recommendation that lineup identification procedures be documented. In theory, proper recording of lineup procedures ought to contribute toward the effectiveness of the motions to suppress safeguard.

Why the *Manson* Test Compromises Motions to Suppress

There are also U.S. Supreme Court decisions and case law that speak of the effectiveness of motions to suppress lineup identification evidence. In *Simmons v. United States* (1968), the Supreme Court ruled that judges should not suppress lineup identification evidence solely because it was gathered in a suggestive manner. Instead, the Court ruled that judges should determine whether the eyewitness identification was likely to be accurate by considering the circumstances surrounding the identification. In subsequent decisions, the Supreme Court further eroded the suggestiveness test by outlining criteria that judges should consider when making their motion decision (*Neil v. Biggers,* 1972). In the *Biggers* decision, the Supreme Court proposed that judges consider five factors when determining the reliability of an eyewitness identification: opportunity for the eyewitness to view the perpetrator, the eyewitness's degree of attention during the crime, the eyewitness's confidence in the lineup identification, the accuracy of the eyewitness's description of the perpetrator, and the length of time between the crime and the identification procedure. Psychological research has demonstrated that these five criteria are not particularly predictive of lineup identification accuracy. Finally, in *Manson v. Brathwaite* (1977), the Supreme Court advised judges to weigh any suggestive elements in the identification procedure against the five criteria outlined in *Biggers.*

Timothy O'Toole and Giovanna Shay have chronicled how protections against due process violations have eroded since the *Manson* decision and how this decision has compromised the motion to suppress safeguards. Bringing psychology to bear on this issue, Gary Wells demonstrated the fundamental flaw with the *Manson* decision. Suggestive lineup procedures can distort several of the self-report criteria spelled out by *Biggers,* virtually guaranteeing that an identification produced by suggestive lineup procedures would not be suppressed. In other words, the *Manson* decision makes it unlikely that judges would grant a motion to suppress the identification because they are likely to find at least one of the five redeeming *Biggers* criteria.

One Connecticut case, *State v. Thompson* (2004), delineates clearly the flawed analysis in *Manson.* The Thompson case involves a shooting that seriously wounded the victim, Wesley Gray. Two firefighters at a nearby fire station heard the gun shots, went outside, and saw a man carrying a shotgun. One of the firefighters indicated that he caught a "quick glance" at the man's face before he returned to the fire station, where he continued to observe the man for a few moments. Subsequently, the firefighter went back outside where he saw the individual climbing a fence. The firefighter retrieved the shotgun, handed it to the police, and provided a description. Shortly thereafter, a police officer drove the firefighter witness to a dead-end alley, the location where other officers had apprehended the suspect. The police officer told the witness that the police had apprehended the person who was "probably the shooter," shined the headlights from the police car at the defendant, and asked the firefighter to make an identification. The firefighter indicated that he was "absolutely certain" that suspect was the shooter. The defendant, Jerry Thompson, filed a motion to suppress the identification on the grounds that it was highly suggestive and unnecessary, but the court denied the motion because the "totality of the circumstances" indicated that the identification was sufficiently reliable for the jury to consider. The court relied on three

of the *Biggers* criteria for making its decision: the witness was confident, he had a good look at the suspect, and the identification took place shortly after the incident. The defendant was convicted of assault and possession of a firearm; he appealed on several grounds, including that the trial judge erred in denying the motion to suppress, but the appellate court affirmed the trial court's decision. Neither the trial nor appellate courts recognized that the suggestive identification procedure, perhaps in concert with other factors, can easily distort eyewitnesses' estimates of their opportunity to view the perpetrator, their confidence in their identification, and their estimate of their "degree of attention" at the time of encoding.

In addition to the obvious calls for eliminating any suggestive aspects of lineup identification procedures and adopting best practices for identification tests, Gary Wells recommends a series of alternatives that would remedy the problems created by *Manson.* One of these proposed remedies is to shift the burden of proof in situations where the lineup procedure was suggestive so that the prosecutor would have to demonstrate why the identification should be allowed. This is a simple and reasonable solution to this problem. Should this recommendation be implemented in the future, the decision-making process of judges considering a motion to suppress the lineup identification would change.

Mug Shots

In cases where a criminal's identity is unknown to an eyewitness and investigators have not yet pinpointed a suspect, witnesses may be asked to search through a large number of photographs for a picture of the criminal. This process is known as a mug shot search because the photographs typically come from a database of photographs of arrested people (either computerized or from a file drawer system). Researchers have examined whether viewing hundreds of photographs in search for a criminal may have detrimental effects on a witness's memory of the criminal or later identification accuracy. Specifically, researchers have focused on three potential effects: interference, unconscious transference, and commitment. Regardless of the effect, one caveat with this body of research to date is that it has not yet been tested with real-world witnesses in real criminal cases.

Interference

Interference, in mug shot research, is when postcrime information, in the form of viewing many new faces, weakens or interferes with the witness's memory of the actual criminal. Interference is most commonly tested in research laboratories by exposing two groups of participants to a mock crime, asking one group to look through mug shot photographs and then asking both groups of witnesses to make an identification of the criminal from a six-person lineup. Researchers also manipulate whether or not the mock criminal's photograph is present in the lineup to test whether or not witnesses who viewed the mug shots are more likely to choose an innocent person when the actual target is not present. Although it is reasonable to assume that the process of viewing hundreds of faces in search for a

criminal may influence a witness's ability to later make a correct identification of the criminal, research results to do not support this assumption. Research has shown that viewing mug shots has virtually no effect on later identification accuracy from lineups.

Unconscious Transference

Unconscious transference from viewing mug shots refers to the event in which an innocent lineup member, who is also the only lineup member previously viewed by the witness in a prior mug shot task, seems more familiar than do the other lineup members because he was viewed in the mug shots. The concern is that this sense of familiarity on the part of the witness may lead to an increased rate of selection of the (only) lineup member who was seen previously in a mug shot task. The phenomenon of unconscious transference has likely plagued most adults at one time or another as evidenced in the common question, "Where do I know that face?" For witnesses who view mug shots, followed by a lineup that contains one person seen in those mug shots and five photographs never seen before, they are faced with a similar question. The correct answer is for witnesses to say, "I saw that face in the mug shot task," and the erroneous conclusion is that the face is familiar because it is the face of the criminal.

Support for unconscious transference from mug shots is mixed, with only a few published studies finding support for the effect. Researchers have manipulated variables such as the number of mug shots viewed (from 10 to more than 600) and the delay from viewing the mug shots to the lineup task (immediately to several weeks later) but have been unable to find a consistent predictor of the unconscious transference effect.

Commitment

Commitment refers to the event when a witness selects a (innocent) person from a mug shot task and then selects the same (incorrect) person from a later lineup procedure. Research on the commitment effect is consistent in that it is relatively easy to produce and that it has the largest negative impact on lineup identification accuracy when considered with the other two effects described above. In one research example, almost two-thirds of witnesses who selected an innocent person from a mug shot task went on to later identify that same innocent person from a lineup. A comparison group of participants who did not see mug shots picked the innocent person at a rate of only 20%.

Procedural Matters

As with any identification procedure, there are numerous ways that investigators could conduct the mug shot task that may have differential effects on the outcome. Some procedural variations that have been examined include whether the photographs are sorted by gender, age, race, and type of crime before viewing; the ideal number of mug shots to view; and whether a computerized sorting system yields more accurate identification results than do standard mug shot methods.

In sum, mug shot research has not supported the intuitive concerns that interference and unconscious transference effects generate. Commitment to a photograph, however, does seem to be a strong predictor of identification errors from mug shot searching. Regardless of the area of research described above, an increase in real-world data obtained from field studies will be highly beneficial and informative for future mug shot research.

Neil v. Biggers Criteria for Evaluating Eyewitness Identification

In its 1972 ruling in *Neil v. Biggers,* the U.S. Supreme Court outlined five criteria that should be used in evaluating the accuracy of eyewitness identifications: the witness's certainty, his or her quality of view, the amount of attention paid to the culprit, the agreement between the witness's description and the suspect, and the amount of time between the crime and the identification attempt. For many reasons, these criteria are suboptimal. Some of them directly contradict empirical research, and others can actually be misleading under certain circumstances. Preferable methods for evaluating accuracy include assessing the suggestiveness of the identification procedure, including the instructions given to the witness; examining the structure of the lineup or photo spread; and checking whether the person administering the photo spread knew who the suspect was.

The U.S. Supreme Court's decision in *Neil v. Biggers* (1972) was the first time that the Court had made explicit recommendations about evaluations of eyewitnesses in criminal cases. These criteria, known to eyewitness researchers as the *Biggers* criteria, are

> the opportunity of the witness to view the criminal at the time of the crime, the witness' degree of attention, the accuracy of the witness' prior description of the criminal, the level of certainty demonstrated by the witness at the confrontation, and the length of time between the crime and the confrontation.

Although the *Biggers* criteria are intuitively appealing, psycholegal researchers generally disapprove of them for several reasons. First, reports on the extent to which these criteria are met, especially confidence, are not reliably related to identification accuracy. Second, most of the reports are subjective, provided by the very person whose memory is in dispute when an identification is challenged. Finally, they attempt to postdict accuracy, a goal that has had limited success throughout the empirical study of eyewitnesses. The background of the criminal case that prompted the criteria and the empirical data related to each criterion are presented below.

In the crime for which Biggers was convicted, the victim was taken from her home and raped along the railroad tracks a short distance away. The attack lasted between 15 and 30 minutes. Several times after the assault, the victim was shown photos in both lineups, where multiple photos are shown at a time, and showups, where only one photo is presented. She did not identify anyone from these photos. Seven months after the assault, Biggers was identified in a police station showup. The showup was conducted because the police claimed that they were unable to locate appropriate fillers for a lineup. After the police escorted the victim past the defendant, she asked them to have him say, "Shut up, or I'll kill you," a phrase used by her assailant. She then identified Biggers and indicated that she had "no doubt" about the accuracy of her identification.

The critical issue decided by the Supreme Court was whether the showup was "unnecessarily suggestive" and therefore violated due process. In previous cases, the Court argued that it was possible for identification procedures to be so unnecessarily

suggestive as to render the identification unreliable and therefore a violation of due process. However, such a determination must be considered "on the totality of the circumstances." For example, in *Stovall v. Denno* (1967), the identification procedure did not violate due process because the victim's critical medical condition justified the hospital room showup and the victim subsequently identified the defendant at trial. In another case, the totality of the circumstances analysis indicated that due process was violated because the witness was not able to definitively identify the defendant during either a suggestive lineup or a showup. In that case, it was only after the third exposure to the defendant that the witness produced a confident identification.

Using the criteria described above, the Court (with five justices in the majority) concluded that the showup procedure was not unnecessarily suggestive. First, the victim had ample opportunity to view her attacker, both "under adequate artificial light . . . and under a full moon outdoors." Second, the witness was "no casual observer," suggesting that she had paid close attention to the culprit's face during the assault. Third, her description was "more than ordinarily thorough," including mention of the assailant's height, age, skin tone, and voice. Fourth, she displayed a high level of certainty in her identification, saying "I don't think I could ever forget [that face]." Finally, although 7 months had passed between the crime and the identification of Biggers, the Court reasoned that because the victim never made any other identifications, in spite of many opportunities to do so, "her record for reliability was thus a good one, as she had previously resisted whatever suggestiveness inheres in a showup." Therefore, according to the totality of the circumstances analysis, reports on the criteria were acceptable, suggesting that the witness's identification was accurate in spite of the suggestive procedure used to obtain it. The recommendations articulated in *Biggers* were upheld in *Manson v. Brathwaite* (1977); the Court has not revisited recommendations for evaluating eyewitnesses since 1977.

At the time these recommendations were issued, the field of psychology and law was in a nascent stage; the flagship journal of the field, *Law and Human Behavior,* had not yet been established. Therefore, the justices relied on intuition rather than empirical evidence when designing a set of criteria. Although the criteria are intuitively appealing, several significant problems exist.

Certainty, View, and Attention: Subjective Criteria

Three of the five *Biggers* criteria—certainty, view, and attention—are subjective reports produced by the eyewitness, the very person whose accuracy is at issue in a criminal trial. The most problematic of these is undeniably witnesses' certainty. Perceivers naturally assume that a confident witness is an accurate one. This belief is well-founded under certain circumstances. When witnessing conditions vary widely, there is a strong relationship between confidence and accuracy: Witnesses who had a poor view are less confident than witnesses who had a good view. However, the integrity of the relationship between confidence and accuracy is easily compromised. For example, information suggesting that a co-witness identified the same person inflates certainty, as does identifying the person believed to be the culprit by the photo-spread administrator. The details of the Court's certainty recommendation suggest that there may have been some awareness that confidence is malleable. The critical confidence report, from the Court's perspective, was certainty "at the time of the confrontation," not confidence at the time of the in-court identification. It is possible that the Court's specification derived from an awareness that subsequent reports were vulnerable to influence by external variables.

Unfortunately, the Court's stipulation that certainty at the time of the identification is the relevant report does not ensure that this reported certainty provides useful information about accuracy. Indeed, simple manipulations can dramatically distort witnesses' memories of how certain they were at the time of their identification. A recent meta-analysis summarized the results of 20 experimental tests with more than 2,400 participants. Witnesses who were told that their identification was correct (i.e., "Good, you identified the suspect") reported recalling greater certainty in their identification than did witnesses who were told nothing about the accuracy of their identification. This inflation is especially troubling because in the original experiments, witnesses made identifications from target-absent photo spreads, meaning that their inflated confidence accompanied an incorrect identification. More troubling, this simple manipulation also distorted reports on the two other subjective criteria. Eyewitnesses who heard that their identification was correct reported better views and paying more attention compared with witnesses who heard nothing

about their accuracy. In conclusion, three of the five reports are distorted by simple, legal comments from investigators.

Description and Time: Objective Reports

Description and time are primarily objective reports—evaluations of these criteria do not rely on witnesses' own reports. Evaluators can examine for themselves the degree of match between a witness's description and the appearance of the defendant. Similarly, there is a record of the date of the crime and the date the suspect was positively identified. Psychological literature generally supports the time criterion: Accuracy diminishes as the time between the witnessed event and the identification attempt increases. However, the literature on the description criterion is mixed. One study concluded that there is no connection between an eyewitness's description and identification accuracy. Other studies suggest that witnesses are more likely to identify suspects if the witnesses have given a detailed description. Still other studies complicate the relationship even further by suggesting that the mere process of providing a verbal description of a perpetrator harms identification accuracy (i.e., verbal overshadowing). An empirically validated interviewing style, known as the cognitive interview, increases the quality of witnesses' descriptions but, as predicted by verbal overshadowing, decreases identification accuracy. Fortunately, identification accuracy rates are preserved if a delay exists between the verbal description and the identification attempt. Even though description and time are primarily objective, they are not immune to influence by external variables such as interviewing style.

System Variables Versus Estimator Variables

Most of the *Biggers* criteria are *estimator variables*—that is, variables that are not under the control of the justice system. For example, the justice system has no control over what kind of view the eyewitness had of the culprit. Similarly, the justice system has no control over how much or what kind of attention the witness paid to the culprit. In contrast, the time criterion falls into the *system variable* category—that is, variables that the justice system can control. For example, investigating officers can decide whether to show photos to a witness immediately after a crime is reported or wait until a suspect is located for a live lineup. The ability to make these decisions means that time is a system variable rather than an estimator variable.

The two remaining variables, confidence and description, straddle both categories. In some ways, they are estimator variables because the justice system cannot ensure that crime characteristics lead to high confidence or good descriptions (e.g., by ensuring that the culprit is in view for a long time and has no disguise). However, both criteria have system variable elements. Confidence can be easily manipulated by external factors having nothing to do with identification accuracy. Myriad variables, such as postidentification feedback, co-witness information, and repeated questioning, affect eyewitnesses' confidence. The quality of a witness's description is also influenced by external variables such as the style of interviewing. The cognitive interview increases both the amount and the quality of information gathered from eyewitnesses.

The *Biggers* Criteria Attempt to Postdict Accuracy

The final problem with the *Biggers* criteria is that they attempt to postdict accuracy—that is, to determine from eyewitnesses' own reports whether an identification that had already occurred was accurate or inaccurate. Empirical research reveals limited success in postdicting accuracy. This will be especially difficult when the variables intended to postdict accuracy are so vulnerable to distortion. A preferable strategy is to minimize the likelihood of inaccurate identifications at the time of the confrontation. One clear example of such a change is to require investigators to warn eyewitnesses that the culprit might or might not be present in the set of photos. Another is to obtain a report of the witness's confidence immediately after the identification is made, allowing defense attorneys to challenge inflated confidence reports at trial.

The continuing publicity surrounding DNA exonerations of individuals wrongfully identified should impress on the Court the need to revisit the *Biggers* criteria. Should the Court undertake such a challenge, some preference for system variable changes would likely be articulated by many psycholegal researchers. In the meantime, defense attorneys and expert witnesses alike should continue to challenge the utility of these criteria, especially confidence, in contributing to meaningful evaluations of eyewitness identification accuracy. At best, the criteria outlined by the Court

provide limited information about accuracy. At worst, the criteria provide misleading information, suggesting that triers of fact rely on variables that have tenuous relationships with accuracy.

Novaco Anger Scale

The Novaco Anger Scale (NAS) is a self-report questionnaire with Cognitive, Arousal, and Behavioral subscales that constitute a 48-item NAS Total score. It has a separate 12-item Anger Regulation subscale. This questionnaire is designed to index a person's disposition for anger, which is a risk factor for violence and a dynamic variable amenable to treatment. The NAS was developed in conjunction with the violence risk project of the MacArthur Foundation Research Network on Mental Health and Law. It was later revised, along with its companion scale, the 25-item Provocation Inventory (PI), in conjunction with its publication by Western Psychological Services (WPS). The NAS subscales pertain to anger disposition domains, as linked to an environmental context. The PI assesses self-reported anger intensity in response to provoking situations. Both instruments were developed and validated for use with mentally disordered and normal populations.

Description and Development

The NAS was first constructed in 1990 as a two-part instrument, which entailed the PI as "NAS Part B." In its formal publication in 2003, the NAS and PI were designated as separate instruments, and the Anger Regulation subscale was added. In the 2003 revision, a subset of four "attentional focus" items within the NAS Cognitive subscale was replaced by a subset of 4 items concerning "justification." Some item-wording changes were also made across the instrument.

Scale norms, reliability, and validity were first established for clinical populations in studies with 300 male and female patients, both civil commitment and forensic, at three California State hospitals; 119 male forensic patients in Scotland; 129 male intellectual disability forensic patients in England; and 143 Vietnam combat veterans with posttraumatic stress disorder (PTSD). The WPS standardization sample of 1,546 participants was age stratified (9–84 years) and was obtained from various nonclinical settings across the United States; also added were 171 male offenders in various correctional settings.

Scale Components

NAS Cognitive

The arousal of anger is cognitively mediated, being a function of perception and information processing. A schematic network of memories and meanings centrally influence the experience of anger and its expression. The NAS Cognitive subscale is composed of items operationalizing justification, rumination, hostile attitude, and suspicion.

NAS Arousal

Anger arousal is marked by physiological activation in the cardiovascular, endocrine, and limbic

systems and by tension in the skeletal musculature. Transfer of arousal or excitation residues from a prior provocation can intensify anger to a new one. The NAS Arousal subscale items operationalize intensity, duration, somatic tension, and irritability.

NAS Behavioral

Implicit in the cognitive labeling of anger is an inclination to act in an antagonistic or confrontative manner. The NAS Behavioral subscale items operationalize impulsive reaction, verbal aggression, physical confrontation, and indirect expression. The NAS Behavioral score is the principal NAS index expected to be associated with violence.

NAS Total

This is a summary anger disposition index, created by adding the Cognitive, Arousal, and Behavioral subscales. It does not include the NAS Anger Regulation subscale.

NAS Anger Regulation

A central characteristic of problematic anger is loss of regulatory control, which of course hinges on the environmental context in which the anger has been activated. This subscale is composed of cognitive, arousal, and behavior items. It is an overall index of the person's report of his or her ability to regulate anger-engendering thoughts and thinking styles, effect self-calming, and engage in constructive behavior when faced with provocation.

Inconsistent Responding Index (INC)

As a validity check, the NAS contains an index of response inconsistency, computed from a subset of 8 item pairs that have high correlations in the WPS standardization sample. Details are given in the NAS-PI manual.

Reliability

In its initial version, the NAS Total had an internal reliability (alpha) of .95 and a 2-week test-retest reliability of .84 in studies with psychiatric patients in the California State hospitals. An independent study with male offenders in Canada found NAS Total alpha equal to .95 and test-retest reliability to be .89 for a 4-week interval. In the MacArthur Violence Risk Project involving 1,101 civil commitment psychiatric patients, who were given the NAS while in hospital, the alpha for NAS Total was .94. For the WPS standardization sample, it was .94. In other studies, the NAS Total alpha was .97 for Vietnam combat veterans, .95 for forensic patients in Scotland, .92 for developmental disabled forensic patients in England, .94 for violent prisoners in Sweden, and .90 to .93 for undergraduates in California, Australia, and Sweden.

Validity

The initial NAS-PI was validated in the MacArthur Violence Risk Project, directed by John Monahan and conducted in three U.S. metropolitan areas. The NAS was a significant predictor of postdischarge violence at 10-week and 1-year follow-ups. It was also significantly related to patients' imagined violence while in hospital. In the scale development studies with California patients, it correlated .42 and .47 with Spielberger State Anger, prospectively at 1 and 2 months, respectively. It has robust correlations with the Spielberger Trait Anger measure in concurrent testing in studies with psychiatric patients in California, Scotland, England, Canada, and Sweden and with Vietnam veterans in Hawaii. Independent studies have found it to be related to violence by psychiatric patients before hospital admission, during hospitalization, and in the community after hospital discharge. Among combat veterans, it is strongly related to PTSD symptoms and PTSD diagnosis. Its adaptation to developmental disabilities patients has been demonstrated to have high reliability and validity and to be predictive of assaultive behavior in hospital.

Future Directions

The NAS-PI manual elaborates on the theoretical background and history of instrument development, the principles for its use and interpretation, validity issues, and the psychometric properties ascertained from a number of research investigations. One intended use of the NAS is for evaluation of the treatment received. An important extension in this domain would be for case formulation. Given that anger is now

recognized as a dynamic variable associated with violent behavior and that anger treatment efficacy has been demonstrated, the NAS would seem to have value for case formulation as the cognitive, arousal, and behavioral domains lend themselves to identification of the psychological deficits associated with anger dysregulation.

O

Obscenity

Obscenity is a unique legal phenomenon for three reasons. First, the defendant does not have to know the exact content of the material at issue; he or she only has to know the general nature of the material in order to be convicted. Second, the defendant almost necessarily has to employ social scientists to conduct a study indicating that the material does not offend the community's standards. Third, because the crime of obscenity depends on the community's sentiment, the defendant does not know if he or she has committed a crime until the verdict is returned. Thus, someone can own obscene material and not know that the material is illegal until a jury decides whether it offends community standards. Psychological research is used to measure community standards.

The legal definition and method of determining obscenity were established in *Miller v. California* (1973). Obscenity depends primarily on three factors. A material is obscene if an average person applying community standards would find that it (a) appeals to a prurient interest (i.e., an unhealthy, morbid, or degrading interest in sex), (b) depicts sexual conduct specifically defined by the state as patently offensive, and (c) lacks any artistic, literary, political, or scientific value.

In *Smith v. United States* (1977), the court clarified that "prurient interest" and "patently offensive" were to be determined by an average person applying contemporary community standards. Additionally, in *Pinkus v. United States* (1978), the court found that children are not part of the community included in the community standards criteria. However, these definitions failed to address what constitutes a community.

States have much flexibility in determining what behaviors are considered patently offensive sexual material. The *Miller* ruling and state court rulings have provided some examples. For instance, the Illinois state court in *Ward v. Illinois* (1977) named bestiality and sadomasochism as examples of patently offensive sexual conduct. Currently, seven states do not have obscenity laws. Of those that do, most states include the *Miller* definition as well as provide examples of patently offensive materials. Other than these definitions, stores selling such material and individuals have no explicit guidance on whether a material is obscene or not. Because the definition of obscenity is determined by community sentiment, it is difficult to know whether a material is obscene until a jury makes that determination. Researchers can conduct studies and testify about the community's standards.

Community Standards and Expert Testimony

Following *Miller* (1973), courts began to address whether parties had either the right or the requirement to produce scientific data. *Kaplan v. California* (1973) determined that defendants have the right to introduce expert testimony on the issue of community standards. In *Commonwealth v. Trainor* (1978), the judge stated that public opinion polls are uniquely suited to inform community standards debates. *People v. Nelson* (1980) generally held that experts are needed because otherwise jurors would rely on their own standards instead of the community's standards as the law

requires. However, *Hamling v. United States* (1974) found that expert testimony was not needed if the jury could view the material themselves. More important, the court determined that the defendant does not have the right to produce a poll. Generally, the current trend is to allow polls as long as they are well conducted and not biased.

Psychological research has investigated various aspects of community standards. Research has determined that community standards may vary over time; they may be restrictive at one time while lenient at another. Additionally, research has discovered that urban communities often have less conservative views of obscenity than less populated areas.

Males, younger individuals, and Whites are less likely to consider a material obscene than their counterparts. Furthermore, research has determined that viewing obscene materials does not change an individual's opinion of whether it is obscene or not, but it may make individuals less likely to consider that the material appeals to a prurient interest in sex.

Finally, individuals' perceptions of obscenity do not match their perceptions of the community's standards of obscenity. That is, individuals indicate that their personal views are more lenient than those of the community, even though they are part of the community. This may be problematic in court if individuals believe that their views do not match their community's view; they may determine that a material is obscene by community standards when they personally do not believe it is. Jury members are supposed to overlook their own standards and apply community standards in these cases. Yet if they do not have information about community standards, they may be inclined to believe that the community is much more restrictive than it truly is. As such, expert testimony from researchers who have polled the community can provide jurors with insight into what the community truly believes to be obscene.

Obscenity and the Internet

The most current challenge to the obscenity laws concerns sexual material posted on the Internet, which did not exist when the obscenity definition was established in 1973. Jurisdictional issues become problematic when obscenity cases involve the Internet. Although the material may not be viewed as obscene in the community of the individual who placed it on the Web site, it may be obscene in other communities where it is viewed. Courts have determined that the individual responsible for the obscene material will not be held to the standards of the town where he or she posted the Web site (*Voyeur Dorm, L.C. v. City of Tampa,* 2001). Instead, he will be held to the standards of the community where the material is delivered (*Miller v. California*, 1973). This decision was furthered by *Ashcroft v. ACLU* (2002), which established that Internet material can be judged by the standard of the community that is most likely to be offended by it. As these examples demonstrate, obscenity laws pose difficulties for both lawmakers and psychologists.

Optimality Hypothesis in Eyewitness Identification

As originally proposed by Kenneth Deffenbacher, the optimality hypothesis states that the likelihood of obtaining statistically reliable positive correlations of witness confidence and accuracy varies directly with the degree of optimality of information-processing conditions present for the witness at stimulus encoding,

during memory storage (retention interval), and at memory test. The more nearly ideal the processing conditions are for witnesses, the more they should be able to track accurately the adequacy of their memory performance in overtly expressed confidence ratings. The context in which the optimality hypothesis was proposed is discussed next.

By the end of the first decade of the modern resurgence of interest in conducting research concerned with the psychology of testimony, several dozen studies had accumulated wherein both witness accuracy and confidence in their identification decisions was measured. The commonsense intuition of laypersons, jurists, and researchers alike was that witness confidence should accurately track witness accuracy. In addition, signal detection theory, perhaps the most widely accepted theory of human judgment, made the same prediction. That is, the expectation was that when the accuracy of an identification decision made by each of a number of witnesses was correlated with a measure of their confidence in their decisions, the correlation coefficient expressing the predictability of accuracy from expressed confidence should be positive and relatively strong. The problem was that the empirical findings in this regard were decidedly mixed. Approximately half these initial studies reported positive correlation coefficients, ranging from +.20 to +.95, and the other half reported either correlation coefficients not statistically different from 0 or reversed (negative) correlations of witness accuracy and certainty.

At least on the surface, there would appear to be equal arguments both for and against the prior expectation that witness confidence should track witness accuracy with reasonable fidelity. In an effort to resolve this apparent contradiction of expectation and to account for the very large range of obtained correlation coefficients, a close examination of the studies in question revealed that there was substantial statistical support for the optimality hypothesis. Studies were first classified as having provided either high optimal or low optimal information processing conditions for witnesses. High optimal studies were defined as those wherein overall accuracy was at least 70% and that possessed at least three of the following information-processing conditions: warning of an impending memory test, stress levels low enough to permit adequate monitoring of the environment, ample opportunity to observe the target person, a brief retention interval, high familiarity with the target, similar condition of the target at encoding and memory test, low similarity of the target to foils (an innocent person in a police lineup) at test, unbiased memory test instructions, and additional consistent information presented during the retention interval. Then, both the number of significant positive accuracy-confidence correlation coefficients and the number of not significant or reversed accuracy-confidence correlations were determined for each category of study, those possessing of high and those possessing low optimal processing conditions. Fully 77% of studies had either high optimal processing conditions and a significant positive accuracy-confidence correlation or low optimal conditions and a not significant or reversed correlation coefficient. This proportion of cases is significantly greater than the proportion (.23) of cases wherein high optimal conditions resulted in not significant or reversed correlation coefficients or low optimal conditions produced significant positive correlations. Further analysis showed that this strong support for the optimality hypothesis was not related to whether the information-processing conditions in a study were of greater or lesser forensic relevance.

Since the proposal of the optimality hypothesis, publication of substantially greater numbers of investigations in which accuracy-confidence correlations were computed has occurred, and at least two meta-analyses (assessments of the average effect size, for the accuracy-confidence correlation in this case) have been conducted. As a result, two conclusions may be drawn. First, the average effect size has been estimated to be in the range of +.25 to +.35. That is, only 6% to 12% of the variation in accuracy judgments can be explained by variations in witness confidence. This result can be contrasted with the finding in one study that variations in juror perceptions of witness confidence accounted for as much as 50% of the variance in juror judgments as to witness accuracy. Second, additional empirical support for the optimality hypothesis has been obtained. In one published meta-analysis, clear evidence was found of longer target exposures being associated with a higher accuracy-confidence correlation (+.31) than shorter target face exposures (+.19). Other separate empirical investigations have found moderately strong positive correlations between target face distinctiveness and the size of the accuracy-confidence correlation. Still other studies have obtained markedly higher accuracy-confidence correlations in no-disguise conditions versus disguise conditions and in conditions with lower stress than in conditions with higher witness stress.

Finally, a theoretical analysis has been conducted in which the optimality hypothesis has been derived within the framework provided by signal detection theory. This analysis has resulted in the prediction of the average size of the accuracy-confidence correlation at six different levels of accuracy ranging from zero to very high levels. An example illustrates the utility of this analysis. Within the range of accuracy levels typically obtained in field experiments, a midrange predicted value of the accuracy-confidence correlation coefficient would be +.256, quite close to the estimated population value of +.252 obtained in a published meta-analysis.

Outpatient Commitment, Involuntary

Involuntary outpatient civil commitment is a form of civil commitment in which a court orders an individual to receive treatment and related services in a community setting. Nearly all states in the United States permit outpatient civil commitment, though the manner in which it occurs varies among the states. It is also used in other countries. Whether outpatient commitment should be used has been a source of much debate since the 1970s. While it continues to be controversial, the courts that have considered it have upheld its legality. Research to date suggests that it may be effective in some circumstances for some patients when combined with long-term treatment, though the reasons for its effectiveness are not known at this time.

Outpatient Civil Commitment Defined

Civil commitment is a form of compulsory treatment. Every state has a civil commitment statute that permits the involuntary hospitalization of an individual if certain conditions (generally a mental illness with behavioral consequences, most typically dangerousness to self or others) are found to exist. Many states have broadened the application of involuntary civil commitment statutes to permit individuals to be committed to treatment in outpatient settings.

Because outpatient civil commitment, like inpatient civil commitment, involves some deprivation of individual liberty, state statutes must specify the criteria that will be applied before someone can be ordered into outpatient care. There are three general types of outpatient commitment. The first is a form of "conditional release" used in some circumstances when an individual is going to be discharged from inpatient psychiatric care. The individual must agree on discharge to comply with one or more conditions, including the receipt of treatment in the community. A second type of outpatient commitment statute (most common among the states) uses the same criteria for both inpatient and outpatient commitment but permits a judge to order outpatient treatment as an alternative to inpatient treatment if the judge finds that the person meets the criteria for civil commitment. In the third type of outpatient commitment statute, there are separate statutory provisions for outpatient commitment, and the criteria differ from those used for inpatient commitment.

Criteria for Outpatient Commitment

While most states use the same criteria for inpatient and outpatient commitment, since the mid-1990s there has been more emphasis on the creation of discrete and separate criteria for outpatient commitment. These statutes, best exemplified by those found in New York and North Carolina, use many or all of the following criteria in defining those individuals who may be involuntarily ordered into outpatient treatment:

- The person is 18 years of age or older.
- He or she suffers from a mental illness.
- The individual is unlikely to survive safely in the community without supervision.
- He or she has a history of lack of adherence to treatment for mental illness.
- As a result, within a defined period in the past (usually 36 or 48 months), he or she has been hospitalized or jailed or has engaged in dangerous conduct (including threats).
- The individual refuses treatment or lacks the capacity to accept treatment voluntarily.
- In light of the person's history and condition, the person requires treatment to prevent a relapse or deterioration that could result in harm to the person or others.

A primary difference between criteria such as these and more typical involuntary commitment criteria is that these criteria are preventive in nature, permitting intervention in anticipation of the person's relapse or deterioration. In contrast, most civil commitment statutes permit intervention only after the occurrence of specified behavior, typically defined as being dangerous to either self or others, or an inability to meet basic needs.

These "pure" outpatient commitment statutes also typically require a finding by the judge that treatment will be available to the person if the court orders it. The statute may specify the types of treatment that may be ordered as part of an outpatient treatment order. For example, the New York law (which uses the phrase "assisted outpatient treatment" rather than involuntary outpatient civil commitment) states that ordered treatment

> shall include case management services or assertive community treatment services to provide care coordinate, and may also include any of the following categories of services: medication; periodic blood tests or urinalysis to determine compliance with prescribed medications; individual or group therapy; day or partial day programming activities; educational and vocational training or activities; alcohol or substance abuse treatment and counseling and periodic tests for the presence of alcohol or substance abuse; supervision of living arrangements; and any other services . . . prescribed to treat the person's mental illness and to assist the person in living and functioning in the community, or to attempt to prevent a relapse or deterioration that may reasonably be predicted to result in suicide or the need for hospitalization. (N.Y. Mental Hygiene Law § 9.60(a)(1))

The specific definition of services that must and may be included as part of an outpatient treatment order also differs from a typical involuntary commitment statute, which does not provide such specificity.

Consequence of Noncompliance With an Outpatient Treatment Order

If the person fails to comply with the treatment order, state law typically permits one of two responses. The person may be brought back to court, and the court may impose new conditions, emphasize the importance of complying with the existing conditions, or hold the person in contempt of court—something that rarely, if ever, happens. Second, the person may be ordered to an inpatient setting for assessment to determine whether the person now meets the criteria for inpatient commitment. If so, the person may be hospitalized under the state's involuntary commitment provisions.

One of the primary reasons for the enactment of outpatient civil commitment provisions is the argument that individuals with mental illnesses who quit taking prescribed medication are the group of people most at risk for deterioration and ultimately behavior that endangers them or others. Outpatient commitment laws typically permit a judge to order the person to take medication as part of the commitment order. However, before a person may be forced to take medication, state laws usually require another court hearing to determine if the person lacks the capacity to make decisions regarding medication. If the person is found to have the capacity (i.e., the legal competency) to make decisions about medication, then the person is usually permitted to continue to refuse medication despite the fact that he or she is under an outpatient treatment order.

The Legality of Outpatient Commitment Statutes

Some have criticized outpatient commitment statutes on legal grounds, arguing that they represent an unwarranted and legally suspect extension of the state's authority to force people to accept treatment against their will. However, courts have uniformly upheld the constitutionality of outpatient commitment statutes and in doing so have provided judicial endorsement of

the state's authority to act preventively in certain circumstances. For example, in upholding the constitutionality of New York's outpatient commitment statute, the New York Court of Appeals observed that the statute forwarded the state's interest in "warding off the longer periods of hospitalization that, as the Legislature has found, tend to accompany relapse or deterioration" (*In the Matter of K.L.*, 2004, p. 487).

Issues in Implementing Outpatient Commitment

The implementation of outpatient commitment statutes varies by state. A number of implementation issues have been reported. First, it appears that regardless of the type of statutory provision a state has, outpatient commitment orders are used most frequently at the point of discharge, as a way of attempting to ensure treatment compliance as the person enters the community. Second, there are a number of practical barriers that sometimes reduce the use of outpatient commitment. These include difficulties in transporting the individual, limits on treatment capacity, and lack of adequate social supports such as housing. Third, perceived difficulties in enforcing outpatient commitment orders may reduce its use in some situations.

The Impact of Outpatient Commitment Statutes

There have been two generations of research into the effectiveness of outpatient commitment statutes. The first generation of research generally relied on anecdotal evidence from a particular state or jurisdiction, and while this research often suggested that outpatient commitment was effective, there were significant methodological problems that called the reliability and generalizability of the findings into question.

The second generation of research has been more methodologically rigorous and has examined the impact of pure outpatient commitment statutes, principally in New York and North Carolina. The most comprehensive studies have been conducted in North Carolina. The North Carolina studies relied on random assignment of involuntarily hospitalized individuals meeting the state's criteria for outpatient commitment to either be released from treatment or undergo outpatient commitment. Patients in the latter group could receive a renewable 180-day treatment extension after the original 90 days of treatment. While outcomes between the two groups did not differ significantly on most measures, patients in the latter group who received comparatively more intensive outpatient commitment over a longer time had fewer hospital admissions, had fewer days in hospital, were less likely to be violent or victimized, and were more likely to comply with outpatient treatment. However, a comparably designed study in New York did not find similar outcomes.

While it is not clear from the extant research precisely how outpatient commitment might result in better outcomes for some individuals, the North Carolina studies in particular suggest that outpatient commitment orders must be accompanied by treatment over time to be effective.

P

Parens Patriae Doctrine

Parens patriae translates from the Latin as "father of the people" and is the legal principle that allows the state to intercede on behalf of juveniles, those who are mentally ill, and others who are unable to protect themselves. The parens patriae doctrine was first enunciated in English common law and referred to the king as exercising protective functions in his role as "father of the country." The parens patriae doctrine should not be confused with the in loco parentis doctrine, which is more temporary in nature and not limited to governmental entities. It should also be noted that in the United States parens patriae power is a state government's exercise of power and not one that can be exercised by the federal government. The doctrine was conceived as a benevolent intercession by the government and addressed the obligations of the government to protect individuals. However, because this doctrine allows the usurpation of the rights of natural parents and legal guardians, as well as individuals deemed incapacitated, it has generated controversy on several fronts with regard to the limits of those powers.

Civil Commitment

Civil commitment proceedings, in which the mentally ill are held in a restrictive setting for treatment, appear to have been the earliest exercise of parens patriae power. Until the 1960s, there were few restrictions on the states' exercise of paternalistic benevolence in dealing with the mentally ill. At that time, however, questions arose with regard to the truncation of civil liberties that occurred with incarceration for mental illness and whether or not the state was necessarily acting in a citizen's best interests. Challenges to civil commitment proceedings revolved around the state's reliance on the medical model in determining when a mentally ill individual met criteria for incarceration and whether commitment was, in fact, in an individual's best interests given the conditions and lack of treatment in mental institutions. Issues were also raised as to whether commitment proceedings unreasonably deprived citizens of due process, particularly in situations where the deprivation of rights for the mentally ill was greater than for individuals who were dealt with through the criminal system. Reforms in civil commitment proceedings have considerably narrowed the state's ability to intercede on behalf of the mentally ill and have replaced the assumption of benevolence with the recognition that the state can only deprive individuals of liberty through due process of law. While the state's parens patriae power allows the state to make decisions regarding mental health treatment, the extent of intrusion is limited to "reasonable and necessary treatment."

Juvenile Law

The evolution of juvenile courts is also intimately connected with the parens patriae concept and is another arena in which challenges have generally resulted in a more careful definition of when the state may intercede and how. Originally, the parens patriae doctrine gave the state power to intervene whenever this was

viewed as being in the best interests of the child. However, in 1966, in *Kent v. United States*, there was a recognition that juveniles had the same rights as adults with regard to due process, and the entire juvenile justice system came under scrutiny. In many ways, challenges to the state's ability to intercede in juvenile matters paralleled the challenges raised with regard to incarceration of the mentally ill: the lack of due process, the lack of consistency in defining which juvenile behaviors required intervention, and the absence of clear indicators that the state's intercession resulted in appropriate rehabilitative efforts. Ultimately, it became clear that juveniles, as with the mentally ill, were receiving worse treatment under the parens patriae doctrine than would be afforded to them as adults in criminal settings. Reforms resulted in the state having less discretion than had previously been afforded under parens patriae as formal procedures were subsequently implemented in juvenile hearings.

Child Abuse and Neglect

Another arena in which the doctrine of parens patriae is fundamental has been in the state's intercession on behalf of abused and neglected children. This is an area fraught with conflict between the care and protection of children, on the one hand, and constitutional freedoms related to family privacy and parental liberty, on the other. This conflict is particularly evident in cases involving religious tenets of the parents clashing with recommended medical treatment for their children. In general, courts have concluded that religious freedom does not allow parents to risk impaired health or death for their children. In these cases, the state has relied on the parens patriae doctrine to justify intervention on behalf of the children. As with the previously described arenas in which parens patriae is a fundamental legal concept, the concept has been exercised with considerable latitude historically and then limited by reforms more recently. Difficulties in operationally defining abuse and neglect, as well as the state's inability to prove that its interventions result in a superior outcome for children, have complicated the delicate balance between protecting children and respecting family privacy. This issue has been particularly relevant with regard to the removal of children from the family for placement in the foster care system given the documented flaws in that system. Other areas that have been raised under parens patriae with regard to child abuse and neglect issues have revolved around child labor and school attendance, with clearer justification for the state's interest in intervening.

Parens patriae has been an important doctrine in delineating a protective role by the government toward vulnerable members of society. Although a setting forth of state's obligations toward citizens who are incapable of protecting their own interests is an important aspect of governmental functioning, this doctrine also has the potential to justify incursions into fundamental liberties. In each arena in which this doctrine has been prominent, historically there has been a trend toward limiting the broad powers of the state to intervene in favor of achieving an appropriate balance between the exercise of the state's obligations to its vulnerable citizens and the retention of fundamental freedoms.

Parent-Child Relationship Inventory (PCRI)

The Parent-Child Relationship Inventory (PCRI) is a 78-item self-report instrument designed to measure mothers' and fathers' perceptions of their relationship with an individual child and their attitudes about being parents. Responses are made on a 4-point Likert scale, with high scores indicating parenting behaviors that could advantageously contribute to this relationship and low scores suggesting difficulties. Five scales assess interpersonal dimensions of the individual parent-child dyad. These include Satisfaction with Parenting (SAT), Involvement (INV), Communication (COM), Limit Setting (LIM), and Autonomy (AUT).

The Parental Support (SUP) and Role Orientation (ROL) scales measure parental characteristics that may influence interactions with a child. Each of these scales yields a separate score. Evaluation of the validity of parents' responses is facilitated by the inclusion of a Social Desirability scale (SOC) and 10 correlated items for examining the consistency of their responses in the inventory.

Description and Development

The PCRI was developed, for individual or group administration, to evaluate the quality of parent-child relationships in both applied and research settings. Construction of the scales combined experts' ratings, empirical tests, and subjective critiques by parents and professionals to identify items for inclusion in the measure. The final version of the PCRI was based on standardization data collected from a predominately White sample of 668 mothers and 471 fathers whose children were between the ages of 3 and 15. In most cases, responses were collected from both parents in a family regarding their dyadic relationship with the same child. These normative data were used to develop separate tables for the interpretation of mothers' and fathers' responses that potentially reflect gender differences in parenting. Raw scores can be transformed to percentiles and *T* scores.

Reliability

In the test manual, Anthony Gerard reports alphas (Cronbach's alpha coefficient) for the seven scales ranging from .71 (SUP) to .87 (LIM). Test-retest reliability after 1 week ranges from .68 (COM) to .93 (LIM) and after 5 months from .44 (AUT) to .71 (SUP and ROL).

Validity

Content validity of the PCRI is substantiated by how well the scale items represent parents' attitudes and values based on parenting theory, comparison with the extant literature, and experts' ratings of the items. An iterative process resulted in statistical evidence that the PCRI's scales, and the items included therein, characterize well-established domains of the parent-child relationship. During measure development, construct validity was examined by the assessment of internal consistency and item-scale correlations. Intercorrelations between the scales are attributed to an expected correspondence between particular domains. For example, parents who report that they participate in activities with their children are more likely to respond that they have open and effective communications with their children as well. However, concerns have been raised regarding overlapping constructs that contribute to redundancy among the scales.

Evidence of predictive and criterion-related validity is presented in the PCRI manual. Responses from couples involved in divorce litigation and custody mediation revealed that these parents were more likely to report difficulties in their relationship with their children than did the normative sample. Likewise, adolescent mothers who reported lower satisfaction with their parenting role were more likely to discipline by means of scolding and physical punishment.

Recently, cross-informant convergence was reported for mothers' and fathers' independent self-appraisals of family unity with their own responses on the PCRI. However, only the mothers' self-assessments of family discord corresponded systematically with the PCRI. A similar pattern was found between adolescents' and mothers' appraisals of family unity and discord. The lack of correspondence between mothers' and fathers' responses, as well as between those of fathers and adolescents, is consistent with the literature regarding differences in the relationships mothers and fathers have with their children. Hence, the PCRI may not accomplish convergent validity for both mothers and fathers.

Future Research

Emerging research has corroborated the internal consistency, stability, and validity of the PCRI. Additional research would enhance the measure's external validity. First, families from diverse backgrounds followed longitudinally would contribute to norms for age-related changes in the parent-child relationship as children mature. These data could also contribute to the examination of whether the lower internal consistency reported for the AUT scale is related to a child's age and parental adjustments in nurturing age-appropriate independence. Additionally, norms are not available for differing ethnic or cultural groups. Certain parenting behaviors (i.e., autonomy, discipline, communication) may vary between cultural groups in correspondence to family hierarchies and expectations placed on family members. Given the diversity within

the United States, alternative family configurations—and an extension of the international use of the PCRI—and representative norms are especially needed for clinical and legal arenas.

Second, research that extends cross-informant convergence is needed to describe the bidirectionality of parent-child relationships and the unique parenting roles of mothers and fathers. The contributing influence includes factors such as the following: (a) Who fulfills the primary caretaking role? (b) What is the frequency of time together? (e) Is there ease of communication? (d) Is there mutual knowledge of each other? (f) Do personal as well as cultural or societal expectations influence parent-child relationships in gender-based ways? What needs to be determined is whether mothers' and fathers' self-reports of their dyadic relationships with their children can have convergent validity.

Parenting Satisfaction Scale (PSS)

Child rearing has always been one of life's major challenges and potential sources of self-fulfillment. In today's world, divorce and unwed parenthood often alter parenting time and commitment for both parents, and attractive occupational options or excessive job requirements may affect motivation, time, or energy available for parenting. Connections between parental attitudes and child-rearing behaviors have previously been documented, but standardized instruments to measure parenting satisfaction are not available. The Parenting Satisfaction Scale (PSS) was constructed to meet this need for reliable assessment of an important family variable at a time of a major family change. Scores derived from this 45-item scale enable mental health and judicial personnel to define, compare, and communicate levels of parent satisfaction in three domains: satisfaction with spouse or other parent's child-rearing performance, satisfaction with the responding parent's relationship with the child, and satisfaction with the responding parent's own parenting performance.

Scale Development

Initially, scale items were generated from an open-ended questionnaire administered to a heterogeneous sample of approximately 100 adults ranging in age from 21 to 54 years. A total of 259 items were generated from this procedure. Thirty-five members from the original group then reviewed the items for clarity and critical relevance to the parenting role, and a panel of three experts from the field of child and family development assessed the items' face validity. A pool of 211 items remained after these refining procedures.

A volunteer pilot sample of 78 mothers and 52 fathers was then selected from local community groups. This sample ranged in age from 21 to 71 years, and 91% were Caucasian. Educational levels ranged from less than high school to postdoctoral study, and the ages of children in their families ranged from 6 weeks to 38 years.

The PSS responses from the pilot sample were analyzed using principal components factor analysis and equimax rotation, yielding five factors with the 10 highest-loading items used to construct each scale. These pilot phase factors were examined for criterion validity, using four related scales: the Dyadic Adjustment Scale developed by Spanier; two Marital and Life Satisfaction Scales developed by Lee; and the Life Satisfaction Index developed by Neugarten, Havighurst, and Tobin. The PSS total score related significantly to each of the criterion scales, with correlations ranging from .46 to .56. The internal consistency of this pilot version was examined with Cronbach's alpha, and reliabilities ranged from .76 to .93 for the five individual scales and the total score.

Standardization

Time 1

The final phase of PSS development involved national standardization and validity analyses. In a nationwide "impact of divorce" study by the National Association of School Psychologists, 144 psychologists from 38 states were selected in a stratified random sample based on regional population density. The psychologists randomly selected 699 children from the first, third, and fifth grades to represent samples of divorced-family and intact-family children. From the total sample of 699 families, 341 married and 303 divorced parents completed the scale by the project deadline date. The sample was composed primarily of mothers (89%), Caucasians (88%), and public school parents (97%). The sample was evenly balanced by child's gender, grade in school, and school demographic area.

Factor analyses of these data yielded three factors with eigenvalues greater than one. Separate analyses were done for divorced and intact families, and the factors were found to be equivalent, with congruence coefficients at .93 or greater. The first factor was labeled Satisfaction with Spouse/Ex-Spouse Parenting Performance, the second factor was labeled Satisfaction with Parent-Child Relationship, and the third factor was labeled Satisfaction with Parenting Performance. Internal reliabilities for the three factors were $r = .96$, $r = .86$, and $r = .82$, respectively. These three factors of 15 items each made up the final scale.

Time 2

Two years later, data were gathered on a follow-up subsample of 137 subjects. Chi-square analyses on demographic variables verified that this sample was representative of the original study group. Internal reliabilities for follow-up sample PSS scores were calculated and found again to be high (r is equal to .95, .89, and .82 for the three scales, respectively). Test-retest reliability was moderate across this 2-year span (r is equal to .81, .59, and .64, respectively, for the three factors).

Validity

The extensive battery of instruments used in the nationwide study and the assessment of subjects at two points in time enabled an unusual number of validity comparisons. At Time 1, PSS scales showed consistently significant relationships with children's social and academic performance; family health ratings; children's ratings of parent-child relationships; and parental marital, vocational, and life satisfaction scores. Time 1 PSS scores also significantly predicted a number of important child and parental variables 2 years later. For example, with regard to PSS 1 (Satisfaction with Spouse/Ex-Spouse Support), teachers rated the children of satisfied parents as less withdrawn, happier, working hard, having fewer behavior problems, and receiving higher grades in several school subjects. Time 2 children's health status and teacher ratings of social competence were predicted across the 2-year time interval by all three PSS scales.

Comparing families of high and low parenting satisfaction yielded additional validity information. Using only subjects falling into the top or bottom one third of the PSS distribution at Time 1, consistently significant differences in criterion scores favoring the highly satisfied parents were noted. PSS total scores differed significantly on seven of the eight selected criteria, including total teacher ratings of classroom behavior for two rating scales, academic achievement test scores, parents' ratings of children's behavior problems, parents' life and marital satisfaction scale scores, and children's interview responses about the quality of their relationships with their parents.

In other studies, the PSS demonstrated additional substantial evidence of validity. For example, a study of stress in the lives of college-educated women used PSS 2 and PSS 3 to assess satisfaction with the parent-child relationship and parenting performance. For the 630 women respondents, these PSS scales were strongly related to a broad array of other life measures, including total support from friends, relatives, and the community; marital satisfaction; life satisfaction; and physical health. Two additional studies conducted in urban schools with high-risk special education populations and one done in a child guidance center with behavioral problem children showed strong positive relationships between child adjustment variables and PSS scores.

PSS assessment of 1,710 Chinese parents was done as part of a cross-cultural study conducted in the People's Republic of China. Correlations with child variables were consistently in the expected direction. Better PSS scores related to better academic and social adjustment of children. This cross-cultural validity demonstration further strengthened confidence in the PSS instrument, illustrating that

the item content and the three scales have broad applicability.

The PSS has been refined and validated through large-scale studies on both national and international populations. This standardized instrument can be useful in a variety of situations where individual emotional health is assessed or when parenting or coparenting relationships are the subject of study. For example, court personnel may find it useful when examining the quality of parent-child interactions prior to custody determination or following parenting education interventions. School psychologists may find PSS information useful in understanding the etiology of children's school problems.

Parenting Stress Index (PSI)

The Parenting Stress Index (PSI), developed by Richard Abidin in 1976, is a screening and diagnostic assessment tool commonly used to measure the magnitude of stress in the parent-child system. Abidin describes several potential uses of the PSI including screening for the early identification of parenting and family characteristics that fail to produce normal development and functioning in children, identifying children with behavioral and emotional problems, and screening for parents who are at risk for dysfunctional parenting. Abidin has also suggested that the PSI would be useful as a measure of intervention effectiveness and in clinical research. In recent years, the PSI has been used frequently in research investigating child maltreatment and its sequelae.

Description and Development

The development of the PSI has been influenced by changes in theoretical models specifying the determinants of dysfunctional parenting. Early formulations of the model emphasized "stress" as the central construct leading to dysfunctional parenting. By 1982, a more complex model had emerged. Research revealed that stress and dysfunctional parenting were not related in linear fashion. Instead, child characteristics, parent characteristics, family contact, and life stressors all appeared to contribute to the functioning of the parent-child system. The parenting stress construct had become more complex and multifaceted.

In recent years, research has revealed that stress in the parenting system, especially within the first 3 years of life, is critical to the child's emotional/behavioral development and the parent-child relationship. Moreover, parenting stressors are additive and include objective events such as the death of a family member, as well as more subjective experiences of parental social isolation and concerns about a child's potential to achieve developmental milestones.

In 1995, the PSI was revised to improve scoring ease and to introduce a short form of the measure. The standard PSI is a 120-item self-report inventory with an optional 19-item Life Stress Scale. There are six Child Domain subscales (Distractibility/Hyperactivity, Adaptability, Reinforces Parent, Demandingness, Mood, and Acceptability) and seven Parent Domain subscales (Competence, Isolation, Attachment, Health, Role Restriction, Depression, and Spouse). Subscale scores are combined to generate the Parent Domain, Child Domain, and Total Stress factors. Parents of children as young as 1 month and as old as 12 years may complete the measure.

Administration and Scoring

The PSI can be administered and scored by individuals without professional training, but interpretation of the measure should involve an individual with graduate-level training in tests and measurement. Most parents complete the questionnaire in about 20 minutes, though no time limit is given. Respondents are asked to read the instructions on the first page of the item booklet and then respond to each item by circling SA (strongly agree), A (agree), NS (not sure), D (disagree), or SD (strongly disagree) on the answer sheet. The respondent's answers are recorded on the scoring sheet via carbon transfer (if the EZ score form is

used). The PSI includes a validity scale (Defensive Responding), which should be calculated first. Individuals with a Defensive Responding score of 24 or less are likely to be underreporting stress, and caution should be exercised when interpreting such test protocols. Subscale scores are calculated by summing each of the responses that correspond with the subscale. The subscale scores and the Life Stress scale score (if used) are then transferred from the score sheet to the profile form. The Child Domain subscale and the Parent Domain factor scores are calculated by summing the appropriate subscales within each domain. To obtain the Total Stress score, users sum the Child Domain score and the Parent Domain score. Percentile scores corresponding to each of the subscale raw scores are provided on the profile page. Percentile scores are derived from the frequency distribution of the normative sample. Subscale scores may be interpreted individually; however, scores are best considered in relation to each other. The Total Stress score can be used to gauge whether professional intervention might be warranted. Total Stress raw scores greater than 260 suggest a need for referral to an appropriate professional for consultation.

Standardization

Normative data were collected from 2,633 mothers of children ranging from 1 month to 12 years. Normative data were also collected from 200 fathers with children ranging in age from 6 months to 6 years. The PSI's reading difficulty level is estimated at the fifth grade.

Reliability and Validity

Internal consistency (reliability) has been estimated at .70 to .83 for the subscales comprising the Child Domain and .70 to .84 for the Parent Domain subscales. Broad domain and Total Stress reliability coefficients are greater than .90. Test-retest reliability coefficients (ranging from 3 weeks to 1 year after initial administration) were relatively stable across four studies: .55 to .82 for the Child Domain, .69 to .91 for the Parent Domain, and .65 to .96 for Total Stress.

Several studies support the construct and predictive validity of the PSI. The PSI has been used to identify specific stressors for mothers of children with developmental delays, behavioral disorders, and chronic illness. Validation studies have been conducted in Chinese, Italian, Portuguese, Latin American Hispanic, and French Canadian populations. Collectively, these studies suggested that the PSI's psychometric characteristics are stable and robust across cultural and socioeconomic boundaries.

Parenting Stress Index–Short Form (PSI–SF)

The Parenting Stress Index–Short Form (PSI–SF) was derived from the PSI using factor-analytic procedures at the request of clinicians and researchers who wanted a valid measure of stress in the parent-child system that could be administered in less than 10 minutes. At 36 items, this parent self-report inventory allows rapid screening of parenting stress that derives from parenting a difficult child, problems in the parent-child relationship, and stress that derives from personal factors directly related to parenting. Total Stress and Defensive Responding indicators are also obtained.

Research to date has suggested that the PSI–SF performs similarly to the full-length PSI. The PSI manual reports correlations of .87 to .94 between the major PSI and PSI–SF domains noted above.

Parole Decisions

Parole decisions have important implications. For prisoners, such decisions mean early release or define the conditions of release. For the public, prisoner reentry raises concerns about safety and community integration. Despite waning enthusiasm for rehabilitation in some countries, by using advances in risk

assessment and by partnering with correctional agencies, parole is ideally situated to contribute to offender rehabilitation while also addressing ongoing concerns by the public and politicians regarding the costs of corrections and risk to public safety.

Notwithstanding changes in legislation over the past three decades, parole remains an integral part of the criminal justice system. At both international and domestic levels, parole continues to be relied on to ensure the timely and safe transition of offenders from the confines of incarceration to community supervision. In this manner, it acts as a tollbooth for offenders as they pass from prison back to the community. Parole decision makers, informed by law and policy and on a case-by-case basis, determine the amount of toll required. Despite variations across countries and jurisdictions, their decision is typically informed by guidelines regarding eligibility, some element of desert or judgment that the prisoner has served sufficient time according to the seriousness of his or her crime(s), and a judgment that community safety would not be jeopardized by the offender's release.

Definition

Variability in the use of the term *parole* has been an obstacle in conducting a review of parole research and practice. In this entry, parole refers to discretionary or conditional release. The former reflects release prior to the expiration of the sentence, whereas the latter reflects the designation of conditions that must be met by the offender when he or she is granted mandatory parole. Typically, if the conditions are not met, the offender may be returned for a further period of incarceration. Some jurisdictions impose guidelines regarding limits to eligibility for parole release following breaches in the community on an earlier release.

Context

Despite the waning interest in parole due to a gradual shift in public policy toward a focus on punitive solutions to crime, a 2001 review of U.S. paroling jurisdictions conducted by the Association of Paroling Authorities International indicates that parole boards with legislative discretionary release authority have survived in approximately two thirds (34) of state and federal correctional jurisdictions. Similarly, in Canada, all provinces and the federal correctional system have parole boards, although the federal board has jurisdiction for some provincial offenders. Indeed, Canada has served as a model for numerous countries in terms of parole policy and training (e.g., Australia, Bermuda, Great Britain, Hong Kong, New Zealand, and Russia).

Several examples will serve to highlight the scope of parole and its potential impact on corrections and communities. In 2003, the U.S. Parole Commission made 10,771 decisions regarding release or revocation. In the fiscal year 2004 to 2005, the Pennsylvania Board of Probation and Parole conducted 9,588 hearings regarding parole violations and 19,624 panels/interviews for parole. In 2005, the Massachusetts Parole Board conducted approximately 10,000 face-to-face hearings and rendered decisions on approximately 20,000 cases. It is difficult to determine the exact number of parole decisions made annually, but a reasonable extrapolation from these data suggests that 400,000 would not be inflated. Moreover, since offenders are released on both parole and expiration of sentence, it is not surprising that close to 600,000 offenders are released and return to communities across the United States each year.

In Canada, the numbers are smaller but equally compelling. In 2005, the National Parole Board made an estimated 22,295 decisions. Also, this board made more than 16,711 contacts with victims regarding release decisions and reviewed 22,900 pardon requests. Although these data do not control for population rates, parole decisions clearly affect the lives of a significant number of offenders, their families, and the community at large.

In the United States, from 1980 to 2003, the proportion of discretionary parole releases from state prisons markedly diminished from about 55% to about 22%. During the same time period, mandatory parole releases (conditions imposed) increased from about 18% to about 36%, whereas expiration of sentence releases only modestly increased from 14% to 19%. These changes are partly due to statutory changes eliminating parole release and partly due to increased reluctance on the part of boards of parole to release offenders prior to expiration of sentence. This trend in parole decision making situates potential contributions of parole decision research and can perhaps best be understood through the lens of public policy, particularly in North America.

Prior to 1970, the belief was that the criminal justice system should be used to rehabilitate offenders; this was reflected in indeterminate sentencing and discretionary release practices. However, doubts

regarding evidence of effective rehabilitation programs emerged, paralleling an increase in interest in retribution as a means of addressing criminal justice concerns. This just-deserts model focused on determinancy and consistency in sentencing, clearly at odds with the earlier discretionary model. This justice model also advocated using incarceration sparingly. In the 1980s and 1990s, however, theories of deterrence came to the fore and with them an appetite for harsher punishments. This quickly led to increased incarceration rates and, subsequently, increased costs of prisons. Public policy in this era generally disputed evidence regarding interventions to reduce re-offending and ignored parole as a viable strategy to address increased prison populations. Only since the late 1990s has an abundance of evidence regarding risk assessment and correctional programming been accumulated and more widely disseminated to criminal justice officials, suggesting that a new model for parole might be profitably integrated into the criminal justice system. Nonetheless, these data are still often hotly debated on ideological grounds. Encouragingly, in 2005, the U.S. Congress introduced legislation to allocate $300 million over 4 years in an effort to more successfully transition prisoners to the community. These reentry initiatives highlight how parole might be well situated to complement existing sentencing and correctional strategies, thereby enhancing public safety through attention to evidence-based practice.

Importantly, government publications describing parole policy, parole board member training, and contemporary roles of parole abound. Surprisingly, few of these publications overtly address the issue of parole decision making as a process, although the training handbook referenced above illustrates several different methods employed. Moreover, with the notable exception of the flurry of research on standardized risk assessment instruments in the 1970s and 1980s, academia has generally ignored parole decision making as a research topic. Considering parole research in terms of content (risk assessment, decision frameworks), process (decision strategies), and outcome (recidivism, effective correctional programs) highlights areas warranting further systematic investigation.

Content

Initially, in the mid-1970s, given the reliance on clinical opinion, researchers sought to improve accuracy through the development of statistical instruments that distinguished between successful releases and parole failures. Many parole boards continue to use such instruments to distinguish risk levels among prisoners, and risk is routinely considered in parole decision trees and matrices. Such instruments have consistently been found to be more predictive of outcome than subjective professional judgments. Moreover, they assist in diminishing the frequency with which offenders who are poor parole risks are inappropriately released, increasing the speed with which offenders who are good parole risks are released, and diminishing unnecessary incarceration expenditures. For mandated parole, assessment of risk appears to be used to inform the type and number of conditions imposed by the board.

Risk assessment tools, however, expressly eliminate from consideration any factors unique to the offender or to his or her context. As such, it is important that they not be used without consideration of additional information. Indeed, empirical research demonstrates that estimates of risk derived from statistical tools are not the only factors considered by decision makers in reaching release decisions. For example, offenders' criminal and institutional history and previous release recommendations have been found to affect parole decisions. Interestingly, the use of interviews appears not to improve accuracy in predicting parole success.

In Canada, a framework to guide parole decision makers in integrating statistical and additional information has been developed. Using a statistical risk assessment instrument as its anchor, the framework outlines specific additional areas for consideration (criminal history, risk management, disinhibitors, case-specific factors, institutional adjustment, offender change, and release plan). Preliminary results demonstrate that the use of this framework leads to reductions in decision errors and high rates of predictive accuracy regarding parole outcome. Moreover, feedback suggests that the framework assists in the provision of a decision rationale and is useful in the training of new parole board members.

Process

Parole release obviously involves making judgments; hence, discretion is required. Research, however, is required to demonstrate that parole decisions are consistent and discriminating—that is, board members would arrive at similar decisions for the same case, and

they would distinguish between cases representing good and poor parole risks. Importantly, this distinction should also lead to demonstrations of parole decisions' validity through follow-up research. To date, two structured approaches for parole decision making have been described in the literature. The first is a matrix or grid method, as seen in Maryland, which integrates severity of crime (arson, manslaughter, murder, rape, robbery crimes vs. assault, burglary crimes) and risk (scored information on prior criminal history, age at time of current offense, time crime free, prior escapes or parole violations, substance use) in establishing a range of time to be served corresponding to each cell of a matrix. The second is a sequential or decision tree method, as seen in Pennsylvania. Through the assignment of a rating for type of offense, risk/need assessment, institutional programming, and institutional behavior, a cumulative score helps determine whether the offender is likely or unlikely to be a good parole risk. The sequential method typically incorporates more factors into the process than the matrix. Both approaches are intended to provide structure to parole decision making, but empirical evidence describing and validating the mechanisms underlying these methods is almost absent. Nonetheless, transparency of the decision process should yield less capricious parole decisions.

Outcome

Ultimately, parole boards are held accountable for parole violations, yet this is an imprecise dependent measure of parole decision making. Dynamic risk prediction suggests that proximal factors are important in risk assessment and its management. Hence, if a decision is made to parole a prisoner and 6 months later, owing to deterioration while in the community (e.g., reinvolvement with drugs, loss of job, loss of stable accommodation), the parolee is returned to prison, does this mean that the original decision to grant parole was flawed? In part, it would seem desirable to have a standard of practice that defines a quality decision model against which decisions can be compared. Congruence with this standard of practice may be a more suitable criterion for evaluating parole decision making than outcome. Encouragingly, from a reentry perspective, discretionary parole release appears to be more successful than mandatory release. The latter study controlled for offense type, prior record, age, ethnicity, education, and gender, finding that those released from prison via discretionary parole were more than twice as likely as those on a mandatory release to successfully complete their parole period.

Given the numbers of parole decisions made, as well as the consequences of inaccurate decisions, parole would appear to be an area for optimism. Indeed, parole can serve as an important motivation for prisoners to engage in programs and adhere to supervision conditions. Most important, even modest reductions in decision errors will yield significant gains—individual, social, and financial.

Patient's Rights

Patients who are subjected to involuntary hospitalization in a psychiatric facility or who accept voluntary admission retain certain rights within the institution. Patients hospitalized because of mental illness do not shed their rights at the hospital door. Although they may not leave the hospital, they retain their rights to the fullest extent consistent with their status as mental patients. The Constitution protects the right of patients to communicate with others outside the hospital, to consult with counsel, to petition the courts, to practice their religion, to have reasonably safe conditions of confinement, to be free of unreasonable seclusion and restraint, to receive adequate treatment, to refuse certain treatments, and to receive a hearing if any of these rights are sought to be curtailed or if their

commitment is extended. Modern civil commitment statutes also guarantee these rights as a matter of state law and afford additional rights to patients, including the right to convert their status from involuntary to voluntary admission, to the confidentiality of their clinical records, and to have access to their records.

Right to Treatment

Many state mental hospitals suffer from chronic underfunding that may undermine their ability to deliver effective care and treatment, the very function for which they exist. Although psychotropic medication has become the treatment of choice for the major mental illnesses, other forms of treatment are needed to prepare patients for discharge and the resumption of life within the community with a high level of functioning. These include psychotherapy and other verbal approaches, behavioral therapy, occupational therapy, and social skills training. Psychotropic drugs should be used in conjunction with these other forms of treatment, not as an exclusive therapeutic intervention. Inadequate staffing and funding at many mental institutions, however, sometimes prevents this from occurring.

Can patients assert a right to more treatment than the hospital is delivering? Such a right to treatment is inherent in the fairness principles embodied in notions of due process and is supported by the often vaguely worded statutory right to treatment that state law typically protects. Due process requires a reasonable relationship between the nature and duration of commitment and its purposes. The purposes of commitment are to protect the best interests of patients who are incompetent to make hospitalization and treatment decisions for themselves or to protect the community from the patient's potential dangerousness. Although confinement alone might seem to satisfy this latter purpose, when those with mental illness who are predicted to be dangerous are confined in a mental hospital rather than a prison or a preventive detention facility, the rationale for hospitalization would seem to be the promise of treatment for mental illness designed to reduce the risk of dangerousness. Otherwise, the deprivations and stigma associated with hospitalization would be unnecessary and hence arbitrary, in violation of due process. If treatment can reduce the patient's dangerousness, it may reduce or eliminate the need for further hospitalization, thereby making hospitalization without the provision of such treatment an unnecessary and arbitrary deprivation of liberty. When commitment is justified on parens patriae grounds, the asserted justification is that hospitalization will provide treatment that is necessary to ameliorate the patient's condition that he or she would not choose for himself or herself as a result of his or her incompetency. If the hospital fails to provide adequate treatment tailored to the patient's needs, it would constitute an arbitrary deprivation of liberty in violation of due process.

Several lower federal courts have recognized that patients involuntarily committed have a legally enforceable right to adequate treatment grounded in due process and that hospitals may be mandated to provide needed treatment and services. The U.S. Supreme Court, however, has not gone this far. The Court has recognized that when hospitals fail to provide adequate treatment, it results in an unjustified infringement on liberty for patients who can survive safely in the community. In a case involving an institution for those with mental retardation, the Court recognized that residents have a due process right to minimally adequate facilities, reasonable habilitation and training, and freedom from undue restraint.

Whatever the basis of their hospitalization, depriving patients of the treatment needed to restore them to a degree of functioning that will allow return to community life consistent with their safety and that of the public would render hospitalization an unjustified deprivation of liberty. It also could exacerbate their mental illness in ways that require lengthier hospitalization than otherwise would be needed. Without the provision of needed treatment that could ameliorate suffering and restore functioning, detention in a hospital, with all its deprivations and stigmatization, would seem unnecessary, purposeless, and arbitrary. The massive curtailment of liberty that psychiatric hospitalization imposes can only be justified if such hospitalization is beneficial, and not harmful, to the mental health of those subjected to it. Hospitalization without adequate treatment, therefore, violates the essentials of due process.

Right to Refuse Treatment

Although treatment is an essential purpose of hospitalization, certain treatments delivered in the hospital, notably psychotropic medication and electroconvulsive therapy (ECT), are intrusive and impose direct effects and side effects that many patients find highly unpleasant and debilitating. Can patients refuse these

interventions? Courts and legislatures have accorded patients a qualified right to do so, imposing limitations on the involuntary administration of these treatments.

Psychotropic medication and ECT intrude powerfully and directly into mental processes, bodily integrity, and individual autonomy and, therefore, should be justified only on a showing of compelling necessity. To be imposed involuntarily, they must be medically appropriate and the least intrusive means of accomplishing one or more compelling governmental interests. This standard would be satisfied if treatment were necessary to protect other patients or hospital staff from the patient's dangerousness, but only if less intrusive alternatives, such as seclusion and restraint, would not achieve this purpose. When the state's parens patriae power to protect those whose mental illness renders them incompetent to protect themselves serves as the justification for their hospitalization, this standard also may be satisfied. Many patients with severe mental illness, however, are competent to make treatment decisions. Unless they have been determined to be incompetent to do so, they should participate in treatment decisions and their informed consent should be required. When patients seek to refuse unwanted treatment within the hospital, procedural due process will require a hearing to determine whether the justifications for imposing treatment involuntarily are satisfied.

Communication and Visitation Rights

State statutes typically protect a patient's right to communicate with others. These statutes effectuate the patient's First Amendment right to communicate with those outside the institution. The institution may place reasonable time, place, and manner restrictions on communication and visitation, but it should not be unduly restricted. Patients should enjoy a broad right to freely communicate with and receive visitation from counsel, judges, the press, and friends and relatives.

Free and open communication between patients and the outside world serves as important First Amendment interests, including the deterrence and exposure of institutional abuse. Moreover, free expression has considerable therapeutic value. By continuing the patient's ties to family and friends, it also will facilitate the patient's reentry into the community and the successful resumption of community life.

Right to Be Free of Unreasonable Seclusion and Restraint

Physical restraint and seclusion are standard measures used by hospitals to protect the patient and other patients and staff within the institution from a patient who is dangerous to self or others. Psychotropic medication also sometimes is used for this purpose. All these constitute an additional deprivation of liberty protected by the due process clause, and as a result, they may not be used arbitrarily and must be justified. They should be limited to emergency situations when other measures have failed to prevent serious and imminent harm. Moreover, as clinical tools, these techniques must be medically appropriate for the patient and should not be used as punishment, for the convenience of staff, or to ease hospital administration.

State civil commitment statutes typically contain protections against unreasonable or arbitrary use of these techniques, and regulations of the U.S. Department of Health and Human Services, applicable to all state and local facilities that accept federal funding, limit their use to emergency situations needed to ensure the patient's physical safety when less restrictive interventions have been determined to be ineffective. Because all these techniques involve serious intrusions on liberty, the least restrictive alternative principle of constitutional adjudication applies. Under this principle, all feasible alternatives to these intrusive techniques should first be attempted. Hospital staff should receive training in these alternative methods of containing the risk of violence and should be required to document in the patient's record the various approaches attempted. When other approaches have not succeeded and violence appears imminent, then seclusion, restraint, or medication may be considered, but the patient should be given the opportunity to choose the alternative he or she finds less intrusive and more acceptable. A good way to obtain patient preferences in this regard is through the use of advance directive instruments.

Because these techniques infringe on liberty, they also trigger procedural due process requirements. When time permits, patients should be given notice and at least an informal hearing concerning the need for these measures. When an emergency requires immediate action, however, alternative administrative safeguards should be used in lieu of a hearing, including detailed entries in the patient's chart, authorization by medical staff, and administrative review by a

physician or hospital administrator. Standing orders for these techniques are inappropriate; they should be applied only on an as-needed basis when less restrictive alternative possibilities have proven unsuccessful. The treating physician should be consulted as soon as practicable if such an order is issued by another staff member; the physician should review the medical necessity of such an approach within 1 hour of its imposition; and the duration of the use of these approaches should be sharply limited. Department of Health and Human Services regulations impose these and additional restrictions on the use of seclusion and restraint.

Therapeutic Jurisprudence Perspectives on a Patient's Rights

Recognition that patients have various rights within the institution, including, for example, the right to refuse treatment, gives the patient a choice of whether to exercise the right in question or to refrain from doing so. A patient possessing the right to refuse treatment may decline to exercise it and instead to accept treatment. If so, this choice in favor of treatment has psychological value. It constitutes goal setting and engages positive expectancies that can become self-fulfilling prophecies that set in motion psychological forces that help to bring about goal achievement. Choice provides a measure of intrinsic rather than extrinsic motivation, an important ingredient in goal achievement. Coerced treatment, in contrast, can encourage resentment, anger, and oppositional behavior. According patients the right to refuse treatment thus can have important therapeutic value.

Therapeutic jurisprudence considerations also support the protection of other rights of patients within the institution. The protection of such rights constitutes an important measure of respect for patients' dignity and personhood. When these basic rights are not respected, patients will feel demoralized and dehumanized and will likely experience a diminished sense of self-efficacy. Recognizing that patients within the institution continue to have rights that they can exercise allows patients to retain an important measure of self-determination and to exercise a degree of autonomous decision making that itself is healthy and can help facilitate their recovery. Denying patients these rights or failing to take their rights seriously can have the effect of depriving them of these opportunities for self-determination, impair their functioning, diminish motivation, and produce feelings of depression and in some cases a form of institutional dependency.

Pedophilia

Pedophilia, a sexual preference for prepubescent children, appears early in life, is stable over time, and directs the person's sexuality with regard to thoughts, fantasies, urges, arousal, and behavior. Pedophilia can be diagnosed on the basis of self-report, sexual history, and (among men) penile responses. These indicators of pedophilia predict sexual recidivism among male sex offenders. There is accumulating evidence that pedophilia is a neurodevelopmental disorder. Different treatment approaches for pedophilia have been evaluated but with only mixed success.

Definition

Pedophilia is defined as a sexual preference for prepubescent children, reflected in the person's sexual thoughts, fantasies, urges, arousal, and behavior. There are three key features in this definition: (1) the sexual interest is persistent, so individuals who have occasionally fantasized about sex with a prepubescent child or who have engaged in sexual contact with a child are not necessarily pedophiles; (2) the persons of interest are prepubescent and thus show few or no signs of secondary sexual development; and (3) the person would sexually choose children even when adult partners are available. Individuals who seek sexual contacts with

sexually mature minors are unlikely to be pedophiles, though they may be engaging in illegal behavior given a jurisdiction's legally defined age of sexual consent.

Pedophilia is probably the best-understood paraphilia, given society's concerns about preventing children from becoming victims of sexual offenses. Pedophilia is an important motivation for sexual offending against children, but the two concepts are not synonymous: Some pedophiles have no known history of sexual contacts with children, and perhaps half the sex offenders against children are pedophiles.

Most of what we know about pedophilia is based on research on adult males and samples recruited in clinical or correctional settings. We know little about female pedophiles, though some women meet the diagnostic criteria, and we know relatively little about pedophiles who are not involved in clinical services or who have not been criminally charged for sexual offenses involving children. Pedophiles are much more likely to be male; otherwise, pedophiles are a heterogeneous group with regard to characteristics such as education level, occupation, and socioeconomic status. The prevalence of pedophilia in the general population is not known because epidemiological surveys of sexuality have not included the pertinent questions about the frequency and intensity of sexual thoughts, fantasies, urges, arousal, or behavior regarding prepubescent children.

Assessment and Diagnosis

Pedophilia can be diagnosed on the basis of self-report, sexual history, and penile responses. Self-report is the simplest and most direct source of information, but it is limited by individuals being reluctant to admit to pedophilia. Among sex offenders, pedophilia is positively associated with having boy victims, multiple child victims, younger child victims, or unrelated child victims and the possession of child pornography and is negatively associated with the number of adult sexual partners. One of the most consistent assessment research findings is that pedophilic men (such as sex offenders with many unrelated child victims) can be distinguished from other men in their penile responses when presented with sexual stimuli depicting children or adults during phallometric testing.

Phallometric testing involves the recording of changes in penile circumference or volume as men are presented with audiotaped or visual stimuli. Penile responses are more specific to sexual arousal than other psychophysiological parameters such as skin conductance, heart rate, and pupil dilation. For pedophilia, the measure of interest is how much a man responds to stimuli depicting children compared with stimuli depicting adults. Because the overall penile responsivity can vary for many reasons, including the man's age and health and the amount of time since he last ejaculated, an index of relative response is more informative than absolute responses. For example, interpreting the responses of an individual who exhibits a 10-mm increase in penile circumference in response to pictures of children is possible only when we know whether he exhibits a 5-or a 20-mm increase, for example, in response to pictures of adults. The first set of responses is from someone who is more sexually aroused by children than by adults, indicating a sexual preference for children; the second pattern of responses is from someone who is more sexually aroused by adults than by children, indicating a sexual preference for adults.

Using cutoff values that produce high specificity among nonpedophilic men (e.g., community volunteers, offenders who have committed only nonsexual crimes), the sensitivity of phallometric testing among men who deny pedophilia is approximately 60% using optimal procedures and stimuli. The sensitivity is approximately 90% among men who admit pedophilia. Specificity refers to the proportion of nonpedophilic men identified as such by the phallometric test, while sensitivity refers to the proportion of sex offenders against children who are identified as pedophilic. Phallometrically assessed sexual arousal by children is one of the strongest single predictors of sexual recidivism in quantitative reviews of sex offender follow-up research.

Studies have also shown that pedophiles and sex offenders with child victims can be distinguished from other men in the unobtrusively recorded amount of time they look at pictures of children relative to pictures of adults. No studies have yet demonstrated, however, that viewing-time measures predict sexual recidivism.

There are challenges in making the diagnosis of pedophilia. The *Diagnostic and Statistical Manual* (fourth edition, text revision; *DSM-IV-TR*) diagnostic criteria have not been rigorously evaluated for interrater or test-retest reliability, and different assessment methods may identify overlapping but nonidentical groups of men as pedophiles. In addition, many phallometric

laboratories do not use validated procedures and stimulus sets. Diagnosis is more likely to be reliable and more valid when assessment procedures are standardized. For example, sexual history variables that are associated with pedophilia can be combined to create a short, easy-to-score scale that organizes diagnostic decisions on the basis of these variables (Screening Scale for Pedophilic Interests).

Development

Pedophilia can be described as a sexual preference that is phenomenologically similar to heterosexual or homosexual orientation, in that it emerges prior to or during puberty; is stable over time; and directs the person's sexuality in terms of his thoughts, fantasies, urges, arousal, and behavior. Retrospective studies indicate that some adult sex offenders admit to pedophilia when they were adolescents, and the average age of onset of paraphilic behavior among adolescent sex offenders is around 11 or 12 years. Some pedophiles have reported being aware of their sexual interest in children from a very early age, just as other individuals report being aware of their opposite-sex or same-sex attractions early in life.

Risk Assessment

All other things being equal, pedophilic sex offenders are more likely to sexually re-offend than nonpedophilic sex offenders. There is an interaction between pedophilia and antisocial tendencies; offenders who score higher on measures of both factors are much more likely to sexually re-offend than others. Reflecting the importance of pedophilia in the prediction of sex offender recidivism, many of the actuarial risk scales developed for adult sex offenders include variables that pertain to pedophilia (e.g., phallometrically assessed sexual arousal by children, having boy victims). Examples of these scales include the Sex Offender Risk Appraisal Guide, STATIC–99, and Rapid Risk Assessment for Sexual Offense Recidivism.

A recent study found that child pornography offenders with no known history of sexual contacts with children are significantly more likely than men who have sexually offended against children to be identified as pedophilic on the basis of their phallometric responses. This suggests that pedophilia may not be a sufficient factor to explain the *onset* of sexual offending against children. Antisocial tendencies are also expected to play an important role, but research on the onset (vs. maintenance) of sexual offending is only just beginning.

Etiology

There is accumulating evidence that pedophilia is a neurodevelopmental disorder. Recent studies have shown that pedophilic men score lower on measures of intelligence and other cognitive abilities than nonpedophilic men. In addition, pedophilic men are significantly more likely to have incurred head injuries before age 13 and differ by having less white-matter volume in two tracts that are thought to connect areas of the brain involved in the identification of visual stimuli as sexually relevant.

Other research has confirmed the common belief that many sex offenders against children have themselves been victims of sexual abuse as children. Meta-analytic reviews have found that adolescent sex offenders have almost five times the odds of having been sexually abused than other adolescent offenders, while adult sex offenders have almost three times the odds of having such a history. These significant differences are obtained whether the analysis is restricted to studies based on self-report or studies based on other sources of information. Moreover, sex offenders with child victims are more likely to have been sexually abused than offenders with peer or adult victims; adult sex offenders who report having been sexually abused are more likely to admit being sexually aroused by children; and adolescent sex offenders who were sexually abused showed relatively greater sexual arousal by children, when assessed phallometrically, than those who were not abused.

The mechanisms underlying this association between childhood sexual abuse and sexual offending against children are not known. Possibilities include imitation of the perpetrator's behavior, disruption of emotional and sexual development, and familial transmission of predisposition(s) for sexual offending (because many incidents of child sexual abuse are committed by relatives). The large majority of sexually abused children do not go on to offend, so there must be individual differences in vulnerability. The most obvious candidate for a vulnerability factor is being male, because most sex offenders against children are male, yet the majority of child victims of sexual abuse are female. Other writers have suggested that other vulnerabilities include

poor parent-child attachment, social skills deficits, and emotional regulation problems.

Comorbidity

Pedophilia co-occurs with other paraphilias, such that the prevalence of paraphilias is higher in a sample of pedophiles than in the general population. Two studies suggest that approximately one in six pedophiles has engaged in exhibitionistic behavior, and approximately one in five pedophiles has engaged in voyeuristic behavior. Comorbidity of paraphilias has implications for risk assessment and intervention because evidence of any paraphilic behavior is significantly related to sexual recidivism, and treatment may need to target multiple paraphilias. This comorbidity also has implications for etiological theories because it suggests that the factors influencing the development of one paraphilia may also influence the development of other paraphilias. One implication of the neurodevelopmental research mentioned earlier is that the nature, location, and timing of perturbations (e.g., maternal malnutrition, illness, exposure to toxins) might determine which paraphilias emerge.

Treatment

The most common approaches to the treatment of pedophilia involve arousal conditioning, pharmacological sex drive reduction, or cognitive-behavioral treatments designed to teach pedophilic sex offenders how to identify risky situations and other situational triggers that they can avoid or cope with in order to avoid sexual contacts with children. The evidence regarding these approaches is not strong, however. Many clinicians and investigators assume that pedophilia is a sexual disorder that can be managed but not changed.

There is evidence that aversive conditioning is effective in reducing sexual arousal by children, but it is unclear how long such changes can be maintained once the conditioning sessions have stopped. It is likely that booster sessions are required to maintain any treatment gains. The changes in sexual arousal by children are unlikely to represent a change in pedophilia; instead, participants learn to voluntarily control their sexual arousal in the laboratory. The hope is that this voluntary control can generalize outside the laboratory.

Several randomized clinical trials suggest that some medications can reduce sex drive and subsequently reduce the frequency or intensity of sexual thoughts, fantasies, urges, arousal, and behavior. Surgical castration can also reduce sex drive. Treatment attrition and compliance are serious issues in the drug treatment of pedophilic sex offenders, however, and castration is controversial; it has not been demonstrated that reduced sex drive leads to reductions in recidivism.

There is much debate as well about the efficacy of cognitive-behavioral treatments for pedophilic sex offenders. A recent meta-analysis of sex offender treatment-outcome studies suggested that such treatments are indeed effective, because there was a significant difference between sex offenders in treatment versus those in comparison conditions; however, the methodologically strongest study, California's Sex Offender Treatment and Evaluation Project (SOTEP), found no significant difference between sex offenders randomly assigned to treatment or to a control condition. There was a nonsignificant trend for those who victimized children to be more likely to re-offend after treatment (22% of treated offenders and 17% of controls). In light of these discouraging results, innovative treatment approaches and rigorous evaluations are needed if we are to make advances in the treatment of pedophilia.

Personal Injury and Emotional Distress

Personal injury and emotional distress claims are civil court matters in which psychologists may become involved in several ways. A claim of psychological injury or emotional distress resulting from the intentional or reckless actions of another sets in motion the collection of data to buttress or refute the claim. Treatment providers, whose interventions occur in a helping context, may offer an opinion to the court about the nature, causation, and consequences of the psychological injury. A more objective, investigatory, and wide-ranging investigation offers greater utility to the fact finder, however, and this is the primary contribution of the forensic psychologist in court. This examination may be accomplished at the request of the plaintiff's or the defendant's counsel, and it is characterized by multiple sources and methods of data collection, reliance on reliable and valid measures and techniques, and respect for the limits of psychological expertise in determining matters of interest to the law.

Context

Personal injury claims (also known as tort claims) are made in civil court when one party, usually an individual (the *plaintiff*), seeks compensation from another party, an individual, a corporation, or an agency (the *defendant*), for an injury allegedly suffered because of the negligent act of the defendant. This process of tort litigation exists to make whole again those who are damaged by the willful action of another. This allows society to protect its members from exploitation by others' intentional actions or their failure to take reasonable steps to avoid doing harm. The legal system is called on to first determine whether the defendant had a duty of some sort to the plaintiff. Second, the legal system must determine whether the duty was breached—that is, whether the defendant failed to fulfill its responsibility to the plaintiff. Third, the court must determine whether the plaintiff was harmed by the breach of responsibility. Fourth, the court must determine whether that harm suffered by the plaintiff was reasonably foreseeable—that is, whether the defendant knew, or should have known, that by its negligent action the plaintiff was likely to suffer damage.

Different categories of personal injury or tort litigation include claims against providers of professional services (malpractice cases); claims against employers for discriminatory hiring processes, negligent treatment, workplace harassment, or physical injury on the job (including workers' compensation cases); and claims against manufacturers or suppliers of products (product liability cases). Claims may be made directly by an injured individual or on behalf of an injured dependant, including a child or an adult who lacks competency to manage personal affairs. Suits may be brought on behalf of groups or classes of people, such as all people who received certain services from a provider or all people who purchased a defective product; these are referred to as class action suits. If the class of plaintiffs prevails, the awards are split, after payment of attorneys' fees, among the plaintiffs.

Psychologists' Role

Psychologists may become involved in personal injury claims at any of several points. The most common application in forensic psychology is when the plaintiff claims mental health injury beyond that which would normally be expected to occur under the alleged circumstances. The plaintiff generally offers expert testimony to support that claim. The treating mental health professional's testimony may be offered, by affidavit or in person, to support the claim that the plaintiff has suffered psychological injury. On notice of this offer, the defendant may seek to have its own expert examine the plaintiff, which is often referred to as an independent medical examination (IME). Whether or not the plaintiff intends to offer expert testimony to buttress a claim of mental anguish or other psychological injury, the claim itself is often sufficient to trigger a compelled mental health examination.

The forensic psychologist retained by the plaintiff or the defense conducts a comprehensive examination of the plaintiff to determine whether there is clinical evidence of psychological injury and what data exist to support or refute the claim that that injury was caused by the alleged wrong. This examination, when

sought by the defense, may be resisted on the ground that it will further traumatize the plaintiff or that it is unnecessary because the defendant can probe the same areas of inquiry through cross-examination of the plaintiff's treating experts. However, there are often limitations to the information that can be derived from treatment professionals, and forensic examination may make a significant contribution to the fact finder's deliberation.

The treating professional may accept the plaintiff's reports with less scrutiny, may not seek verification or refutation of reported functioning, and may fail to explore other potential contributors. In contrast, the forensic examiner may develop opinions based on wide-ranging, investigative examination employing multiple data sources and assessment methods. This reliable testimony is useful to the court in establishing causation. Finally, forensic examiners are mindful of the need to stop short when they lack the data to make assertions; clinical practitioners may not fully grasp the implications of offering opinions on matters of causation.

Focus of Examination

To determine whether the plaintiff suffered psychological injury, the forensic psychologist explores the plaintiff's functioning across three periods of time—before, during, and immediately following the alleged event—and then considers how the plaintiff may be expected to function in the future. Of particular interest to the court is whether there will be a need for ongoing mental health treatment and, if so, the type and frequency or duration of that treatment. Other factors or events in the life of the plaintiff may have contributed to the changes in psychological functioning or may account for the plaintiff's future need for treatment. If it is found that the plaintiff was significantly psychologically injured before the instant event, the psychologist will attempt to determine whether the earlier injury wholly accounts for the plaintiff's present psychological injury. Alternatively, the earlier event may have increased the plaintiff's vulnerability to the present injury. This previously injured plaintiff is sometimes called an "eggshell" plaintiff. It is often difficult to clearly determine the contribution of this psychological vulnerability to the present symptom picture or to future treatment needs. While the law must attempt to make such fine distinctions in causation, psychological expertise can provide only some assistance to the fact finder in the search for causation.

The stress of litigation alone may add to the litigant's suffering. The plaintiff may lack financial resources, while the defense, possibly an insurance company or a large corporation, may be able to afford extended litigation with a team of experts. The plaintiff's counsel may pay for the expertise out of its own pocket or have experts work under a letter of protection, to be paid only if and when the case is settled in the plaintiff's favor. There are potential ethical implications in such arrangements, specifically regarding compromised objectivity, and forensic psychologists decline such engagements. An exception may be warranted when the forensic psychologist is retained as a nontestifying trial consultant whose objectivity will therefore not be relied on by the court.

Informed Consent

When the examination of the plaintiff is compelled rather than voluntarily sought for treatment purposes, the process of informed consent becomes particularly significant. The court order makes the assessment involuntary, so the plaintiff, by definition, cannot "freely and voluntarily consent." The psychologist nevertheless notifies the plaintiff or the authorized legal representative, or both, of the purpose of the assessment, the range of potential consequences, the party responsible for payment for the examiner's time, and the absence of confidentiality in the process.

Observers

The plaintiff may request an observer, such as the attorney, a therapist, or a family member, in the examination. This is especially likely when the plaintiff is a child. In some jurisdictions, the law clearly permits this accompaniment, and the examiner may have limited options to oppose it; in other jurisdictions, the matter of an observer may be decided on a case-by-case basis.

One concern about observation of the examination is that it renders the administration of some instruments a nonstandard administration and may affect the outcome in unknown ways. Some efforts have been made to assess the effects of observers or of audio recording on tests of cognitive functioning, and although there have been mixed results, there appears to be a modest impact on performance in some cognitive domains.

Second, the presence of an observer who has a stake in the outcome may significantly affect the plaintiff's presentation. The plaintiff may be less able to answer

questions honestly or spontaneously when someone else is in the room. The effect of the observer on the outcome may be particularly powerful when the plaintiff is a child and the observer is the therapist or a parent who has a distinct opinion about what happened and how it affected the child. The child may be aware of the parent's or therapist's view and may capitulate to it in any case, but it is possibly more likely to do so when the parent or the therapist is in the room.

Third, observers sometimes have difficulty remaining passive or silent. They may attempt to contribute to the discussion, speaking for the plaintiff. Indirectly, they may telegraph their attitudes to the plaintiff and affect the plaintiff's answers to questions. When multiple interviews occur, observers may intervene between interviews by pointing out to the examinee any problem areas and suggesting alternative answers to questions.

Examiners may, for all of these reasons, object to the presence of an observer or may attempt to structure the observation. This structuring might include, for example, offering to audio or video record the examination (possibly through an observation window) in lieu of having an observer in the room, requesting a neutral observer whose input is limited to ending the interview if the plaintiff seems to be in need of such protection, or seating the observer outside the line of vision of the examiner. Ultimately, however, the court may override these requests in favor of unrestricted observation.

Techniques Used in Personal Injury Assessment

The techniques and instruments that may be useful in personal injury assessment are as varied as the nature of the claimed psychological injury. Often the data collected by the forensic examiner through interview or questionnaires address day-to-day functioning. The examiner may ask for collateral data in the form of documents, records, or interviews with people who would have relevant information about the plaintiff's past and present lifestyle. Information is gathered regarding how the plaintiff lived before, including the interests, activities, and pleasure in life that are reflected in collateral information. Also explored are the plaintiff's coping resources as manifested in the handling of previous crises or trauma.

Testing may include formal assessment of any claimed loss in cognitive function, as well as assessment of general personality functioning, response style, or impression management and in-depth exploration of specific reported symptoms. While there is a proliferation of instruments designed to assess trauma or posttraumatic stress, face validity may render these instruments so vulnerable to dissimulation that their utility is limited for forensic purposes. Similarly, checklists without well-designed measures of response style may generate unreliable results regarding depression or anxiety. Multisource, multimethod assessment accomplished with reliable tools leads to robust psychological findings that are useful to the court.

Report of Findings

Ordinarily, the referring attorney is given the findings of an examination, and then, he or she determines whether they are sufficiently useful to justify calling the psychologist to testify. If the psychologist is designated as a testifying expert, opposing counsel may request a deposition to determine what opinions will be offered and the foundation for those opinions. Personal injury matters are often, but not always, resolved at some point before the case is set for trial. If settlement efforts fail and the case goes to court, the expert may testify to the findings of the examination. The fact finder (generally a jury but sometimes a judge alone) makes the determination about whether the defendant owed a duty, whether that duty was breached, whether the plaintiff was injured as a result of the breach, and what the defendant owes to make the plaintiff whole. This determination may be reached, at least in part, by relying on expert testimony, but the expert does not make the determination. Rather it is a matter for the fact finder to decide.

Personality Disorders

Personality disorders, formerly known as character disorders, make up a class of heterogeneous mental disorders characterized by chronic, maladaptive, and rigid patterns of cognition, affect, and behavior. They are coded on Axis II of the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders*, fourth edition (*DSM-IV*) and reflect patterns of thought, affect, and behavior that deviate from the expectations of a person's culture and impair social and occupational functioning. Some, but not all, cause emotional distress. Personality disorders do not stem from inadequate reactions to acute stress, but rather, they develop gradually and are expressed in adolescence or early adulthood. Many traits associated with personality disorders may be shared by nondisordered individuals. Although the signs and symptoms of personality disorders may describe characteristics that all people exhibit from time to time to a certain extent, a personality disorder is defined by the maladaptive pervasiveness and inflexibility of certain character traits.

Specific Personality Disorders

The *DSM-IV* arranges personality disorders into three clusters on the basis of similarities among the disorders.

Cluster A: Individuals with these disorders often seem odd or eccentric. The symptoms of these disorders are somewhat similar to the less severe symptoms of schizophrenia, especially in its prodromal or residual phases. This cluster includes paranoid, schizoid, and schizotypal personality disorders.

Cluster B: Individuals with these disorders are commonly described as dramatic, impulsive, and erratic. This cluster includes histrionic, narcissistic, antisocial, and borderline personality disorders.

Cluster C: Individuals with these disorders often present as anxious and fearful. It can be difficult to distinguish these personality disorders from the anxiety-based Axis I disorders in some individuals. This cluster includes avoidant, dependent, and obsessive-compulsive personality disorders.

Paranoid Personality Disorder

Individuals with paranoid personality disorder (PPD) are suspicious of others, expecting to be mistreated by others. They expect harm to come to themselves and are sensitive to any evidence of impending attacks, without sufficient basis or without considering alternative explanations. They tend to see themselves as blameless, instead finding fault for their misfortunes in others, and they are likely to look for clues that validate their expectations. They are preoccupied with doubts about the loyalty or trustworthiness of others and are, therefore, unlikely to confide in others. They are hypersensitive in interactions with others, often ascribing pejorative intent to even benign remarks or events. Behaviorally, they are often described as "vigilant," and their interpersonal relationships are marked by hostility. Their internal anxiety is related to their almost constant fear of being harmed by others. They commonly bear grudges and are unlikely to forgive perceived slights, often reacting with anger. Although some individuals diagnosed with PPD exhibit transient psychotic symptoms (e.g., persecutory delusions), they are typically in contact with reality and do not exhibit the perceptual disturbances and cognitive and behavioral disorganization often found in psychoses. Some research has suggested that PPD may be more closely related to delusional disorder than schizophrenia. PPD occurs more frequently in men and is most likely comorbid with schizotypal, avoidant, and borderline personality disorders. Its prevalence rate in the general population is between 2% and 4%, and its prevalence in outpatient psychiatric settings is about 4%.

Schizoid Personality Disorder

Individuals with schizoid personality disorders (SPD) typically exhibit an inability to form social relationships, including relationships with their family, as well as a lack of interest in doing so. The *DSM-IV* criteria for SPD include a pattern of detachment from social relationships and a restricted range of affect in interpersonal settings, as evidenced by at least four of the following characteristics: the individual with SPD neither desires nor enjoys close relationships (including with his or her family); almost always chooses solitary activities; has little or no interest in sexual experiences; takes pleasure in few activities; lacks friends or confidants (except for first-degree relatives); is indifferent to praise or criticism; exhibits emotional detachment, coldness, or flattened affect. Although it was earlier believed that SPD was a precursor to schizophrenia, there has been no strong genetic link found between these two disorders. Research has suggested that there are genetic links between SPD and Asperger syndrome, autism, and pervasive developmental disorder, not otherwise specified. Recent epidemiological studies suggest that the prevalence rate of SPD in the general population is between 1% and 3%, and the prevalence rate in outpatient psychiatric settings is about 1%. The preference for solitude and the lack of general distress in SPD may account for the low prevalence rates in psychiatric populations. Behaviorally, individuals with SPD are often described as "loners" or "lethargic," and interpersonally they desire distance from others. They are likely to feel comfortable with the interpersonal emptiness of their lives.

Schizotypal Personality Disorder

Individuals with schizotypal personality disorder (STPD) typically have odd or peculiar beliefs or appearance accompanied by social and interpersonal deficits. They tend to have cognitive and perceptual disturbances and are eccentric in their communication with others. Like individuals with schizoid personality disorder, those with STPD are socially isolated and withdrawn, but the schizotypal personality also involves oddities of thought, speech, and perception. *DSM-IV* diagnostic criteria for STPD include a pervasive pattern of social and interpersonal deficits marked by acute discomfort with close relationships as well as eccentricities in thought, perceptions, and behavior, as evidenced by at least five of the following: ideas of reference (but not delusions of reference); odd or magical thinking; unusual perceptual experiences; odd thinking and speech; suspiciousness or paranoid thinking; inappropriate or constricted affect; odd, eccentric behavior or appearance; lack of a close friend other than first-degree relatives; and excessive social anxiety that is associated with paranoid fears. Individuals with STPD may present with an erratic or bizarre manner, peculiar speech (vague or overelaborated), ruminative thinking, and atypical perceptual experiences that do not reach the level of psychosis (e.g., illusions). These individuals may report being clairvoyant or telepathic and are likely to be superstitious. Epidemiological studies place prevalence rates in the general population at less than 1% and prevalence rates in outpatient psychiatric settings at less than 1%. Research has suggested a genetic link between STPD and schizophrenic spectrum disorders. Oddities of speech and behavior have been found in children who later develop the disorder.

Histrionic Personality Disorder

Histrionic personality disorder (HPD), formerly called hysterical personality, describes individuals who are overly dramatic, attention seeking, and highly emotional. They are often uncomfortable in situations where they are not the center of attention, and they are likely to exhibit sexually seductive or provocative behavior in their interactions with others. They consistently use their physical appearance (i.e., unusual clothes, makeup, hair color) to draw attention to themselves. They exhibit rapidly shifting, shallow emotions that are often theatrical and exaggerated. Their speech is impressionistic but lacking in detail. They often misinterpret relationships to be more intimate than they actually are, and they are often highly suggestible. They are usually self-centered and can be overconcerned about the approval of others. Behaviorally, they may be seen as seductive, and interpersonally, they tend to have stormy interpersonal relationships. They often are seen as emotionally labile, capricious, and emotionally superficial. HPD has a prevalence rate in the general population of about 2% and is more common among women. It remains unclear whether the differential rate of diagnosis is due to gender bias. Comorbidity with borderline personality disorder is

relatively high. The prevalence rate in outpatient psychiatric settings is about 1%. The lower prevalence rate in psychiatric settings may be due to the culturally adaptive characteristics associated with the symptoms of the disorder.

Narcissistic Personality Disorder

Individuals with narcissistic personality disorder (NPD) have a grandiose view of their own uniqueness or worth, a preoccupation with being admired, a preoccupation with fantasies of success, and a lack of empathy for others. They often present as conceited and boastful, they are self-centered, they have a sense of entitlement, and they have a tendency to try to dominate conversations with others. They, therefore, frequently alienate others, and their lack of empathy makes the creation and maintenance of meaningful relationships difficult. Although they are sensitive to criticism, they present as arrogant and superior as a way of protecting themselves. They are often envious of others or believe that others are envious of them. When their expectations of others are not met, they are likely to react with rage, avoiding shame or dysphoria. Like individuals with borderline personality, those with NPD are likely to vacillate between idealizing and devaluing others, depending on how the other person makes them feel about themselves. Recent epidemiological studies indicate that the prevalence rate of NPD in the general population is less than 1% and that prevalence in outpatient psychiatric populations is about 2%. Some studies suggest that it may be more frequently observed in men than in women.

Antisocial Personality Disorder

Individuals with antisocial personality disorder (ASPD) consistently violate and show disregard for the law or the rights of others. They control or manipulate others without remorse or shame. This pattern of deceit and manipulation begins in childhood or early adolescence and is reflected in at least three of the following *DSM-IV* diagnostic criteria: failure to conform to social norms as indicated by unlawful behaviors; deceitfulness; impulsivity, aggressiveness, and irritability; reckless disregard for the safety of self or others; irresponsibility in work or financial matters; and lack of remorse. Furthermore, a prerequisite for the diagnosis is the presence of conduct disorder prior to age 15. Thus, for a diagnosis of ASPD, not only should there be antisocial behavior, but this pattern of behaviors should have begun in childhood. Historically, the diagnosis was synonymous with psychopathy, but this term has come to have a specific meaning (see below). Behaviorally, antisocial individuals may be described as aggressive and controlling, and interpersonally, they manipulate others through deceit or coercion. Antisocial individuals are likely to take risks, break laws, and seek excitement and sensation. They fail to plan ahead, as evidenced by impulsive and reckless behaviors. They seldom take responsibility for their behaviors, and they are motivated by their own selfish needs. They lack the responsibility and feelings for others that are required to maintain meaningful long-term relationships and are likely to be occupationally and financially irresponsible. They may be cunning, glib, and socially skilled, thereby hiding their selfish motives from others. They are likely to be easily bored and have a low tolerance for frustration or depression, acting out aggressively in response to negative emotions. Once they have acted out aggressively, they are unlikely to experience remorse for any harm to others. Any overt expression of shame or remorse is likely to be shallow, transient, or insincere. Antisocial individuals are unlikely to seek mental health treatment independently, instead presenting for treatment when coerced by others, especially legal authorities. Epidemiological research suggests that prevalence rates in the general population is about 1% to 4% and prevalence in outpatient psychiatric settings between 3% and 4%. The prevalence is thought to be three times higher in men than in women and much higher among young adults than older adults. Diagnosis is also more common among people of low socioeconomic status. It has been estimated that about 75% of convicted felons meet the diagnostic criteria for ASPD. ASPD is comorbid with a number of other diagnoses, especially substance abuse.

Psychopathy

Although psychopathy is not included in the *DSM-IV*, it is a widely accepted and clearly defined personality disorder supported by a growing body of empirical research. Despite a significant overlap in the diagnostic criteria for antisocial personality disorder, psychopathy remains a distinct disorder. Whereas the diagnosis of antisocial personality disorder focuses primarily on overt behaviors, psychopathy also includes affective and interpersonal deficits. Although the majority of psychopaths would meet the diagnostic criteria for antisocial personality disorder, only a minority of antisocial

individuals would also meet the criteria for psychopathy. The "psychopathic personality" was described by Emil Kraepelin in 1915 while referring to a subgroup of criminals who lacked a sense of morals. In 1941, Hervey Cleckley elaborated the construct through detailed case studies in his groundbreaking book, *The Mask of Sanity.* Cleckley's conceptualization of the psychopathic personality as manipulative, selfish, impulsive, and lacking empathy, remorse, and anxiety has since remained more or less intact. The defining characteristics of psychopathy include a combination of both interpersonal and affective deficits as well as overt antisocial behavior. These two factors were referred to as primary and secondary psychopathy, respectively, and remain at the foundation of modern assessment.

Borderline Personality Disorder

The term *borderline personality* was originally used to refer to individuals who were thought to be on the "border" between neurosis and psychosis. As it is currently defined, however, borderline personality disorder (BPD) is characterized by instability in affect, interpersonal relationships, and self-image, as well as markedly impulsive behavior. Individuals with BPD exhibit serious disturbances in basic identity. As a result of their unstable self-images, they also have highly unstable and intense interpersonal relationships, characterized by alternating between extremes of idealization and devaluation of others. They make desperate efforts to avoid real or imagined abandonment. Borderline individuals commonly have an intolerance for being alone. Their behavioral impulsivity may be in the areas of sex, gambling, spending sprees, substance abuse, reckless driving, or binge eating. Recurrent suicidal behavior is common, including self-mutilation or "cutting" behavior. Suicide attempts or gestures are often clearly manipulative, intended to elicit the response of others. They report chronic feelings of emptiness and often have difficulty controlling inappropriate expressions of anger. They may experience transient stress-related symptoms such as paranoid ideation or severe dissociative symptoms. BPD is one of the most lethal psychiatric disorders, with up to 10% of identified patients completing suicides. Those who successfully suicide are more likely to have comorbid major depressive disorder and/or a family history of substance abuse. Recent studies estimate that prevalence rates in the general population are at about 1% and about 9% in an outpatient psychiatric setting. Women are three times more likely than men to be diagnosed with the disorder. There is an ongoing debate regarding the possibility of gender bias and the power of applying the label of borderline to a female patient. BPD is associated with increased utilization of psychological services and psychopharmacological treatment. Recent research has suggested that the etiology of BPD can be explained by an interaction of genetic/biological and environmental factors. Comorbidity is found with substance abuse, PTSD, eating disorders, mood disorders, and personality disorders from Cluster A.

Avoidant Personality Disorder

Individuals with avoidant personality disorder (AVPD) have a pattern of extreme social inhibition and withdrawal due to the fear of being rejected, embarrassed, or criticized. They often report feelings of inadequacy. Because of their hypersensitivity to criticism and potential rejection, they avoid other people, but, unlike schizoid individuals, they desire interpersonal contact and are often lonely or bored. *DSM-IV* diagnostic criteria include at least four of the following characteristics: avoidance of occupational activities that involve significant interpersonal contact due to a fear of criticism, disapproval, or rejection; unwillingness to get involved in relationships unless certain of being liked; restraint in intimate relationships due to a fear of being shamed or ridiculed; preoccupation with being criticized or rejected in social situations; inhibition in new interpersonal situations due to feelings of inadequacy; view of self as socially inept, unappealing, or inferior; reluctance to take personal risks or engage in new activities that might result in embarrassment. Behaviorally, individuals with AVPD are described as shy and guarded, and although they desire interpersonal relationships, they are unlikely to engage in them. They may present as aloof and apprehensive and are likely to make little eye contact. Epidemiological estimates place the prevalence of AVPD at between 2% and 5% in the general population and at about 15% in an outpatient psychiatric setting.

Dependent Personality Disorder

Individuals with dependent personality disorder (DPD), due to a lack of both self-confidence and autonomy, have an intense need to be taken care of. They view themselves as weak and incompetent and others as strong, leading to submissive and clinging behaviors due to an extreme fear of separation. They

cultivate relationships that provide protection and support, and they often defer to others excessively. They often fail to express anger at or disagreement with others for fear of losing their support and love, and they are prone to being involved in psychologically or physically abusive relationships. They often have difficulty making everyday decisions without excessive advice and reassurance from others, and they look for others to assume responsibility for major areas of their lives. They have difficulty initiating projects due to lack of self-confidence in their judgment or abilities. They often will volunteer to do things that are unpleasant in order to obtain nurturance from others. They report feeling uncomfortable or helpless when they are alone due to an exaggerated fear of being incapable of caring for themselves. When a close relationship ends, they often will seek another relationship immediately as a source of support. Current estimates suggest that the prevalence rate of the disorder is 0.5% in the general population and around 1.5% in an outpatient psychiatric population. These data conflict with the *DSM-IV* assertion that DPD is one of the most frequently reported personality disorders encountered in outpatient clinics. Studies on inpatient rates suggest a higher prevalence rate, between 15% and 25%. DPD frequently co-occurs with other personality disorders as well as mood, anxiety, and eating disorders.

Obsessive-Compulsive Personality Disorder

Individuals with obsessive-compulsive disorder (OCPD) exhibit a pervasive pattern of perfectionism, orderliness, and control that interferes with flexibility, efficiency, task completion, and social interactions. Such individuals are often driven to maintain mental and interpersonal control through their preoccupation with details, lists, schedules, and rules. Their perfectionism interferes with their ability to complete a task because they believe that they cannot meet their overly strict standards. Although they are excessively devoted to work to the exclusion of leisure activities and friendships, they often are inefficient in work because they are preoccupied with trivial details. They tend to be inflexible about matters of morality, ethics, or values. Behaviorally, they are often described as stubborn and perfectionist, and they may have difficulty with interpersonal relationships due to their inflexibility. Although it was previously thought that OCPD reflected a predisposition for Axis I obsessive-compulsive disorder, more recent research suggests that OCPD is more highly comorbid with avoidant personality disorder. Prevalence rates in the general population are estimated to be between 2% and 8% and between 8% and 9% in an outpatient psychiatric setting.

Categorical Versus Dimensional Approaches

One of the most controversial topics in psychopathology over the past few decades has been the classification of personality disorders. The categorical model (e.g., *DSM*) assumes that personality disorders can be defined by a relatively small number of "disorders" or "types" that are essentially orthogonal. Each disorder has a specific set of symptoms and signs, and individuals within each diagnostic category are presumed to make up a homogeneous group. Dimensional approaches would replace the categorical classification now in use with a recognition that mental disorders lie on a continuum with mildly disturbed and normal behavior rather than being qualitatively distinct. Personality disorders, therefore, could be regarded as extreme variants of common personality characteristics, and personality disorder symptoms could be described in terms of relative standing on a number of traits. Personality disorders were first placed on a separate axis in the *DSM* in 1980, based primarily on the expert opinions of *DSM* work group members and without strong empirical evidence that these disorders existed with discrete and distinct clinical features. Later researchers have argued that the categorical classification approach of the *DSM* is inadequate. For example, they point to high levels of comorbidity; many individuals meet the diagnostic criteria for more than one personality disorder or for a personality disorder and an Axis I disorder. Work continues on the development of dimensional models (e.g., the five-factor model). Nonetheless, until a unified system of classification is developed and agreed on, the categorical system employed by the *DSM* will be the mostly widely-used by clinicians.

Plea Bargaining

Plea bargaining is a process in a criminal case whereby the defendant agrees with the prosecutor to plead guilty (or no contest) in exchange for a reduction in charges or a reduction of sentence. By pleading guilty, the defendant gives up the right to go to trial. Contrary to the widespread belief that criminal cases are usually resolved through jury trials, in reality as many as 95% of criminal cases are handled by plea bargaining. This bargaining process has been viewed by some as a rational one in which the participants take into account both the probability of conviction and the likely sentence if the defendant were to be found guilty at trial; the participants arrive at a bargain that is fair to both sides. Critics of plea bargaining have focused on the flaws in the system that distort the process, such as heavy case loads, which cause prosecutors or public defenders to favor plea bargains over trials in almost all circumstances, regardless of the merits of the case. Additional causes for imperfect bargains involve psychological influences that lead to poor decision making. In spite of its importance to the criminal justice system, only a limited amount of research exists on the topic of plea bargaining.

Decision Theory Approach

Decision theory's concept of value maximization has been used to explain the plea bargaining decisions made by the prosecution and the defense. According to this model, both sides consider both the probability of conviction at trial and the severity of sentence given a jury finding of guilt; multiplying the probability of conviction by the sentence gives one the expected value of going to trial. The desirability of a plea bargain offer is based on its comparison with the expected value of going to trial. For example, consider a case in which, based on the evidence, there was a 50% chance that the jury would find the defendant guilty and, if found guilty, the sentence would be 10 years of imprisonment. The expected value of going to trial would be 5 years (.5 × 10 years). A plea bargain agreement of anything less than 5 years would be a good bargain for the defense, whereas anything over 5 years would be a good bargain for the prosecution. A bargain that would be acceptable to both sides would be close to 5 years. In a perfectly rational world, taking the case to trial and plea bargaining would have the same value, and one might expect the participants to be somewhat indifferent between trial and plea bargain.

Research has shown that plea bargaining participants do, in fact, consider the probability of conviction and the severity of the sentence. Plea bargaining decisions by prosecutors and the defense have been found to be influenced by both variables; however, these two variables alone do not suffice to explain the plea bargaining decisions. Other factors are involved.

Self-Interests of the Bargainers

Certain influences on plea bargaining that are exogenous to the merits of the case affect all the major participants—prosecutor, defense attorney/defendant, and judge. Each of these participants has self-interests outside the merits of the case that might distort the plea bargaining process.

Prosecutors

It has been argued, and there is some empirical support for the idea, that prosecutors favor resolving cases by plea bargaining as opposed to trials. Trials involve a much greater commitment of the prosecutor's time and resources. It has been argued that prosecutors do not have the resources to take any more than a small proportion of their cases to trial; thus, by necessity they must use the more efficient plea bargain to resolve most cases. However, some research has shown that even in districts where the case loads are light, plea bargaining rates remain at the same high level. Even when the case load is low, a prosecutor might prefer not to devote all the time and energy required for a jury trial, particularly given the way prosecutorial performance is evaluated. Prosecutors' reputations are based on their conviction rates. A case in which a defendant pleads guilty as a result of a plea bargain counts as a conviction for the prosecutor. Thus, for the prosecutor, even if a plea-bargained sentence is under the decision theory expected value, from a self-interest standpoint, it is still desirable because it counts as a conviction.

Public Defenders

Defense attorneys may also have certain self-interests that affect their plea bargaining decisions. One type of defense attorney, the public defender, has much in common with the prosecutor. Like prosecutors, public defenders are paid a fixed salary; whether they plea bargain a case or take it to trial has no financial impact on them. Also similar to the prosecutor, many public defenders have large case loads that would be virtually impossible to handle if any more than a limited few went to trial. Plea bargaining is a means of handling these large numbers of cases. Additional pressure on public defenders to plea bargain comes from prosecutors and judges. Due to the extremely large number of cases that public defenders must handle, there is a great deal of contact with prosecutors and judges. The personal relationships that develop as a result of this contact make them particularly vulnerable to pressure. Refusal to plea bargain on the case at hand when that process is desired by the prosecutor and/or the judge might well jeopardize clients in future cases, who might receive harsher treatment in reprisal.

Privately Hired Attorneys

Privately hired defense attorneys also have self-interests that influence their plea bargaining decisions. Prominent defense attorneys with wealthy clients may favor trials over plea bargaining for financial reasons. Attorneys for wealthy clients are paid by the hour, in most cases. The time spent in preparing for a trial and on the trial itself are all billable hours; in contrast, if a case is resolved through plea bargaining, the billable hours are considerably fewer. Taking a case to trial and winning is important to such attorneys for building their reputation as outstanding trial lawyers; such a reputation is crucial for attracting wealthy clients. Other privately hired attorneys may attempt to maximize their financial gain by emphasizing quantity over quality. Many individuals who are charged with crimes have very limited resources; they lack the means to pay an attorney to do all the background work to prepare a case and present it at trial. However, some defense attorneys take on a large number of these cases at a modest fixed rate and then handle the cases very quickly through plea bargaining. Plea bargaining allows this type of attorney to have a profitable practice based on quantity.

Judges

Although most of the actual bargaining goes on between the prosecutor and the defense attorney, the judge plays a significant role. It is the judge who must agree to the terms of the plea bargain; this is particularly true when there has been sentence bargaining as opposed to charge bargaining. As with the other actors in this process, judges may also have self-interest concerns that bias their reactions in the direction of plea bargaining. First, there is the workload issue. Plea bargains are an efficient way to reduce a judge's workload. A second, more subtle issue concerns a judge's reputation. A judge's reputation is harmed when through some judicial error the results of a trial are reversed on appeal. However, when a case is plea bargained, there is no trial and hence no possibility of a judicial trial error. The judge's interest in plea-bargained solutions often results in direct or indirect pressure on the other actors to plea bargain.

Defendant

Obviously the defendant has a self-interest in the way the case is handled; it is his or her freedom that is at stake. However, there are a number of issues that affect a defendant's preference for trial or plea bargain above and beyond the merits of the particular case. There are financial concerns. For those defendants represented by a private attorney, a plea bargain may be seen as a financially less expensive option than the much more costly trial. Furthermore, there may be incarceration time issues above and beyond the potential outcome of a trial. For the defendant who cannot make bail for a relatively minor offense, it is possible that even being found not guilty at trial would result in more jail time than a plea bargain of guilt.

A major concern of critics of plea bargaining is that innocent defendants will plead guilty to a crime that they did not commit. Rather than basing decisions on a rational assessment of the strength of the case and the probability of conviction, defendants base their decisions on faulty information and advice from the actors who are a part of the system. Although it would be extremely difficult to document how frequently innocent individuals actually accept a plea bargain, some experimental research has found that innocent defendants are less likely to agree to a plea bargain than are guilty defendants.

Psychological Influences

In addition to the various ways in which the self-interest of the various actors might distort plea bargaining decisions, a number of psychological influences have been found to distort decision making in any number of situations. For example, how decision alternatives are framed has been found to have a major impact on people's willingness to take risks. It has often been shown that when the decision alternatives are framed in terms of losses, the decision makers become more averse to risk; in contrast, when the alternatives are framed in terms of gains, individuals are more willing to take chances. Consider the case in which a plea bargain of 5 years is being evaluated in light of the probability of conviction at trial of 50%, with a sentence of 10 years. Defendant A is told that if he goes to trial, there is a 50% chance that he will lose an additional 5 years of his life above the plea bargain. In contrast, defendant B is told that if he were to go to trial, there is a 50% chance that he would gain an additional 5 years of his life as compared with the plea bargain. Although both defendants are facing the same situation, Defendant A will plea bargain to avoid the loss, and Defendant B will take the risk of going to trial for the potential gain. Framing can influence defense attorneys and prosecutors as well as defendants.

When people attempt to form judgments in ambiguous situations, they will often start from some anchor point and then make adjustments. If a prosecutor makes an unreasonable initial plea bargain offer of 20 years, which is summarily rejected, it still acts as an anchor against which subsequent bargains are evaluated. A subsequent offer of 10 years that would have been rejected had it been the first offer now becomes desirable when compared with the 20-year anchor. As with framing, anchoring effects influence prosecutors and defense attorneys as well as defendants.

Various types of attributional biases also play a part in plea bargaining. For example, one type of attribution bias that protects us from feelings of vulnerability is unrealistic optimism. Individuals tend to believe that bad things happen to other people but not to them. It would be quite natural for the defendant to believe that if the case were to go to trial, there would be a verdict of not guilty; this bias would be one of the factors causing a defendant to prefer a trial to a plea bargain.

Limitations of Research on Plea Bargaining

It should be noted that our knowledge about plea bargaining is based on an extremely small body of research. In contrast to other topics in psychology and law, such as juror decision making or eyewitness testimony, for which there are literally hundreds of studies, only a handful of studies exist on plea bargaining. It is particularly surprising that the topic of juror decision making has been so heavily researched, since only 5% to 10% of cases are resolved by jury. In addition to the limited number of studies on plea bargaining, much of the research that has been conducted has been poorly controlled. Much of our understanding of plea bargaining is based on interviews or observations of individuals who were available to the researcher as opposed to individuals selected through systematic sampling techniques. Most of the support for psychological influences is based on generalizations from other bargaining situations rather than on plea bargaining situations themselves. Given the centrality of plea bargaining to the criminal justice system, it is imperative that we increase both the quality and the quantity of research on how this process works.

Police as Eyewitnesses

Criminal cases often hinge on the testimony of eyewitnesses; sometimes those eyewitnesses are police officers. Police eyewitnesses perform the same tasks as

civilian eyewitnesses: They provide descriptions to police officers during interviews, attempt to identify perpetrators from lineups, and provide testimony during court trials. Laboratory research, along with evidence from actual court cases, has shown that eyewitness identifications are often unreliable or inaccurate. It is not clear if we can expect the abilities of a police officer as an eyewitness to be better than those of the average citizen. Findings and theories from a variety of psychological disciplines provide several hypotheses about police eyewitness performance, and research that compares police with civilian performance has produced varying results. Surveys indicate that most people believe that police eyewitness reports are more accurate and of better quality than civilian reports. When police eyewitnesses testify in court, the jury may view them as more credible, regardless of whether their identifications are indeed accurate. Psychologists sometimes testify as experts on eyewitness accuracy and face the question whether the police may be a more accurate population of eyewitnesses.

Findings from psychological research on perception and memory do not provide much evidence to support the notion that any one group of adults would perform better at eyewitness tasks. There is little evidence that certain groups of adults are inherently better at recalling and communicating the details of events or recognizing people, although there are some performance differences based on age and some variability in skill among individuals. Although some studies show that training can enhance identification abilities, others do not. Research in the area of expert cognitive processing demonstrates that as people develop domain expertise, they improve their ability to notice important details and filter out useless information. These research findings indicate, perhaps not surprisingly, that police officers may not have innately better memories but, rather, their specialized training and experience may increase their ability to recognize and recall specific details of crime situations.

Theories grounded in social psychology indicate that police eyewitnesses may be less accurate than civilians because of increased internal and external pressures to perform well. This social pressure may be particularly salient for new officers looking to impress their peers and superiors. Officers may unintentionally choose an innocent suspect from a lineup because they trust that their peers have arrested the correct suspect or they are highly motivated to capture the perpetrator. Furthermore, investigators may not use standard eyewitness safeguards with their peers, such as careful interviewing techniques and lineup instructions.

The psychological research that has directly investigated police officers as eyewitnesses provides only inconclusive answers. These studies used a wide variety of methodologies, such as live incidents, video incidents, verbal descriptions, and written descriptions, and compared police officers with a variety of civilian samples, such as college students, teachers, lawyers, and the general public. In these studies, the participants performed tasks such as providing descriptions and/or making identifications after witnessing a mock crime, distinguishing criminal activity from noncriminal activity, matching previously viewed faces with new faces, and performing eyewitness tasks while under stress.

Research comparing the police with civilians as they recall the details of an event sometimes has found that police descriptions are more detailed and accurate. When researchers examined the types of descriptive information the police and civilians provide, they found that the police provide more detail about perpetrators and the crime events. In some studies, the police show a greater tendency to perceive, or misperceive, suspicious or criminal events. Other research found no difference in description accuracy between police officers and civilians. Researchers found no differences in recall ability between police officers and civilians in stressful situations; however, both groups perform better in nonstressful than in stressful conditions. Research investigating eyewitness abilities based on police experience shows that experienced police officers outperform less experienced officers and civilians. In addition, experienced officers tend to provide more crime-specific information, such as details concerning violence and technical information related to the scene, than do newer officers and civilians.

Research tends to show that police officers and civilians are equally accurate when identifying criminal perpetrators from lineups. However, some studies found that police officers tend to misidentify innocent lineup members at greater rates than do civilians. This finding varies with experience, with newer officers making a greater number of incorrect identifications than do experienced officers.

Police officers testify as eyewitnesses in court just as do civilians. Surveys have found that jurors give greater weight to the testimony of witnesses who appear more confident. Some studies indicate that the police tend to have high confidence in their identification accuracy, irrespective of whether they are in fact

correct or incorrect. Because police officers regularly testify in court and may appear more reliable as witnesses, this leaves open the possibility that jurors may weigh the accuracy and importance of police officer identifications above other evidence. When psychologists testify about eyewitness accuracy, they have only these varied results to guide them in the courtroom.

Police Decision Making

Police officers are gatekeepers of the criminal court system and must make a number of critical decisions during their interactions with citizens and in the performance of their duties. To make decisions, officers use normative criteria such as responsibility and blameworthiness as well as pragmatic and efficiency criteria such as the likelihood of conviction, the amount of time and effort needed, and the organizational barriers that may prevent a desired result. Because officers have much legal authority and make many critical decisions that affect citizens' liberty and safety, it is important to understand how officers arrive at their decisions and the societal consequences of these decisions.

This entry examines what criteria police officers use to make these decisions and what community, departmental, and personal factors affect how they interpret situations, interact with citizens, decide when to stop citizens, ask for consent to search, conduct searches, informally warn suspects, arrest suspects, and decide whether suspects are lying during questioning or interrogation. Using schema theory to examine officers' decision frames, this entry discusses racial disparity in police decision making. Much research supports the contention that compared with Caucasians, African Americans are disproportionately stopped, searched, arrested, and subjected to physical force. Cultural stereotypes and organizational policies contribute to this racial disparity. This entry explores this research on racial disparities, particularly with regard to surveillance, the decision to arrest, and the use of force.

Police work traditionally has been reactive and involves responding to citizens' calls when crimes have already been committed and when community peace has been disrupted. Police duties also involve proactive surveillance to detect criminal activity as it is being committed; for example, police officers may patrol areas that have high rates of drug dealing, prostitution, or gang-related crimes and must decide when to intervene and whether to arrest offenders. Similarly, officers may park their car to detect speeders; officers must decide which of the speeders to pull over, whether to give the speeder a ticket, and whether to search citizens or vehicles for possible illegal contraband such as drugs or weapons. Community policing, where police officers are assigned certain neighborhoods to patrol using bikes or walking, is part of proactive police work and has been implemented to prevent criminal activity and to improve the relationship between the police and citizens so that citizens are more likely to report crimes or suspicious activity to the police. Thus, it is important to examine decision making in both proactive and reactive policy work.

Officers' Decision Frames and Response Styles

Researchers have investigated whether police officers have certain operational styles, developed from their general attitudes regarding justice and law enforcement duties, that guide their decisions to arrest. Several studies have examined three overarching response styles: (1) the tough law enforcer, who arrests serious criminals and rule violators; (2) the negotiator, who emphasizes maintaining community peace and often uses mediation and other informal methods to resolve disturbances; and (3) the rule follower, who bases arrest decisions on organizational policies or legal statutes. Research generally has found that officers do not consistently decide whether to arrest on the basis of their operational ideals or overall attitudes. Moreover,

officers have much discretion on how to interpret organizational policies and legal statutes because such policies are difficult to apply consistently to ambiguous situations.

Rather than operational styles that are linked to overall attitudes and personalities, *schema theory* provides a more empirically supported framework to understand how officers make decisions. Schema theory suggests that officers have several possible guiding decision frames about how to investigate incidents, what information is most critical, and what questions should be asked to arrive at a decision. The situational context and characteristics of the incident determine which decision frame is given priority in a specific situation. Two major decision frames are the *normative* frame and the *efficiency* frame. In the normative frame, officers focus on who is responsible for the harm; in the efficiency frame, they focus on whether there is sufficient evidence to obtain a conviction, the repercussions if they do not arrest, and the credibility of the witnesses.

The number of years on the force has been shown to be the only consistent officer characteristic related to arrest decisions. More experienced officers, compared with rookie officers, tend to resolve calls more often without making an arrest, and experienced officers make fewer arrests because they are more likely to assign greater importance to efficiency and pragmatic concerns. Efficiency or pragmatic framing also can explain why officers often arrest mentally ill persons who have not committed crimes but may need involuntary commitment to a mental health hospital. Several interview studies indicate that officers are frustrated by barriers to the mental health system, by the amount of time they spend off the streets and in hospitals trying to obtain an involuntary commitment, and by the hospital staff's releasing individuals back on the streets within a few days of admittance. All these system barriers indicate to the officers that involuntary commitment decisions are neither pragmatic nor efficient decisions.

In proactive community policing duties, college-educated officers may have better performance and achieve greater neighborhood trust of the police. Studies have found that compared with high-school-educated officers, college-educated officers have higher citizen satisfaction ratings, fewer citizen complaints, and higher job performance ratings from their superiors. Based on empirical research, college-educated officers are more likely to be open minded, to have better communication skills, and to be less authoritarian.

Several studies have examined whether African American officers and Caucasian officers differ in their arrest rates, use of force, and other attitudes. Among the findings are that general attitudes toward the job are similar for African American and Caucasian officers. Research has generally found that African American and Caucasian officers do not differ on arrest rates. Only one study, however, has examined whether they differ on the criteria they use to make arrest decisions. Caucasian and African American officers both were more likely to arrest suspects if they were juveniles, visibly intoxicated, or disrespectful toward officers or if the offense was a felony. However, African American officers also considered other criteria that Caucasian officers did not: whether a crime was committed in their presence, the number of bystanders witnessing the encounter, whether the suspect was male, and the length of the officer's time on the job. Recent research has found that African American and Caucasian officers have a similar likelihood of arresting African American suspects, but African American officers are significantly less likely to arrest Caucasian suspects. Thus, racial disparity in arrest rates occurs among both Caucasian and African American officers.

Police Decisions and Racial Disparity

Racial stereotypes are widespread and permeate the media, the schools, the business community, and the criminal justice system. Individuals of all races are aware of negative racial stereotypes—for example, that African Americans are more prone to violence and more likely to be involved in the use and sale of illegal drugs. Even when individual officers are not prejudiced against African Americans or members of other ethnic minorities, these cultural stereotypes affect how police officers perform their duties. Furthermore, in attempting to reduce the distribution of illegal drugs, some studies indicate that police departments place disproportionate resources in areas where there is a high concentration of ethnic minorities. For example, based on a needle exchange survey and ethnographic observations of two open-air drug markets in Seattle, researchers determined the racial composition of dealers who distributed heroin, cocaine, methamphetamine, crack, or ecstasy. In this study, the majority of drug dealers (more than 80%)

who distributed heroin, methamphetamine, or ecstasy were Caucasian; about equal proportions of Caucasians, Latinos, and African Americans sold cocaine; and only in the distribution of crack cocaine were African Americans more frequently dealers (47%) than Caucasians (41%). In comparing the racial composition of dealers with Seattle's police departments arrest data for the sale of these five illicit drugs during the same time period, researchers found that African Americans were disproportionately arrested for drug dealing: 64% of all arrests involved African Americans, 17% involved Caucasians, and 14% involved Latinos. Although only 47% of crack cocaine dealers were African Americans, 79% of those arrested for dealing crack cocaine were African Americans; only 8.6% of arrestees were Caucasians, even though Caucasians comprised 41% of crack cocaine dealers. Similar and significant racial disparity was found for heroin dealers. Two police department mandates contribute to this substantial racial disparity in arrests for drug dealing: greater emphasis on formally arresting crack cocaine dealers than dealers of other illicit drugs and greater surveillance resources in ethnically diverse open-air drug markets. A greater propensity of violence among crack cocaine dealers cannot explain the departments' allocation of resources; arrests of crack dealers were less likely to involve gun seizures than arrests of other illicit drug dealers, and the police department noted that violence was typically not associated with crack dealing at the time of the study. Second, the primarily Caucasian open-air drug market received undersurveillance as determined by the amount of drug and other crime activity, whereas the ethnically diverse open-air market received oversurveillance, and 25 times more arrests were made there. Higher crime rates or a higher number of citizens' complaints cannot explain the police department's oversurveillance of the ethnically diverse market. The racial disparity also cannot be explained by the possibility that Caucasian drug dealing occurs in more private indoor areas. African Americans were more likely to be arrested in both outdoors and indoors areas and also were overrepresented in arrests in both the primarily Caucasian open-air and the ethnically diverse open-air drug markets. Other research also found that African Americans were more likely to be disproportionately arrested for drug possession.

Police officers may follow these organizational mandates to concentrate resources in specific areas, and then the cultural racial stereotype, which may not be a part of conscious awareness, may affect their choice of which drug dealers to arrest. Research does not show that African Americans are more likely to be drug dealers or users, nor does it indicate that African Americans are more likely to be caught because their activity is more visible. Instead, officers follow organizational mandates that increase the chances of perceiving drug dealing by African Americans, and even in primarily Caucasian open-air drug markets, officers' unconscious awareness of cultural stereotypes may direct their attention toward African American dealers. In short, cultural stereotypes may affect officers who are not racially prejudiced.

Much research suggests that young African American and Latino men are more likely to be stopped, given traffic citations, searched or asked for a consent search, arrested, and subjected to officers' use of force than are Caucasian men. Racial profiling, begun during the U.S. government's "war on drugs," is a controversial decision strategy in law enforcement that has reinforced using race as a criterion in law enforcement decisions. The use of racial profiling as a legitimate decision strategy is now being widely questioned. Numerous studies suggest that officers pull over African American drivers less for obvious traffic violations and more on the basis of race (e.g., "driving while black/brown"). Research further does not support that the stopping and subsequently higher rate of searching of minority offenders indicates a higher rate of illegal contraband possession. Thus, minorities compared with Caucasians do not have a higher rate of actual drug possession. Studies have found that minority drivers are not more likely to have illegal drugs or weapons than are Caucasian drivers, and a few studies have found that searched Caucasian drivers are significantly more likely to have illegal contraband than are minority drivers.

Police Decisions on the Use of Force

During questioning of potential suspects, police officers must decide when and how much physical force to use to stop citizens who are perceived as resisting or disrespecting their legal authority. Police departments receive much negative publicity when officers decide to use what the public perceives as excessive force to restrain citizens or when officers incorrectly perceive resistance and use weapons to force citizens to comply. For example, in recent years, media reports have revealed incidents in which officers, using

batons, flashlights, and fists, have beaten citizens who are having seizures because they incorrectly labeled the citizens' actions as unresponsive and resistant. Officers also have used inappropriate force when they misperceived mentally ill persons' actions as disrespectful and unresponsive to their legal authority; media publicity about such incidents has served as an impetus for police departments to develop special units, strategies, and training to improve officers' interactions with mentally ill citizens. It is difficult to examine what situational and officers' characteristics contribute to the use of excessive or incorrect force because individuals cannot agree (except at the most extreme) on what actions constitute excessive force. However, based on surveys completed by police officers, between 13% and 20% of officers reported having observed a fellow officer using considerably more physical force than was necessary or harass a citizen based most likely on his or her race.

Good police performance requires the ability to know when to use any coercive verbal statements or physical actions. Officers may use coercive actions, most of which are verbal, in attempting to get persons to comply with their orders and acknowledge their legitimate legal authority. Studies of the use of force often examine verbal commands and threats as well as physical force, with physical force sometimes ordered from least to more severe. Several studies have found that officers are more likely to arrest and use force against suspects who have a disrespectful demeanor than suspects who are respectful. The influence of suspects' demeanor on arrest and use-of-force decisions cannot be accounted for entirely by disrespectful suspects being more likely to commit crimes during their interactions with officers. Demeanor also receives significant consideration in officers' decisions to take juvenile offenders into custody. Demeanor and citizens' resistance also contribute to officers' use of verbal and physical force. That is, officers are more likely to use verbal or physical force against suspects who resist responding to commands or questions and/or who are more verbally or physically aggressive toward police officers. Studies have determined a relationship between citizens' resistance and officers' use of force, but it is unclear how often officers use verbal threats or physical force against nonresisting and respectful citizens.

Research has shown inconsistent findings on whether minority offenders are more likely to resist answering officers' questions or complying with commands and to use verbal or physical aggression against officers. Given the mixed results, the racial disparity in the use of force against minority offenders cannot be explained by offenders' propensity to resist or use verbal or physical aggression.

Several situational characteristics are related to officers' use of force. Officers have indicated that departmental policies concerning use of force affect their decisions to use force. In addition, studies have found that officers are more likely to use verbal coercion or physical force in situations involving conflict, against intoxicated suspects or offenders who have a weapon, when there is evidence of a crime, when two or more officers are present, when bystanders are not present, and when they are attempting to prevent crime or intervene while a crime is in progress. Officers may be more likely to use force when other officers are present because they have witnesses who can testify that the force was reasonable given the suspect's behavior; similarly, the presence of a greater number of bystanders reduces the likelihood of officers using verbal or physical force, because it increases the chance of witnesses testifying against them. Younger suspects and those of a lower socioeconomic status have a greater chance of both verbal and physical force being used against them. Minorities and male suspects are more likely to experience physical force but are not more likely to experience verbal coercion.

Some officer characteristics are related to the use of force. Officers who have job burnout reported more support for the use of force, reported greater frequency of using force, and were more likely to be independently observed using force. Officers with a greater number of years on the police force are less likely to use verbal or physical force. Compared with officers having only a high school education, officers with a college degree and those with some college experience are less likely to use coercive verbal demands or threats, and officers with a college degree are less likely to use physical force.

Police Decision Making and Domestic Violence

All states have enacted mandatory or preferred arrest statutes that require or encourage officers to arrest the batterer in domestic violence incidents when probable cause exists. Mandatory arrest laws still allow officers much choice about when to arrest, because the criteria for whether there is enough evidence to meet the standard of probable cause are ambiguous. Officers use several legal and extralegal criteria to make arrest decisions and also rely on stereotypes to form inferences about specific cases. This entry describes findings from numerous studies that have examined how officers interpret, investigate, and respond to domestic violence situations. A focus on how officers infer and interpret information is important to design effective academy training that addresses the unintentional effects of stereotypes and improves police decision making so that equal protection is provided to all victims of domestic violence. Although research shows that academy training has little effect on police arrest decisions, prior training has not focused on how officers arrive at decisions.

How Officers Think About Domestic Violence

Decision frames are a set of rules about how to make arrest decisions; they guide what questions are asked, what inferences are drawn, and what criteria receive the most consideration in arrest decisions. Decision frames derive from socialization and are connected to officers' values, attitudes, and worldviews. Officers may use three decision frames to investigate and interpret information: legal, normative, and efficiency.

The legal frame assumes that officers apply policies or statutes using only legal criteria and a strict interpretation of the statutes. The legal frame assumes a rational decision maker who does not use attitudes or stereotypes to interpret information. Much research shows that the legal frame is not an accurate portrayal of officers' decision making.

Officers typically give greater consideration to the normative and efficiency frames in asking questions during an investigation and making decisions about arrest. The normative frame emphasizes the following questions: Who is responsible? Was his or her actions justified or not? Using the normative frame, officers examine what happened in the past and evaluate the moral appropriateness of each party's actions and their moral character. In the case of domestic violence, officers using the normative frame would arrest both disputants if the parties are equally blameworthy. However, when the normative frame is used, battered women may be blamed for the violence when they deviate from social gender-biased norms.

Officers using the efficiency frame do not attempt to unravel the past but assess the credibility of each disputant to determine whether an arrest is likely to lead to a successful conviction. To avoid mistakes that cause lawsuits or unfavorable media publicity, they assess the likelihood that each party will commit further violence. In the efficiency frame, officers focus on the present and future ramifications of their decisions and are concerned with how an arrest will affect their time, raises, and promotions. The efficiency frame also allows departmental and system procedures to influence officers' decisions. Officers are less likely to make an arrest if more paperwork is required when a suspect is arrested, and this finding has led to policies that require officers to complete a report irrespective of whether they arrest or do not arrest a suspect. Research has found that arrest rates did not increase after mandatory-arrest state laws were enacted; however, arrest rates increased if the counties had coordinated responses, whereby the prosecutors and courts followed through with certain sanctions for arrested batterers. Research has found that when departmental policy is to arrest both parties when both claim self-defense, officers will follow this policy even when state laws discourage the arrest of both parties.

Research also has found that novice and experienced officers employed different frames for making decisions. In making arrest decisions, novice officers focused on the blameworthiness of each party, whereas experienced officers focused on their ability to substantiate claims and the risk of future violence. The shift from focusing on normative to efficiency issues occurs relatively swiftly, after 1 year of service.

Officers also use stereotypes of domestic violence, social class, mental illness, race, gender, and other salient categories. Stereotypes help officers complete missing information, interpret conflicting stories, and make assumptions about likely outcomes or responses. Research has found that experienced officers considered their stereotypic beliefs about battered women's propensity to use self-defense in arriving at their arrest decision. Moreover, individual officers have different stereotypes about domestic violence, especially regarding how much women provoke the violence or react in self-defense. Officers inferred that men who abused wives who were hallucinating or drunk were less dangerous and that wives were more responsible for the violence, suggesting that stereotypes about mental illness also guide their interpretations when suspects or victims exhibit mental illness. These stereotypes thus affect officers' inferences about the situation and may lead officers to provide unequal protection for victims who have a mental illness or violate social or gender norms.

Criteria Used in Arrest Decisions

Legal criteria that have been found to consistently increase the likelihood of arrest include a disrespectful attitude toward the police, the presence of witnesses, the presence of a weapon, the presence of the perpetrator, and a violation of an order of protection. Officers typically make an arrest only in 20% to 50% of the cases where there is clear evidence of a violation of an order of protection. This finding indicates that officers use their discretion and interpret the dangerousness and risk to the victim in determining whether to make an arrest when a perpetrator has violated an order of protection. Several studies have found that a violation of an order of protection increases the incidence of arrest, but its effect on arrest is no greater than that of other situational criteria.

Several criteria have been inconsistently related to arrest decisions: the suspect's gender or race, victim's or suspect's use of alcohol, marital status of the suspect and the victim, presence of children, presence of injuries, victim's preference for arrest, and suspect's gender. The influence of these criteria depends on other environmental and situational characteristics. For example, research based on police reports found that substance use or the presence of children decreased the likelihood that the batterer would be arrested if the victim was African American but increased the chance of arrest if the victim was Caucasian.

Research has found that arrest rates for cases involving visible injuries vary from 30% to 73% across police departments. Across archival and vignette studies from the early 1980s until 2005, the presence or seriousness of visible injuries is not sufficient to invoke arrests, and its influence on arrest decisions depends on other situational characteristics. For example, visible injuries increased the chance of arrest when the perpetrator is present but had no effect when the perpetrator has fled the scene before the police arrived. Officers also were more likely to use the presence of visible injuries in their arrest decisions when departments had a clear policy to arrest when the victim has injuries or when the jurisdiction had a coordinated response to domestic violence.

The importance of the victim's preference in arrest decisions clearly varies across departments, studies, and cases. Police officers often do not include the victim's preference in the police report even when it is a standard part of the police form, which suggests that it often is not an important criterion. Studies generally find that the victim's preference for arrest has a modest impact, accounting for 4% to 5% of variation in officers' decisions on whether or not to make an arrest. Officers often are not persuaded by the victim's preference for arrest because they think that most victims will drop charges, do not know what they want at that time, or are not providing an honest account of what happened. Officers' stereotypes about battered women and domestic violence also may affect how they interpret the victim's preference for arrest.

Police officers do not provide all battered women with the same protection. Several studies have shown that police officers are less likely to arrest perpetrators who attack women who are drunk or having affairs. Officers who use a normative frame are more likely to arrest the husband if the battered wife is mentally ill because they believe that he is more blameworthy for hitting someone who cannot control her actions. In contrast, officers using an efficiency frame are less likely to make an arrest in this circumstance because

they see the mentally ill wife as less credible and more dangerous. Interview studies have found that police officers are less likely to make an arrest in cases involving minority victims than when Caucasian victims are involved. Thus, the guiding decision frame and stereotypes determine which victims who violate social norms are more likely to receive protection.

Domestic Battery Versus Stranger or Acquaintance Battery

Are officers less likely to arrest perpetrators of intimate partner violence than perpetrators of violence against strangers or acquaintances? Mixed findings from research indicate that this question has not been resolved. Research in the 1980s found that both intimate partner and other violent crimes had similar arrest rates. Research conducted after mandatory arrest statutes were enacted has revealed inconsistent findings. Although several studies found that arrest is less likely to occur in intimate partner battery, these studies did not ensure that domestic and acquaintance battery cases were similar and thus were unable to eliminate alternative explanations. Other research indicates that whether officers treat acquaintance or stranger battery cases and domestic violence cases differently depends on situational characteristics. For example, when the suspect has fled the initial scene, officers are more likely to investigate, find, and arrest stranger or acquaintance batterers than domestic batterers. This bias occurs even though both types of victim request arrest as often and intimate partners are more likely to inform officers where the suspect can be found. Conversely, when the victim is the only witness, as in a typical domestic violence incident, officers are more likely to arrest domestic batterers than stranger or acquaintance batterers. Thus, officers under some circumstances may respond to domestic violence differently than to stranger violence, but further research is needed to obtain a more complete understanding of these circumstances.

Officers' Personal Characteristics and Decision Making

Several studies have investigated how police officers' race and gender shape their interpretation and handling of domestic violence situations. Officers' race has not been shown to influence their decisions. However, men and women officers do have different stereotypes about domestic violence, have different responses, and consider different criteria. Compared with men, women tended to perceive that wives more often acted in self-defense and were more likely to be the only party injured and that husbands had committed intentional and unjustifiable violence. Men were more likely than women to support gender-biased attitudes. Male officers who held gender-biased attitudes were more likely to believe that few cases of domestic violence involved battered women committing violence in self-defense.

Despite these differences in beliefs, male and female rookie officers typically recommended marriage counseling and only in one out of five cases referred the battered woman to a shelter. After probationary status, experienced women officers acted more in accordance with their stereotypic beliefs. Experienced female officers were less likely than males to recommend marriage counseling and more likely to refer battered women to shelters.

Male and female officers, regardless of experience, had similar arrest rates but used different criteria. Both men and women were more likely to arrest when injuries were visible or they perceived that severe future injuries were likely to occur. However, women were less likely to arrest if the battered woman was willing to settle the argument, whereas men did not consider the victim's preference. Thus, through professional socialization, women and men developed similar perceptions about their law enforcement role. However, when women officers had achieved greater job security and could defend their views, they were more likely to act on their different beliefs about domestic violence and received higher satisfaction ratings from victims. Thus, although women officers do not arrest perpetrators more often, they are more likely to provide support and information to victims and are less likely to hold gender-biased attitudes or stereotypes.

Police Interaction With Mentally Ill Individuals

Police calls for service sometimes involve the police interacting with and responding to people with mental illness. The dismantling of state mental hospitals, the changing mentally ill population, the tightening of requirements for receiving mental health support, and the offering of limited psychological services are bringing the police into contact with more people with mental illness. Police-invoked law enforcement, police-invoked order maintenance, citizen-invoked law enforcement, and citizen-invoked order maintenance are four types of police interactions with the mentally ill who violate the law. They involve the police either initiating or responding to a call for service and either enforcing the law or maintaining social order.

How the police employ their work-style attitudes and exercise their discretionary power has an impact on the outcomes of police interactions with people with mental illness. Custodial police decisions are arrest, involuntary emergency evaluation, or involuntary commitment. Noncustodial decisions are counseling, release and referral, or voluntary emergency evaluation. The police are receiving some training in these alternatives for handling people with mental illness. In some contacts with the mentally ill, police agencies that have specially trained mental health crisis teams deploy them to carry out custodial or noncustodial options to resolve police calls for service.

Prevalence and Situational Profile

Researchers have estimated that between 5% and 10% of police-citizen contacts involve people with mental illness. These numbers reflect an increase since the 1960s deinstitutionalization of state psychiatric hospitals that housed the mentally ill, offered them some treatment, kept them safe, and protected the public from the real or perceived danger of coming into contact with them. Overcrowded and poor living conditions, the insensitive treatment of the mentally ill, the economic expense of housing them, the availability of psychotropic medications such as chlorpromazine (Thorazine), the tightening of involuntary commitment procedures, and the creation of community mental health centers were the factors that shaped the deinstitutionalization movement.

The closing of many state psychiatric facilities resulted in the displacement of people with mental illness—from living in locked state warehouses to living in open community settings such as group homes, family residences, halfway houses, nursing homes, and homeless shelters that offer different levels of care. Researchers estimate that 1 of every 10 persons has some form of mental illness and that between 1 and 4 million persons in the United States have a serious mental illness.

Police contacts with the mentally ill often occur in the home. Interactions with them also occur in the streets, at halfway houses, at mental health agencies, and in public buildings. Police encounters are increasing during the night and weekend hours because mental health resources are usually unavailable at such times. Behaviors that the mentally ill frequently demonstrate during their contacts with the police include confusion, unusual or bizarre mannerisms, and aggression. Empirical investigations suggest a link between mental illness and criminal behavior. For example, persons who suffer from bipolar disorder or schizophrenia are more likely to express antisocial behaviors that society criminalizes. Most mentally ill offenders are under the influence of alcohol or drugs when they commit crimes. There is some increased risk of mentally ill individuals becoming violent.

Because many people with mental illness now languish in a variety of community settings with too few mental heath treatment centers available, they routinely

encounter the police when they manifest abnormal behaviors that require police attention.

Types of Police Interactions With the Mentally Ill

The police are responsible for safeguarding the well-being of the community. They fulfill this responsibility by enforcing laws and maintaining social order and, thus, most often respond to persons with mental illness when such persons display behaviors that rise to a level that society criminalizes. Responses may originate from police-invoked law enforcement, police-invoked order maintenance, citizen-invoked law enforcement, or citizen-invoked order maintenance.

Police-invoked law enforcement is a self-initiated response by an officer to a violation of the law by a mentally ill person. The law violation and police department policies and procedures force the officer to make contact with the mentally ill law violator.

Police-invoked order maintenance is also a self-initiated officer contact with a person with mental illness who violates the law. But in this situation, the law-violating behavior is of a less serious kind. It reflects a social order disturbance that tends to be noninjurious to others, such as public drunkenness and vagrancy.

A police call for service that originates from a complaint by a citizen can bring an officer into contact with a person with mental illness. Citizen-invoked law enforcement involves a citizen reporting that a mentally ill person has violated the law. Similarly, citizen-invoked order maintenance also involves a citizen calling for police service, but like police-invoked order maintenance, it involves law-violating behaviors that are of a less serious nature, occur less often, happen at unexpected times, and take place usually in the private homes of citizens (e.g., verbal arguments).

Whether the police are initiating or responding to calls for service or whether they are enforcing laws or maintaining social order, their work-style attitudes and use of discretion have an impact on the way they actually handle situations involving mentally ill individuals.

Police Handling of the Mentally Ill

Not all police-citizen contacts have an absolute set of official rules and procedures on how best to handle them, especially police contacts with the mentally ill whose behaviors amount to some infraction of the law. Although there is some official guidance that stems from the law, policy, training, and supervision, the police have some leeway or discretion in deciding on a response option from a range of possible responses available in a given law-violating police intervention situation. For example, in police-invoked situations with mentally ill law violators, there are no demands by citizens for the police to invoke the law mechanically. The police are free to exercise their work-style attitudes, which include some attitudes toward, perceptions of, and assumptions about people with mental illness. Thus, the mentally ill person who demonstrates public drunkenness is most vulnerable to an officer's discretionary power.

If, for example, the officer holds a legalistic perspective about policing—preoccupied with arresting law violators and performing to the letter of the law, then custodial police options such as arrest, involuntary emergency evaluation, or involuntary commitment are likely outcomes. If, however, the officer uses a problem-solving policing style—concerned about finding permanent solutions to problems, then non-custodial options such as counseling, release, and referral or voluntary emergency evaluation are attractive because they offer the person with mental illness some needed mental health treatment, thereby reducing future police contacts.

Citizen-invoked calls for police service routinely carry with them less opportunity for the police to exercise their discretion. The police concentrate their work effort on responding to citizens' complaints and meeting citizens' needs. For example, a citizen may want an officer to arrest a mentally ill person who assaulted him or her. This situation gives the officer little chance to make a discretionary decision such as suggesting a voluntary emergency mental health evaluation. In a different situation, for example, the citizen may not want to press charges for assault. The officer could make an intervention decision that calls for releasing the offender and making a mental health referral. Normally, though, the officer will choose an option that satisfies both police and citizen interests in citizen-invoked interactions with the mentally ill.

Police Training

Most police officers receive some education and training in the handling of people with mental illness. Basic recruit training hours can range from roughly 0 to 41. Fewer police officers receive continuing education at the in-service level. Among those that do,

some receive information at roll call, and others get it during formal annual blocks of instruction. Training time varies from a recommended 16-hour block devoted to mental illness.

The content of police training varies at both the recruit and the in-service training levels. Sources of training curricula are the agency itself, the state commission on peace officers' standards and training, profit and nonprofit organizations, and local mental health professionals. Police officers or mental health professionals, or both, usually deliver the training. One formal and well-recognized training curriculum developed by the Police Executive Research Forum includes seven learning modules that address police responses to people with mental illness. Generally, police officers learn to recognize their attitudes toward, perceptions of, and assumptions about the mentally ill and to dispel their misconceptions about them. Mental illness is not a crime, and people having mental illness live in their communities, have professional vocations, and call for police services.

The police learn to recognize specific symptoms and forms of mental illness, such as schizophrenia and mood, anxiety, and dissociative and personality disorders. They learn to employ techniques to handle them effectively. For example, an officer encounters a mentally ill person whose speech is high-speed and nonstop and uncontrollable and meaningless. This behavior signals to the officer that the person is in a state of high arousal and has an anxiety disorder. The officer interrupts the person's speech by asking a series of questions—for example, What is your name? How old are you? Where do you live? Where do you work? What the officer expects is to break the person's pattern of compulsive behavior and control it to some extent.

Not all police interactions with the mentally ill require arrests. The police learn both custodial and noncustodial alternatives to respond to people with mental illness whose behaviors amount to some infraction of the law. They learn community, problem-oriented strategies to resolve problems related to the mentally ill. Handling such problems, however, sometimes involves using specialized mental health crisis teams.

Some police agencies report having specially trained teams that respond to calls for service involving mentally ill persons in crisis. Police agencies that employ a team approach generally adopt one of three models: police-based response (only specially trained police officers), police/mental health–based response (both police officers and mental health professionals), or mental-health-based response (only mental health professionals). Current research suggests that most police agencies deploy a team composed of only specially trained police. Despite variations in using particular response teams, team members are receiving the specially needed training to respond to people with mental illness.

Police department policies on contacts with people with mental illness have helped departments standardize the nature of their officers' responses while giving officers flexibility to meet the needs of people with mental illness. Although people who have mental illness may commit a crime, be a victim of crime, or report a crime, police responses to encounters with them have improved with training.

Police Occupational Socialization

Police occupational socialization is the process whereby individuals learn to be fit for performing police work by becoming aware of organizational and occupational practices, internalizing them, and carrying them out as participating members of their work

group. Learning takes place through three social phases: pre-entry, entry, and in-service. This sequence involves individuals making a choice to become a police officer, learning formal and informal lessons during police recruit or academy training, and learning them on the job, respectively.

How officers make sense of these social events affects the way they perceive, influence, and interact with citizens in a law enforcement capacity. At the pre-entry phase, individuals learn about themselves, evaluate their personal qualities by comparing themselves with what they know about the police, and make a decision to become a police officer. During the entry phase, they begin to construct a self-concept that is coherent with what they learn about police roles, activities, and relationships with citizens. They begin to form a social identity about themselves as group members of the police profession. They learn to make social inferences about the citizens they meet. Finally, at the in-service phase, they strengthen and defend their self-concepts and social identity. They learn to conform to organizational and occupational norms so that they can act comfortably within the police culture. Officers develop different work-style attitudes that reflect subjective outlooks that include beliefs and values affecting how they interact with citizens during police-citizen contacts. Police socialization ensures that individuals acquire the necessary knowledge to perform adequately on the job. Understanding the role that thinking or mental processes play during socialization is at the heart of comprehending why officers act the way they do in their occupational settings.

Pre-Entry Phase

Who am I? What do I think of myself? Who is a police officer? What does a police officer do? These questions are a focal point of the pre-entry phase, in which the process of making a choice to become a police officer is a major social psychological paradigm. At the pre-entry phase, individuals explore what they know about themselves (or self-concept) and what they know about the roles and activities of police officers. Individuals piece together some understanding of "who I am" from both self-knowledge and knowledge held by others. They construct self-knowledge from inferring their personal characteristics or qualities from their past behaviors. They use what other people know about them or think about them when forming opinions about themselves.

When constructing knowledge of policing, individuals use factual or fictional perceptions. Friends or relatives who are police officers are factual or genuine sources of learning who is a cop, what characteristics he or she has, and what he or she does on the job. Fictional or imagined perceptions of policing often come from media sources. For example, television or movie cops as portrayed by actors such as Mel Gibson demonstrate characteristics of power, toughness, and aggressiveness. Steady streams of these media images define police officers as being tough, strong, and invulnerable and fitting into a box that defines machismo. Whether real or imagined, these values often become part of "who I must be."

Individuals reason from "who I am" to "who I must be," including knowledge of both the self and the police. They employ four kinds of schemas that help them generate a hypothetical picture about themselves in the police role: a person schema (who is a police officer), a self-schema (who I am), a role schema (what behaviors I expect to perform in a given situation), and an event schema (how the situation will unfold). What explains in part the decision to become a police officer is the perceived discrepancy between "who I am," on the one hand, and "who I must be," on the other: The greater the discrepancy, the higher the probability that individuals will not self-select themselves for law enforcement training.

Individuals who see themselves as trainable and suitable for the job apply for it. Before they become police officers, however, they must pass through a rigorous selection process, which most often includes a written test, a physical agility test, background investigation, a personal interview, a medical exam, and a battery of psychological tests. A police administrator considers applicants who have ideal police characteristics and the ability to perform necessary job functions. The employment decision along with the selection process usually produces a homogeneous group of applicants who demonstrate a willingness to conform to organizational (official) and occupational (both official and unofficial or working) police practices. These police applicants or recruits experience formal socialization when they enter training at the police academy.

Entry Phase

Police recruit training refines the cohort of acceptable applicants through formal and informal lessons that weed out those applicants who do not conform to

established police practices. Formal lessons involve instruction in a training curriculum, which usually includes the subject areas of administration of justice, fitness, law, police procedures, use of force, police professionalism, and community relations. Informal lessons about the job often take the form of war stories told by police academy instructors. Officers begin to learn from instructors and from their peers at the academy about unwritten rules, work attitudes, values, and beliefs of the occupational culture.

During academy training, the prevailing social psychological paradigms are self-concept, social identity, and social inferences. Officers begin to identify with the police subculture by constructing self-concepts that are coherent with what they learn about policing through formal and informal lessons at the academy. They fit into their self-concepts distinct characteristics of the police subculture, such as an ethos of toughness, autonomy, suspiciousness, secrecy, solidarity, and bravery. Officers begin to form a police identity from characteristics that belong uniquely to the police subculture and that they share with other officers. Police identification turns "I" into "we," which extends "who I am." Officers see themselves as members of the police subculture—a process known as self-categorization.

When officers self-categorize themselves, they view out-group members or non–police officers as outsiders (intergroup discrimination). They favor in-group members or police officers (in-group favoritism) because they see themselves as having more in common. The language officers use to refer to out-group members helps create and feed in-group bias. For example, "Let's get the bad guys" or "It's us against them." The in-group/out-group arrangement is implicit when officers use pronouns such as "we" and "they" or "us" and "them." Viewing themselves as part of the police subculture produces feelings of friendship, solidarity, and trust among officers. A cooperative work effort helps them tackle the challenges of contemporary policing.

At times, however, there are costs for expressing in-group favoritism. Officers might see citizens as being the same or interchangeable. For example, an officer says, "They all act alike" when speaking about members of a particular group. In this instance, the officer does not appreciate the diversity of citizens. Putting citizens into an out-group category might lead officers to process information about them differently. For example, an officer legitimizes and defends in-group beliefs and behaviors, whereas he or she marginalizes and attacks out-group ones. Officers who hold and show in-group favoritism have a tendency to accentuate in-group/out-group differences. Citizens know the differential power arrangement of police-citizen interactions. Police power coupled with certain citizen tension sometimes leads citizens to resist the police, especially when officers make evident their "us and them" mentality.

Besides officers learning to hold a worldview of "us" and "them," formal and informal training lessons teach officers to make social inferences about police-citizen interactions. Officers learn to process people and events through a cognitive lens of present danger. For example, an officer uses force against a suspect. The event happens at 1:00 a.m. If one uses the situational cue "time of day" to help explain the officer's behavior, the ecological validity of the model would be poor. Using the cue's natural metric 1:00 a.m. would reduce the accuracy of the explanation because the officer's acquisition of the cue in the force situation was subjectively different. The officer learned to form a scaled impression of 1:00 a.m. in terms of present danger.

Police work involves the possibility of danger all the time. Danger shapes police-training practices. Officers learn to see citizens as potentially uncooperative, armed, and dangerous. They learn that they work in an environment of condition yellow: always occupied with the present danger of people and events. Developing a police worldview through a cognitive lens of present danger is a major social psychological theme at both the recruit and the in-service levels of training.

In-Service Phase

At the in-service phase, integrative expressions of the social and the psychological disciplines emerge. Generally, officers, or now "rookies," reconcile their self-concepts and their social identity. They conform to police norms and develop work-style attitudes.

When rookies graduate from academy training, they usually ride along with field-training (or incumbent) officers who provide on-the-job training. Rookies learn formal lessons such as work-area-relevant information and agency-specific policies and procedures. They learn informal lessons that usually consist of a set of unwritten rules, outlooks, and behaviors such as being "tough" that officers in their agency consider normal and expected in the occupational culture. Field-training officers teach rookies "how it's done here." What lessons rookies learn help

them to reconcile inconsistencies in their self-concepts and social identity, and thus strengthen and defend them.

Formal and informal lessons during the field-training period cause rookie and incumbent officers to become more alike. Rookies conform to police norms or shared rules of conduct that establish in-the-box behaviors that most officers in most police situations accept and expect. Rookies accept a degree of conformity to these norms because they want to feel included and accepted by their peers. They learn quickly that there is a price to pay for acting outside the box. For example, a rookie officer responds with incumbent officers to a service call for disorderly conduct. The incumbent officers endorse values of toughness, aggressiveness, and respect. When the officers arrive, a male suspect becomes verbally abusive toward the rookie. While the rookie officer has a range of verbal skills available to manage this kind of behavior, the officer fears "losing face" and the consequences of outside-the-box behaviors, such as being labeled a "wimp" or "not a real cop." The rookie mixes his or her response choice with ideals of enforcing the law or preserving group norms. Because the incumbent officers endorse toughness, aggressiveness, and respect, the rookie becomes tough and aggressive and uses a forceful response to earn respect where none is necessary. In this way, the rookie meets the expectations of incumbent officers.

Rookie officers learn that police calls for service can be tense and uncertain: Calls sometimes evolve rapidly. Once rookies graduate from their field-training period, they find themselves in a new role, having a degree of autonomy in handling police calls for service, holding a police worldview of danger, having broad discretionary power, and asserting authority to carry out police objectives. To meet the demands of police service, initial changes in their psychological makeup often occur. Rookies develop different personal work-style attitudes that reflect in part their experience and organizational and occupational practices. The content and structure of their attitudes might reflect a professional, tough-cop, clean-beat crime-fighter, problem-solver, or avoider style of policing. For example, the rookie officer who assumes a tough-cop perspective believes that citizens are hostile to the police, holds a police worldview of danger, and carries out an aggressive style of policing to keep safe. Initial changes in rookies' work-style attitudes suggest that they are recognizing and responding to the role demands of a police officer. Although some rookies' work-style attitudes might remain stable throughout their career, others might modify them to cope with changing policing strategies, job functions, calls for service, and subjective outlooks.

Police Psychologists

Over the past four decades, a rapidly growing specialty area of psychology has been that of psychologists working within the realm of law enforcement. Police psychologists are involved in the selection of employees; fitness-for-duty evaluations; various therapeutic programs, both individual and group; the evaluation, treatment, and referral of substance abuse, domestic violence, and gambling; the development and facilitation of various training initiatives; and research and consultation. On a more operational level, police psychologists respond to crisis situations including officer-involved shootings, significant traumatic events, suicide interventions, and crisis and hostage negotiations.

A functional dichotomy within police psychology is that of actual primary roles for the psychologist. Major metropolitan police departments will most likely employ multiple staff police psychologists. Generally speaking, the in-house staff psychologist is involved in day-to-day undertakings within the department, thereby compelling an immersion of his or her professional activities directly within the police environment. This constant exposure to the police culture allows for a more rapid and complete acceptance by departmental police officers, civilian support staff, and the senior-level

command staff. Typically, the staff psychologist acquires confidence and, most important, trust and credibility as a member of the department. Although not often discussed, power, hence professional influence, is of utmost significance for the in-house staff psychologist. Power in this context is operationalized as the individual psychologist's ability to professionally influence administrative and supervisory decisions. Such influence can only be attained via consistent, accurate, and professional consultative recommendations provided by the staff psychologist. Thus, it is imperative that the in-house police psychologist be administratively placed as close to the highest-ranking official in the department, usually the chief/director or sheriff, as possible. In most large departments, given the sensitivity and confidentiality of some situations (e.g., substance abuse or domestic violence), it is best for the staff psychologist to be placed one rung directly below the chief/director or sheriff in the administrative chain of command. Therefore, the in-house police psychologist is usually administratively assigned the position of an assistant/deputy chief or director. This administrative position potentially provides the staff psychologist with extraordinary positive influence within a police organization. However, the staff psychologist must always be cognizant of this fact and limit his or her activities—both professional and casual—with the senior command staff. For if the rank-and-file officers and civilian support employees perceive the in-house psychologist as being too friendly with upper-echelon supervisors, the overall trust for the staff psychologist will be severely compromised. The resulting outcome will be a significant reduction in departmental employees seeking clinical assistance with the professional staff at the psychological services section. As such, the in-house staff psychologist must always be aware of the potential impact of dual or multiple relationships.

A dual or multiple relationship occurs when a psychologist is in a professional role with a person and concurrently is in another role with the same person or when a psychologist is in a relationship with a person closely associated with, or related to, the person with whom the psychologist has the professional relationship. For example, a police psychologist would enter into a multiple relationship if he or she entered into a therapeutic/clinical relationship with the commander of the special response team with whom the staff psychologist regularly consults on tactical operation callouts. Other advantages for the in-house staff psychologist is the ability to be knowledgeable about the unspoken/unwritten rules of the department as well as the various rumors within the organization. With this in mind, the staff psychologist is able to develop a network that can quickly ameliorate conflicts and potential opportunities. Another significant advantage for the in-house staff psychologist is the ability to recognize critical training opportunities and rapidly implement appropriate training blocks. A secondary advantage to the rapid implementation of departmental training is the actual facilitation of the training blocks by the staff psychologist and his or her staff. The facilitation of the didactic block provides the opportunity for the staff psychologist and his or her staff to interact within the safety of the training environment. Often, departmental employees will initiate the scheduling of therapy on meeting the staff psychologist during the training experience.

Other primary responsibilities of the in-house staff psychologist include the provision of direct clinical intervention—usually, short-term therapy, substance abuse intervention, clinical referral, training and consultation, and crisis and hostage negotiation training and consultation. Most likely, the in-house staff psychologist is on call 24 hours a day, 7 days a week for crisis response, including officer-involved shootings and other crises, such as suicide and domestic violence. The latter professional demands of constant on-call responsibilities, including hostage and crisis intervention as well as other posttrauma and critical event responses (e.g., employee trauma and death), compel significant introspection by the psychologist considering the acceptance of the position of internal police psychologist. The constant on-call status itself can be insidiously stressful to the psychologist as well as to his or her family. In addition, it is evident that the vicissitudes of traumatic event response can lead to the dynamic of vicarious traumatization in some police psychologists. Vicarious traumatization occurs as a function of mental health professionals' consistently intervening in traumatic events. As a result of routinely being exposed to the traumatic sequelae of others, the responding psychologist may develop concomitant symptoms, such as social isolation/withdrawal, sleep and appetitive disorders, burnout, and substance abuse.

The other role for psychologists is that of an external consultant, sometimes jocularly referred to as the "out-house" psychologist. The external consultant's primary responsibility is pre-employment screening,

to be discussed in more detail later in this entry. Along with this most demanding responsibility, the external consultant is also responsible for clinical intervention, including crisis intervention, as well as training and consultation. Like the in-house staff psychologist, the external consulting police psychologist should report either directly to the chief/director or sheriff or to the next highest-ranking official in the executive chain of command. Developing a close working relationship with the highest-ranking official in the police chain of command establishes the organizational power and support necessary to effectuate departmental innovations and a more receptive consideration of professional recommendations.

The most glaring disadvantage of the external consulting psychologist is that he or she is frequently perceived as an outsider and is never completely trusted by either the command staff or the rank-and-file sworn officers, as well as the civilian support personnel.

History of Police Psychology

Psychologists began entering the realm of law enforcement during the 1950s and 1960s, when the concept of vicarious liability and negligent retention began to affect the provision of services by police departments. As such, the first role for the burgeoning field of police psychology was to develop psychometric instruments to predict job suitability of police officer candidates. Over the years, pre-employment testing/screening has become a precondition for hiring in the law enforcement selection process. Along with the early psychological testing, the nascent police psychologists consulting within major city departments were tasked with the development of prototypical employee assistance programs for alcohol abuse treatment. However, in some major departments such as San Francisco, Boston, and New York, there was no concomitant intervention for stress/emotional problems other than those related to alcohol. Consequently, many departments, notably those in Boston, New York City, Chicago, Los Angeles County, and Miami, initiated hybrid employee assistance programs known as "stress programs." Following the recommendations of the President's Commission on Law, Law Enforcement and the Administration of Justice (1967), the Los Angeles Police Department hired the first full-time in-house staff psychologist, Martin Reiser, in 1968. Reiser is widely known as the "father of police psychology." In 1971, Mike Roberts was hired as a consulting clinical psychologist for the San Jose Police Department, and so began the dichotomy of the provision of psychological services to law enforcement personnel. Reiser provided services on both a voluntary and a mandatory basis, while Roberts provided therapy solely on a voluntary basis and referred to an external consultant any counseling or testing for which an officer or employee of the department was involuntarily mandated. Today, most mental health professionals agree that voluntary referral is preferable to mandatory referral in that the latter usually raises practical as well as ethical issues and conflicts. In organizations that use mandatory referrals (ostensibly, fitness-for-duty evaluations), external consultants are contracted to provide the clinical services.

In 1973, Harvey Schlossberg became the first policeman to earn a doctoral degree in clinical psychology and become a departmental police psychologist for the New York City Police Department. Later that year, he assisted in successfully negotiating the release of hostages in the "Williamsburg Siege." Soon thereafter, under Schlossberg's direction, the New York City Police Department established the country's first hostage negotiation unit. Today, almost every major department and midsize local municipal agency uses a fully operational tactical and negotiator team with access to either full- or part-time mental health professionals for consultation.

As can be seen, police psychology has evolved into a recognized and robust specialty area within psychology. A contributing factor in the growing popularity and success of police psychology is the willingness of police psychology practitioners to remain actively involved in the dissemination of information through journals, books, and other publications. It should first be noted, however, that the Behavioral Sciences Unit of the Federal Bureau of Investigation (FBI) was instrumental in providing the forum for police psychologists from around the United States to meet and present papers germane to this new field of psychological application. A further energizing force is the networking dynamics of two relatively new professional organizations within the field of police psychology. During the FBI national conferences of 1977 and 1984, these pioneer police psychologists set in motion the establishment of two professional organizations, the Police and Public Safety Psychology Section of Division 18 of the American Psychological Association (APA) (1983) and the Police Psychological Services of the International Association of Chiefs of

Police (IACP) (1986). Some of the more significant applications of this specialty area are discussed in the following sections.

Pre-Employment Selection

Pre-employment selection has been the earliest known usage of psychology in law enforcement. Recent research has concluded that police recruitment selection procedures vary greatly, that there is no standard assessment process, and that there is an extensive variety of test battery composition. In an attempt to provide specific standards and constraints for a process with wide variance, both the Police and Public Safety Psychology Section of Division 18 of the APA and the Police Psychological Services section of the IACP proposed and ratified, via membership vote, a set of guidelines for pre-employment psychological evaluation. These guidelines established that only licensed or certified psychologists trained and experienced in psychological test interpretation and law enforcement psychological assessment techniques should conduct psychological screening for police agencies. Furthermore, police psychologists must adhere to the ethical principles and standards of the APA and all state and federal laws, including the Americans with Disabilities Act. The test battery must include objective, job-related, validated psychological instruments, including a cognitive test. Every test battery must also include an individual face-to-face, semistructured interview.

Fitness-for-Duty Evaluations

Along with pre-employment screening for police candidates, the external police consultant often has the task of facilitating mandatory fitness-for-duty evaluations (FFDE). According to the IACP (Psychological Fitness-For-Duty Evaluation Guidelines, 2004), a psychological FFDE is a formal, specialized examination of an incumbent employee (typically a sworn police officer) that results from objective evidence that the employee may be unable to safely or effectively perform a defined job task and/or a reasonable basis for believing that this may be attributable to psychological factors. The central purpose of an FFDE is to determine whether the employee is psychologically fit to safely and effectively carry out essential job tasks and responsibilities. At a minimum, the evaluator should be a licensed psychologist or psychiatrist with training and experience in psychological assessment, especially in the evaluation of law enforcement personnel. The police psychologist evaluator provides recommendations to the referring department. The department is responsible for the ultimate determination of the disposition of the employee.

Clinical Intervention

The more typical responsibility, especially for the in-house staff psychologist, is the provision of clinical intervention and responses. Interestingly, in major metropolitan police departments, crisis responses—such as officer-involved shootings, severe vehicular accidents, major injuries and deaths, suicide attempts and completions, and SWAT (special weapons and tactics) callouts—are quite common, occurring on average once per week. Critical incidents within the law enforcement community are conceptualized as traumatic events. Thus, the event is conceptualized as the officer's having experienced an event significantly outside the range of typical human experience, such that his or her responses are typical reactions to the abnormal event. The most frequently occurring psychological sequelae following a critical incident within law enforcement (especially if the police officer has the thought, "I'm going to die") are social isolation/withdrawal, sleep disturbances, flashbacks, depression and anxiety, a heightened sense of danger, hypervigilance, and increased alcohol/substance abuse. Concurrent with crisis response capability, the staff psychologist is actively involved in providing stress inoculation training at the department's training bureau. Stress inoculation training has been found to be successful in empowering police officers to prevent, or at least lessen, the psychological impact of stress within the responsibilities of police responses.

The more typical psychological interventions police psychologists routinely undertake are individual, marital, and family counseling. The most frequent presenting issues for individual therapy are stress/anxiety, depression, substance abuse, domestic violence, and, more recently, compulsive gambling. The affective disorders and marital and family interventions are triaged by the staff psychologist to other licensed mental health staff members of the psychological services section. These mental health professionals are then tasked with providing confidential intervention, usually on a short-term basis of 8 to 12 weeks of therapy. All substance abuse, domestic violence, and compulsive gambling cases are assigned to

specific members of the section who have experience in the assessment, treatment, and referral (if clinically necessary) of these more complicated and long-term issues. Many departments have developed peer-support aftercare groups for long-term maintenance and groups for substance abuse and gambling cases.

A final matter of profound significance for the police psychologist's unwavering attention is police suicide. Some experts in police psychology claim that the incidence of suicide among police officers is approaching epidemic proportions. Therefore, it is incumbent on the police psychologist to develop and maintain an effective training and intervention program focused on ameliorating the incidence of police suicide.

Crisis and Hostage Negotiation

Many police psychologists have become actively involved in the operational responsibility of assisting law enforcement tactical teams (SWAT teams) in the area of crisis and hostage negotiation. A hostage situation is defined as any situation in which individuals are being held via active coercion by another person or people and demands are being made by the hostage taker(s). Typically, the police psychologist maintains two overlapping roles in the SWAT team. Prior to providing any information or influence within a police tactical operation, the police psychologist must always remain cognizant that he or she is always bound by federal and state legal constraints, as well as by professional and ethical standards. In the role of a professional, the police psychologist provides the general theoretical and practical applications of behavioral science information. In the role of a consultant, the police psychologist designs and implements negotiator selection and training. A second function in the role of a consultant is the provision of specific behavioral recommendations to the operational chain of command. Owing to ethical constraints, other than in a rare exigent situation, the police psychologist never actively speaks with the affected individual.

Training for a Career as a Police Psychologist

At the time of writing, there are no formal graduate programs specifically for police psychology. It is suggested that psychology students interested in becoming active in this specialty area seek a doctoral degree (Ph.D. or Psy.D.) within the established fields of clinical, counseling, forensic, or industrial/organizational psychology. For those students with a preference for the role of the internal staff psychologist, it is highly recommended that they become experienced in the clinical areas of individual, couples, and marital therapy. Special emphasis should be directed at didactic and experiential training in crisis intervention. Once a psychologist is hired by a police department, crisis and hostage negotiation training is usually extended through a basic, introductory course on crisis and hostage negotiation facilitated by the Behavioral Sciences Unit of the FBI in Quantico, Virginia. Parenthetically, it should be mentioned that the position of psychological profiling is rarely offered as a freestanding occupational position within the law enforcement community. Psychological, criminal profiling is only one job task within the overall occupational realm of the police psychologist. For the doctoral student who endeavors to become an external consulting psychologist, it is clearly recommended that the area of psychological assessment be an educational and experiential imperative. Along with a clear understanding of all aspects of personality assessment, organizational consultation and crisis intervention should also be areas of competency. Some universities are affiliated with police departments for either a predoctoral practicum or predoctoral internship experiences, although such programs are very limited in scope. Regardless of either a practicum or an internship placement, however, it is important for anyone interested in a career in police psychology to become familiar with the dynamics and culture of law enforcement. As such, it is highly recommended that during the doctoral experience, the student actively seek membership in the Psychological Services sections of both the APA and the IACP. Finally, it is suggested that, if possible, the doctoral student seek out an established police psychologist in the vicinity of the campus of doctoral study, in the hope that this police psychologist will agree to provide information regarding the field of police psychology and also to establish a doctoral practicum at his or her professional practice. Ultimately, the goal for the doctoral student would be to develop a mentoring relationship with the police psychologist. Such a relationship would greatly facilitate the attainment of career goals for the doctoral graduate student and would include the actual experience of the practicum placement in police psychology, consistent interaction with a police psychologist to answer various occupational questions and career development

issues, and the potential for participation in police psychology research and introduction to other police psychologists by being sponsored to attend local and national police psychology conferences.

Police Psychology

Police psychology, the practice of psychology in police settings, has been part of American policing since the late 1960s and has traditionally been a clinical endeavor by clinical psychologists. Although many large police agencies and some medium-sized ones employ full-time clinical psychologists, most agencies contract for part-time work with clinical psychologists who often maintain separate private practices. The practice of psychology in police settings has also been a research, consultation, and training endeavor by psychologists who have backgrounds in, for instance, experimental, social, and industrial-organizational psychology. Therefore, generally, police psychology is a field of practice in which psychologists of different training investigate and apply psychological knowledge to police settings and problems. (Here, this does not include other law enforcement settings and professionals, such as sheriffs, marshals, or correctional officers, who at times perform job tasks similar to police officers.) Psychological services for the police have traditionally involved evaluating police applicants, educating and training police officers, evaluating job tasks and duties, and carrying out fitness-for-duty assessments.

Evaluating Police Applicants

Since the 1960s, organizations and commissions such as the President's Commission on Law Enforcement and the Administration of Justice, the Commission on Accreditation for Law Enforcement Agencies, and the International Association of Chiefs of Police have recommended that police agencies evaluate the psychological fitness of police applicants. Today, most police agencies recognize and use a psychological evaluation as one part of the selection of police officers. Typically, licensed clinical psychologists carry out the evaluation. Some psychologists use a "select-in" evaluation strategy, whereby they look for applicants who demonstrate the qualities necessary to be successful on the job and recommend that police agencies accept them for law enforcement training. Other psychologists screen out applicants who demonstrate undesirable characteristics and recommend that police agencies no longer consider employing them. Many psychologists use both screen-out and select-in evaluation strategies, by which they screen out psychopathology and select in ideal police characteristics. Both focus on screening for suitable applicants. Evaluations typically involve administering a battery of psychological tests, carrying out a personal interview, giving situational tests, and making a selection recommendation.

Psychological test batteries administered by psychologists have included intelligence tests, personality tests, projective tests, and situational tests. Intelligence tests, such as the Stanford-Binet Intelligence Test, measure applicants' cognitive abilities. Scholarly research has linked intelligence tests with success on the job and in recruit training. Psychologists use personality tests to measure the relatively stable characteristics or traits of applicants. Commonly used tests are the Minnesota Multiphasic Personality Inventory (MMPI), the California Psychological Inventory (CPI), and the Inwald Personality Inventory (IPI). These tests are self-report, paper-and-pencil personality inventories. Research has shown empirical support for their usefulness in

predicting what police applicants might say or do on the job—for example, being late or absent, using drugs, violating police procedures and rules, and using excessive force. Few psychologists continue to use projective tests, which ask applicants to respond to unstructured situations or stimuli, such as the Rorschach Inkblot Test. Less frequent among psychologists is the use of situational tests, in which police applicants engage a role-playing exercise usually representative of job-related work conditions. There has been little empirical evidence supporting the use of projective and situational tests in screening police applicants for law enforcement training.

Psychologists supplement test scores from a battery of psychological tests with information obtained from a personal interview, a common component of the psychological evaluation. Psychologists use a personal history questionnaire to gather information on applicants' background (e.g., family, work, health, and any criminal behavior). Their interview, in part, usually involves a structured question format. Psychologists, however, often ask probing questions that follow up applicants' responses and sometimes ask questions that their police agency clients request. Personal interviews with police applicants help psychologists interpret and validate test data sources.

Educating and Training Police Officers

The police have the responsibility to keep the peace, maintain order, enforce laws, and safeguard the well-being of the community. This kind of duty to act involves the possibility of danger all the time, puts police officers at risk, and requires education and training. Critical issues in police education and training to which psychologists have given considerable attention are negotiating hostage and barricaded-suspect (HBS) situations, handling people with mental illness, conducting criminal investigations, and managing job-related stress.

Negotiating Hostage and Barricaded-Suspect Situations. Most police agencies have and employ critical incident teams, sometimes called special response teams (SRT) or special weapons and tactics (SWAT) teams, to resolve or assist in resolving high-threat or special-threat conditions, such as HBS situations. Police use of critical incident teams has evolved since the highly publicized HBS situation during the 1972 Olympic Games in Munich, West Germany. The first police approach to handling an HBS situation was an *assault,* which involved officers primarily using forceful options, often with lethal consequences for suspects. Sometimes, suspects' family members subsequently took legal action against the police.

In the early 1970s, psychologists and sworn personnel developed verbal tactics as alternatives to the assault option. Such tactics focused on police officers extending incident time to de-escalate the situation and talking suspects into surrendering. Police records have shown that critical incidents teams successfully resolve most HBS situations without injury to participants when police officers negotiate verbally. When police agencies used clinical psychologists to negotiate such situations, the rate of success without injury to participants increased.

HBS negotiation training is available at the Federal Bureau of Investigation (FBI) academy in Quantico, Virginia. The FBI's Crisis Negotiation Unit delivers training to all FBI negotiators and other law enforcement negotiators. There are also private companies that develop and deliver specialized training in negotiation skills. Trainers are usually experienced police negotiators who are sometimes psychologists. Police agencies that employ full-time clinical psychologists sometimes use them to educate and train their critical incident team negotiators and work at times with them to resolve, or assist in resolving, HBS calls for service. Negotiation activities primarily focus on containing suspects, negotiating with them, uncovering the personal factors motivating their behavior, and extending incident time, which gives suspects the opportunity to vent their emotions and make sensible decisions. Negotiation training typically emphasizes developing active listening skills through role-playing. Scholarly research on the effectiveness of negotiation training is in its infancy. A recent preliminary finding showed that FBI agents significantly improved their active listening skills following participation in the FBI's National Crisis Negotiation Course. Generally, however, there is much research that needs to be done in order to evaluate the effectiveness of crisis negotiation training.

Handling People With Mental Illness. The police are having more contacts with people with mental illness. Researchers have estimated that between 5% and 10% of police-citizen contacts involve people with mental illness. Contacts often occur in the home, family members sometimes call for police services, and the police usually resolve calls without incident. Some

researchers have suggested that the dismantling of state mental hospitals, the changing mentally ill population, the tightening of requirements for receiving mental health support, and the offering of limited psychological services are possible explanations.

The police are receiving education and training in the handling of people with mental illness. They recognize that mental illness is not a crime and that people having mental illness live in their communities, have professional vocations, and call for police services. The police also know that empirical investigations have found a link between mental illness and criminal behavior. For example, persons who suffer from bipolar disorder or schizophrenia are more likely to express antisocial behaviors that society criminalizes. Most mentally ill offenders are under the influence of alcohol or drugs when they commit crimes. There is some increased risk of mentally ill individuals becoming violent.

Although people who have a mental illness may commit a crime, be a victim of crime, or report a crime, police responses to encounters with them have improved with training. Police personnel, psychologists, and other mental health professionals have developed training curricula that include topics such as symptomatology of mental conditions, nonarrest and arrest options, and community police responses. They have developed and made available model police policies for contacts with people with mental illness. These policies have helped police administrators standardize the nature of their departments' response while giving the police flexibility to meet the needs of people with mental illness.

Conducting Criminal Investigations. Psychologists have studied the procedures and tactics used by the police in criminal investigations. They have produced psychological knowledge and have helped the police apply it to criminal investigation techniques such as eyewitness identification. For example, a police detective has a crime suspect and asks an eyewitness to identify him or her by viewing photos. The detective shows the eyewitness eight photos one at a time (sequentially) rather than all at the same time (simultaneously) to reduce the chances of misidentification caused by the eyewitness comparing photos and trying to decide which one looks most like the suspect. Chances of misidentification are less when the detective does not know the actual identity of the suspect, tells the eyewitness that the suspect's photo may or may not be present, gives the eyewitness no feedback during or after the identification procedure, and asks the eyewitness about his or her level of confidence in the identification.

What psychologists have known about police interrogation tactics is that some of them lead to false confessions. For example, a police detective has a suspect of a crime and interrogates him or her for several hours. An interrogation is a stressful experience for the suspect. In a state of high stress, some suspects are highly suggestible and might come to believe that the accusations made by the detective are true. Other suspects may confess if the detective threatens punishment or makes promises during the interrogation—even if the suspect knows that he or she is innocent. In other cases, the desire for attention or fame, especially in a highly publicized crime, might motivate the suspect to confess despite having done nothing wrong.

Police detection of the lies told by suspects during interrogation has received considerable research attention by psychologists. The police know that uncontrollable physiological arousal often accompanies a suspect's lying. For example, a police detective has a suspect of a crime and uses the polygraph technique (or device) in interrogation. The polygraph examiner asks the suspect several non-crime-related questions that generate emotional responses (e.g., about past behaviors) and several crime-related questions. Both provoke physiological responses, but the crime-related questions provoke more physiological responses than the non-crime-related (or control) ones, which suggests that the suspect is guilty. Most courts do not accept polygraph results as evidence. Psychological research has suggested that the rate of accurately detecting deception is low and the rate of false positives is high. The police, however, continue to use the technique with others and try to convince suspects that they cannot beat the device and that they should admit the fact of having committed a crime.

Hypnosis is another investigative technique available to the police. Usually psychologists, psychiatrists, or trained forensic hypnotists conduct interviews using hypnosis. They use the technique mostly to obtain information from eyewitnesses or victims and rarely to obtain information from suspects. There is little empirical evidence to support the belief that hypnosis elicits reliable memories.

Criminal profiling is a set of investigative techniques used to identify the characteristics of suspects most likely to have committed a crime. For example,

a police detective analyzes a crime scene, investigates the personal history of the victim, considers motivating factors, links the nature of the crime with similar behaviors of criminals, and finally generates a hypothesis about the suspect's sex, age, race, education, marital status, personality, and other personal characteristics. Specialized training in criminal profiling is available at the FBI Academy. Police profilers use behavioral science techniques along with other techniques of criminal investigation. They use criminal profiles to focus investigations in part on particular types of suspects while continuing investigative efforts on all possible suspects. How effective is criminal profiling? Some research suggests that professional profilers do better at extracting information from crimes and making predictions about suspects than do nonprofessionals.

Managing Job-Related Stress. Police stress is a reaction (or effect) caused by unfavorable physical, psychological, or social forces. Reactions may include physical, cognitive, behavioral, and affective changes in police behavior. Police stress may stem from law enforcement work, personal life, the criminal justice system, the police organization, or the public. Stress related to law enforcement work has received considerable research, training, and counseling attention, especially incidents involving force by and against the police, such as officer-involved shootings.

Police agencies are educating and training their officers to manage job-related tasks that can be stressful. Training curricula include recognizing stress reactions and learning skills to manage their potential harmful effects. Police agencies routinely provide their officers and families with information about job-related stress and mental health support. They establish peer support teams composed of officers and psychologists or other mental health professionals. Postincident debriefings are common following critical police incidents. They serve as an early crisis intervention effort, facilitate discussion with officers, assist in restoring normalcy in officers' lives, and help police administrators identify officers who need professional mental health support. Peer support teams are usually part of the postincident debriefing.

Evaluating Job Tasks and Duties

Psychologists with training in industrial-organizational psychology have contributed mostly to the study of police officers at work. A job analysis determines what responsibilities the police have, what tasks they perform, what knowledge and skills they possess, and what results they achieve. Analysis methods primarily involve reviewing the literature on policing, reviewing departmental literature (e.g., operational manuals, rules and procedures, policies, and general orders), observing the police at work (e.g., ride-alongs and training), conducting interviews with police personnel, and administering survey questionnaires. This battery of techniques produces an exhaustive list of job duties, such as crime prevention and law enforcement, and job tasks, such as making arrests and writing reports. Police agencies use information from the job analysis to make informed decisions about organizational operations such as police selection and promotional procedures.

A job analysis is lengthy and expensive. It requires organizational cooperation and commitment at all levels; it validates pre-employment standards and selection procedures. The Americans with Disabilities Act puts police agencies on notice that they must link their pre-employment standards and selection procedures with job-related behaviors. Staying current and consistent with job analyses gives police agencies some protection against claims of discriminatory selection procedures.

Carrying Out Fitness-for-Duty Assessments

Police agencies have a responsibility to monitor the psychological fitness of their officers. They have a right to order psychological evaluations of officers who develop patterns of problematic job-related behaviors. Misconduct might take the form of abusing authority, using excessive force, misusing drugs and alcohol, and engaging in criminal behavior. Police agencies must collect and document information on the problem behaviors they wish to correct. Documentation might include performance evaluations, pre-employment psychological screening reports, disciplinary actions, medical or counseling records, and other types of relevant reports that support a fitness-for-duty evaluation. Officers who go through a fitness-for-duty evaluation must give written consent.

Only licensed or certified psychologists (or psychiatrists) who have clinical experience can carry out a fitness-for-duty evaluation. The police agency requesting the evaluation is the client and not the officer going through it. Large police departments that have in-house psychologists usually have them perform the

evaluation. However, a dual relationship occurs when in-house or outside psychologists counsel or have counseled an officer whom the police agency refers for a fitness-for-duty evaluation. Most police agencies contract with outside psychologists to avoid the conflicts that such dual relationships produce. Police departments must make every effort to avoid dual relationships.

The Psychological Services section of the International Association of Chiefs of Police recommends that psychologists have training and experience in psychological testing and police assessment techniques and that they have knowledge of police job-related functions and the legal issues surrounding employment practices. An assessment of job-related mental fitness usually involves reviewing background information, administering a battery of psychological tests, conducting a clinical interview, generating a report, and making recommendations. The scope of the assessment is breadth and depth of psychological fitness, with the aim of identifying the absence or presence of personal characteristics essential for performing job-related behaviors that the officer falls short of doing. Outcome recommendations first specify "fit" or "not fit." Police chiefs or other police stakeholders (the client) may request additional recommendations, such as mental health counseling, remedial training, or other remedies.

Police Selection

Police selection is a process by which police agencies decide on which applicants are suitable for law enforcement training. The application of psychology to the selection of police officers has long been a part of the process, usually in the form of a psychological evaluation performed by a licensed clinical psychologist. The evaluation typically involves considering a selection strategy, administering a battery of psychological tests, carrying out a personal interview, giving situational tests, and making a selection recommendation.

Selection Strategy

"Selecting-in" police applicants who demonstrate the qualities necessary to be successful on the job is one strategy some psychologists use to evaluate applicants' suitability for law enforcement training. A job-task analysis, usually performed by industrial-organizational psychologists, is one way psychologists obtain select-in information about necessary job skills and traits to perform them. The evolving nature of policing, however, can lead to selecting in applicants who have "no-longer-needed skills" and traits to perform the job well. Though some psychologists use select-in criteria to accept police applicants, there is a lack of consensus among police and community stakeholders on the qualities needed to be successful in the police profession. There is more agreement on the unwanted qualities of police applicants.

In practice, the selection of suitable police applicants often involves screening out those applicants who demonstrate undesirable police characteristics. Psychologists are concerned with mental stability because an unstable officer, not surprisingly, is more likely to perform poorly on the job than a stable one. Empirical evidence suggesting that a screening-out focus best predicts which candidates are more likely to experience on-the-job difficulties falls short of being consistent.

Today, many psychologists use an evaluation strategy that screens out psychopathology and selects in ideal police characteristics. Their select-in and screen-out procedures must (a) adhere to ethical principles and standards of practice, (b) focus on applicants' ability to perform necessary job functions, (c) avoid clinical diagnoses, and (d) use objective and validated tests that specify what police functions they intend to

measure. Psychologists must carry out select-in and screen-out procedures that include evaluations of mental health in accordance with the Americans with Disabilities Act, and only after a conditional offer of employment to the police applicant. Prior to conditional offers, psychologists can use personality tests and other methods that do not include evaluations of mental health. Both conditional- and preconditional-offer psychological evaluations, however, focus on screening for suitable applicants.

Psychological Tests

The Minnesota Multiphasic Personality Inventory (MMPI), the California Psychological Inventory (CPI), and the Inwald Personality Inventory (IPI) are the psychological tests commonly used for screening police applicants. The MMPI and the CPI are general self-report, paper-and-pencil, personality inventories used to assess the relatively stable characteristics of applicants. They tap a number of dimensions thought to make up a police applicant's personality, which can affect his or her on-the-job performance. The MMPI is a clinical instrument designed to measure dimensions of deviant personality and maladaptive behavior. It is composed of 550 true-or-false items. Above-average scale scores suggest a greater probability of having job performance problems. Some empirical support has linked MMPI scores with police performance ratings and disciplinary actions such as termination and suspension from duty. Authors have updated and restandardized the original MMPI; its current version is the MMPI–2.

The CPI is a nonclinical instrument designed to measure normal personality traits important for social living and interaction. Test takers complete 480 true-false questions. Empirical studies have found that below-average scale scores increase the chances of police applicants having job-related problems such as using illegal drugs, using excessive force, and violating other department rules and procedures. The authors of the MMPI and the author of the CPI did not design the instruments to screen police applicants. There are, however, police and public safety reports available for both the MMPI and the CPI.

In contrast to the MMPI and CPI, the IPI, designed to screen police applicants, predicts normal and deviant police job performance patterns of test takers. It is a self-report, paper-and-pencil questionnaire, which consists of 310 true-or-false items developed from more than 2,000 pre-employment interviews with law enforcement candidates. Test scales measure behaviors such as absenteeism, lateness, trouble with the law, depression, suspiciousness, and anxiety. Research has shown an association between above-average IPI scale scores and negative behaviors by police recruits, such as lateness, absenteeism, and dereliction of duty during academy training.

Besides the MMPI, CPI, and IPI, psychologists have used other psychological tests, such as the Sixteen Personality Factor Questionnaire, Eysenck Personality Questionnaire, Five Factor Personality Test, and Hilson Safety/Security Risk Inventory. Psychologists usually couple personality tests with cognitive ability tests such as the Stanford-Binet Intelligence Test, which have some empirical support for predicting on-the-job and police academy performance. Some psychologists also use projective tests that ask applicants to respond to unstructured stimuli or situations, such as completing a series of unfinished sentences or describing a set of inkblots; however, the use of projective tests in the selection of police officers has declined.

Psychological tests capture a sample of the police applicant's behaviors. Psychologists generally administer multiple tests, sometimes three or four. The diagnostic value of these tests is to forecast what the applicant might say or do under police work conditions. Research has linked personality test data from the MMPI, CPI, and IPI with police job-related problems and success. However, not all psychologically suitable police applicants are free from job-related problems. Poor work performance might be an artifact of attitudes and belief systems that develop after selection. Police experience and effects of the occupational culture might lead to job-related problems not predicted by applicants' psychological profiles. Situational factors might interact with personal factors to determine some inappropriate job behaviors. In short, psychological test responses, in part, help select in and screen out police applicants, but applicants might lean toward making favorable impressions in an effort to appear well suited for police work. Psychological tests together with personal interviews and situational tests round out the selection of suitable police applicants for law enforcement training and work.

Personal Interview

Personal interviews are a common selection component of psychological evaluations. Psychologists use

police applicants' interview performance to supplement their psychological test scores. They usually gather background information obtained from a personal history questionnaire, which includes questions about work, family, health, and criminal behavior. Sometimes, police agencies supply psychologists with applicants' background investigation reports. Such reports help psychologists check applicants' psychological test data.

Interviews can involve asking standardized questions, while allowing psychologists to probe the responses of police applicants. Standardized interviews let psychologists compare applicants and check cross-interviewer reliability. The interview process can expose personal characteristics not revealed by self-report questionnaires; for example, the applicant's body language during the interview may show anxiety or tension. Sometimes, psychologists ask questions requested by their police clients who have uncovered personal characteristics of applicants that are suspect. Personal interviews, when used with psychological tests, help interpret test data and help answer the complex question, Who is a suitable applicant?

Situational Tests

Psychologists have used situational tests or role-playing exercises designed to measure a sample of behaviors the police applicant might use on the job. Situational tests are usually representative of job-related work conditions. Some preliminary empirical evidence supports the use of situational tests in the selection of police officers. For example, police applicants who performed well on a "Clues Test," which asked them to investigate clues about the disappearance of a hypothetical employee, also performed well during their recruit training.

Situational tests have a practical appeal. Advanced computer technology allows police trainers to administer situational training and tests to incumbent officers. For example, an interactive computer simulation asks police officers how they would respond to different suspect behaviors directed toward them during an arrest. Officers make decisions, and trainers evaluate them.

Police psychologists appear to be slow at developing situational tests and using computer technology to administer them as part of the selection process. Law enforcement assessment centers, however, are typically private agencies that have a history of using situational tests to evaluate incumbent officers and sometimes police applicants. Situational tests make possible the observation of hidden values that only appear under conditions that require quick decisions. With situational tests, psychologists can measure behaviors deliberately concealed from pencil-and-paper tests and personal interviews. Situational tests have a lifelike quality, are time-consuming and expensive, but are becoming attractive to psychologists.

Selection Recommendation

Police agencies that psychologically screen their police applicants consider the importance of the evaluation differently. Some consider it modestly, with other selection procedures frequently used, such as the civil service exam, physical fitness assessment, background investigation, and personal interview with police personnel. Most consider it a pass-or-fail component of the selection process. They no longer consider employing applicants whom psychologists fail. Psychologists' selection recommendations are not always simple dichotomies: pass or fail, or suitable or unsuitable for law enforcement training. There are psychologists who use Likert-type scales to make their recommendations—3, 4, or 5 points ranging from not suitable to suitable.

A favorable recommendation or endorsement of an applicant by a psychologist does not guarantee that the applicant will be successful on the job. Selection recommendations are probabilistic events. They might be wrong because psychologists make their decisions under probable or uncertain conditions and with limited information that is sometimes imperfect. Psychologists will be incorrect (or False Accept) if their decision is "suitable" when the applicant's actual status is "not suitable." Psychologists will also be incorrect (or False Reject) if their decision is "not suitable" when the applicant's actual status is "suitable." Best evaluation practices to maximize "True Accept" and minimize the total number of "False Accept" and "False Reject" errors involve psychologists using personal interviews and multiple tests and validating them.

Current Trends

The Commission on Accreditation for Law Enforcement Agencies and the International Association of Chiefs of Police have recommended the psychological evaluation of police applicants.

Most police agencies recognize and use the psychological evaluation as one component of the police selection process, but not all states legislatively mandate it or require applicants to pass it. Those police agencies that do not use police selection procedures that include a psychological evaluation are mostly small departments. Some courts have looked at the failure to screen police applicants' mental fitness as negligence.

Despite the limitations associated with preemployment psychological evaluations, psychologists predict a greater number of unsuitable police applicants than one would expect to find by chance alone. Psychologically evaluating police applicants continues to be an integral and evolving component of the selection of police officers.

Police Stress

This entry defines police officer stress and describes its consequences, origins, and the individual and organizational methods to control it. Controlling stress can enhance the delivery of police services and guide officers toward healthy lifestyles. One definition of stress is the wear and tear our bodies and minds experience as we react to physiological, psychological, and environmental changes throughout our lives. It is a nonspecific response of the body to a demand for change. Its centerpiece is the relationship between an external event and an internal response: For every action, there's a reaction.

Stress is fundamental to life, but its consequences are experienced differently. When, for example, Hurricane Katrina set down in August 2005, each of us reacted differently to it. Such reactions depend on many factors, according to Hans Selye, the individual who coined the term *stress.* Different reactions to similar events are expected because we are different: physically (age and health), psychologically (intelligence and experiences), and environmentally (family, community, and personal relationships). Also, our body contains its own unique pharmacy, which produces a chemical reaction of sorts, triggering a physiological and psychological response. Some responses are involuntary; for example, when we are extremely nervous, our palms moisten.

Good stress (*eustress*) and bad stress (*distress*) are everywhere. Without stress, there could be no life. Just as distress fosters sickness and failure, eustress promotes wellness and success. Every aspect of policing is stressful because experiences can instantly change: When an officer provides emergency care, that officer can become a victim, too. The FBI reports that each year, approximately 12 of every 100 (or 60,000) officers are assaulted. Police experiences can change from patrolling silent avenues to challenging dangerous suspects.

The consequences of uncontrolled or untreated stress among officers show that they are 30% more likely to experience health problems than other personnel, 3 times more likely to abuse spouses, 5 times more likely to abuse alcohol, 6 times more likely to experience anxiety, 10 times more likely to become depressed, and, oddly, the least likely of all occupational groups to seek help.

Stress is accumulative and, left untreated, can lead to a compromised immune system, illness, and death. Burnout or traumatic stress response is a coping device characterized by physical or psychological avoidance or distancing. Traumatic stress disorders include acute stress disorder (posttraumatic stress, consistent with overwhelming fear and revulsion), conversion reaction (hysteria, development of physical symptoms including

blindness or paralysis), counter disaster syndrome (excessive excitement and overinvolvement), peacekeepers' acute syndrome (rage, delusion, and frustration responding to atrocities), and Stockholm syndrome (identification with aggressors).

No one experiences all these disorders, but without treatment or individual resolution, officers are more likely to manifest some of these characteristics.

Sources of Stress in Police Work

Sources of police stress include stressors derived from critical incidents, general work, family, gender, and the organization. *Critical incidents* are events beyond the realm of usual experiences, igniting the emergence of a crisis reaction in those adversely affected. Characteristically, a critical incident is an unexpected occurrence disrupting an officer's control, beliefs, and values. It represents a life threat, triggering emotional or physical vulnerability, and might include events such as a fellow officer being killed or assaulted, barricaded subjects, apprehending emotionally disturbed offenders, or harming or killing an innocent person.

Events represent stressors, and reactions represent *critical responses*, which can be seen as an attempt at psychological homeostasis or a mental balance as a result of the experience of a stressor. The degree an officer is affected depends on the intensity, duration, and unexpectedness of the event. But it also depends on the officer's primary (participant) or secondary (observer) involvement, previous experiences, and mental health. (Clearly, an officer who was policing in Chicago when Hurricane Katrina arrived would have experienced a different degree of stress than a New Orleans officer.) Also, diagnostic criteria include actual or threatened death or serious injury, or a threat to an officer's integrity producing reactions of intense fear, helplessness, or horror.

Professional crisis intervention with officers experiencing critical events enhances self-esteem and discourages abusive behavior and substance abuse. Effective crisis intervention requires an immediate mandatory *debriefing*: a short-term psychological method of stabilizing and guiding an officer toward independent functioning. Debriefing includes ventilation and abreaction, social support, and adaptive coping.

Debriefing provides a standard of care, which may include making tactical plans to adapt to the incident, communication of coordinated actions, and avoidance of independent action or separation of partners during felony pursuits. However, officer resilience suggests that the same factors contributing to an officer's vulnerability to stress are the factors that contribute to resilience or *intuitive policing*: Experienced officers observe behaviors exhibited by criminals sending danger signals, moving an officer toward a reaction of public safety. Intuitive policing represents a decision-making process learned through critical-incident experiences. Critics of debriefing contend that while it would aid in immediate stress responses to some extent, it would not help resolve long-term psychological disturbances, it would accentuate stress responses, and it would exacerbate traumatic stress responses.

General Work Stressors. These are stressors arising during officer routines, such as conflict with regulations, paperwork, public disrespect, domestic violence stops, losing control on service calls, child abuse calls, another officer reported injured, lack of recognition, poor supervisor support, disrespect by the courts, shift work, death notification, poor fringe benefits, and accidents in patrol vehicles. General work stressors can change depending on experience.

Family Stressors. These stressors arise from personal relationships, but officers view family life as less of a stressor than expected. However, family members view the job of an officer as stressful for them. Officers' spouses report that shift work, concern over their spouse's cynicism, the need to feel in control at home, and an inability or unwillingness to express feelings frustrate them. Then, too, because officers seek adventure and work in distant neighborhoods at odd hours, infidelity is an option adding to family member stress and divorce.

Gender Stressors. Female and male officers share similar police stressors, but significant differences emerge for females because of differential treatment from male officers, supervisors, courts, and the public. Stress in association with gender comes from a lack of acceptance by a predominantly male force and subsequent denial of needed information, alliances, protection, and sponsorship from supervisors and colleagues; a lack of role models and mentors; the pressure to prove oneself to colleagues; exclusion from informal channels of support; and a lack of decision-making influence. A turning point leading to female officers' resignation can result from perceptions of stagnated

careers, an intense experience that brings accumulated frustrations to the foreground, lack of career fulfillment, family considerations, coworker conduct, policy, and new employment opportunities. Women tend to respond more directly to stress than men because they tend to talk about their feelings and take days off for professional and personal help to aid them.

Organizational Stressors. Police organizations differ in size, resources, and initiatives; however, organizational structures are consistent with a hierarchical bureaucracy. Therefore, the internal stressors affecting officers may include a political climate whereby commanders control policy less often than anticipated by police personnel; supervision is consistent with a hierarchical bureaucratic structure that stifles quality police services; paramilitary police models mandate strict enforcement practice, which alienates officers; local federal intervention targeting terrorists becomes a stress beehive among officers and supervisors; and officer professionalism is inhibited by the chain-of-command tradition.

Organizational stressors are a greater source of disruptive stress among officers and their supervisors than critical incidents, general work, family stressors, and gender stressors. This is consistent with officer resistance to new police initiatives and a lack of professionalism; consequently, officers band together in a police subculture for protection.

Resolving Stress

Officers and professionals can apply public health medicine's model of prevention in their development of a stress reduction model, which includes educating the healthy, educating those at risk, and treating those infected.

Individual initiatives include pervasive actions taken by an officer to curb stress because it is individually acknowledged that stress left unattended leads to poor police services and fewer quality-of-life choices among officers. Many officers believe that stress is a private matter and, consequently, resolve its effects silently through positive participation at church and in their families; through hobbies, school and training activities, and workouts; and sometimes through inappropriate activities such as substance abuse and other forms of deviant behavior.

Person-centered initiatives relate to professional or peer group intervention models. There are many choices available depending on departmental resources, objectives, and policy. Stress reduction providers include in-house units, external units, and hybrid services.

In-house units include formal employee assistance programs developed and administrated through a department to provide stress intervention services and pre-employment screening of police candidates. Informally, officers can develop volunteer peer groups to aid in stress control. Also, there are many peer groups initiated and developed among officers, and many patrol officers and supervisors admired by their peers are often sought out for guidance. In-house units are typified by stress units or volunteers employed by the organization.

External programs use an independent psychologically trained agency to provide stress intervention, including debriefing sessions and pre-employment screening.

Hybrid programs are typified by organizations that use both in-house and external programs. Departments can use personnel from other police agencies, as well; for example, the Massachusetts State Troopers stress unit also serves Boston police officers.

Obstacles associated with individual- and person-centered stress strategies include the following: (a) stress intervention is performed through a multimodal process; (b) treatment is not encouraged by the public, supervisors, and police subculture; (c) seeking help or showing feelings is seen as a weakness or shedding the uniform; (d) officers may hold an unrealistic view of the job; and (e) administrative expectation and demands.

Prescribed medication by some licensed stress practitioners includes antidepressants such as fluoxetine (Prozac) or sertraline (Zoloft), which may do little to achieve positive mood changes. However, some research suggests that such drugs may improve the way brain receptors (neurotransmitters) process crucial brain chemicals, most notably serotonin. Medication is intended to "readjust" brain functioning back to its optimal condition. Bupropion (Wellbutrin) works in a different way but may be equally effective. Most police psychologists discourage the use of medication, simply because it is too risky. In some situations, officers are drug tested, and in other situations, psychological dependence is possible. A good rule of thumb is that medication can be an alternative but only with recommendations from more than one physician.

Pre-employment screening can identify at-risk candidates who inappropriately rationalize excessive use of force, have engaged in substance abuse and crime,

hold racist attitudes, or experience severe family conflicts. Departments can develop systems of intervention targeted toward different groups of officers at different phases of their careers, resulting in the identification, treatment, and resolution of suspect officers. If potentially problematic officers go undetected, it is more likely that they will engage in the use of lethal force regardless of the situation because risk behaviors are intensified through other experiences. Desirable personality traits could be enhanced through preservice and in-service training, which would aid in the development of a personnel standard resulting in higher officer morale, fewer human rights violations, and enhanced quality of police services.

Police Training and Evaluation

Police training is a process by which teachers communicate to police personnel job-related knowledge and skills and assist them in mastery of the material. Training occurs at recruit, field, and in-service levels. Sworn police personnel, nonsworn personnel, or police psychologists, who have special knowledge of police behavior, present the training topics. Psychological knowledge, in part from experimental, social, heath, clinical, industrial-organizational, educational, and sport psychology, has informed police recruits and incumbent officers in three general topical areas of training: wellness, information and skills, and supervision and management. Training sometimes crosses over all three areas. Police trainers make informed decisions about the effectiveness of training when they evaluate police performance and training curricula. Psychological knowledge has provided trainers an understanding of the conceptual grounding and application of evaluation methods at the individual officer level and at the training program level.

Recruit, Field, and In-Service Training

Agency-affiliated, regional, and college-sponsored police academies provide recruit (or basic) training. Large municipal and state police agencies usually establish agency-affiliated (or individual) academies. Regional (or statewide) academies typically provide basic training for local city and town police recruits. In some states such as California, some individuals interested in becoming police officers attend college-sponsored police-training academies, where they take part in basic police training and earn college credit. Among academies, the length of training time varies. Some recruits receive as little as 8 weeks of training, whereas others receive as much as 32 weeks. State Peace Officer Standards and Training (POST) commissions set the minimum length of recruit training time. Police academies may add training time to the minimum required by state POST commissions. Generally, agency-affiliated training academies require more hours of training than do regional or college-sponsored ones.

When police recruits graduate from basic training, most of them enter Field Training Officer (FTO) programs implemented by their agencies. FTO programs have recruits—now field trainees—ride along with incumbent officers who have formal training in teaching established program curricula and evaluating trainee performance in actual work conditions. Police trainees learn agency-specific policies and practices and work-area-relevant information. The duration of their field training and evaluation period may be as little as 10 weeks or as much as 24 weeks.

Once police trainees complete their FTO programs, they receive periodic in-service (or refresher) training during which they relearn, practice, and correct acquired job-related knowledge and skills. In-service training aims to reduce forgetting and performance deterioration, which naturally result from the passage of time. It sometimes involves acquiring new knowledge or specialized skills. Some police agencies require officers from all organizational levels to participate in in-service training. Some agencies excuse

their executive officers (e.g., chiefs) from having to participate in some types of in-service training, such as self-defense tactics, because executive officers rarely respond to calls for service that have a potential for violence. The length of in-service training varies among police agencies. It sometimes depends on the minimum standards set by state POST commissions. Often, training time is a function of departmental fiscal budgets, legislative mandates, and union contracts. The content of in-service training curricula also varies among police agencies: Some include only subject matter that is legislatively mandated (e.g., firearms training); some include a variety of topics, such as domestic violence, use of force, and diversity training; and others include curricula established by state POST commissions.

At the recruit-training level, state POST commissions determine and approve the basic training curricula. Generally, they require training in the subject areas of administration of justice, fitness, law, police procedures, use of force, police professionalism, and community relations. Typical examples of training within these subject areas are examining the role of the police, making lifestyle changes, using discretionary power, making decisions to use force against citizens, becoming aware of personal cultural influences, and responding to perceptions of bias-based policing. These exemplars represent issues surrounding police behavior that have their roots in the field of psychology.

Wellness Training

There is concern about officers' health having an impact on their job performance. Unhealthy behaviors, from poor diet to glumness, contribute to illness and poor job performance. Training that promotes wellness can assist officers in controlling unhealthy behaviors, making positive lifestyle changes, developing healthy attitudes, and performing job-related tasks at optimal levels. Some topics that are a part of wellness training for the police are alcohol abuse, critical incident survival, and stress management.

Alcohol Abuse. Following a work shift, drinking with brother and sister officers—jocularly known as "choir practice"—is a tradition through which police officers socialize, develop camaraderie, and manage stress. Choir practice often involves excessive drinking. Teaching police officers to make positive and healthy decisions about alcohol use is a part of wellness training.

Critical Incident Survival. A majority of law enforcement officers leave their jobs within 5 years of taking part in critical incidents such as an officer-involved shooting. Police officers may experience negative thoughts and feelings and perceptual distortions during critical incidents, which affect their performance levels. Educating police officers about responses to critical incidents, and the physical and mental techniques that can be used to survive them, is a preventive effort that is a part of critical-incident survival training.

Stress Management. Police officers find their work stressful because of unfavorable physical, psychological, or social stressors, such as working late shifts, making deadly-force decisions, or working with poor equipment. Health issues, alcoholism, family problems, and suicide are correlates of police stress. Helping police officers inoculate themselves against stress by making life- and work-style changes, giving them skills to offset negative stress effects, and providing information on peer support services and mental health programs are a part of stress management training.

Other Wellness-Related Training Topics. Psychological knowledge is available on eating healthy, controlling weight, and stopping smoking, which are health-enhancing behaviors that police trainers may discuss as a part of wellness training.

Information and Skills Training

Police academies and agencies have a responsibility to provide police officers with information on, and skills training in, particular tasks they are likely to perform on the job. Police trainers use different pedagogical methods such as classroom lectures, experiential activities, role-plays, and simulated scenarios to present information and skills-training topics. Hands-on training involves individual skill work, which focuses on individual responsibilities. Sometimes, trainers couple individual skill work with collective skill work, which focuses on team or group training. The following are some topics that are a part of information and skills training.

Managing Intercultural Differences. Police-citizen contacts sometimes involve the police confronting the values and practices of members of cultures different

from their own, which leads to uncertainty and intercultural conflicts. When police officers make hitherto unknown cultures familiar, understand individuals and families from cultures different from their own, and understand the cultural meaning of their own behaviors, they broaden their cultural problem-solving strategies. All these behaviors are a part of training that helps the police develop cross-cultural competence to manage intercultural differences.

Profiling. Profiling is a long-standing policing method by which officers measure criminal suspicion. Police officers make decisions of criminal suspicion under probable or uncertain conditions and with limited information that is sometimes imperfect, and thus, their decisions to act may be wrong. Informing police officers about how mental processes—heuristics, subjective reality, confirmation bias, intuition, common sense, forming impressions, overconfidence, and response bias—may wrongly influence their decisions of criminal suspicion is a part of training on police profiling.

Conducting Criminal Investigations. Conducting eyewitness identification procedures, interrogating suspects, and using lie detection equipment are crucial activities in criminal investigations. Information and skills training, in which police trainers use pyschological knowledge of best investigative practices, includes teaching police officers that showing eyewitnesses photos sequentially rather than simultaneously reduces the chances of misidentification, that threatening punishment during custodial interrogations sometimes causes suspects to confess falsely, and that using the control question technique in concert with the polygraph device is preferable.

Other Information and Skills Training Topics. Managing interactions with mentally ill individuals, making use-of-force decisions, and handling barricaded suspect/hostage situations are all job-related events for the police. Police trainers may present such topics as a part of information and skills training.

Supervisory and Management Training

Supervisory and management training is an essential part of organizational health. It focuses on police managers (or supervisors) developing skills so that they can effectively and efficiently influence, lead, and supervise police personnel to meet agency needs and carry out agency objectives. Managers need cognitive skills to diagnose personnel problems, behavioral skills to help personnel modify problem behaviors, and communication skills to communicate desired behaviors to accomplish organizational goals. Training associated with such skills has its roots in psychology, which has helped the police develop a rudimentary understanding of the workings of police behavior in the organizational setting. These skills are a part of advanced police-training programs that law enforcement, academic institutions, and private organizations offer. For example, the Federal Bureau of Investigation National Academy offers a course to develop managers of police organizations. Particular training areas, which constitute the course curriculum and have psychological knowledge richly embedded in them, are leadership development and behavioral science. Diagnosing, managing, and changing behavioral problems in the police setting are a part of the leadership development component. A part of the behavioral science unit of training is the psychology of stress.

Evaluation Methods

Evaluation of police performance and training curricula occurs at the individual officer and training program levels, respectively. At the individual officer level, police trainers use informal and formal evaluation methods. Informal evaluation of police performance occurs during teaching activities. Trainers consider officers' learning and memory differences and monitor their performance in these terms: knowledge, capacity, strategic, retrieval, and gender. For example, police trainers recognize that officers have different learning styles: visual, auditory, reading, writing, and tactile-kinesthetic. They present course material in a visual and written format; they encourage officers to take notes, ask questions, and be active in classroom dialogues; they lecture; and they have officers participate in hands-on tasks.

Formal evaluation methods take the form of written tests or practical examinations. Written tests rely on content validity. Police trainers achieve content validity by using only material that they present during training to construct written tests. To make sure that written tests are representative of the training material, trainers sometimes construct a complete list of the training material and select questions randomly from it. The purpose of using written tests to evaluate police personnel is to determine whether they have mastered the content of the training program.

Practical examinations involve evaluation of performance on hands-on or scenario-based tasks. For example, a police trainer evaluates an officer's performance on an interactive computer-simulated enforcement task that requires the officer to respond to a suspect who is actively resisting arrest. The trainer evaluates the extent to which the officer's response and decision making reflect endorsed training practices, accepted legal principles, and approved police policies.

At the training program level, evaluating the effectiveness of a program is a challenging and expensive task that requires cooperation at all levels of the police organization. Carrying out a program evaluation requires knowledge and skills in social science research and statistical methodology. Police psychologists (or other social scientists) who have knowledge of the police culture are the ones most likely to evaluate a police-training program. They may do a utilization-focused evaluation, which is a comprehensive approach that focuses on the intended use of the training program by intended users. Major evaluation activities are describing the training program and evaluating its process, outcomes, and utilization. Not all police-training programs are subjected to evaluation or are worth evaluating, especially poorly designed ones. Police administrators and trainers make informed program decisions, however, when they use outcomes from what evaluators do measure.

Police Use of Force

Police use of force is the application in a law enforcement capacity of physical or psychological coercion against citizens. Under the law, police officers have the authority to use force for enforcing laws, preventing criminal activity, defending others, and defending themselves. They have the discretionary power to use different degrees of force against citizens who choose to violate the law. Forceful responses can range from officer presence to the use of weapons. One approach to understanding forceful responses against citizens is psychological. There is psychological knowledge bearing on (a) how officers formulate and carry out their decisions to use force by encoding situational information, making a decision to act, developing a plan of action, and initiating action; (b) how officers' involvement in a force situation puts them at risk of experiencing stress that causes unfavorable changes in their perception and memory; (c) how police candidates with particular personality traits are at risk of on-the-job problems with using force; and (d) how officers whose job-related experiences involve traumatic force situations are vulnerable to developing behaviors that lead to the use of excessive force.

Decision Making

An officer formulates and carries out a decision to use force against a citizen by encoding situational information, making a decision to act, developing a plan of action, and initiating action.

Encoding Situational Information. Encoding is a process in which the officer attends to situational conditions. It involves the sensory register, the first structure of the officer's memory system. The sensory register is responsible for registering all features of the force situation through sensory functions—for example, seeing a citizen holding a gun, hearing a gunshot, and smelling gunfire. Sensory systems keep the officer informed about the force situation. They extract information and convert it to electrical impulses that travel to the thalamus, which is located in the diencephalon of the brain. The thalamus directs sensory input to associated cortex areas of the brain, where the officer becomes aware of sensation and interprets it.

Making a Decision to Act. Making a decision to act takes place in the officer's short-term memory. The officer consciously discriminates, selects, and attends to sensations that are most dangerous, while reducing attention to less dangerous information. The officer considers the magnitude of the force situation and the probability of harm occurring if he or she takes no protective or enforcement action. What researchers

know with confidence is that officers consider citizen behavior most important when making decisions to use force. A need to use force triggers cognitive events that help the officer develop a best plan of action. If the officer fails to pay attention to important sensory input, his or her plan of action will be less than optimal.

The limbic system is associated with making a decision to act in response to situational demands. It surrounds the upper brainstem and consists of interconnected neural structures, which include the amygdala and the hippocampus. The amygdala helps regulate emotion, and it contributes to the officer's drive to act. The hippocampus is responsible for memory storage. It gives the officer access to experience when making a decision to act.

Developing a Plan of Action. Once the officer makes a decision to act, he or she begins developing a plan of action. The officer accesses long-term memory and matches the sensory input with a response that best fits the conditions of the force situation. The appropriateness of the response depends on the extent to which the officer selected important sensory stimuli, and the officer's response reflects endorsed training practices, accepted legal principles, and approved police policies. In familiar force situations, responses are available. In novel situations, the officer might search his or her experience for possible responses or use a past strategy.

Developing a plan of action begins in the brain's association cortex areas, which integrate sensory input. They carry out the processes that take place between sensation and action, which include perceiving, learning, remembering, and planning. Neural structures of the projection system—basal ganglia, cerebellum, and motor cortex—relay details of the officer's plan to the spinal system.

Initiating Action. The spinal system is responsible for initiating the plan of action. It sends motor neurons that carry details of the plan of action out to various muscle groups that will perform the action of force. It serves as the final pathway that links the central nervous system with the skeletal muscular system.

Stress Effects

Stress is a state of psychological tension. It is a reaction or effect caused by unfavorable physical, psychological, or social forces, such as in a force situation. The force situation acts as an alarm signal that triggers the stress response. The officer's sympathetic nervous system becomes abnormally active. It starts autonomic and endocrine responses that prepare the officer's body for a fight or flight. Hormonal discharges, such as the secretion of corticotrophin-releasing factor, adrenocorticotropic hormone, cortisol, epinephrine, and norepinephrine, energize the officer's body. The stress response helps the officer perform at his or her best in the force situation. However, exposure to the force situation can lead to an increase in arousal that amounts to a peak stress condition. When in a state of peak stress, an officer experiences unfavorable changes in his or her memory and perception.

Memory. The adrenal gland secretes cortisol. Research shows that high cortisol levels impair memory functions. The effect, however, is temporary. Memory functions return as cortisol levels return to normal. The officer might find it difficult to access long-term memory and match sensory input with a response that best fits the demands of the force situation.

Perception. The officer's pupils dilate to gather extra situational information, but his or her perceptual system narrows its field of focus. There is a loss of peripheral vision. The officer might retreat to widen his or her peripheral field. The officer might also overlook important visual cues and develop a less than optimal plan of action. Other possible perceptual distortions include auditory blunting, auditory exclusion, and tachypsychia.

The dominant response to peak stress is *hypervigilance*. The hypervigilant officer panics and becomes hypersensitive to situational cues. The officer cannot discriminate threatening from nonthreatening cues. A lack of attention to important situational cues might lead the officer to choose an incorrect response to the force situation.

Optimal stress in a force situation depends on factors that are unique to the officer. Some officers perform better with arousal than do others. A skillful officer who has good coping abilities can offset the negative stress effects. Under peak stress conditions, officers experience delays in encoding situational information, making a decision to act, developing a plan of action, and initiating action.

Personality Traits

Police psychologists use personality tests to predict police candidates' behavioral predispositions to use force. Candidates must demonstrate a willingness to use force. Yet they must show self-restraint. Psychologists have linked job-related uses of force with test scores on personality tests such as the California Psychological Inventory (CPI) and the Minnesota Multiphasic Personality Inventory (MMPI). Low CPI scale scores on socialization, self-control, and well-being have led to disciplinary actions against officers for unnecessary use of force. Elevated MMPI scale scores on infrequency, psychopathic deviation, and hypomania, combined with control in psychological adjustment, correctly classified aggressive officers who received disciplinary actions for aggressive misconduct against offenders, inmates, coworkers, or family members.

Which police candidates are prone to the abuse of force? Personality tests contribute some knowledge about candidates' tendency to use force. What police psychologists know is that most often, police candidates who are successful on the job do not demonstrate personality traits of impulsivity, hostility, undue aggression, and poor frustration tolerance, which put them at risk of having difficulty with on-the-job use of force. Being prone to the abuse of force, however, might be more than a matter of personality traits measured at the candidate or predisposition level. Researchers have found that some officers who had high rates of excessive force complaints had also received superior supervisory performance ratings. Psychologists had rated them as suitable for police training and work.

Not all psychologically healthy officers are free from the abuse of force. Using excessive force or using force excessively might be an outcome of personality traits that police candidates develop on the job rather than something that they bring to the job. For example, police work involves the possibility of danger all the time. Danger shapes police-training practices. Officers learn to see citizens as potentially uncooperative, armed, and dangerous. They work in an environment of condition yellow: continually occupied with the present danger of the police-citizen contact. Some researchers have suggested that because officers focus on the interpersonal dangers of police-citizen contacts, they develop a suspicious and authoritarian work personality. To cope with danger and keep safe, they employ a heavy-handed or take-charge work attitude. They are at risk of using force against citizens where none is usually necessary.

Police use of force is not a simple extension of predispositional or changing personality patterns of officers. Situational factors such as instigation might determine some acts of excessive force not predicted by officers' psychological profiles. Organizational factors such as endorsed training practices, accepted legal principles, and approved police policies might attenuate the effects of personality traits. Psychological paradigms offer some insight into police personality traits that might manifest themselves in the form of undue force against citizens.

Job-Related Experiences

Officers routinely respond to calls for service that involve violence and danger. Exposure to traumatic job-related events, such as participating in officer-involved shootings, puts officers at risk of developing posttraumatic stress disorder, which can lead to difficulties with on-the-job use of force. For example, some officers lose control or use excessive force when they suppress postshooting trauma or other job-related trauma. Responses to postshooting trauma sometimes involve officers rushing possible force situations to experience the thrill again. Symptoms of postshooting trauma, such as trouble sleeping, emotional fatigue, anger, alcohol abuse, and anxiety, sometimes reveal themselves in the form of excessive use of force.

Police burnout, shift work, role expectations, and organizational stress are other job-related experiences that can result in undue use of force. Steps in place to understand and control police use of force are preemployment psychological screening, use-of-force training, and psychological monitoring. Police psychologists use psychological tests to screen out police candidates who show particular personality traits that might lead to difficulties with on-the-job use of force. Use-of-force training occurs at the recruit and incumbent levels. Psychological perspectives on police decision making and performance in use-of-force situations are typical topics that police trainers discuss. Monitoring the psychological fitness of officers following their involvement in traumatic job-related force situations involves officers participating in critical-incident debriefings, peer support programs, or individual counseling.

Polygraph and Polygraph Techniques

Polygraph is a general term that refers to the use of autonomic physiological measures to make assessments about a person's credibility. Polygraph techniques find wide application in the criminal justice and national security systems of many countries, and their use is growing worldwide. There are two major families of polygraph techniques. *Knowledge approaches* look for responses that indicate knowledge possessed by a person attempting deception. *Deception approaches* assess credibility by examining a person's response to accusatory questions that directly address the issues under investigation. Both approaches have strengths and weaknesses, and both are the subject of controversy in the scientific literature. This entry describes the approaches, their strengths and weaknesses, their application in practice, and the controversy concerning them.

History

The desire to use physiological responses as indices of truth or deception is a very old one. The lore of many cultures contains stories of trials by ordeal that have some basis in autonomic physiology. For example, many Asian cultures have legends of placing dry rice in the mouth of the accused. If the accused was able to spit out the rice it was assumed that he or she was not nervous and that he or she was truthful. If, however, the mouth was dry and the rice stuck, it was assumed that he or she was deceptive. Scientific research on the topic also has a long history, with reports of attempts to detect deception with physiological measures going back to the first psychologists and the end of the 19th century. However, this approach has one basic difficulty: To date, no specific physiological response, or pattern of physiological responses, has been identified that is uniquely identified with truth or deception. Therefore, efforts to use physiological measures have to rely on techniques of stimulus control and inference to assess credibility. During much of the 20th century, there was little interest in credibility assessment by scientific psychology, and the application of the polygraph for that purpose grew as a profession in law enforcement and national security agencies, primarily in the United States. A modern era of research began in the early 1970s in the laboratory of David Raskin at the University of Utah. In the past decade, applications of the polygraph and research on physiological deception detection have grown rapidly worldwide.

Standard Physiological Measures in Modern Polygraphs

Several companies around the world manufacture polygraph instruments for use in the field as credibility assessment devices. A typical field polygraph instrument takes measures of respiration, blood pressure, and the electrodermal response. Respiration is measured from stretch sensors placed over the upper chest and abdomen. A continuous measure of relative blood pressure is monitored from an inflated cuff on the upper arm. Electrodermal activity (galvanic skin response) is recorded from the palmar surface of the hand. Some polygraph instruments in current field use also measure the peripheral vasomotor response (blood flow near the surface of the skin), usually from the thumb. Most of the instruments in current field use are digital computer-based systems. Currently, there is little controversy concerning the ability of field polygraph instruments to adequately measure the physiological values they claim to measure.

During the past decade, the U.S. government has invested in a number of research projects in an effort to find new dependent physiological measures for credibility assessment. Electroencephalograms, neural imaging, thermal imaging, eye movement, and

others have been examined, but as yet, none of these new measures have achieved sufficient scientific basis for use in application.

The Knowledge Approach

Technique

In the knowledge approach, which is often referred to as the Guilty Knowledge Test or, more correctly, as the Concealed Knowledge Test (CKT), the subject is presented with a series of items in multiple-choice format. The items are designed to represent some bit of knowledge that the truthful person would not know. For example, John Doe is murdered with a pistol that the police have determined to be a .380 automatic. The media reports indicated that the victim was shot to death, but the police never publicized the exact type of weapon. A suspect might be asked, If you shot John Doe, you would know the type of weapon: Was the gun used to shoot John Doe a .38 special revolver? A .45-caliber automatic? A .357 Magnum? A .380 automatic? A 9mm automatic? A .22-caliber revolver? A window of approximately 20 seconds would follow each alternative to allow for the suspect's autonomic responses to take place and then recover. Because people tend to produce physiological responses to the first item in any series, the critical item is never placed in the first position, and the first item in the CKT series is never evaluated.

It is assumed that on recognition of the correct alternative, the deceptive person will generate autonomic responses. It is also assumed that the truthful person will have no reason to produce a specific response to the critical item and will thus be producing nonspecific responses at random. Thus, the likelihood that an innocent person would produce his or her largest response to the critical item in a 1-item CKT is 0.20. With a 2-item CKT, the likelihood that an innocent person would give his or her largest response to the critical item on both CKT series is 0.20×0.20, or 0.04. As the number of items increases, the likelihood of making a false-positive error (a truthful person appearing deceptive) is thus definable and rapidly becomes quite small.

Strengths of the CKT

The CKT has two principle strengths. First, it is possible to precisely define the likelihood of making a false-positive error and to control that error rate by the number of items used in the CKT. Research has consistently shown that the statistical prediction holds well in application. It is also possible to pretest the transparency of the items in a CKT by presenting the series of items and alternatives to persons known to be truthful regarding knowledge of the crime. Transparency refers to the ability of innocent persons to guess the critical item from a series. While testing for transparency of items is common in research settings, it is not known whether or not it is a common practice in the field.

The second great strength of the CKT is that it is a very simple test to administer. With a few hours of training with the equipment, an undergraduate research assistant can administer the CKT as well as an experienced polygraph examiner. There are examples in the literature of the CKT being completely automated for machine administration.

Weaknesses of the CKT

The CKT has three primary weaknesses. The first, known as memorability, concerns the fact that for the CKT to work, the deceptive person must remember the details of the crime. In that regard, the extensive research on eyewitness memory indicates that eyewitnesses, particularly those under stress, are prone to make mistakes in recounting the details of a crime. The perpetrator of a crime is an eyewitness to that crime, and it is likely that the perpetrator will be a highly stressed eyewitness of the crime. Moreover, many perpetrators are also intoxicated. To date, there is no theory to predict what specific details from a crime scene are likely to be remembered. The memorability problem is avoided in most laboratory research on the CKT by screening a number of details of the crime scene with pilot subjects and then using only the highly memorable items in the subsequent testing or by using overlearned items of personal history. Such a screening of items is not possible in real cases. Laboratory research on the CKT has revealed a slight tendency toward false-negative errors—that is, toward deceptive individuals appearing truthful on the test. However, the few existing field studies of the CKT suggest that the false-negative rate in the field may be as high as 50%.

The second major weakness of the CKT is one of applicability. Research conducted by the Federal Bureau of Investigation in the United States found that fewer than 10% of their cases were amenable to the use of the CKT, if they had wanted to use it. In nearly 90% of the FBI case files examined, the nature of the case was such that there were not enough items of concealed knowledge to conduct a CKT.

The third weakness of the CKT concerns countermeasures—that is, things that a deceptive person might do in an effort to defeat or distort the test. Research shows the CKT to be susceptible to mental and physical countermeasures if subjects are knowledgeable about the technique and have received training in the use of countermeasures.

Application of the CKT

Although a great deal is written about the CKT in the scientific literature, it presently has very little application in either law enforcement or national security. There is essentially no application of the CKT in the United States. The only country that reports a general use of the CKT in law enforcement is Japan. In Japan, persons with special training in psychology and eyewitness memory are part of the crime scene investigation team, and they actively search for and document possible bits of information for use in CKT when the crime scene is first investigated. It may be that this careful crime scene documentation results in a higher rate of applicability for the technique. However, a clear explanation of how Japanese examiners overcome the memorability problem is not presently in evidence.

The Deception Approach

The Techniques

The Relevant-Irrelevant Test. The deception approach asks direct accusatory questions (referred to as Relevant questions) under the assumption that persons attempting deception will produce physiological responses when they lie. The earliest version of the deception approach was the Relevant-Irrelevant Test (RIT). Along with direct accusatory questions (e.g., Did you shoot John Doe?), the RIT also asks irrelevant (neutral) questions, to which the person is assumed to be responding truthfully (e.g., Are the lights on in this room?). The working assumption of the RIT is that persons attempting deception will produce a large and consistent physiological response to the relevant questions, whereas the truthful will not distinguish between the irrelevant and the relevant questions.

Virtually all the scientists who work in this area dismiss the working assumptions of the RIT as naive. Clearly the truthful will recognize the relevant questions as the more important class of stimuli and are thus likely to produce physiological responses to them, and in fact, research does show a very large number of false-positive outcomes to the RIT. As a result, the RIT has very little application in forensic polygraph testing. However, the RIT is still in use for periodic screening of sex offenders and in screening job applicants. At this time, any use of the RIT is highly controversial, and the scientists active in this area do not support its use.

Comparison Question Tests. John Reid developed the notion of an active comparison question in the context of law enforcement examinations during the late 1940s in response to the obvious problems with the RIT. The idea of the active comparison question was to provide a stimulus in the test that would evoke physiological responses from the innocent but not from the guilty. The comparison question took the form of a question that the subject was probably going to respond to with a lie. For example, after discussing the death of John Doe and after the subject of the examination has denied being involved in John Doe's death, the polygraph examiner would tell the subject that he or she is going to be asked some questions about his or her basic character in an effort to show that he or she is not the type of person who would have shot John Doe. The subject would then be asked a question such as "Before the year 2006, did you ever hurt someone?" The comparison question is deliberately vague and covers a long period of time. In the context of the examination, the subject is led to believe that an affirmative response is damaging because it shows that he or she is the kind of person who would have committed the crime. However, for virtually all subjects, it can be assumed that a definitive "No" response is probably a lie in view of the deliberately vague presentation of the comparison question.

The working assumption of the Comparison Question Test (CQT) is that guilty participants will produce consistent physiological responses to the relevant questions, while they will respond only minimally to the comparison questions. Although the guilty are assumed to be lying in their answers to the comparison questions, it is assumed that the comparisons are likely to be viewed as unimportant compared with the relevant questions, which directly address the issues under investigation. The innocent are expected to respond more to the comparison questions because they know that they are lying or are at least uncertain about the veracity of their answers to the comparison questions, whereas they know they are responding

with the truth to the relevant questions. Thus, differential reactivity is expected from the innocent and the guilty. Guilty subjects should produce consistently greater physiological responses to the relevant questions than to the comparison questions, and innocent subjects should produce consistently greater physiological responses to the comparison questions than to the relevant questions. If differential reactivity is not observed—that is, no response to either question type or equal response to both question types, the test is considered to be inconclusive.

In application, a CQT will contain between two and four relevant questions and a similar number of comparison questions. The question series will also contain some neutral and other questions that are not used directly for credibility assessment. The questions will be repeated a minimum of three times, but more presentations may be obtained. The resultant data are evaluated by making systematic comparisons between the responses to relevant questions and contiguous comparison questions. The standard in application is a human-based system that is semi-objective in that it is rule based, and in some physiological response systems, actual objective measures of physiological response are made (e.g., the electrodermal response), but in other response systems, human judgment is involved in making evaluations (e.g., the respiratory responses). Currently, there are three human-based scoring systems in use in the field, and persons trained in those systems show high levels of reliability in their total scores. Reliability coefficients for total scores are usually .9 or better.

Validity studies of the CQT have produced a range of estimates. However, current meta-analyses seem to be converging on a validity estimate for the CQT of near 90% accuracy for decisions (i.e., excluding approximately 8% of the tests that are inconclusive.) That said, there is controversy in the literature concerning the appropriate methodology for both laboratory and field studies in this area and about the generalizability of currently obtained results. By manipulating those studies that one views as having adequate methodology, the estimate of the validity of the CQT can be increased or decreased in reference to the figure mentioned above.

Strengths of the CQT

The great strength of the CQT is its wide applicability. The CQT is a highly versatile technique that can be applied to most credibility assessment situations. If unambiguous relevant questions can be formulated, then the applicability of the CQT would seem to be limited only by the subject's mental competence. In the laboratory and in many field studies, the CQT has been shown to be capable of a high level of accuracy.

Weakness of the CQT

The CQT is criticized at a number of levels. At one level, the CQT is criticized because it lacks a well-developed theory of underlying processes to explain why it works. Certainly, the lack of theory has hampered basic research in this area. An articulated theory would be useful in guiding research and in predicting conditions of generalizability of research results. However, the CQT polygraph is not unique in being a technology in successful widespread application without complete understanding of the underlying processes. Aspirin was in widespread use as a fever reducer and pain reliever for over 100 years before a complete explanation of its mechanisms was forthcoming.

A more telling criticism of the application of the CQT, particularly in the United States, concerns a lack of professional standards and regulation. Polygraph testing in the United States is controlled by a patchwork of standards and state licensing regulations. In many states, there is no regulation at all. As a result, the quality of practice in the polygraph profession in the United States is highly variable. Worldwide, this may not be the case. In Israel and Japan, psychologists are heavily involved in polygraph programs. In the People's Republic of China, the government polygraph program is organized within the Chinese National Academy of Sciences. One positive development concerning standards is that the American Association of Testing and Materials International (ASTM) has recently formed committees and is promulgating consensus standards for the administration of polygraph tests and for the training of polygraph examiners.

It has been suggested that some police agencies in the United States use the polygraph primarily as an interrogation prop to aid in obtaining confessions. Anecdotally, there are several well-known exoneration cases that have involved polygraph examinations as part of the process leading to false confessions. This is a topic clearly in need of additional research.

Finally, the CQT shares with the CKT a similar weakness regarding countermeasures. Some knowledgeable subjects can use mental and physical countermeasures to produce false-negative outcomes in

laboratory settings. As with the CKT, we do not know how successful countermeasure attempts are against the CQT in the field.

Application of the CQT

The CQT is in widespread application around the world as an investigative tool, as a screening tool for national security, and in the monitoring and treatment of sexual offenders on their release from incarceration. In some jurisdictions, the results of polygraph examinations are used as evidence in courts of law. The use of the polygraph in postconviction mitigation and sentencing seems to be growing. Although the controversy in the scientific literature remains, the use of the CQT worldwide seems to be accelerating.

Popout Effect in Eyewitness Identification

The "popout" effect refers to the subjective experience of witnesses who report virtually immediate or apparently automatic recognition of the perpetrator of a crime from a photo array or lineup. Researchers have detected this experience among witnesses by asking them to endorse one of several statements about the decision strategy they used when making their decision about a simultaneous lineup. In some (though not all) studies, witnesses who were accurate more frequently endorsed statements such as "I just recognized him, I cannot say why" and "His face just popped out at me" (automatic processing) than did inaccurate witnesses. The latter more often endorsed items such as "I compared the faces with one other to narrow the choices" and "I first eliminated the ones that were definitely not him, then chose among the rest" (deliberative processing). The popout effect has been of interest to eyewitness researchers and is relevant to the criminal justice system because such subjective reports could potentially be used as an indication of whether or not an identification decision is likely to have been accurate.

Evidence for the popout effect comes almost exclusively from examination of the relationship between identification accuracy and the characteristics of the subjective reports described above. While eyewitness researchers might well consider popout to be intuitively plausible, the reliance on retrospective reports to validate the effect is problematic. Indeed, it has been suggested that the demands associated with providing such retrospective reports might lead witnesses who have a very strong memorial image of the offender (and hence find it relatively easy to detect a match or an absence of a match in a lineup) to endorse items suggesting the occurrence of popout regardless of the actual characteristics of their search or decision processes.

Moreover, the view that reports of popout most likely imply an accurate identification is challenged by the finding that witnesses who misidentified a very similar looking but innocent foil from a simultaneous lineup were as likely to report popout as witnesses who accurately identified the perpetrator. This again points to the unreliability of subjective reports of the decision process as indicators of identification accuracy. Moreover, researchers have also shown that witnesses may be more likely to endorse the statement that the perpetrators' face "popped out" at them and that they "just recognized him, I don't know why" if they had been told that they picked the suspect from the lineup (when the perpetrator was in fact not present in the lineup), even though such feedback following the identification cannot have affected the actual

decision process. There may be other factors that influence the extent to which popout is reported retrospectively, such as the typicality (in comparison with the broader population) of the face, the size of the array, and the location of the target in the array.

Despite these problems with validating the popout phenomenon, it is at least not inconsistent with data from studies in which the time taken to make the identification decision, identification response latency, has been examined. These studies show that accurate identification responses are, on average, significantly faster than inaccurate responses. Furthermore, there is at least some evidence that participants who endorsed more items suggestive of automatic processing tended to be those who made faster identifications, whereas those who endorsed more deliberative processing items tended to be slower.

The popout effect has been distinguished from another type of decision process, an absolute decision strategy, on the ground that an absolute decision strategy does not predict shorter decision latencies whereas popout does. The reason for shorter decision latencies when popout occurs is that the examination of the lineup may cease after the face has popped out of the array. In contrast, an absolute decision strategy is characterized by witnesses comparing the members of the lineup with their memory of the perpetrator, with this occurring for each member of a simultaneous lineup array. Other behavioral data, such as eye movement recordings, have not, as yet, been investigated to provide converging evidence for the popout effect, but they could help validate the effect. If popout occurs, it would be expected that witnesses would engage in very little scanning of the members of the lineup, fixating quickly on the lineup member that pops out. This eye movement pattern should differ from both an absolute judgment strategy, where each lineup member should be fixated but overt comparisons between lineup members should not be detected, and a relative judgment strategy, where eye movements should indicate comparisons between the various lineup members.

It is worth noting that basic research in the area of visual search points to a phenomenon that appears to parallel the popout experience attributed to some witnesses when viewing a photo array. The popout effect in the visual search paradigm appears to derive from an early, "preattentive" registration of the key features of a stimulus during parallel processing of the full stimulus array, with this leading to rapid termination of the search of the stimulus array.

In sum, the popout effect has been argued to occur on the basis of witnesses' subjective reports of the decision strategy used to make an identification decision and the time taken to make the decision. It is important because it could potentially be helpful in distinguishing accurate from inaccurate identification decisions. However, the reliance on retrospective reports to demonstrate the phenomenon is problematic, with future research needing to be directed at identifying behavioral measures of popout.

Pornography, Effects of Exposure to

For as long as people have been able to draw and write, they have created pornography. Greek vases and Roman brothels contain ancient, sexually explicit images. Modern technologies for delivering sexually explicit images, such as the Internet, have made pornography ubiquitous. The affordability, accessibility, and anonymity of Internet pornography have also

proved a boon to the industry. The total market for adult material in the United States is now estimated to be $13 billion a year.

The subjective experience of viewing sexually explicit materials and societal reactions to their availability are characterized by shifting definitions and mores. Over the past 150 years, concern about the psychological effects of exposure to pornography on the viewer's character, morality, and, lately, tendency to engage in sexually violent behavior has driven social/legal policy as well as social science research on the problem of pornography.

Psychological investigations have focused on how the thoughts, attitudes, and behaviors of individuals are influenced by exposure to sexually explicit messages. To understand pornography research, it is useful to consider it in the context of the debate about pornography's effects in society. The terms of this debate have often framed the research agenda. One way of organizing the theory and research on the effects of sexually explicit material is by the normative concepts *pornography, erotica,* and *obscenity.* The term *obscene* is derived from the Latin *ob*, meaning "to," and *caenum*, meaning "filth." Obscenity has traditionally been associated with filth and offensiveness, disgust, shame, and the idea of insulting or breaching an accepted community moral standard. *Pornography* is derived from the Greek *porne*, meaning "whore," and *graphein*, meaning "to write." Pornography then literally means the "writing of harlots" or the depiction of women as prostitutes. *Erotica*, derived from the Greek god *Eros*, refers to sexual love. It is often used to refer to literary or artistic works that have a sexual quality or theme.

The Obscenity Theoretical Perspective

Currently, the law in the United States is organized around a test formulated for obscenity fashioned by the Supreme Court in 1973, which emphasizes the filth and offensiveness, disgust and shame associated with viewing sexually explicit materials. The test states that the basic guidelines for the trier of fact must be (a) whether "the average person, applying contemporary community standards" would find that the work, taken as a whole, appeals to the prurient interest (defined as a "shameful, morbid, unhealthy interest in sex"); (b) whether the work depicts or describes, in a patently offensive way, sexual conduct specifically defined by applicable state law; and (c) whether the work, taken as a whole, lacks serious literary, artistic, political, or scientific value.

This test with its focus on community standards has meant that magazines such as *Playboy* and *Penthouse* may be banned in towns with conservative values. Theoretically, the decision makes every local community the arbiter of what is acceptable. Both the prosecution and the defense are entitled to introduce evidence during an obscenity prosecution regarding the types of depictions a given community will accept given the current social climate, social mores, and so on. The evidence of community standards may include expert testimony, surveys, and comparable materials.

The social-psychological research on perceptions of community standards for sexually explicit depictions has involved several communities across the United States and has found considerable slippage between community sentiment and legal actors' presumptions. In a few studies, community residents were randomly assigned to view sexually explicit films charged in obscenity cases. The results showed that residents believed, contrary to prosecutors, that sexually explicit films charged in the case do not appeal to a morbid unhealthy interest in sex and are not patently offensive. The community members indicate that they would be substantially less accepting of sexually explicit materials, however, if they contained rape and bondage, and they show no acceptance of child actors. Other research has confirmed that the majority of residents randomly selected from the community do not judge materials before the court to appeal to a prurient interest in sex and have tolerance for such materials. A lower percentage of people believe that others in the community tolerated the materials they personally found acceptable.

Psychological research has been conducted on the idea that exposure to sexually explicit materials insults or breaches an accepted moral standard and that these materials induce greater promiscuity and a loss of respect for marriage and fidelity and other traditional moral values. This research has attempted to test the hypothesis derived from the "obscenity" theoretical perspective that exposure to sexually explicit material has a corrosive effect on men's relationships with women and a negative impact on male intimacy and sexual performance and satisfaction within marriage.

The survey research suggests that people who report being happily married are less likely to report using Internet pornography. This research supports the idea that married women may be distressed by their

husbands' use of sexually explicit material and that this may threaten the stability of their marriage. The survey data by the American Academy of Matrimonial Lawyers in Chicago, Illinois, regarding the impact of Internet usage on marriages indicate that the Internet had been a significant factor in divorces they had handled during the past year and that a majority of divorce cases involved one party having an obsessive interest in pornographic Web sites.

Decreased sexual satisfaction with traditional sexual relationships has also been observed after exposure to sexually explicit materials. One study looked at the impact of consuming nonviolent pornographic material on male and female participants drawn from college and nonstudent populations from a midwestern city. As part of the study, participants were exposed to either pornographic or innocuous, nonpornographic content in hourly sessions for six consecutive weeks. In the seventh week, participants were asked to rate their personal happiness regarding various domains of experience and the relative importance of gratifying experiences. The results showed that exposure to pornography negatively affected self-assessment of sexual experience. The male and female participants reported less satisfaction with their intimate partner generally and with their partner's affection, physical appearance, sexual curiosity, and sexual performance. Additionally, the participants who were repeatedly exposed to pornographic material assigned increased importance to sexual relations without emotional involvement.

The proponents of the obscenity/traditional moral values theoretical perspective have also attempted research into whether the compulsive behavior associated with repeated exposure to sexually explicit materials is psychologically damaging. This research is inconclusive, and there is skepticism among psychiatrists and other mental health professionals regarding the case for including pornography addiction as a mental disorder.

Theoretical Perspectives on Pornography

Some feminists have argued that pornography both discriminates against women and provokes violence against women. Catherine Mackinnon and Andrea Dworkin proposed not a criminal obscenity law but an antidiscrimination civil law designed to confront pornography. As an alternative to obscenity law, several communities revised their discrimination laws to reflect this concern. Such a law was adopted in Indianapolis in 1984. The law declared that works that portrayed the graphic, sexually explicit subordination of women, whether in pictures or in words, were pornographic if they also included scenes or pictures in which women are presented as sexual objects who enjoy pain or humiliation; experience sexual pleasure in being raped; or are tied up, cut up, or mutilated or in which women are presented as being dominated, violated, exploited, or possessed through postures or positions of servility or submission. Women could sue on behalf of all women or a group or themselves for damages.

The Seventh U.S. Circuit Court of Appeals ruled that the law was unconstitutionally vague and that the kind of expression it sought to bar was protected by the First Amendment. The court noted that under the Indianapolis law, sexually explicit speech or expression is pornography or not depending on the perspective of the author; this is viewpoint discrimination. According to the court, speech that subordinates women is pornography no matter how great the literary or political value of the work. On the other hand, according to the law, speech that portrays women in positions of equality is lawful no matter how graphic the sexual conduct.

Research testing feminist sociolegal theory has examined pornography's effect on attitudes that justify violence against women, such as rape myth acceptance, and undermine viewer sensitivity to victims of rape and violence. The research literature examining the association between acceptance of rape myths and exposure to pornography has been examined in a meta-analysis. This analysis shows that nonexperimental studies show almost no effect—exposure to pornography does not increase rape myth acceptance. The laboratory experimental studies have found that exposure to pornography does increase rape myth acceptance; however, this effect occurs primarily for violent pornography rather than nonviolent pornography. The generalization of the finding causes some concern because of the difference demonstrated between experimental and nonexperimental research.

Neil Malamuth and his colleagues have conducted research testing feminist sociolegal theory that has also examined sexual arousal to depictions of rape. A series of studies examining the effects of exposure to sexual violence in the media on perceptions of rape victims have been conducted. Specifically, these studies have been concerned with the impact of positive- versus negative-outcome rape in pornographic

portrayals. These studies have generally taken the following form: Male subjects were either exposed to depictions of mutually consenting sex, a rape in which the female victim eventually becomes aroused (positive outcome), or rape that is abhorred (negative outcome) by the victim. Afterward, the subjects were shown a rape depiction and asked about their perceptions of the act and the victim. The males exposed to the positive rape portrayal perceive the second rape as less negative and more normal than those first exposed to other depictions. The researchers have also conducted studies that have asked male subjects how they think women in general would react to being victimized by sexual violence. Those first exposed to a positive rape portrayal believed that a higher percentage of women would derive pleasure from being sexually assaulted. The effect of the portrayal was particularly apparent in men with self-reported inclinations to aggress against women.

Edward Donnerstein and his colleagues have conducted research on the effects of exposure to pornography on aggressive behavior. Meta-analytic reviews have been undertaken of the effect of exposure to pornography on aggressive behavior under laboratory conditions, considering a variety of possible moderating variables, such as level of sexual arousal, level of prior anger, type of pornography, gender of subject, gender of target of aggression, and medium used to convey the sexually explicit message. The results demonstrated that nudity actually reduces subsequent aggressive behavior, that consumption of pornography depicting nonviolent sexual activity increases aggressive behavior slightly, but that media depictions of violent sexual activity generate more aggression than depictions of nonviolent sexual activity. No other moderator variable produced homogeneous findings in the meta-analysis.

The data collected from women participating in a battered women's program have also been examined to determine whether pornography use increases the probability that battered women will be sexually abused by their partners. This research shows that certain disinhibitory factors, such as alcohol use, mediate or exacerbate the effects of pornography on sexual violence. Compared with batterers who do not use pornography and alcohol, the combination of alcohol and pornography does increase the odds of sexual abuse.

This theoretical perspective has also fueled research on discriminatory and sexually aggressive behavior. The research shows that short-term exposure to nonviolent sexual media stimuli can produce cognitive changes in men that, in turn, can affect attitudes toward women. Daniel Linz and colleagues tested whether viewing these materials affects their judgment of women in subsequent face-to-face interactions. Sex-typed men and non-sex-typed men viewed one of three equally stimulating films: sexually explicit and degrading, sexually explicit and nondegrading, and nonsex. After the viewing, the men interacted with women and then evaluated their partners' intellectual competence and sexual interest. The results indicated that men's sex role orientation moderated the film effects for men's evaluations of their female partners' intellectual competence and sexual interest.

High pornography use is not necessarily indicative of high risk of sexual aggression unless other variables come into play. The combination of sexually explicit media with personality variables has also been examined within this theoretical perspective. Research by Neil Malamuth and his colleagues suggests that pornography is most likely to affect behavior when two streams of dispositional variables, one labeled "sexual promiscuity" (measured by the number of times an individual has had sexual intercourse and age at the time of the first intercourse) and the other "hostile masculinity" (a general sense of hostility as well as more specific hostility toward women), coalesce. Among men classified as being relatively low risk for sexual aggression on the basis of their levels of hostile masculinity and sexual promiscuity, there is only a minor difference between those who report sexual aggression and differing levels of pornography use. For men who were previously determined to be at high risk for sexual aggression based on hostile masculinity and sexual promiscuity, research has shown that those who are additionally very frequent users of pornography were much more likely to have engaged in sexual aggression than their counterparts who consume pornography less frequently.

This perspective has also generated research on the more general culture of violence against women cultivated by the media. Daniel Linz and his colleagues have conducted research on the effects of "slasher" films, films that often juxtapose sex and violence for male and female victims and that pair sexiness with the torture and death of female victims. Men who repeatedly viewed movies depicting violence against women came to have fewer negative emotional reactions to the films, to consider them as significantly less violent, and to consider them less degrading to women. It has also been found that there is a tendency for the desensitization to filmed violence against women to spill

over into subjects' judgments of female victims in other contexts. Men who were exposed to large doses of filmed violence against women judged the victim of violent assault and rape to be significantly less injured than did the control groups.

The Liberal Normative Theory

This perspective emphasizes that the free flow of ideas is so valuable to the discovery of sexual truths and erotic art and literature that it should be interrupted only when a grave harm to another person occurs as a result of exposure to sex-related materials. The threshold for censorship should be set high to guard against frivolous attempts to censor ideas that are taboo now but may be acceptable later. This position emphasizes that as long as the recipient of sexually explicit messages restricts his or her behavior to private actions, such as sexual fantasy, or only acts on these ideas with a consenting partner, society has no right to interfere. For example, only if it can be shown that consumption of sex depictions is causally related to rape or other violent crimes can the government regulate such depictions. No effect short of these direct threats of violence is sufficient justification for society to interfere with the individual's right to view sex-related materials and with the right of others to produce it. This position embraces findings such as the meta-analyses focusing on the use of pornography by convicted sex offenders, as compared with men from the noncriminal general population. Studies have examined several types of dependent measures, including frequency of pornography use, age at first exposure, the degree to which pornography was a prelude to some sexual act, and degree of sexual arousal. The findings showed a slight difference but not one that was judged to be reliable.

This theory of freedom of expression has led to concerns with methodological problems in laboratory studies on the effects of sexually explicit materials. For example, in the laboratory, only attitudes toward rape or, at best, physiological arousal can be measured, not, of course, actual rapes. However, these critics point out, when privately consumed, pornography is often associated with masturbation or consenting sex, and thus, laboratory settings may be dissimilar to the typical experience with pornography. By attempting to simply arouse subjects in the laboratory, such studies ignore completely the potential that pornography consumption and masturbation may serve as a substitute for rape that results from the use of pornography to release sexual tension.

These critics note that the incidence of rape in the United States has actually declined in the past 25 years, while pornography has become freely available to teenagers and adults through the Internet. Studies have shown, for example, that while the nationwide incidence of rape was showing a drastic decline, the incidence of rape in the four states having the least access to the Internet showed an increase over the same time period. The four states having the most access to the Internet have shown declines in rape. More sophisticated analyses controlling for offender age have found that the effect of the Internet on rape is concentrated among those for whom access to the Internet is greatest—males aged 15 to 19 years. They have also found that the advent of the Internet was associated with a reduction in rape incidence. However, the growth in Internet usage has had no apparent effect on other crimes.

Postdoctoral Residencies in Forensic Psychology

Forensic psychology was formally recognized as a specialty by the American Psychological Association (APA) in 2001 (through the Committee for Recognition

of Specialties and Proficiencies in Professional Psychology). The basic elements of specialty training in professional psychology are graduate education (doctoral program), internship, and postdoctoral training. This model of training is pyramidal in structure: Students receive a broad and general education at the graduate level, more specific applied experience at the internship level, and advanced specialized knowledge and skills at the postdoctoral level. An organized, systemic postdoctoral program is called a residency or a postdoctoral fellowship (these terms are interchangeable). Although the APA does not yet accredit forensic residency programs, the American Board of Forensic Psychology has developed some interim recommendations that can be used by students who are interested in applying to residencies.

The first formal concerted effort to develop training models in forensic psychology was convened in 1997 (the "Villanova Conference"). The participants in that conference discussed the entire range of training and specifically noted that there were inadequate numbers of postdoctoral fellowships (or residencies) to meet the training needs of all those seeking forensic specialization. In 2001, when forensic psychology was recognized as a specialty by APA, 11 residency programs in forensic psychology were identified. A recent search of ads in the *American Psychological Association Monitor,* the Web site of the American Psychology-Law Society, and an Internet search resulted in identification of 17 residency programs as of March 2007. Although there may be a few more programs that were not identified, it is clear that there are still too few programs to meet the demands of students interested in becoming forensic psychologists. Many psychologists will obtain alternative means of training (e.g., through continuing education activities and individually arranged supervision of forensic work), but residency programs remain the "gold standard" for preparation for forensic specialization.

Accreditation Issues

The APA's Committee on Accreditation accredits postdoctoral residencies, based on general principles for such programs, buttressed by specific Specialty Education and Training Guidelines. The Forensic Specialty Council is the entity responsible for developing such guidelines for forensic psychology, and it is anticipated that these will be available in 2008. In the interim, there is no mechanism for formal accreditation of forensic residency programs. However, the American Board of Forensic Psychology (ABFP), which is a Specialty Board of the American Board of Professional Psychology (ABPP), which awards diplomate status to qualified practitioners, has developed its own guidelines. The ABFP has recognized the value of residency training in forensic psychology and has determined that successful completion of such a residency is considered equivalent to 4 years of postdoctoral experience and, thus, would meet the experiential requirements to apply for diplomate status. The ABFP had identified the following criteria to recognize residency programs for this purpose (with a caveat that these will be superseded by the criteria to be developed by the Forensic Specialty Council as noted above):

1. The residents must have completed all requirements for their doctoral degree, including an internship, prior to beginning residency training.
2. There must be an identifiable director of training who either has a diploma in forensic psychology from ABPP, has at least 5 years' experience practicing forensic psychology, or is certified by their jurisdiction (through statute or regulations) to perform forensic evaluations.
3. The residents must be formally identified as trainees, paid a stipend, and be given a diploma or certificate of completion.
4. The residency must have a structured written curriculum, including didactic training or a regular series of seminars. Although the ABFP does not identify a required curriculum, it does require that the didactic training include a course on case law, ethics, and sociocultural factors/ethnic factors that affect individuals who are provided forensic evaluations or treatment.
5. The residency must include clinical experiences in forensic practice.
6. The residency program must include at least 2,000 hours of training, over a minimum 9-month period and a maximum of 24 months. At least 25% of the resident's time must be spent providing professional forensic psychological services.
7. A minimum of 2 hours a week of supervision by a licensed psychologist is required.
8. The residency program must have a formal evaluation process that includes a written assessment of the resident's progress and skill attainment.

Standard Elements of Forensic Residency Programs

Gary Melton and colleagues, in one of the classic books on forensic psychology, identified, in addition to basic clinical training, the following elements of specialized knowledge and experience required by forensic psychologists:

1. Understanding of how the legal system works
2. Forensic evaluation methodologies, including specialized forensic instruments
3. Legal doctrines relevant to forensic evaluations
4. Research about areas that are relevant to forensic psychology but that are not part of the standard "clinical" preparation
5. Rules, procedures, and techniques related to providing expert witness testimony

An additional, important element relates to special ethical dilemmas and practice issues that are unique to forensic practice. All forensic psychologists must be familiar with the Specialty Guidelines for Forensic Psychologists (which were developed in 1991 jointly by the American Psychology-Law Society and the American Academy of Forensic Psychology and are currently being revised). Residency training programs in forensic psychology should prepare residents for forensic practice by providing education and training within all these areas, at a minimum.

Accessing Information About Programs

The majority of the current forensic residency programs emphasize forensic work within the criminal justice system (as opposed to areas of civil practice). Most programs focus on work with adults (in areas such as competency to stand trial, criminal responsibility, aid in sentencing, violence risk assessments, sex offender evaluations), although some focus on juveniles. At least one program focuses on civil work with children and families, including child custody issues and termination of parental rights. As there is no current directory of forensic residency programs, specific information about the available programs can be obtained either through their advertisements in the *APA Monitor* (publication of the APA) or through the *American Psychology-Law Society Newsletter*.

Postevent Information and Eyewitness Memory

Human memory, however accurate generally, is not a perfect processing system. Over time, our memory becomes less accurate, primarily for two reasons. First, our memory is not permanent, and information fades from memory over time. Most people are familiar from experience with this unfortunate feature of memory but are less familiar with the second factor that influences the accuracy of memory—memory can be distorted by the influence of postevent information. Although memory can be influenced by subsequent experiences, there are constraints on the conditions under which this is likely to occur. Nonetheless, when memory accuracy is a premium, such as in forensic situations involving eyewitness memory, it is important to recognize that eyewitness memory can be suggestively influenced. In these situations, the impact of postevent information should be minimized by avoiding misleading questions, and when it is relevant to do so, jurors should be informed about the potential fallacies in eyewitness memory that can result from a suggestive interview.

How can postevent information influence memory? Take the example of eyewitnesses who observe a convenience store robbery. From their observations, they construct a memory for what transpired during the robbery. Most of the time, it is this memory that police officers want to examine. However, virtually all eyewitnesses to crimes who eventually testify in court are interviewed by police officers at least once and typically multiple times. In police interviews, the eyewitness is questioned about what happened, and if the investigating officer has specific suspicions about what occurred, the interview may include some leading questions (e.g., "Was it a white four-door sedan?" "Was he or she wearing athletic clothing?" "Was he or she carrying anything?" "May he or she have had a gun in his or her hand that was in his or her jacket pocket?"). Questioning such as this presents one source of postevent information. Another source of postevent information is self-generation; that is, the eyewitness may introduce new information by just thinking about or talking about the robbery. Either way, the postevent information affects one's memory of the original observed event, and over time, individuals become less able to differentiate between the information that is in their memory because it was actually observed and the information that was introduced after the event by postevent information.

Most of the time, the influence of postevent information is minimal and inconsequential. However, in the case of an eyewitness to a crime, when it is important to know exactly what transpired, postevent information may be an important source of memory error. For this reason, the distortion in memory that results from postevent information is often referred to as the *misinformation effect.*

Research on the Effect of Postevent Information

There is a great deal of research on the effect of postevent information, much of it spawned from the early work of Elizabeth Loftus. In a typical experiment on this topic, participants first view a sequence of slides, a videotape, or a film of an event. After viewing this event, they read a narrative or are asked some questions that intentionally mislead them about the identity of a small set of target items viewed in the original event (the misled condition), or they do not receive the misleading information (the control condition). The principal result is that the participants are more accurate recognizing the original target item in the control condition than in the misled condition; that is, they are misled by the postevent information presented in the narrative or questions.

In a related paradigm for studying the effect of postevent information, Elizabeth Loftus had individuals view a video of a traffic accident. They were subsequently asked questions regarding how fast the cars were traveling prior to the accident. Whereas individuals who were asked, "About how fast were the two cars going when they *hit* each other?" provided a mean response of 34 mph, individuals asked, "About how fast were the two cars going when they *smashed* each other?" responded with a mean speed of 40.8 mph. Surprisingly, the wording of this question—the postevent information—also affected their memory of the car accident more generally. One week later these individuals were questioned again. When asked whether they had seen broken glass in the film, whereas 34% of the individuals who had received the question, including the word *smashed*, indicated having seen broken glass in the film, only 14% of those who received the *hit* question reported remembering broken glass. The impact of postevent information is thus not limited to immediate questioning but can have long-term consequences as well.

Cognitive Interpretations of the Effect of Postevent Information

There are several explanations for how postevent information influences memory, and there is evidence that the cognitive mechanisms underlying each of these explanations play some role in the misinformation effect. Take for an example Elizabeth Loftus's now classic study in which participants viewed a car approaching an intersection with a *stop sign.* In the misled condition, the sign was later suggested to be a *yield sign* ("Did another car pass the red Datsun while it was stopped at the *yield sign*?"). In a subsequent test, individuals were less likely to recognize the stop sign if they had been in the misled condition. One interpretation of this result is that the postevent information impairs memory of the observed event. That is, being presented the *yield sign* literally degrades and replaces memory of the observed *stop sign*. A second interpretation of the misinformation effect is that the original information (*stop sign*) and the suggested information (*yield sign*) are both present in memory, but individuals make what Marcia Johnson calls a source-monitoring error and confuse what was seen with what was subsequently suggested. A third interpretation of

the effect of postevent information is that the misleading postevent information simply substitutes information in memory when there is no accessible memory for the relevant details of the original event. In fact, even when we pay attention, we do not remember everything about an event that we observe. According to this interpretation, only if individuals cannot remember seeing a *stop sign* are they likely to incorporate the suggested *yield sign.*

This latter interpretation, referred to as the *trace strength theory of suggestibility*, has important implications for some of the constraints on the effect of postevent information. Although memory is a constructive process, and we can incorporate postevent information into our memory for what we observe, in fact our memory is generally quite accurate. What is the vehicle by which the veracity of memory is preserved? It is now clear from a number of research studies that stronger memories are more likely to resist suggestion than weaker memories; we are less likely to be misled about details of events if we saw them very clearly to begin with and remember them well than if we did not remember them well. Kathy Pezdek conducted a research study in which children were presented a sequence of slides depicting an event. The target slides that were presented once or twice each were included in the sequence. A postevent narrative was then read that described the same event; in the narrative were several misleading sentences that suggested a change in what had been observed in the slides. The children were significantly less likely to be misled by the postevent narrative if they had observed the target slides twice rather than once; the stronger memory was more resistant to suggestibility. This conclusion is also supported by the results of other studies in which it has been reported that children are less suggestible in domains in which they have greater knowledge (i.e., greater memory strength).

Can Postevent Information Plant False Events in Memory?

Research on the influence of postevent information is often used to imply that it is relatively easy to suggestively mislead a person to believe that an entirely new event had occurred when it had not. This assumption is at the heart of the false-memory debate. This debate concerns the veracity of delayed memory for incidents of childhood sexual abuse. Analyses by Jennifer Freyd and her colleagues have established the pervasiveness of childhood sexual abuse. Nonetheless, some claims of childhood sexual abuse might be based on "false memories"; that is, the abuse never occurred, but memory of the abuse was planted by postevent information, such as suggestive questioning by overzealous police officers, social workers, or therapists who interviewed the child.

According to the trace strength theory of suggestibility, if a child is recalling an event that was experienced several times, he or she would be expected to have a more accurate memory of the event and be less vulnerable to suggestive influences such as biased interviewing procedures than if the event had occurred only once. This is especially important in child abuse cases because it is common for a perpetrator to frequently abuse the same child. A child's memory for an incident that occurred frequently would be expected to be relatively reliable, even in the face of possibly suggestive interviewing.

Another important constraint on the effect of postevent suggestion is that implausible events are less likely to be suggestively planted in memory than plausible events. In one study on this point, Kathy Pezdek and her colleagues had 20 confederates read descriptions of one true event and two false events to a younger sibling or close relative. The more plausible false event described the relative being lost in a mall while shopping; the less plausible false event described the relative receiving an enema. Three events were falsely remembered: all were the more plausible events. Thus, all memories are not equally likely to be suggestively planted in memory, and individuals with differing prior experience and prior knowledge are not equally vulnerable to suggestion. The relative ease of suggestively planting false childhood memories of sexual abuse versus being lost in a mall while shopping should be related to the relative plausibility of these two events to a particular individual. This research demonstrates that although memory can be influenced by postevent information, there are constraints on the conditions under which this is likely to occur.

Posttraumatic Stress Disorder (PTSD)

This entry briefly examines the history of the diagnosis of PTSD, the current symptoms that characterize this syndrome, risk factors for PTSD, and evidence about the prevalence of this disorder in relation to specific traumas. It also summarizes the debate about the expression of PTSD in children and other special populations and discusses the ongoing controversies surrounding this diagnosis. A special effort is made to include mention of forensic issues relevant to the diagnosis of PTSD.

History of the PTSD Diagnosis

PTSD was officially introduced into the mental health nomenclature in 1980 with the publication of the American Psychiatric Association's *Diagnostic and Statistical Manual*, third edition (*DSM-III*). The concept of a cluster of symptoms that occur in response to a particular stressor, however, has existed for centuries and has been referred to by terms such as *nerve-trauma hypothesis, shell shock,* and *stress response syndrome.* In *DSM-I*, veterans of World War II and the Korean War who continued to experience traumatic symptoms were diagnosed as having *gross stress reactions.* By *DSM-II*, in 1968, this term was replaced with *transient adjustment disorder of adult life.* The actual addition of the diagnosis of PTSD to the *DSM-III* has been attributed to the political and social pressure applied by advocates and psychiatrists after the Vietnam War; although these individuals more specifically lobbied for the inclusion of a *DSM* diagnosis of *post-Vietnam syndrome.* However, the *DSM-III* Task Force argued against including a diagnosis that was tied to a specific political event, while they were simultaneously persuaded by data showing that similar stress reactions occurred in victims exposed to other traumatic stressors, including natural disasters, rape, and/or confinement in a concentration camp. The *DSM-III* Task Force thus decided that an individual suffering from PTSD must have been exposed to a traumatic event, including but not necessarily restricted to combat, that was outside the realm of ordinary experience to meet the criteria for PTSD. Consequently, PTSD and the recently included diagnosis of acute stress disorder are distinctive in the *DSM* system because, unlike the majority of *DSM* diagnoses, the causal origin of these disorders is explicitly delineated in the diagnostic criteria.

Current PTSD Diagnostic Criteria

The research related to the disorder was greatly intensified after the inclusion of PTSD in the official nomenclature of *DSM-III*, was instrumental in the development of a variety of assessment tools geared toward measuring trauma symptoms, and led to the development of scholarly journals devoted to the topic of trauma. These events, in turn, provided much of the information to be considered by the task forces dedicated to creating the *DSM-III-R*, which was published in 1987; the *DSM-IV*, which was published in 1994; and the *DSM-IV-TR*, which was published in 2000. Considerable changes to the diagnostic criteria for PTSD were introduced in these revisions. One striking difference was in the nature of the trauma that had to be experienced to receive this diagnosis. The trauma criteria in *DSM-IV-TR* now specify that the affected person had to experience, witness, or be confronted with an event(s) that involved actual or threatened death, serious injury, or a threat to the physical integrity of self or others. The person also had to experience intense fear, helplessness, and/or horror in response to the traumatic event or events.

These changes have considerably broadened the types of events that can be considered as precipitants to PTSD since the traumatic event did not have to be directly experienced by the individual with PTSD symptoms or be highly unusual or statistically infrequent. Consequently, PTSD has now been claimed to result after a variety of events, including a difficult labor (even with a healthy baby), a miscarriage, watching a traumatic event on TV, the shock of receiving

even inaccurate bad news from a doctor, learning that one's child has a chronic disease such as diabetes, and completing work duties as a policeman or fireman. Of particular relevance to forensic psychologists is the determination that PTSD can also occur as a result of automobile accidents or workplace injuries and even in response to hearing sexual jokes or experiencing verbal harassment. Compensation for traumatic symptoms resulting from these types of events is now routinely being sought through legal channels.

The symptom criteria for PTSD in *DSM-IV-TR* were also changed. To receive the diagnosis, the traumatized person is now required to report at least one reexperiencing symptom, three or more avoidant/numbing symptoms, and two or more symptoms of hyperarousal as a response to the traumatizing event. Moreover, according to the *DSM-IV-TR*, the traumatized individual has to experience these symptoms for at least 1 month, which is considerably less than the 6 months required for the PTSD diagnosis as specified in the *DSM-III*.

Another noteworthy addition is that PTSD is one of the few *DSM-IV-TR* diagnoses in which malingering is specifically identified as a necessary component of the differential diagnosis. Malingering has been defined as the intentional production of false or grossly exaggerated symptoms, as a result of external incentives. Therefore, clinicians assessing PTSD need to be able to rule out malingering as a diagnosis when financial remuneration and/or benefit eligibility are a part of their patient's clinical picture. For example, more than 90% of veterans experiencing PTSD symptoms seek financial compensation for their emotional distress. Determining which, if any, of these patients are malingering is difficult because most PTSD symptoms are obtained by self-report measures and easily feigned clinical interviews. Therefore, one of the major problems with the diagnosis is that many PTSD symptoms are nonspecific and subjective.

It is now recommended that symptom validity tests be routinely included in PTSD assessment procedures. Clinicians also need to be able to detect when a patient has been coached to report particular symptoms (i.e., by his or her attorney or by a family member), as malingering has been considered a threat to the therapeutic alliance and has been shown to have a significant negative economic impact. Detecting malingering may require clinicians to collect accurate historical records related to the trauma and to interview other family members about the patient and his or her symptoms. Clinicians may also need to ask for specific examples of reported symptoms, look for inconsistencies in the self-report, and obtain physiological measures of responses to trauma-related versus neutral stimuli, if possible. Efforts should also be made to determine how to best manage and/or treat patients who have, or are thought to have, exaggerated or feigned their PTSD symptoms, as this may be a relatively common event in some settings.

Prevalence of PTSD

The *DSM-IV-TR* indicates that the lifetime prevalence for PTSD is approximately 8% in the population of U.S. adults. Women are at significantly greater risk of developing PTSD than are men. However, estimates of the rates of the disorder in at-risk or high-risk populations have varied substantially. For example, among the survivors of the Oklahoma City bombing, only about 35% developed PTSD. There is also evidence that the prevalence of PTSD has been increasing across cultures, perhaps as a consequence of the broadened criteria for what constitutes a significant trauma. Since only a small number of individuals who experience trauma go on to develop PTSD, researchers have concentrated on delineating risk factors for developing the disorder. These include lower intelligence, experiences of childhood trauma and interpersonal violence, having a psychiatric diagnosis prior to experiencing the trauma, dissociation in the weeks following the event, use of avoidance rather than problem-focused coping strategies, a poor social support network, and perhaps having a genetic vulnerability to strong physiological reactions to stress. The national comorbidity study also identified a number of consequences associated with a diagnosis of PTSD. These included increased risk of developing other psychiatric disorders, committing suicide, failing school, experiencing a teenage pregnancy or marital difficulties, and having an unstable work history.

Issues Related to Diagnosing PTSD in Children and Other Special Populations

Diagnosing PTSD is especially difficult in children because they may not have experienced significant distress at the time of the event (i.e., in some cases of childhood sexual abuse). They may also have limited

verbal abilities, especially when they are very young, and may have little insight about their thoughts and feelings to offer the clinician. Children may also have a different symptom pattern that is not well represented by the adult criteria for PTSD. For example, it has been suggested that children may have longer durations of avoidance and fewer symptoms of reexperiencing (e.g., visual flashbacks) than adults have. Children may also be more likely than adults to mask their feelings of fear, helplessness, or horror with rage, hostility, refusal to go to school, and behavioral outbursts that may be more suggestive of conduct disorder than PTSD. Children may also report more concentration difficulties and cognitive changes posttrauma than adults do. Finally, some studies have shown that there are large numbers of children who have been exposed to a severe discrete trauma who fail to meet the full criteria for PTSD as specified for adults; yet these reactions were of sufficient severity to create a functional impairment for the child. Taken as a whole, these findings have led researchers, such as Michael Scheeringa and colleagues, to delineate an alternative set of criteria for PTSD that can be used with infants and very young children. The efficacy of these criteria is currently being considered.

Diagnosing PTSD in individuals who have suffered a traumatic brain injury is also controversial. Specifically, it has been questioned whether a person who has posttrauma amnesia for the traumatic event can receive a diagnosis of PTSD since these individuals also have no recollection of feeling helpless, fearful, or horrified in response to the trauma.

The symptom pattern of PTSD may also be different and more complex in individuals who have experienced a chronic stressor (such as childhood physical or sexual abuse or kidnapping and torture) as opposed to those who have experienced a discrete stressor. Some have argued that complex PTSD is better described by the *International Classification of Diseases*, 10th revision (*ICD–10*) diagnosis of *enduring personality change after catastrophic experience* than by the symptom pattern detailed for PTSD.

PTSD: Current Controversies

Many controversies currently surround the diagnosis of PTSD. As stated previously, there are differences of opinion about which types of trauma should be considered as significant enough to generate symptoms of PTSD. There is also debate about the number of symptoms needed for the diagnosis, with some experts arguing that significant impairment can still occur in individuals who fail to qualify fully for the diagnosis. Moreover, PTSD has been shown to have high rates of comorbidity with other diagnoses such as major depressive disorder, alcohol dependence, and other anxiety disorders. These may be due to the high degree of symptom overlap between PTSD and other disorders. For example, PTSD and depression share symptoms of insomnia, impaired concentration, social withdrawal, and diminished interest in or satisfaction from previously pleasurable activities. Similarly, PTSD and generalized anxiety disorder share symptoms of irritability, hypervigilance, exaggerated startle response, impaired concentration, insomnia, and autonomic hyperarousal. Thus, the degree to which there is an identifiable stress reaction has been questioned, and debate continues about how to differentiate a normal reaction to a horrific event from an abnormal reaction to a horrific event, such that it would constitute a psychological disorder. Additionally, PTSD is theorized to have a dose-response relationship with experienced trauma, such that more severe stressors are thought to be associated with worse symptoms and a greater likelihood of receiving the diagnosis of PTSD. While some researchers have found evidence in support of this relationship, data from other studies have failed to establish a linear relationship between the severity of the trauma experienced and the likelihood of experiencing PTSD symptoms.

The development of a theoretical model for what causes PTSD to occur in some but not all individuals has also engendered debate, as the prevalence of PTSD is rather rare (between 1% and 8% of the general population) relative to the number of Americans known to have been exposed to a sufficiently severe and potentially traumatizing stressor (estimates suggest 66% or more of the general population). These findings have led researchers to conclude that trauma is necessary but not sufficient to cause PTSD and that the person's subjective experience of and attributions about the trauma may be as important as the event itself.

Another controversy that surrounds the diagnosis of PTSD has focused on the validity of recovered memories of trauma. For example, if recovered memories of childhood sexual abuse are not accurate, then can they cause PTSD? Additionally, studies have shown that trauma memories change across time, are dynamic rather than static, and are related to a person's current clinical state.

Last, further concern has been generated with regard to the efficacy of using early psychological

interventions to promote recovery from posttraumatic stress. Data have accumulated that suggest that routine, one-shot psychological debriefing after trauma may not augment the recovery process and, in some cases, may actually impede it. Therefore, controversy about what constitutes a best-practice prevention effort for PTSD is ongoing.

Presence of Counsel Safeguard and Eyewitness Identification

The presence-of-counsel safeguard, provided by the Sixth Amendment of the United States Constitution, guarantees every defendant the right to an attorney both at trial and during pretrial proceedings, including live, postindictment lineups. The presence of an attorney at live, postindictment lineups serves to protect defendants from erroneous convictions resulting from mistaken eyewitness identifications by allowing attorneys to attend pretrial identifications, advise their client of their legal rights and obligations, oppose the use of suggestive lineup procedures, and observe and record any suggestive procedures used during the identification test. Research has examined attorney behavior to determine the effectiveness of this safeguard.

The effectiveness of the presence-of-counsel safeguard rests on several psychological assumptions about attorney behavior. Specifically, for the presence-of-counsel safeguard to be effective, attorneys must be knowledgeable about factors that influence lineup suggestiveness and be able to recognize these factors when present in an identification test. Furthermore, this safeguard is effective only if attorneys attend their clients' lineups and document any suggestive factors to support a motion to suppress the identification evidence or challenge the identification through cross-examination at trial.

How effective is the presence-of-counsel safeguard? Although a number of studies have examined attorney knowledge and opinions of the factors influencing eyewitness memory and identification accuracy, to date, only one study has examined attorney sensitivity to factors present in lineups and known to influence eyewitness identification accuracy.

Veronica Stinson and colleagues assessed attorney sensitivity to lineup suggestiveness by creating a videotaped lineup wherein aspects of the lineup known to produce higher rates of false identifications were manipulated. These lineup features included the individuals presented along with the suspect, called foils (biased vs. unbiased); the instructions given to the eyewitness (biased vs. unbiased); and the presentation of the lineup members (simultaneous vs. sequential). Prior to viewing one version of the videotaped lineup, attorneys were instructed to assume that the suspect in the videotaped lineup was their client, and they were provided with a photograph of the person suspected of the crime along with a written description of the eyewitness's memory of the event and of the perpetrator. After viewing the lineup, attorneys evaluated the suggestiveness and fairness of the overall lineup procedure and of the foils, instructions, and presentation of the lineup. Attorneys were also asked to indicate the likelihood that they would file a motion to have the identification suppressed at trial.

The results indicated that attorneys are effective in safeguarding their clients from foil-biased lineup procedures. Attorneys, however, may not fully safeguard their clients from instruction-biased lineup procedures. Although attorneys appeared to be sensitive to the harmful effects of instruction bias and to recognize biased instructions in a lineup procedure, they did not believe that biased instructions reduced the fairness of

the lineup. Furthermore, attorneys reported that they would be unlikely to file a motion with the court to suppress the identification when the lineup instructions are biased. Research, however, has shown that judges are more likely to grant a motion to suppress an identification when the lineup instructions are biased than when they are unbiased. Finally, attorneys lacked knowledge regarding the beneficial effects of sequentially presented lineups, suggesting that they are unable to effectively safeguard their clients from presentation-biased lineup procedures.

Although this study would suggest that attorneys are somewhat sensitive to factors influencing lineup suggestiveness, the presence-of-counsel safeguard is effective only if attorneys are actually present at their client's postindictment lineups. Surveys of attorneys and police officers, however, suggest that defense attorneys are rarely present at the construction or presentation of their clients' identification tests. Thus, the effectiveness of the presence-of-counsel safeguard may be limited not only by attorney knowledge of and sensitivity to factors influencing lineup suggestiveness but also by the absence of attorneys at their clients' lineups.

Presentence Evaluations

Presentence evaluations are those assessments conducted prior to the sentencing stage of proceedings to assist the court in making an appropriate disposition. Individual differences in crimes, criminals, and circumstances justify the need for personalized sentences in each case. Mental health professionals, probation officers, and social workers are among those in the forensic field called on to conduct these assessments. This entry explores the importance of presentence assessments, the content of such assessments, and standards of practice in completing high-quality assessments.

Historically, the goals of punishment were retribution, incapacitation, and general deterrence. These objectives do not require in-depth knowledge of the offender. However, with the aims of reform and rehabilitation came a need for further information regarding the offender prior to imposing a sentence. Indeed, some scholars have suggested that the sentencing decision may be the most important decision made about a defendant in the entire court process. It is now common practice for the court to order the completion of a presentence report to assist the court in making an appropriate disposition. Probation officers are frequently involved in the preparation of these reports; however, if mental health issues arise, the mental health professional may be called on to complete an assessment at this stage. The ordering of such evaluations varies in different jurisdictions, and consistent criteria do not exist. Some information suggests that judicial decisions to order assessments at this stage may be influenced by the judge's commitment to rehabilitation or retribution.

Specific requests made by the court will dictate the focus of these evaluations, and the content of reports will vary depending on the needs of the court as well as of practitioner called on to conduct the evaluation. The specific role of the mental health professional will be in providing information relating to culpability, which would include aggravating and mitigating factors in offending; risk assessment, such as risk management strategies; and mental status and treatability assessments, including identifying specific and appropriate treatment needs of the offender and an evaluation of the treatability of the offender. Indeed, judges have requested that the examiner inform the court why a particular recommendation is needed,

what form it should take, and what impact it is likely to have on the offender.

When mental health professionals are called on to conduct an assessment of the accused at this stage of proceedings, the report is likely to follow a fairly standard format that typically includes a review of the following: (a) personal and family data, including information regarding the offender's childhood, school, employment, relationships, substance use, and mental and physical health; (b) offense information, which moves beyond a simple recounting of events to include motivation for the offense and the defendant's attitude toward the offense; (c) a review of criminal history, including juvenile adjudications, past response to corrections, and criminal behaviors not resulting in arrest; (d) an evaluation of the accused, which may include the results of testing as well as a current mental status assessment; (e) a risk assessment; and (f) conclusions including recommendations and risk management strategies.

There has been relatively little research on judge's views of presentence reports. That research that has been conducted appears to have asked the question generally instead of focusing on specific reports. Although responses have been favorable in many cases, those criticisms that do exist focus on the unrealistic recommendations made and the jargon used in reports. Indeed, research suggests the need to tie the content of the report to its purpose—that is, to concentrate on issues relevant to understanding the offending behavior and considering constructive responses to it. In doing so, the examiner should also consider the seriousness of the offense, as this has been a criticism of past reports. Furthermore, reports should make use of appropriate language free from jargon, prejudicial or stereotypical language, and spelling and grammatical errors. In addition, standards of practice would require providing thorough but concise information in a logical format and presenting information from a variety of sources including, but not limited to, a file review of police records, court transcripts, and criminal record; an interview with the offender, including testing information; and interviews with collateral sources, such as family members, spouses, employers, and other relevant community contacts. Additionally, the offender may be asked to sign release forms so that records may be obtained from various community agencies with which the accused has had prior contact, including hospital and community mental health centers, substance abuse treatment programs, and community corrections.

Despite some criticism, presentence evaluations or the recommendations such assessments provide appear to play a prominent role in sentencing decisions. As such, providing reports of consistent quality is of paramount importance because failure to do so may contribute to inequality in outcomes. There is a need for further research to examine the quality of these assessments and the impact they have in sentencing offenders. Such information will assist the examiner in providing evaluations of the highest quality and help ensure that these evaluations meet the needs of the court.

Pretrial Publicity, Impact on Juries

When a trial is deemed newsworthy by the press, it is likely that information about the nature of the allegations, the character of the defendant, or other case-relevant information is reported in the media. Although the First Amendment to the Constitution guarantees the right to free speech and a free press, there is concern among the courts and scholars that providing information about a case to potential jury members before a trial may bias the jury pool by creating negative perceptions of the defendant and

entrenching jurors' opinions about the defendant's guilt before they hear the evidence that is introduced at trial. Empirical research suggests that exposure to pretrial publicity causes jurors to be more conviction prone, especially when the publicity is designed to elicit an emotional response rather than present facts. Results from trial simulation studies suggest that traditional remedies for the negative influence of pretrial publicity on juror decisions, including voir dire, judicial instruction, and continuances, may not be effective in eliminating bias.

Effects of Pretrial Publicity on Juror Decisions

Some of the information provided to the general public, such as comments on the defendant's character, discussion of a defendant's prior criminal record, or presentation of evidence against the defendant (e.g., a confession made by the defendant), may create bias in a potential jury member and prevent him or her from hearing the case fairly. In fact, some of the evidence that the media report pretrial may be ruled inadmissible at trial. A community member exposed to inadmissible evidence via pretrial publicity (PTP) may be unable to put aside or ignore the prohibited information if he or she is chosen to serve as a juror for the case. These kinds of biases violate the defendant's Sixth Amendment right to a fair and impartial jury.

Researchers have typically examined the effects of PTP through field studies and experimental studies. In field studies, PTP is assessed by surveying community members from the venue in which a case will be tried regarding the extent of their exposure to media regarding the case, the information they know or remember about the case, and their perceptions of the defendant's guilt. Similar information is obtained from community members in other venues to which the case may be moved, generally locations in which the media coverage of the case was less or nonexistent. Knowing this information, researchers can compare both the amount of PTP and the perceived guilt of the defendant between the different venues. The relationship between PTP exposure (as reported by the community members) and pretrial judgments of the defendant's guilt can also be examined. In general, field studies have shown that community members who reside in the venue in which the trial is to be held and therefore have received the most PTP exposure possess significantly more biased attitudes against the defendant than community members in remote venues. Field studies have the benefit of studying PTP in naturally occurring environments; however, this method also has its shortcomings. Field studies cannot estimate the effects of PTP after the presentation of evidence, its processing, and deliberation with other jurors. Experimental methods are needed to make such assessments.

As opposed to field studies, experimental studies are typically conducted in a laboratory in which the nature and extent of PTP are manipulated while holding other variables constant. Typically, after exposure to PTP, participants watch a trial stimulus and are asked to judge the guilt of the defendant, either on their own or after deliberation with other mock jurors. The effects of varying levels of PTP on verdict choices are examined. The primary advantage of experimental methods is the ability to make causal conclusions about the effects observed. However, experimental studies have often used relatively artificial PTP exposure, as well as undergraduate college students as participants, and therefore have been criticized for their low ecological validity.

In general, experimental research indicates that PTP negatively influences perceptions of the defendant; as more pieces of prejudicial information are presented pretrial, jurors' pretrial perceptions of the defendant become more negative. The prejudicial impact of the PTP persists even after jurors hear trial evidence. Mock jurors who are presented with negative PTP are more likely to find the defendant guilty than jurors who are not presented information pretrial. The prejudicial effect of PTP has been found in both criminal and civil cases and is greater when the PTP is emotionally based (e.g., graphic details of a brutal rape) rather than factual (e.g., details of the defendant's past criminal history). Furthermore, research indicates that even publicity that is topically, but not directly, related to a case (known as general PTP) can influence jurors' evaluations of trial evidence as well as their verdict choices.

Potential Remedies for Prejudicial Effects of PTP

The American Bar Association recognized the harm that prejudicial PTP can cause and has suggested a number of methods to counteract its effects, including voir dire, judicial instruction, continuance, and change of venue. Unfortunately, research has failed to

show that most of these methods successfully decrease the effects of PTP on juror judgments.

One of the most common methods used to combat PTP effects is voir dire. During voir dire, attorneys and/or judges question potential jurors about biases they may hold that would prevent them from hearing the case fairly. When PTP is a concern, the judge has the option to extend voir dire questioning to uncover any juror bias that may be the result of exposure to PTP. Empirical research, however, has identified several issues concerning voir dire that prevent its effectiveness. Research has shown that attorneys' ability to uncover general juror bias is limited. It may be difficult to identify biased jurors in part because attorneys must rely on jurors to self-report their bias, and jurors may lack the ability to recognize the factors that influence their decision making, including exposure to PTP. Exacerbating the problem of self-report is jurors' motivation to answer voir dire questions in socially desirable ways, feeling a responsibility to the court to remain unbiased. Although it is possible that voir dire may be a vehicle for encouraging jurors to set aside their biases, research thus far has failed to show its effectiveness in reducing the bias produced by PTP exposure.

Another potential remedy for PTP effects is judicial instruction to jurors about their duty to avoid being influenced by PTP. The instructions emphasize the importance of disregarding previously heard information about the case and relying solely on the information presented during the trial. Although research has shown that jurors generally do not follow judicial instructions to disregard information, these instructions have been found to be more effective when paired with a rationale for why the information should be disregarded. Early research found support for judicial instructions as a remedy for PTP; however, the methodologies of these early studies have been criticized. Methodologically sound research is yet to provide support for the usefulness of these instructions.

Continuance—delaying the start of a trial—has been used as a remedy to PTP, with the hope that the effects of PTP will decrease as time passes since the last exposure to the prejudicial media. Research on continuance is limited, but some studies have indicated that the passage of time can decrease the effects of factual PTP but not emotional PTP. A meta-analysis, however, suggests that longer delays between PTP and a trial can actually increase PTP effects. These findings may be due to a sleeper effect—the tendency of unreliable information to become more influential over time because the information becomes detached from the unreliable source in memory. Similarly, information presented in PTP may be difficult to disregard even when jurors are instructed to do so, because the information becomes separated from its source over time, making it impossible for jurors to identify which information in memory came from the trial evidence and which information came from PTP.

Finally, a trial may be moved from one venue to another that is less saturated by PTP in an attempt to minimize the effects of PTP on juror judgments. Empirical research shows that a change of venue is the most effective way to remedy PTP effects, as studies have found that jurors in areas more heavily saturated by PTP are more biased in support of the prosecution and against the defendant than jurors in areas less saturated by PTP. It has been argued that in extremely high-profile cases, finding a venue where potential jurors have not been tainted by PTP is impossible. However, content analyses of actual media coverage have shown that even in highly publicized cases such as the Oklahoma City bombing, alternative venues with little, or at least reduced, PTP can be found. Thus, even if a change of venue cannot eliminate PTP effects, it may be able to reduce them.

Psychological Consultation in PTP Cases

When a defendant believes that community members have been exposed to a significant amount of PTP concerning the case, his or her counsel may file a motion to seek remedies to counteract the bias that may result from the prejudicial information. When such motions are filed, either side may call an expert who may provide testimony to the judge making determinations about whether to implement any remedies, such as expanded voir dire or a change of venue. The expert may testify about experimental psychological research on PTP, including the negative impact it has on jurors' perceptions of the defendant and on verdict decisions. The expert may make comparisons between the types of PTP used in research and the types of publicity that have been released in the current case. The expert may also testify about experimental research testing the effectiveness of the suggested remedies. Although research indicates that most traditional remedies besides change of venue are ineffective, judges themselves report a strong belief in the effectiveness of remedies such as extended voir dire and judicial instruction.

Additionally, when experts are testifying in a change-of-venue hearing, they may provide the court with data they have collected to assess the level of prejudice in that particular case by comparing the responses from community members in the current venue with community members' reports of bias in alternative venues. The expert may present differences in the amount of PTP exposure reported by community members, their level of knowledge about case facts, and their perceptions of the defendant's character and likelihood of guilt as a function of the community in which the respondents live. Additionally, the expert may present results from content analyses of the quantity and quality of PTP in the current venue as well as possible alternative venues. The expert may then testify about differences in media exposure between the communities, including the number of articles reporting on the case, the types of prejudicial information divulged, and the amount of emotional PTP in each of the venues.

PTP continues to be a concern to defendants, the courts, and researchers. Research has consistently demonstrated that exposure to negative information about the defendant pretrial affects jurors' perceptions of the defendant, that these negative perceptions persist even after trial evidence is presented, and that these perceptions have been shown to influence jurors' verdict decisions. Additionally, many of the most commonly implemented remedies to counteract PTP have proved to be ineffective when empirically tested. Of the remedies, change of venue seems to be the best method for reducing the negative effects of PTP. Expert testimony addressing these research findings as well as results from surveys assessing the communities' level of prejudice against the defendant may assist the courts in their quest to provide the defendant with a fair and impartial jury.

Prison Overcrowding

With well over 2 million individuals confined in jails and prisons in the United States, it is easy to understand why the federal prison system and 24 state prison systems were above their rated capacity at the end of 2004. The data supplied by the Bureau of Justice Statistics revealed that the federal prison system had the highest rate of overcrowding in 2004 (140%), but this was only because states such as Alabama, California, Delaware, and Illinois housed a significant portion of their inmate populations in private and contract facilities. Local and county jails held 747,529 offenders in mid-2005, which represents approximately one third of the incarcerated population. These facilities were at 95% capacity, although this figure is deceptive because research indicates that smaller jails often operate well below their rated capacity, whereas larger metropolitan jails often operate well above their rated capacity.

Prison overcrowding is of particular interest in the United States, in part because of the number of people

who are confined in American jails and prisons and in part because of several well-known court cases in which states have been ordered to improve the conditions of confinement to include alleviating overcrowding. However, prison overcrowding is neither a particularly new nor an exclusively American problem. With the advent of the prisoners' rights movement in the early 1970s, prison conditions have come under increased scrutiny. One such area of increased scrutiny is the degree to which the inmate population exceeds the rated capacity of the institution in which it is housed. Furthermore, concerns about prison overcrowding extend beyond the borders of the United States. Canada, Great Britain, and the Scandinavian countries have recently raised concerns about prison overcrowding, and many nations in Africa, Asia, and South America have prisons that are more crowded than those in the United States.

Measurement

Prison overcrowding has traditionally been defined by density (i.e., the proportion of inmates to rated capacity of an institution; the ratio of single cells to multiple-person cells). A distinction can be drawn, however, between overcrowding and density. Whereas overcrowding is a psychological condition based on a perception of limited space by an incarcerated individual, density is a physical condition, such as the ratio of inmates to available space in an institution. There are two forms of density: spatial density and social density. Spatial density, the measure most often used in prison-overcrowding research, is normally calculated as the proportion of inmates in an institution or prison system to the available space as established by the rated capacity of the institution or system. Prison and jail officials often consider their institutions overcrowded when they exceed 80% of the rated capacity. Social density, on the other hand, is measured by the amount of double and triple bunking found in a correctional institution. Research indicates that inmate health problems and violence may rise as social density increases.

Causes

The overriding cause of prison overcrowding is fairly obvious: The number of inmates exceeds the spatial and social capacity of correctional institutions and prison systems to house these inmates. On the other hand, the underlying cause of this surplus of inmates is less apparent. Several sets of factors appear to have contributed to the growth of jail and prison populations in the United States and other parts of the world. One important factor, at least in the United States, is a punitive public. Many people in the United States want to see those who violate society's rules punished for their actions. Politicians frequently comply with the public's demand for greater punishment because they do not want to appear weak on crime. Accordingly, they introduce legislation that provides for mandatory, determinate, or longer sentences; reduces good-conduct time credit; and restricts or eliminates early-release programs such as parole.

In addition to the legislative response of politicians and policymakers to a punitive public, there are several other factors that may contribute to prison overcrowding. Drug use is instrumental in a quarter to a third of all new jail and prison admissions and is the leading cause of parole and conditional release violation. As such, drugs are both directly and indirectly (harsher sentences for drug offenses) linked to prison overcrowding. Demographic changes contribute to prison overcrowding, as exemplified by the crime explosion of the mid-1960s when the baby boomers were in the age range most conducive to crime (late teens to mid-20s). Over time, prisons age and become less efficient; some may even be closed. This places an increased burden on existing facilities and adds to the growing overcrowding problem. With advances in technology, law enforcement may become more efficient, which could potentially increase the jail and prison populations and contribute to prison overcrowding.

Consequences

The most frequently mentioned consequence of prison overcrowding is aggression. Early research on overcrowding in rodents indicated that mice and rats raised in a crowded environment were more violent, stressed, and diseased than mice and rats raised in an uncrowded environment. Studies conducted on prison overcrowding, however, have yielded mixed results. In some studies, prison overcrowding has been found to correspond to an increase in future disciplinary problems, particularly aggression. In other studies, prison overcrowding has failed to correlate with aggressive and nonaggressive disciplinary problems.

In still other studies, prison overcrowding is associated with a noticeable decline in future aggressive and nonaggressive disciplinary problems.

There are several possible explanations for these inconclusive and sometimes anomalous findings. First, because younger individuals often have trouble avoiding getting disciplinary reports in prison, it is possible that changes in the age structure of the prison or the practice of housing older and younger prisoners in separate facilities could influence the results of overcrowding research. Second, most of these studies overlook the positive or ameliorative effects that may reduce the negative impact of prison overcrowding. When researchers examine the effect of educational, occupational, and psychological programming on prison-based aggression, they frequently find that these positive pursuits can have a calming effect. Both these factors, age and positive influences, suggest that a systems approach should guide research on prison overcrowding.

Aggression and disciplinary problems may be the principal outcome measures used in research on prison overcrowding, but they are not the only possible consequences of overcrowding. Additional consequences of prison overcrowding include reduced recreation time for prisoners, decreased access to health and mental health care, poor staff morale, increased facility maintenance costs, diminished institution security, and fewer opportunities for inmates to learn trades and attend school. These consequences, as well as the possibility of a rise in future aggression, illustrate the importance of finding a solution to the problem of overcrowding. A solution may not be immediately forthcoming, but by paying close attention to the systemic nature of prison overcrowding a solution, or combination of solutions, may well be found.

Solutions

Potential solutions to the problem of prison overcrowding can be divided into three general categories: administrative responses, front-end strategies, and back-end strategies. The most common administrative response is to build more prisons, although this is an expensive proposition that may fail to produce its desired effect. Prison construction will have little impact on prison overcrowding if the problem resides with the jail and its inability to manage pretrial and short-sentence inmates. Other administrative responses that could potentially offer a solution to the overcrowding problem include converting existing prison and nonprison facilities into inmate housing units, double and triple bunking, transferring inmates to private or contract facilities, and achieving greater multiagency communication and cooperation.

Front-end strategies are designed to manage prison overcrowding by reducing the number of new inmates entering the prison system. One of the most obvious front-end strategies is to prevent crime before it occurs. Even when crime does occur, incarceration may not always be the best option. Diversion programs that call on the individual to perform community service and the use of special drug and mental health courts can relieve overcrowding by diverting individuals who commit nuisance and petty crimes away from the prison system and into programs tailored to their individual needs. House arrest, intensive probation supervision, and drug surveillance in lieu of incarceration are additional ways to manage first-time offenders convicted of nonviolent crimes without resorting to incarceration and adding to the already burgeoning correctional rolls.

Back-end strategies help reduce prison overcrowding by releasing individuals from prison months or even years before their statutory release dates. Releasing inmates to halfway houses 6 to 12 months before their scheduled release can help ease prison overcrowding while maintaining some modicum of supervision over the inmate. If an individual does well in the halfway house, then the next logical step would be home confinement with monitoring provided by an electronic bracelet or similar surveillance device. Early release through parole is another back-end strategy capable of alleviating prison overcrowding. Allowing incarcerated offenders to earn good-time credit every month for good behavior, which would then move the offender's release date up, is another example of how prison overcrowding can be reduced with a back-end strategy.

Future Research

Prison overcrowding research, practice, and policy could benefit from a number of alterations in how the field is conceptualized and studied. First, several researchers have recommended a systems approach to research on prison overcrowding. A systems approach would show that new prison construction may not always be the solution to prison overcrowding. Not only is new prison construction expensive, but it also

fails to address issues such as pertinent overcrowded jails, excessive sentences, and distinguishing between those who require incarceration and those who can be managed in a less restrictive environment. The systems approach also suggests that resolving prison overcrowding will require cooperation and to some extent integration of the three primary approaches to reducing prison overcrowding: namely, administrative responses, front-end strategies, and back-end strategies.

Much of the research on prison overcrowding has taken a molar approach to the problem of overcrowding by using aggregate data from prisons or entire prison systems. Although this has shed light on the causes and consequences of prison overcrowding and pointed out possible solutions, it also has limitations. In recent years, researchers have called for more research on individual-level factors that may moderate the consequences of overcrowding. The few studies that have been conducted on this issue have produced potentially important findings, such as the fact that some white inmates, particularly those who were raised in rural areas, are more likely to perceive prison conditions as overcrowded than black inmates, who are often raised in more crowded urban environments. Another interesting line of research suggests that individuals who interpret or misinterpret behavior as aggressive are more likely to perceive the prison environment as overcrowded.

Adopting a systems approach to research on prison overcrowding and including individual-level moderator variables in the analysis may enable us to better understand prison overcrowding and its effect on the inmates and staff who live and work in correctional institutions and attain a firmer grasp of how overcrowding can be effectively managed in the correctional environment.

Probation Decisions

Probation officers' decisions affect the legal experiences and case outcomes of a substantial number of defendants and offenders. Probation officers exercise discretion and use subjective judgments and standardized assessment tools in making decisions that influence the dispositions of criminal cases and offenders' progress under community supervision. Probation officers serve the court by providing judges with information, protect the community by enforcing the conditions of probation, and assist offenders to reintegrate into the community by brokering services and other resources. Probation officers make decisions at the pretrial, presentence, and postsentence stages of the criminal justice process.

Pretrial Decisions

At the pretrial level, probation officers evaluate defendants for release on bail or pretrial supervision, which allows them to remain free while their case is pending. The evaluation process focuses on defendants' risk of flight and their likelihood of continuing their criminal activity. Probation officers collect information on a variety of factors that are related to offenders' ties to the community and their propensity to continue their criminal activity. Officers use interviewing techniques and data collection forms as the basis for their judgments. They must decide whether to recommend pretrial release and, if so, whether to

recommend a bail amount or conditions of pretrial supervision, including curfews, home confinement, and drug testing. They also must decide what constitutes an infraction or violation of those conditions and how to respond to the infraction—for example, asking the judge to issue a warrant for a person's arrest and ordering that the person be detained in jail until the case is heard in court.

Presentence Decisions

When the case proceeds to the trial or plea bargaining stage, probation officers help judges render sentences through presentence investigation (PSI) reports. Judges order presentence investigations, mostly in felony cases, to obtain background information that will guide them in imposing the most appropriate sanction. In particular, PSIs assist judges in ascertaining whether prison is an appropriate sentence in light of the crime and the offender's criminal and social history. Information in a PSI places the offense in a larger context that informs the judge in determining whether probation is a sufficiently punitive and fitting alternative to incarceration.

To obtain information for PSIs, probation officers interview offenders; review their criminal, educational, and military records; and contact family members and others who know important details about the offender's life. The PSI report presents the judge with the offender's comprehensive social, criminological, and psychological profile. The report covers the offender's history of treatment for medical, psychiatric, and substance use disorders as well as the circumstances of the offense. In addition, it covers his or her social and family relationships, present living conditions, and financial and housing status.

The PSI report also describes the resources available to help people who might be sentenced to probation and contains specific sentencing recommendations, if requested by the court or required by the statute. A probation officer can present his or her opinions regarding the offender's motivation and readiness to change and the circumstances surrounding the offender's criminal involvement. The PSI formulates an appropriate supervision or treatment plan, and if the person is sentenced to prison, it helps prison administrators decide whether the person should be placed in a minimum-, medium-, or maximum-security facility. Probation officers exercise discretion when conducting a PSI, deciding what questions to ask, how to ask the questions, what details to include in or exclude from the report, and whether the offender will be better served by probation or imprisonment.

Probation officers display their own particular styles in the PSI information-gathering process. For example, the officer whose style reflects a social work orientation might focus on psychological data, whereas the officer oriented toward rule enforcement might focus on the offender's criminal record and current charges. Individual differences among officers and variations in department standards produce wide disparities in the manner in which presentence investigations are prepared by officers and used by judges.

Postconviction Decisions

Probation requires offenders to be supervised in the community under conditions of release. All probationers are subject to statutorily mandated or standard conditions of release, such as reporting to their probation officer and getting permission from the sentencing judge to leave the jurisdiction. They also are prohibited from owning a gun. An arrest on probation constitutes a violation that could result in a prison sentence. The special conditions of probation can be punitive (paying restitution) or rehabilitative (attending drug treatment) and are designed to respond to the particular facts of the case or needs of the offender. Probation officers are responsible for enforcing the conditions of probation and reporting to the court violations of probation.

Shortly after an offender is sentenced to probation, probation officers conduct an intake interview to assess an offender's risk and needs. Risk assessment strategies evaluate the likelihood that an offender will be rearrested while on probation, whereas need assessment strategies evaluate offenders' problems and needs for services in areas such as addiction, mental health, and employment. Probation officers use case classification tools that structure their decisions about case management strategies. These tools contain static (age, instant offense, and number of previous convictions) and dynamic (employment, educational level, and substance use disorders) factors. The most common tool, the Level of Service Inventory–Revised, examines both dynamic and static variables to classify cases for supervision and services.

In the intake assessment process, probation officers must determine the degree to which offenders are likely to recidivate and identify which members of their caseloads pose a threat to public safety. Based on this determination, officers devise and implement a

supervision strategy that monitors probationers at a level commensurate with their likelihood of future criminal activity. The officer's duty as a control agent is to ensure that the conditions of probation are fully satisfied, investigate reports or indications of behavior that could jeopardize the safety of others, and initiate probation revocation proceedings to remove offenders from the community for failing to comply with the conditions of their probation sentence.

The reintegration of offenders into the community requires an evaluation of probationers' needs and an identification of their major problem areas and deficiencies. The purpose of the evaluation is to formulate a treatment plan that will encourage offenders to fulfill the probation contract. Officers act as counselors in their efforts to rehabilitate offenders. The probation officer's basic function in this area is to support the probationer in making important transitions: from law-abiding free citizen to convicted offender under supervision, and finally a return to free citizen.

Although probation officers are usually the principal change agent in offenders' lives, they are often unable to deliver all the interventions necessary to accomplish the successful reintegration of offenders. Limited departmental programs and personnel and large caseloads demand the use of community resources. The probation officer as resource broker assesses the service needs of the probationer, locates the social service agencies that address those needs, refers the probationer to the appropriate program, and verifies that the probationer has actually received services. The officer is responsible for facilitating the delivery of services that are unavailable in the community.

Probation officers perform a number of tasks throughout the probation process to protect the community and foster offender change. The supervisory decision, which is central to the surveillance or control aspect of probation, consists of two components. The first component pertains to the frequency with which a probationer reports to the officer. Although limited by legal statute and specified at the time of sentencing, the frequency of contacts is typically modified in accordance with the court's or officer's assessment of the offender's risk of continued criminal behavior (potential threat to the community). Probationers can report on a monthly (the prescribed and most common frequency), bimonthly, or weekly basis. In general, offenders who are at greater risk report more often.

The second component pertains to the type or mode of supervision. An officer can monitor a probationer through office visits, telephone contacts, mail-in reports, or electronic contacts. An offender's assessed level of risk determines the selection of a supervision mode. For example, felony probationers are required to visit the probation office regularly or observe a curfew; people who have committed less serious offenses are allowed mail-in reports. Related to the determination of a supervisory mode is the officer's decision to assume a particular interactive posture with different members of their caseload. The changes in posture involve shifts in a probation officer's attitudes, focus, and emotional tone during contacts with offenders.

Officers' supervisory styles are altered in response to probationers' demeanor on report days; their genuine willingness to cooperate in the rehabilitation process; and their expressed resolve to lead a productive and law-abiding life (e.g., find a job, finish school, and refrain from gang activity). These factors are generically referred to as the probationer's "attitude." Offenders who are honest in their self-disclosures and willingly accept the conditions of their sentence are viewed as possessing a positive attitude. A negative attitude, in contrast, is expressed in a probationer's belligerence, indifference, sarcasm, or blatant attempts to patronize or curry favor with an officer. Such behaviors are indicative of a poor adjustment to probation.

At any point during the probation sentence, an officer can initiate collateral contacts or cultivate relationships with a probationer's spouse, parent, teacher, friends, or employer or representatives of other agencies serving the offender. These contacts verify information such as residence, employment, and compliance with special conditions. They can also be initiated to enlist the aid of significant others in efforts to control, rehabilitate, and reintegrate the offender. If officers suspect that a probationer has resumed illegal activities, they can request reports that detail subsequent arrests or charges that the probationer might have incurred during the probation sentence.

Another discretionary decision of probation officers involves the determination of whether the probationer can benefit from counseling or extradepartmental resources. This decision consists of a gross evaluation of major problem areas (emotional, physical, interpersonal, and financial). During initial meetings with a probationer, the officer searches for telltale signs and symptoms of drug or alcohol abuse, psychological disorders, intellectual deficits, or inadequate social or vocational skills.

In the past, probation officers relied on their own sensitivity, common sense, and subjective judgments

to alert them to probationer needs and direct them in formulating problem-solving strategies. For example, studies have shown that probation officers, especially veterans, have stereotypes of offenders ("burglar," "white-collar criminal," "gang member") that affect their decisions about supervision. The type of counseling services delivered by officers typically follows a didactic, instructional model. Officers are reluctant to render treatment services because of their educational backgrounds, which have not prepared them to conduct actual psychotherapy sessions. However, officers are increasingly likely to use cognitive behavioral therapy, which is an evidence-based technique for changing offender behavior.

Officers are faced with two limitations in selecting an appropriate treatment: The time they spend counseling or advising an offender is restricted because of large caseloads, and the choice of referrals is dictated by situations or factors outside the officer's control (e.g., economic conditions that limit the number of job referrals; a lack of government funds, which limits openings in drug treatment programs). Therefore, officers must be highly selective in choosing probationers who need treatment most and are most likely to benefit from interventions. Offenders who take the initiative in requesting services or are younger, have shorter criminal records, and display a positive attitude are generally considered the best candidates for counseling and adjunctive resources.

Probation officers can recommend an offender for early termination if the offender is no longer a significant risk to the community, has exhibited exemplary behaviors (taken the necessary steps toward becoming a functional member of society), and has shown that the continuation of the sentence might disrupt the offender's pursuit of a noncriminal lifestyle (early termination can be recommended on the basis of an offender's request to leave the state for gainful employment). In contrast, officers can ask the court to extend periods of supervision beyond the expiration of the original sentence. Final authority in this matter rests with the court. However, because judges are so dependent on the information furnished by probation officers, they generally concur with the officer's request.

The prospect of early termination is an incentive for good behavior and demonstrates to probationers that cooperation and compliance with rules are rewarded. A key factor in the decision to recommend early termination is the regularity of the offender's reporting. If a probationer has been reporting regularly, it increases the likelihood that his or her case will be reviewed for early termination. The best probationers are those who routinely report at their scheduled times. If a cancellation is unavoidable, they promptly call their officers to inform them about the extenuating circumstances that prevented their attendance. The probationers who are frequently tardy, periodically skip appointments, and call with untenable excuses for failing to report are evaluated negatively. In fact, when queried about the progress of a case, officers are likely to respond on the basis of a quick tally of the number of times the particular individual has missed a report day.

The final discretionary task of a probation officer is the decision to initiate revocation proceedings. In most circumstances, if offenders have perpetrated a crime during the probation term, their sentence is automatically revoked. However, if the violation does not involve a new offense or the breaking of a serious rule, the officer can evaluate the offender's criminal history, attitude, report behavior, and employment status before filing a violation of probation petition to the court. A probationer who is seen as having potential for healthy change is often "given a pass" for minor transgressions. The officer carefully screens and selects the violations that are eventually brought to the court's attention.

Following the filing of a revocation petition, the officer must decide whether or not to recommend revocation and a sentence to prison or a continuance or extension of the probation sentence. This determination is based on the same set of factors as the one used to decide whether to file a violation-of-probation petition. On occasion, officers will suggest a short stay in jail when the probationer seems to have promise but needs to be "jolted" by serving some "hard time." The court does not always follow the probation officer's recommendations. Nonetheless, as in the case of early termination, the court usually abides by the officer's suggested course of action.

Procedural Justice

This entry focuses on the psychology of procedural justice (PJ) and the law. PJ is a judgment about the fairness of the procedures employed to resolve conflict. Psychological research shows that PJ enhances satisfaction with conflict procedures and outcomes independent of actual dispute outcomes or outcome fairness. Among the procedural criteria that enhance fairness are having one's say, neutrality, benevolence, and respect—an effect that occurs in legal contexts across cultures. Research has shown that procedural fairness effects are diminished and outcome effects are enhanced when outcomes are favorable or when they pose threats to central moral values. The psychology of retributive justice concerns the fairness of responding to rule violations or legal infractions. PJ research can assist in the evaluation of alternative dispute resolution procedures, such as mediation and restorative conferences.

Procedural Justice and the Law

The earliest research on the psychology of fairness focused on people's beliefs as to whether the outcomes of their conflict were fair. This distributive justice research was the first to conduct empirical tests of the proposition that people's satisfaction with the resolution of conflict is influenced by outcome fairness rather than exclusively by outcome favorability—a proposition that dates to Aristotle. Although the original demonstrations of distributive fairness effects on satisfaction were not conducted in legal settings, subsequent research established the importance of outcome fairness for people's satisfaction with the resolution of conflicts in legal settings as well. For example, a study of felony defendants found that their belief that their sentence was fair was a better predictor of their satisfaction with the outcome of their case than was the duration of their incarceration.

The first systematic research concerning the psychology of procedural fairness was conducted by John Thibaut, a professor of psychology, and Laurens Walker, a professor of law. Their seminal work led them to theorize that disputants' satisfaction with the resolution of their conflicts was influenced by the fairness of the conflict resolution procedures as well as the fairness of the outcomes produced by those procedures. Furthermore, they proposed that beliefs about procedural fairness were influenced by the manner in which control was distributed between disputants and potential third parties in litigation procedures (e.g., autocratic, adversarial, or negotiation procedures). Finally, they asserted that beliefs about procedural fairness were a critical determinant of litigants' (and observers') procedural preferences and their satisfaction with legal procedures and outcomes.

Thibaut and Walker's theory of PJ postulated that disputant process control and decision control were critical determinants of procedural fairness and satisfaction. The adversarial procedure was asserted to be superior because of its optimal distribution of control—allocating process control to the litigants or their lawyers (permitting each party to present evidence on their behalf) and decision control to the judge (thus ensuring that a decision would be imposed, even in high-conflict settings). One early study compared the procedural preferences of undergraduate students from four countries (France, West Germany, Britain, and the United States). This study found the adversarial procedure (common to U.S. courtrooms) to be perceived as fairer and preferred to alternative procedures by U.S. residents as well as by citizens in the European countries where the adversarial procedure is not legally institutionalized and where judges typically exert a greater degree of process control than in U.S. courtrooms.

Most important, Thibaut and Walker's laboratory research was the first to demonstrate what is referred to as the *fair process effect*: that the use of fair procedures enhanced disputants' acceptance of contested outcomes. This was a profoundly important finding for the fields of psychology and law, and it has been replicated in numerous studies of people engaged in

actual disputes in legal settings. While subsequent PJ research focused heavily on the procedural criteria of process control (or "voice") and decision control, research has also established that numerous other procedural criteria, including correctability, consistency, decision accuracy, and ethicality, also enhance procedural fairness.

Challenges to Procedural Justice Theory

The original PJ theory was developed out of research conducted in high-conflict settings (legal disputes). It assumed that disputants were motivated to obtain fair outcomes, and therefore preferred procedures that permitted them to express their views about appropriate outcomes and be influential in shaping those outcomes. Although the theory was well supported, some findings did not fit well with its predictions. For instance, the theory predicted that process control was important because it increased the likelihood of obtaining fair and beneficial outcomes. However, research showed that voice (i.e., process control) enhanced fairness even when disputants did not think that their voice was influential. This noninstrumental voice effect led two psychologists, Tom Tyler and Allan Lind, to propose a group value theory of PJ. This theory has profoundly influenced subsequent research and theory on PJ.

Group Value and Interactional Justice Theories

Whereas PJ theory is an instrumental theory that emphasizes disputants' concern with control, the group value theory emphasizes people's concern with their social relationships with groups and institutions and the authorities representing those institutions; it asserts that when people encounter authorities who represent valued groups (such as legal institutions), they look for information concerning their group belonging and group standing. This theory also asserts that three procedural criteria are particularly influential for beliefs about group standing and, hence, fair treatment: neutrality; benevolent authorities; and respectful treatment. In this view, voice—the opportunity to express one's views, even without any influence on one's outcomes, enhances procedural fairness for symbolic rather than instrumental reasons because it communicates one's favorable group standing. A related theory, interactional justice theory, likewise asserted that interpersonal concerns such as polite treatment shape judgments of procedural fairness.

An extensive body of research, including experiments conducted with undergraduate participants in psychology laboratories and surveys of citizens about their actual legal encounters (e.g., encounters with judges or the police), provides strong support for the central claims of the group value and interactional justice theories. This research shows that fair treatment enhances people's satisfaction with legal authorities, legal institutions, and outcomes. Furthermore, this fair treatment effect remains after controlling for the absolute outcomes and the distributive fairness of these legal encounters; it occurs in civil and criminal cases and among misdemeanors and felons and participants and observers.

Whereas the earliest research was strongly supportive of the claim that process control and decision control increased procedural fairness, more recent research has supported the group value theory's claim that neutrality, benevolent authorities, and respectful treatment increase procedural fairness because of what this treatment communicates about people's relationships with valued groups and authorities.

Moderators of the Influence of Procedures and Procedural Fairness

Researchers have also examined the conditions under which procedural fairness exerts more or less influence on legal attitudes and behavior. Two lines of research concerning moderating influences have been particularly influential. One has shown that the impact of procedural fairness is diminished when outcome favorability is high (and is enhanced when outcome favorability is low). A second has investigated the moderating influence of moral beliefs on the importance of procedural fairness. While the research described above shows that fair procedures lead to increased acceptance of undesirable outcomes, or increased perceptions of distributive fairness (a "fair process" effect), additional research has demonstrated that the fair process effect is diminished when people view certain trial outcomes (such as convicting a guilty defendant or acquitting an innocent one) as morally mandated. This research suggests that among those who perceive a particular outcome as morally mandated, the fair process effect does not occur. For these people, due process affects outcome satisfaction

less than their belief that the morally mandated outcome was obtained.

Justice Approaches to Legitimacy and Compliance With the Law

Deterrence approaches to compliance with the law are guided by the instrumental perspective that people's compliance is shaped by their estimates of the penalties that will result from noncompliance. According to a deterrence perspective, the likelihood of crime decreases as the certainty and severity of punishment for crime increase. PJ research and theory suggests an alternative, normative approach to compliance: People will voluntarily obey the law when they believe it is the right thing to do. Morality and beliefs about legitimacy (of the law or legal authorities) are normative perspectives on compliance. A legal authority is said to have legitimacy when people think it is appropriate to comply with their decisions because the authority deserves to be in power and is entitled to obedience.

While research in legal settings has shown that compliance with the law is influenced by beliefs about the likelihood and severity of punishment, other research that compares expectations about punishment and beliefs about legitimacy as determinants of compliance shows that legitimacy is more influential. A considerable body of research in legal and other (e.g., organizational and political) settings indicates that authorities and institutions are perceived as more legitimate, and elicit greater levels of compliance with their decisions, when they enact procedures fairly. For example, one study asked civilians about their encounters with the police. This survey found that citizen's reports that they were treated fairly were influenced by procedural criteria such as process control, neutrality, and respect and that as beliefs about fair treatment increased, so did citizens' beliefs about the legitimacy of the legal authorities and their intent to comply with the law.

Cross-Cultural Views

The question of the cross-cultural generalizability of PJ theories has been addressed in numerous studies, starting with the earliest work by Thibaut and Walker. Research described above showed that European residents showed the same preference for adversarial procedures over autocratic ones evidenced by the U.S. residents, despite the fact that the adversarial procedures are not institutionalized and are less familiar to participants in these European countries. Similar findings have been replicated in other countries, including Hong Kong, Japan, and Spain. Similarly, cross-cultural research has supported the claims of the interactional justice and group value theories.

Whereas the earliest tests of cross-cultural generalizability compared PJ effects in various countries, more recent research has shifted from a country focus to a focus on the cross-cultural variability of social values. This work has examined the way in which the cultural variability of social values moderates the influence of PJ criteria such as voice, benevolence, neutrality, and respect. Two dimensions of social values have received considerable attention: individualism-collectivism (the degree to which ties among individuals in society are weak, such as in individualist societies, where people are expected to look after themselves, or strong, as in collectivist societies, where people are integrated into stable, cohesive in-groups that place a high value on harmonious social relations) and power distance (the degree to which people expect or accept inequality in formal power among persons, with high-power-distance individuals being the most accepting of power differentials and low-power-distance individuals being more in favor of equality).

Although the general pattern of findings is supportive of the role of voice, benevolence, neutrality, and respect across cultures, this work has also shown that the strength of the relationships between procedural criteria and procedural preferences and fairness judgments varies with individualism-collectivism and with power distance. For example, people in collectivist societies, such as China, express a greater preference for mediation (a procedure that places greater reliance on cooperation and interpersonal harmony than do adversarial procedures) than people in individualist societies, such as the United States. Similarly, research has shown that individuals in societies high in power distance (such as the Arab and Latin American countries) are more tolerant of disrespectful or unfair treatment from authorities and are less sensitive to variations in opportunities for voice than individuals from low-power-distance societies (such as the Scandinavian countries). Although this research points to cultural variability on power distance and individualism-collectivism, there is also considerable variability among individuals within cultures, and the effects shown to result from cultural variation on these

constructs are expected to result from individual differences on these constructs as well.

Retributive Justice

Although there is an abundance of research on procedural and distributive justice, less attention has been paid to the psychology of retributive justice, concerning reactions to rule violation. When an injustice is addressed in the legal system, options for sanction largely involve victim compensation and offender punishment. Research suggests that a primary determinant of the impulse to punish rule-breaking behavior is the perpetrator's state of mind. If victims and third parties judge perpetrators to have committed harm unintentionally (negligence), psychological reasoning focuses on compensation for harm. However, when perpetrators are thought to have intentionally violated group norms and values, observers are motivated to punish the offender.

Proportionality is a central characteristic of retributive sentencing. The severity of the punishment assigned by observers increases with the perceived seriousness of the offense and the harm caused. Additional factors, such as the offender's age or previous criminal record, or the observer's cultural background, can also affect the severity of sanctions. Mitigations and justifications may eliminate or suppress the relationship between the severity of an intentionally committed offense and the severity of the punishment (e.g., when an offender kills someone who threatens his or her own life or the life of another). Studies have found that apologies and expressions of remorse also decrease the severity of the sentences recommended.

Sentencing in the criminal justice system has several underlying aims, including deterrence, rehabilitation, incapacitation, and retribution. Retribution is the only sentencing aim that is nonutilitarian and based on judgments of "just deserts"; as such, it is often considered a retrograde and vindictive motive for sanction. However, research on retributive justice suggests that retribution can be forward looking, in that it aims to ensure that problems of the past do not recur. Retributive justice performs an important role in maintaining the cohesion of social groups and is motivated by group members' concern for the group's welfare. Criminal violations of social norms constitute a salient threat to an individual's well-being, and offenses against innocent victims threaten group members' stable worldviews, in which one's environment is perceived as predictable and controllable. Punishment is seen as a stabilizing force, used to prevent future violations of group norms and restore the social order. Research supports the fundamental role of retribution in people's reactions to norm violations, suggesting that people assign punishment for just deserts rather than utilitarian motives. In addition to the rational, group-stabilizing motivation behind the desire for retribution, recent research demonstrates the role of moral emotions in assigning sanctions for norm violation. The severity of observers' assigned punishments for offenses increases when those offenses elicit, in particular, anger and moral outrage.

Alternative Dispute Resolution (ADR)

In recent decades, various procedures have emerged as alternatives to the court in resolving legal disputes. They include small-claims mediation, divorce mediation, judicially mediated plea bargaining, judicial settlement conferences, court-annexed arbitration, and summary jury trials. The Dispute Resolution Act of 1998 requires every federal district court in the United States to implement a dispute resolution program where one does not already exist and to improve existing programs. The growing popularity of ADR programs has prompted extensive investigation into disputants' responses to ADR.

While ADR procedures can be distinguished according to legal and structural characteristics (e.g., whether the procedure is voluntary, whether it is binding, the identity of the third party, the degree of formality, and the nature of the outcome), they can also be distinguished according to the degree of control that disputants retain over the process and the decision. For example, in court-annexed arbitration, participants retain process control in the presentation of evidence but relinquish decision control to the arbiter. In mediation procedures, participants retain process control, presenting their version of events, but also retain decision control, aiming to reach a bilateral agreement. Consistent with psychological theory about PJ, research suggests that the increased levels of participation and voice, as well as the respectful treatment from benevolent authorities that can accompany these alternative procedures, enhance fairness and satisfaction. Correlational field studies have also found that mediation procedures are more likely to produce decisions that are obeyed than are adjudication procedures.

Restorative Justice (RJ)

Restorative justice (RJ) is an approach to criminal behavior that emphasizes healing victims, offenders, and communities. This variant of ADR is being increasingly adopted by justice systems worldwide. The basic premise of RJ is that crime is a violation of individuals and communities, not merely a violation of law. RJ prioritizes the goal of reparation of harm rather than the traditional punitive goal of just deserts. RJ is fundamentally different from other ADR and traditional courtroom procedures in its emphasis on the psychological importance of group belonging and its core goal of reintegrating offenders into important social groups. The group value model offers clues as to why people support restorative sanctions: Restorative sentencing emphasizes that an offender has lost his or her status as a respected member of the group and should perform reparative acts to regain that status.

RJ consists of a variety of practices at various stages of the criminal legal process, including court diversion, actions taken in conjunction with police and court decisions, reparation boards, and meetings between victims and offenders. RJ procedures are more prevalent in juvenile than in adult justice systems but are becoming more common in dealing with adult offenders. In the United States, RJ programs tend to be privately run or community based, with a number of RJ programs also developed by individual probation departments. Other nations, however, tend to implement RJ programs more systematically, incorporating RJ procedures as one component in a hierarchy of legislated responses to juvenile crime.

One common RJ practice is conferencing, in which the offender, the victim, and their supporters come together to discuss an offense. At the end of a conference, all participants, including the victim and offender, decide on a course of action for the offender to complete. The agreement is an undertaking by the offender to make reparation for the harm caused by the crime and might include, for example, community service or monetary compensation.

Consistent with research showing that ADR procedures engender greater disputant satisfaction, RJ conference participants report fairer treatment than their counterparts who experience court procedures. The RISE project in Australia, one of the few experimental studies of conferencing, randomly assigned cases to either RJ conference or court. Across all offense types included in the study (youth violence, drunk driving, shoplifting, and property crime with personal victims), participants' fairness judgments were higher in the conference condition. Studies on RJ conferencing have also found that recidivism is lower following conferencing than after court procedures.

Although early evaluations of RJ are promising, both the predominance of nonexperimental studies (with potential selection biases in participants, programs, and types and severity of offenses studied) and the need for systematic examinations of the psychological processes underlying participants' responses to RJ preclude authoritative conclusions about its effectiveness.

Profiling

Profiling is a relatively new investigative technique that, in the past 30 years, has developed from what used to be described as an art to a rigorous science based on advanced empirical research. Results from the first wave of research have shown that there is

validity to the idea that aspects of an offender's characteristics may be inferred from the way the offender acts at the crime scene. Ongoing research is focused on refining these efforts so that a systematic and reliable framework may be put in place, one that can provide a solid basis for constructing a useful psychological tool for police investigations.

Definition

Profiling (also known as offender profiling, crime scene profiling, psychological profiling, and personality profiling) is the process of linking an offender's actions at the crime scene to their most likely characteristics to help police investigators narrow down and prioritize a pool of most likely suspects. Investigators' efforts are focused on matching an offender's behavior in one situation to behaviors or characteristics in another situation.

Psychologists are sometimes called on during a police investigation to analyze the behavioral indicators of the crime and, based on these, to draw up a profile of the most likely characteristics of an offender responsible for such actions. In addition, psychologists continue to be involved in researching the processes of profiling itself, so as to establish its validity and utility as a police investigation tool.

Development

Although profiling was attempted as long ago as the mid-1880s, in the Jack the Ripper serial murder case in London, profiling as it is known today is a relatively new area in forensic psychology. Much of the early work in profiling dates back to the 1970s and 1980s, when there was an initiative to focus on analysis of the crime scene itself. Most of this work, typically done by practicing clinicians or police investigators, was based on understanding an individual's behavior at the crime scene through interviews with actual offenders and primarily focusing on the offender's internal motivations and drives, in addition to identifying specific behaviors.

With its increasing popularity through the 1980s, and also with more recent efforts to bring profiling into court as evidence, the method came under increasingly close scrutiny by researchers within the field. Consequently, the 1990s saw the creation of a new area of forensic psychology, investigative psychology, spearheaded by David Canter and colleagues, that focuses on the contribution of psychology to police investigations. Researchers in this growing field have stressed the importance of providing a solid methodological approach and framework for establishing an empirically based science testing the psychological principles on which profiling rests.

Early evaluation studies of the emerging field of profiling showed that extant models of criminal behavior were mostly unsubstantiated and not founded on rigorous scientific study. Other work evaluating actual written profiles showed that these included much unsubstantiated information. Based on these results, researchers in profiling have emphasized the importance of empirically validated research to establish a link between the actions of offenders at the crime scene and their corresponding characteristics.

Components

The main psychological premise behind profiling is that there will be consistency between the way offenders act at the crime scene and who they are. This is based on the broader findings from longitudinal studies and cross-situational consistency in general as well as from findings on the development of criminal behavior. By understanding consistencies in offenders' development and change over time, the suggestion is that we can link the way they behave at the crime scene with how they have previously behaved in different contexts. Three general interlinked areas have been the focus of recent profiling research: individual differentiation, behavioral consistency, and inferences about offender characteristics.

Individual differentiation aims to establish differences between the behavioral actions of offenders and uses this to identify subgroups of crime scene types. The focus here is on analyzing the observable, rather than motivational, aspects of the crime to increase the reliability and practical utility of these models in actual investigations. Although it is important to gain insight into the cognitions of offenders and add these to emerging models, research has shown that motivations are inherently more subjective and difficult to measure. As such, behaviors provide a more reliable unit of analysis, at least at the first stages of building models of criminal differentiation that are valid, reliable, and ultimately useful and applicable to actual investigations.

Behavioral studies of differentiation usually focus on differences among crimes scenes in various observable factors, including victim characteristics, interaction with the victim, nature of the violence, and other activities engaged in by the offender at the crime

scene. Much of this work has aimed to understand how an offender engages in patterns of actions that all demonstrate a similar underlying psychological dimension or subset. Any crime can be profiled using the appropriate frameworks, and work to date has included theft, burglary, robbery, arson, fraud, rape, pedophilia, crimes committed by youths, homicide, serial homicide, and others. The relevant psychological dimensions depend on the crimes analyzed. Some examples used in homicide work include behaviors indicative of expressive and instrumental types of aggression—such as treating a victim as an object or as a person, acting in a controlled or an impulsive manner—all of which are already well-established thematic classifications of human behavior in the general psychological literature.

Behavioral consistency is a key issue in profiling, specifically for understanding both the development of an offender's criminal career and an individual's consistency across a series of crimes—that is, whether the same subsets of actions are displayed at each crime scene over a series (linking serial crime). Much of this work has focused on whether consistency in criminal behavior can be established over time, as well as how individuals change and develop through learning and experience and whether offenders specialize or are generalists.

The search for consistencies has been approached in various ways in the theoretical literature, notably by establishing whether the offender acts according to the same psychological subtype or theme from one crime to the next (e.g., expressive or instrumental), whether the offender engages in the same specific behaviors from one crime to the next (modus operandi), or whether the offender engages in highly specialized behaviors unique to him or her and that are related more to his or her personal agenda, or fantasies (signature). The first few published studies on empirically validating these theoretical concepts indicate that although some consistency is evident, our understanding of the intricacies of the actual patterns over time requires closer empirical study, specifically in terms of how offenders develop, mature, experiment, and change in a consistent manner across time, as well as how situational factors influence an offender's behavioral consistency.

Inferences about offender characteristics is at the core of profiling and also uses consistency analysis as its main focus. At this stage, however, the main aim is to establish the link between subgroups of crime scene actions and subgroups of offender background characteristics in order to make predictions about an offender based on his or her criminal actions at the crime scene. This can then ultimately be used as a primary tool for the police to narrow their suspect pool down to statistically the most likely offender. Offender characteristics focused on typically include demographics, such as gender, age, and education, previous interpersonal and criminal history, home location and travel patterns (also known as geographical profiling), and the offender's relationship with the victim.

Prosecutorial Misconduct

Prosecutorial misconduct is any courtroom behavior on the part of the prosecutor that violates trial rules and denies defendants their right to due process. Examples of misconduct may include making unfair or improper comments about the defendant, defense counsel, or a defense witness; suppressing, tampering

with, or fabricating evidence; or making material misstatements regarding law or fact. The legal and psychological importance of examining prosecutorial misconduct is its potential to induce a jury to consider improper factors during the decision-making process.

Legal scholars contend that prosecutorial misconduct often occurs because of the prosecutor's quest to secure a conviction. In doing so, prosecutors compromise impartiality by using improper methods to establish guilt—for example, inappropriately inferring guilt from a defendant's silence. Although higher courts consistently express disapproval of improper prosecutor conduct, they frequently affirm the conviction, concluding that some prosecutorial errors are harmless. For an error to be considered harmless, reviewing courts need to establish that the outcome of the trial was not significantly affected by the error.

Forms of Prosecutorial Misconduct

The most common form of prosecutorial misconduct occurs in argument to the jury; however, it can also take place in evidence hearings, opening statements, and cross-examination. For example, it is misconduct to comment on a defendant's failure to testify. Similarly, it is improper for the prosecutor to address the credibility of the testimony of codefendants or co-conspirators. Commenting on a defendant's silence, or inferring questionable relationships among defendants, improperly suggests guilt and encourages a jury to find the defendant guilty. It is also considered misconduct for the prosecutor to question the integrity of the defense counsel. This includes unconfirmed claims that defense counsel fabricated evidence, courtroom displays of dissatisfaction with defense witnesses, or interruptions of defense objections. In general, any unsupported, damaging comments on the part of the prosecutor that challenge a defendant's constitutional rights can be considered misconduct.

A review of appellate decisions also finds prosecutors cited for misconduct regarding issues related to evidence. Prosecutors must not introduce or attempt to introduce inadmissible evidence and, in the same vein, must disclose evidence favorable to the defendant. It is misconduct for prosecutors to use false or misleading evidence, misrepresent evidence to the jury, or destroy or tamper with evidence. In addition, it is improper for the prosecutor to make material misstatements of law or fact. Opening statements must be limited to offering admissible evidence, and closing arguments must be limited to evidence presented. Repeated instances of uncorrected misstatements could result in ordering a new trial.

Prosecutorial Misconduct in Capital Trials

Prosecutorial misconduct has been identified as a leading cause of unfairness during the sentencing phase of capital trials. Courts have expressly condemned this type of misconduct, which occurs in closing arguments. Defense attorneys contend that improper prosecutor remarks during the closing argument have the potential to inflame the sentencing jury if the argument introduces arbitrary factors to the jury's recommendation of the death penalty. Empirical evidence indicates that individuals exposed to improper statements made by the prosecutor in the closing argument recommended the death penalty significantly more often than those not exposed to the statements. These results support the need to address regulating the penalty phase to minimize the likelihood that the jury will sentence the defendant to death for improper reasons.

Although the Supreme Court has not yet established specific guidelines determining the parameters of permissible prosecutorial argument, lower courts have provided general principles for defining improper penalty-phase arguments. In general, prosecutors are prohibited from stating their personal belief in the death penalty or from referring to their discretionary decision to seek the death penalty. It is misconduct to mislead the jury about its responsibility by implying that imposing the death penalty would deter others or protect the community. It is also considered improper to argue support for the death penalty in a religious context. Some state courts have ruled it improper for prosecutors to discuss the impact of the crime on the victim's family or to argue that a victim's family deserves a particular verdict. Overall, rulings on improper prosecutor arguments appear to be based on distinguishing between those that merely communicate misinformation and those that introduce extralegal factors that are likely to influence a jury's sentencing recommendation.

Remedies for Prosecutorial Misconduct

There is a considerable body of legal literature addressing remedies, or cures, for prosecutorial misconduct. Legal professionals concur that prosecutorial

misconduct is unlikely to affect the jury if countered by the defense attorney's objections or corrected by the judge's instructions. The Supreme Court has indicated that arguments with the potential to unduly influence the jury should be clarified by a specific judicial instruction. This instruction rebuts the inferences or implications made by the prosecutor in the closing argument. Similarly, defense attorneys stress the need to form prompt, articulate objections to improper statements to avoid any problems on appeal. The underlying assumption of each of these legal safeguards is their potential to minimize the effects of the prosecutor's improper argument on the jury.

In assessing the effect of prosecutorial misconduct, the pertinent question is whether the misconduct caused the trial proceedings to be fundamentally unfair. The standard for reviewing a prosecutor's improper penalty-phase argument is whether the argument affected the defendant's due process right or whether the argument unduly influenced the jury's recommendation of death.

Proxy Decision Making

Proxy decision making (also known as substituted judgment) refers to the use of the legal system to replace one person's judgment with that of another. This process exists to protect individuals from exploitation while allowing them to retain as much decision-making latitude as possible. Society's interests are served by preventing persons with mental disabilities from engaging in physically, financially, or otherwise harmful conduct. Different categories of proxy decision making include substitutions for prior judgment (as previously expressed in wills and other advance directives); present judgment (involving current capacity to provide informed consent to treatment or to refuse treatment); and future judgment (concerning projected ability to conduct personal and financial affairs).

In 1540, the Statute of Wills enabled English citizens for the first time to bequeath "real property" such as buildings and land. Within 2 years, this law was amended to invalidate wills by persons who were not "sane." Modern legal challenges still seek to determine whether the testator (a) understood what it means to make a will, (b) was aware of the nature and extent of his or her property, (c) could describe a rational plan for distributing that property, and (d) could identify the "natural objects of one's bounty"—meaning the persons one would normally expect to inherit the possessions in question. If such challenges succeed or if it can be proven that the will was substantially affected by another person's "undue influence," then a probate court will substitute its judgment for that of the deceased. Psychologists testifying in such proceedings may conduct a *psychological autopsy,* reflecting all currently available information about the decedent's cognitive status, medical condition, and interpersonal relationships during the period in question.

In recent years, the law has provided for a range of *advance directives* that allows persons to preordain specific aspects of their future care. These include *living wills* (conveying the desire to forgo artificial means of life-sustaining treatment) and *health care surrogacy* (empowering another person to make general health care decisions in the event of future incapacity). If an advance directive is successfully challenged on the grounds that it was not the product of a rational decision, then the individual's prior judgment may be set aside.

Substitutions for present judgment may occur when persons are unable or unwilling to provide informed consent to health care services. Typically, medical treatment cannot be delivered unless patients assent to it without coercion, after being provided with an explanation of potential risks and benefits, as well as any available alternatives, in language that the patient is capable of understanding. The Capacity to Consent to Treatment Instrument and the MacArthur Competence Assessment Tool for Treatment are

among the instruments psychologists may use to determine a patient's capacity to provide informed consent.

Persons may be hospitalized for a brief period without their informed consent if a qualified health professional determines that an emergency exists. A petition for lengthier periods of civil commitment may be upheld if the court concludes that, based on a qualifying mental condition, the patient presents a danger of harm to self or others, no less restrictive alternative to hospitalization exists, and the patient may reasonably benefit from the treatment provided in that setting. If patients refuse to provide informed consent to psychiatric medication once they have been civilly committed, the facility may attempt to obtain a separate court order to compel this form of treatment if failure to take such medication will constitute a further danger of harm to self or others. Criminal defendants may not be medicated for the purpose of achieving trial competency without their informed consent, unless the medication in question is medically appropriate, will significantly enhance the likelihood of a fair trial, and represents the least restrictive alternative available to further this purpose.

Substitutions for future judgment may occur as a result of guardianship proceedings, in which a person is alleged to be incapable of making decisions at a later date about a specified range of personal and financial affairs. The court may ultimately appoint a guardian to oversee or prevent the respondent's participation in activities such as voting, marrying, consenting to medical treatment, driving an automobile, or choosing a place to live. Guardians may also control the respondent's ability to spend money, sell property, and otherwise make contracts, or this may become the separate responsibility of a court-appointed conservator charged with monitoring solely financial matters. Psychologists participate in such proceedings based on their skill in assessing strengths and weaknesses in each area in question. In the past, courts typically rendered "all-or-none" decisions regarding guardianship, such that respondents found lacking capacity in one or more areas would find all their activities subject to supervision; now, however, most jurisdictions provide for "limited" or "partial" guardianship plans that are tailored to the unique needs of the individual.

Psychiatric Advance Directives

Psychiatric advance directives (PADs) allow competent persons to document advance instructions for their future mental health treatment or designate a health care agent to make decisions for them in the event of an incapacitating psychiatric crisis. PADs may enhance patient self-determination, improve therapeutic alliance, and prevent psychiatric crises; however, there are a number of legal, ethical, and logistical barriers preventing the effective implementation of PAD laws. Research shows that most people with mental illness would want a PAD if they received help and that a manualized facilitation increased completion and understanding of PADs as well as improved working alliance and perceived met treatment need. Studies also show that people with mental illness incorporate clinically useful information in PADs but that much more work is needed to bolster the use of PADs in actual clinical practice.

PADs are relatively new legal instruments. Prior to the 1990s, most laws involving people with mental illness, such as involuntary civil commitment, on balance have placed limits on patient autonomy in the interest of public safety or the patient's "best medical interests." In the past 15 years, however, PADs have been promulgated with the goal of promoting greater self-determination among people with mental illness. If followed by treatment providers, PADs may help patients gain better access to the types of treatment that work best for them—especially during times when they are most in need of care but least able to speak for themselves. Furthermore, the very exercise of preparing a PAD, and discussing it with a mental health professional, may enhance therapeutic alliance and improve treatment engagement.

In theory, PADs provide a transportable document—increasingly accessible through electronic directories—to convey information about a patient's treatment history, including medical disorders, emergency contact information, and medication side effects. Clinicians often have limited background clinical information about psychiatric patients who present in crisis centers or hospital emergency departments. Nonetheless, these are the typical settings in which clinicians are called on to make critical patient management and treatment decisions, using whatever limited data may be available. With PADs, clinicians could gain immediate access to relevant information about individual cases and thus improve the quality of clinical decision making—appropriately managing risk to patients' and others' safety while also enhancing patients' long-term autonomy.

The use of legal coercion in mental health services remains highly controversial, as it exposes a fault line between two important societal values: respecting the rights of individuals to choose their own health care and accepting social responsibility to care for those who are unable to care for themselves. Although involuntary treatment may well be effective in improving treatment adherence in the short run, it comes at the price of reducing personal liberty. Insofar as PADs may provide a means to promote both autonomy and beneficial treatment for persons with severe mental illness, some scholars believe that PADs may help resolve this fundamental dilemma in mental health law and policy by reducing the need for involuntary treatment.

As of 2006, 25 states had passed specific PAD statutory provisions. However, all states provide some type of legal instrument—typically a health care power of attorney—that patients can use to plan for their psychiatric as well as medical treatment during future periods of decisional incapacity. States' advance directive laws were given added force by the federal Patient Self-Determination Act (PSDA) of 1991. The PSDA requires that all hospitals receiving federal funds inform patients of their rights, including the right to prepare advance directives as authorized under state law and to institute policies for implementing advance directives. In short, federal law helps ensure that people with mental illness, in whatever state they live, can use medical advance directives to specify mental health treatment preferences or assign proxy decision makers for mental health decisions.

Ethical and Legal Questions

PADs pose certain ethical and legal dilemmas. For example, how should a clinician react if a severely mentally ill patient presents a PAD refusing treatment? Although doctors typically cannot override end-of-life advance directives, most of the new PAD statutes allow doctors to trump mental health treatment preferences that are inconsistent with appropriate psychiatric care as defined by community standards of practice. However, in *Hargrave v. Vermont* (2003), the U.S. Court of Appeals for the 2nd Circuit recently upheld a lower court's decision striking down a state law that allowed mental health professionals to override a hospitalized person's advance refusal of psychotropic medications through a general health care proxy. The court ruled that the Vermont override law—which applied only to persons with psychiatric disorders in the state hospital—was discriminatory on the basis of disability and thus violated the Americans with Disabilities Act, Title 3.

Some commentators worry that the *Hargrave* decision could have perverse consequences. Assuming that some severely mentally ill individuals prefer to remain unmedicated and assuming that they are able to document such preferences in advance while fully competent, the question arises, What are the ethical and fiscal implications of a state policy that, in effect, sanctions indefinite involuntary confinement of such persons when they become incapacitated but without providing them effective treatment? Should taxpayers be expected to shoulder the burden of paying for substantially longer hospital stays for psychiatric patients with PADs refusing medications? Another unintended consequence of *Hargrave* is that psychiatrists, in reaction to the specter of treatment-refusal PADs and

potential legal liability in such cases, may be reluctant to support PADs or to encourage patients to complete them. Although understandable, this reaction would beg the question of whether any substantial number of patients actually use PADs to document advance refusals of all medication; new research suggests that this may be a moot concern.

The presumption of competence to execute PADs is another controversial legal feature of these statutes. On the one hand, some mental health professionals would argue that a clinical assessment of competence should be required for patients who want to complete PADs, in view of the fluctuating decisional capacity that often characterizes severe mental illness. On the other hand, some scholars have noted that mandatory screening for competence—placing the burden on people with mental illness to prove that they are competent before completing a legal document—would amount to discrimination against adults with disabilities.

Currently, only two jurisdictions, Indiana and Louisiana, require that persons with mental illness be deemed competent before they write a valid PAD. However, in states where this is not required, there could still be practical reasons for patients to voluntarily request a clinical assessment of their competence prior to completing a PAD. Even people who do not have mental illnesses may elect to have a competence assessment at the time they prepare a legal document such as a will—precisely to avoid the problem of later challenges to testamentary capacity and thus ensure that their wishes are followed. With respect to implementing PADs, the practical question is, How can people with severe mental illness best ensure that future clinicians will abide by their preferences as documented in advance, without unduly questioning their competence to make those advance decisions and thus calling into doubt the PAD's legal validity?

Current Research and Trends

While a number of legal and ethical questions about PADs remain unanswered, a body of empirical research on PADs has begun to emerge. Studies indicate that although approximately 70% of patients with mental illness would want a PAD if offered assistance in completing one, less than 10% have actually completed a PAD. Why is there a gap between interest in and completion of PADs? First, people with mental illness report difficulty in understanding advance directives, skepticism about their benefit, and lack of contact with a trusted individual who could serve as proxy decision maker. The sheer complexity of filling out these legal forms, obtaining witnesses, having the documents notarized, and filing the documents in a medical record or registry may pose a formidable barrier.

Recent surveys of mental health professionals' attitudes about PADs suggest that they are generally supportive of these legal instruments but have significant concerns about some features of PADs and the feasibility of implementing them in usual care settings. Clinicians are concerned, for example, about following PADs that may contain treatment refusals or medically inappropriate instructions. They also worry about lack of access to PAD documents in a crisis, lack of staff training on PADs, lack of communication between staff across different components of mental health systems, and lack of time to review the advance directive documents.

For these reasons, among others, PADs have yet to gain widespread use in systems of care for people with severe mental illness. The research indicates, however, that as more people learn about these laws, PADs will be used more frequently. For instance, whereas most of the psychiatrists, social workers, and psychologists surveyed believed that PADs would help people with severe mental illnesses, clinicians with more legal knowledge about PADs were more likely to endorse PADs as a beneficial part of patients' treatment planning. Additionally, research indicates that PADs typically contain clinically useful information and almost never include medically inappropriate information. Swanson and colleagues analyzed the content of more than 100 PAD documents and found that psychiatrists rated the advance directives to be highly consistent with standards of community practice. Most participants used the advance directive to refuse some medications but provided clear reasons for their choices; none used an advance directive to refuse all treatment. Instead, most people who completed PADs used these documents to request that inpatient staff treat them with respect and talk with them about their treatment. More than one third listed specific medical conditions and/or medication side effects that would directly lead to more informed clinical decision making by doctors in emergency departments and inpatient settings.

Finally, new evidence is emerging from a large-scale randomized clinical trial of $N = 469$ individuals with mental illness, suggesting that a manualized

PAD facilitation helps overcome patient barriers to completing PADs and may improve working alliance and treatment engagement among people with severe mental illness. The authors found that 61% of participants in the facilitated session completed an advance directive or authorized a proxy decision maker, compared with only 3% of control group participants. At 1-month follow-up, participants in the facilitated session had a greater working alliance with their clinicians and were more likely than those in the control group to report receiving the mental health services they believed they needed.

In another analysis from this clinical trial, the authors systematically examined competence to complete PADs, using a newly developed instrument that evaluates patients' understanding, appreciation, and reasoning ability applied to PADs and the specific treatment decisions contained in PADs. The authors found that the majority of participants at baseline scored above 50% of the highest possible point total on this instrument. That people with mental illness are generally able to understand, appreciate, and reason adequately with respect to PADs is consistent with prior research reaching the same conclusion.

The study also showed that the manualized PAD facilitation significantly improved patients' competence to complete PADs, as well as their capacity to make reasonable treatment decisions within the framework of a PAD. The facilitation intervention increased PAD competence most dramatically for patients with low cognitive functioning and limited initial understanding of PADs.

Concluding Remarks

In sum, PADs were designed as legal instruments for persons with mental illness to retain some control over their treatment during periods of decisional incapacity. In practice, PADs could yield other indirect benefits, such as improving communication between providers, patients, and family caregivers; enhancing therapeutic alliance and treatment engagement; and mobilizing clinical resources. Jointly, these influences could work together to help avert psychiatric crises, as well as to improve the management of such crises when they do occur, without resorting to involuntary commitment.

However, it may be necessary to provide resources to assist persons with mental disorders in completing PADs, configure information systems to make PADs accessible, and educate clinicians about the potential benefits and drawbacks of PADs and their legal obligations regarding PAD compliance. The National Resource Center on Psychiatric Advanced Directives disseminates state-by-state information on PADs and educational material to patients, family members, policymakers, and clinicians through its Web site. Such steps could be critical to ensuring that these legal instruments are implemented effectively in clinical practice and that people with mental disorders are afforded the opportunity to plan and participate in their own mental health treatment.

Psychological Autopsies

A psychological autopsy (or psychiatric autopsy—the terms are used interchangeably) is a reconstructive mental state evaluation (RMSE) focused on understanding a deceased individual's mental state at and around the time of death, typically for the purpose of identifying the cause of death (accident vs. suicide or another explanation). Norman Faberow, Robert Litman, and Edwin Shneidman are credited with developing the concept and pioneering the technique of the psychological autopsy in connection with their consultation with the Los Angeles County Coroner's Office, which requested that they assist in determining the cause of death (i.e., suicide or accident) in a subset of "equivocal" cases.

The psychological autopsy is one form of RMSE that can be defined as an expert inquiry focused on discerning some aspect of the mental state of a deceased person at an earlier point in time. Expert opinions formed by mental health professionals and based on RMSEs are typically—but not always—conducted in connection with some type of legal proceeding. As such, RMSEs can be considered as a forensic evaluation or forensic inquiry the goal of which is to provide the legal decision maker (i.e., judge or jury) with information that it would not otherwise have (based on the expert's inquiry and opinions), so that it can make a more informed and accurate decision in the legal issue at hand. For example, expert testimony regarding a deceased person's mental state has been introduced in testamentary capacity proceedings (when a deceased individual's capacity to execute a valid will at some prior time is at issue), life insurance and workers' compensation litigation (when the cause of an individual's death, including the existence of potential psychological contributors, is at issue), and criminal litigation (when the psychological state of a decedent is relevant to some aspect of a criminal proceeding). In addition, mental health professionals and mental health agencies sometimes employ psychological autopsies as a quality assurance mechanism in cases where clients commit suicide. Such inquires serve to aid in understanding what caused the suicide and identifying good or bad professional practice surrounding the person's care, both of which are seen as having the potential to improve future care and practice.

Because the person of interest (i.e., the decedent) is not available, the mental health professional conducting a psychological autopsy must rely solely on collateral, or "third-party" sources of information, including interviews with persons familiar with the individual of interest; interviews with persons who had contact with the individual at and around the time in question (e.g., around the time the will was executed or the decedent died); and a review of various documents including the individual's health care records, writings, or correspondence. Depending on the type of case and the issues at hand, areas of inquiry that may be relevant include (a) alcohol and drug use; (b) medical status and history; (c) mental health status and history; (d) economic and psychosocial stressors; (e) the nature and quality of interpersonal, family, and marital relationships; (f) behavior and verbal and written communications; and (g) legal history and records.

There are a number of limitations inherent to RMSEs, some of which also affect more commonly practiced psychological evaluations, including both therapeutic and forensic evaluations. First, as noted above, the lack of a standard assessment technique or procedure increases the likelihood of unreliable assessments and invalid opinions. Second, an obvious limitation is the psychologist's inability to assess the individual whose mental state at some prior time is of relevance (via either interview or administration of psychological testing, if indicated). Third, because the time of interest is in the (often distant) past, the available records may be limited and the recollections of third parties who may be interviewed by the examiner may suffer and be less accurate as a result. Fourth, third-party informants who are interviewed by the psychologist may distort representations of the decedent's mental state and behavior, either knowingly (e.g., because of their desire to bring about a particular outcome in a legal case, such as when a potential beneficiary intentionally denies the deceased testator's severely impaired mental state at the time the will is executed so that the will is declared and the beneficiary receives the inheritance) or unknowingly (e.g., when a spouse fails to recognize and report the deceased spouse's suicidal behaviors because of guilt over the death).

Little research has been conducted examining the reliability and validity of opinions formed using RMSEs. Of course, assessing the validity of this technique is challenging because of problems with criterion validation. That is, to examine the accuracy of opinions that are formed using an RMSE, one must be able to compare the formed opinions with the actual

facts or outcome (which is never knowable or known). As a result of the limited data regarding the reliability and validity of opinions formed when using RMSE techniques, commentators have recommended that professionals who are asked to conduct such examinations proceed cautiously and make clear the limitations inherent in such inquiries.

Psychological Inventory of Criminal Thinking Styles

The Psychological Inventory of Criminal Thinking Styles (PICTS) is an 80-item self-report inventory designed to measure eight thinking styles presumed to reinforce, support, and maintain a criminal lifestyle. The eight thinking styles assessed by the PICTS are Mollification, Cutoff, Entitlement, Power Orientation, Superoptimism, Sentimentality, Cognitive Indolence, and Discontinuity. The PICTS also contains two validity scales—Confusion and Defensiveness; four factor scales—Problem Avoidance, Interpersonal Hostility, Self-Assertion/Deception, and Denial of Harm; two content scales—Current and Historical; two composite scales—Proactive Criminal Thinking (P) and Reactive Criminal Thinking (R); and a general score covering all 64 criminal thinking items—General Criminal Thinking (GCT).

Description and Development

There were 32 items on the PICTS when it first appeared in 1989, 4 for each thinking style. In 1990, the PICTS was expanded to 40 items with the addition of two validity scales, and the ratings went from 3 points (*agree, uncertain, disagree*) to 4 points (*strongly agree, agree, uncertain, disagree*). In 1992, the number of items per scale was raised to 8 to produce an inventory of 80 items. Norms were established by administering this third version of the PICTS to 150 minimum-security male federal inmates, 150 medium-security male federal inmates, 150 maximum-security male federal inmates, and 227 state and federal female inmates. The PICTS validity scales were successfully revised in 2001, leading to the fourth and current version of the PICTS, in which the content (phrasing) and position (item number) of the 64 thinking-style items and 8 retained validity scale items remained constant across Versions 3.0 and 4.0. Consequently, research studies and norms from Version 3.0 should be applicable to Version 4.0.

Hierarchical Organization

Factor analytic research has revealed one-, two-, four-, and eight-factor solutions for the PICTS. Like the criminal thinking it is designed to measure, the PICTS is factorially complex and hierarchically organized. The eight PICTS scales are at the bottom of the hierarchy. The P and R scales are in the middle of the hierarchy, with the Mollification, Entitlement, and Superoptimism thinking-style scales loading heaviest on P and the Cutoff, Cognitive Indolence, and Discontinuity thinking-style scales loading heaviest on R. At the top of the hierarchy, P and R merge to form general criminal thinking, as measured by the GCT.

Reliability

Internal consistency (Cronbach's alpha coefficient) is .54 to .79 for the PICTS scales, .80 to .91 for the P and R scales, and .93 for the GCT. Test-retest reliability (Pearson *r*) after 2 weeks is .73 to .93 on the thinking-style scales, .88 to .96 on the P and R scales, and .85 to .93 on the GCT. Test-retest reliability (Pearson *r*) after 12 weeks is .47 to .86 on the thinking-style scales, .70 to .88 on the P and R scales, and .84 to .85 on the GCT.

Validity

The content validity of the PICTS is supported by the fact that inmates familiar with the lifestyle concept participated in the measure's development and furnished the content for several PICTS items. Furthermore, the eight thinking styles believed to support a criminal lifestyle are assessed on the PICTS.

In early studies evaluating the predictive validity of the PICTS, it was determined that several of the PICTS thinking-style scales, Cutoff and Entitlement in particular, predicted future disciplinary problems in prison and subsequent arrests in the community. More recent research has shown that higher-level PICTS scales—such as the P and R, and GCT—are incrementally valid predictors of future disciplinary problems and recidivism when age, prior arrests, and popular non-self-report rating scales such as the Psychopathy Checklist: Screening Version are controlled.

Exploratory and confirmatory factor analyses have been used to support the construct validity of the PICTS as a factorially complex and hierarchically organized construct with both general (GCT) and specific (eight thinking-style scales) features. Furthermore, the pattern of convergent and discriminant correlations between the PICTS thinking-style scales and various measures of personality indicate that the PICTS correlates better with similar constructs (antisocial personality) than with dissimilar constructs (depression, anxiety, schizophrenia).

Future Research

One direction for future research is testing the cross-national validity of the PICTS. Promising results have been reported in studies from Canada, the United Kingdom, Ireland, and Australia. Although the PICTS has been translated into a number of different languages and dialects, there have been no studies to date examining its utility in non-English-speaking populations.

A second direction for future PICTS research is using it to measure change in offenders enrolled in psychological programming. Although studies indicate that several PICTS scales appear to change over the course of intervention, longitudinal studies are required to ascertain whether a change on the PICTS reflects a meaningful change in thinking and behavior and whether or not this has a direct bearing on future recidivism.

Recent studies have shown that the latent structure of criminal thinking, like the latent structure of psychopathy and antisocial personality, is dimensional rather than categorical in nature. What needs to be determined is whether the dimensionality observed on the PICTS is the same or different from the dimensional structure of psychopathy and antisocial personality.

Psychopathic Personality Inventory (PPI)

The PPI is a widely used self-report measure designed to detect the principal personality traits of psychopathy. Revised in 2005 as the Psychopathic Personality Inventory–Revised (PPI–R), it consists of 154 items arrayed in a 4-point Likert-type format. The PPI–R, like the original PPI, yields a Total score reflecting global psychopathy as well as eight-factor analytically derived content scales reflecting specific facets of psychopathy: Machiavellian Egocentricity, Rebellious Nonconformity (formerly Impulsive Noncomformity), Blame Externalization (formerly Alienation), Carefree Nonplanfulness, Social Influence (formerly Social Potency),

Fearlessness, Stress Immunity, and Coldheartedness. The PPI–R also contains three validity scales designed to detect aberrant response styles that are potentially problematic among psychopathic individuals: Virtuous Responding (formerly Unlikely Virtues), Deviant Responding, and Inconsistent Responding (formerly Variable Response Inconsistency).

Construction of the PPI and PPI–R

The PPI, consisting of 187 items, was developed over the span of several years in the late 1980s. It was constructed largely in response to a perceived need for an easily administered questionnaire measure of psychopathy that would facilitate research on, and the clinical assessment of, psychopathy. In contrast to most previous measures of psychopathy, it was developed to be applicable to nonclinical (e.g., student, community) as well as clinical (e.g., offender, substance abuse) samples. Prior to the construction of self-report measures of psychopathy, most of the research on this condition was limited to offenders, primarily because extant measures of psychopathy required access to detailed file information. The development of the PPI and other self-report measures of psychopathy has facilitated research concerning the manifestations of this condition in community and student settings, permitting investigators to examine the characteristics of "successful" or "adaptive" individuals with high levels of psychopathic traits.

The PPI was designed to detect the key personality traits of psychopathy, such as superficial charm, dishonesty, manipulativeness, guiltlessness, callousness, fearlessness, self-centeredness, externalization of blame, and poor impulse control. The initial constructs targeted for inclusion in the PPI were derived from a comprehensive review of the clinical and research literatures on psychopathy, including the seminal writings of Hervey Cleckley, Benjamin Karpman, David Lykken, Robert Hare, and Herbert Quay. In an effort to distinguish psychopathy from cognate but separable constructs (e.g., antisocial personality disorder, crime proneness), items explicitly assessing antisocial and criminal behaviors were not included in the prospective item pool. To enhance the likelihood that the psychopathic respondents would be willing to endorse trait-relevant items, most PPI items were phrased to be socially normative.

The PPI items and constructs were progressively refined by means of factor analyses on three successive undergraduate samples, with a total sample size of 1,156 participants. The eight lower-order factors that make up the PPI emerged across all three rounds of test development and appeared to assess the core affective and interpersonal traits of psychopathy. The three validity scales of the PPI assist with detection of socially desirable responding and malingering, which may be particular causes for concern in forensic settings.

The PPI was revised in 2005 to reduce its length, decrease its reading level, eliminate psychometrically suboptimal and culturally specific items, and develop norms for general population and offender samples. Based on factor analyses of large student, community, and offender samples, a number of inadequately functioning PPI items were eliminated or rewritten. The revised version of the test, the PPI–R, consists of 154 items divided into the same eight content scales and three validity scales as the PPI.

Higher-Order Factor Structure

Higher-order-factor analyses of the PPI–R content scales have generally yielded a two-factor structure. One factor, called "Fearless Dominance," consists of the Social Influence, Fearlessness, and Stress Immunity content scales. The other factor, called "Self-Centered Impulsivity," consists of the Machiavellian Egocentricity, Rebellious Nonconformity, Blame Externalization, and Carefree Nonplanfulness content scales. The eighth PPI–R content scale, Coldheartedness, does not load substantially on either higher-order factor. The analyses indicate that the two PPI–R higher-order factors display markedly divergent correlates. For example, Fearless Dominance correlates negatively with indices of depression, anxiety, and suicidality, whereas Self-Centered Impulsivity correlates positively with these indices.

Reliability

The test-retest reliability of the PPI–R Total score (average 20-day retest interval) in a general population sample is .93, with the test-retest reliabilities of the PPI–R content scales ranging from .82 to .95. The internal consistency (Cronbach's alpha) of the PPI–R Total score in a general population sample is .92, with internal consistencies of the PPI–R content scales ranging from .78 to .87. These test-retest and internal consistency figures are comparable with, and slightly higher than, those generally reported for the PPI. The

internal consistency of the PPI–R Total score in an offender sample is somewhat lower (.84), with the internal consistencies of the PPI–R content scales ranging from .71 to .83.

Validity

Numerous studies in college and offender samples provide support for the construct validity of the PPI and PPI–R. The Total scores on these measures correlate moderately to highly with other self-report, interview-based, and observer measures of psychopathy. The PPI Total score correlates moderately with measures of personality disorders known to overlap with psychopathy, such as narcissistic, histrionic, and borderline personality disorders, but weakly with measures of most other (e.g., schizoid) personality disorders. Moreover, the PPI and PPI–R Total scores display adequate discriminant validity from measures of constructs that are theoretically distinct from psychopathy (e.g., depression, schizotypy, psychosis proneness, social desirability).

In addition, the PPI and PPI–R Total scores correlate negatively with several traits of the well-known "five-factor model" of personality, especially Conscientiousness and Agreeableness, and positively with measures of sensation seeking and Machiavellianism. Finally, the PPI Total score demonstrates positive correlations with measures of delinquent behaviors and substance abuse, laboratory measures of poor impulse control and planning, and offender disciplinary infractions. Future research should help determine whether (a) the PPI–R exhibits incremental validity above and beyond other well-validated measures of psychopathy (e.g., the largely interview-based Psychopathy Checklist–Revised), (b) observer reports of psychopathy can supplement the PPI–R by filling in some of the "blind spots" generated by psychopathic individuals' lack of insight regarding the nature of their symptoms, and (c) the PPI–R can help identify potentially adaptive expressions of psychopathy, such as charismatic leadership and heroic forms of altruism.

Psychopathy

Although psychopathy may be viewed as an evolutionary adaptation that serves the individual well, it typically is construed as a personality disorder, or a chronic, inflexible, and maladaptive pattern of relating to the world. Most conceptualizations of psychopathy emphasize traits of emotional detachment, including callousness, failure to form close emotional bonds, low anxiety proneness, remorselessness, and deceitfulness. However, the most widely used measure of psychopathy goes beyond these traits to assess repeated involvement in antisocial behavior. The Revised Psychopathy Checklist (PCL–R) was developed with criminal offenders and weighs past antisocial behavior as strongly as traits of emotional detachment in diagnosing psychopathy. Predominant use of the PCL–R and offender samples has established a large research literature on unsuccessful psychopathy. Relatively little is known about individuals with traits of emotional detachment who escape contact with the legal system; express their psychopathic tendencies in a manner that does not conflict with the law; or even attain success in business, political, and other settings. Indeed, most contemporary research and virtually all practical interest in psychopathy revolve around the utility of the PCL–R in forecasting offenders' violent and antisocial behavior and, to a lesser extent, offenders' treatment amenability. Recent research challenges the prevailing assumptions that (a) traits of emotional detachment per se predict violence and (b) individuals with psychopathic traits cannot be effectively treated. In this entry, research on these practical issues is reviewed before turning to more fundamental questions about the basic nature and manifestations of psychopathy. Theoretically driven research on the potential mechanisms that underpin the disorder reveal the importance of emotional detachment as a likely manifestation of classic or "primary" psychopathy. Such research also suggests that there

may be a "secondary" variant of psychopathy, marked by psychological disturbance and violence potential.

Practical Interest in Psychopathy

A variety of psycholegal issues that arise in the criminal and juvenile justice system call for the identification of individuals who are inalterably dangerous. Increasingly, measures of psychopathy are being applied to inform decisions about the length of offenders' sentences, their level of institutional supervision, whether they should be released from prison on parole, whether they should receive any treatment, and whether they should be sentenced to death. Psychopathy measures predominantly are used as prosecution tools. As shown in this section, there are reasons to question the assumption that these measures identify individuals who are inalterably dangerous.

Violence Prediction

The most widely used measure of psychopathy is also the number one tool used to assess risk of future violence. In fact, forensic psychologists use the PCL–R to assess risk twice as often as they use tools that were specifically designed as risk assessment tools. This is not the case for other well-validated measures of psychopathy such as the Psychopathic Personality Inventory (PPI). Instead, the diagnostic measure for personality disorders has become the most widely used tool for assessing violence risk, owing to a series of studies indicating that the PCL measures robustly predict violence and recidivism for offenders, forensic patients, and even psychiatric patients. Although the absolute size of this relationship is weak ($r \approx .25$), the PCL–R is among the strongest single predictors of violence and other criminal behavior, on a level that competes with leading risk assessment tools.

Although this relationship suggests that emotionally detached psychopaths callously use violence to achieve control over and exploit others, recent research suggests otherwise. The lion's share of the PCL–R's utility in predicting violence is attributable to its saturation with indices of past violence and criminality. Although there is debate about its factor structure, the original PCL–R model has two moderately correlated scales: The first assesses core interpersonal and affective features of *emotional detachment* that are central to most conceptualizations of psychopathy; the second assesses impulsivity, irresponsibility, poor anger controls, and *antisocial behavior*, which some view as peripheral to psychopathy. A meta-analysis of 42 studies indicated that the PCL–R's antisocial behavior scale is significantly more predictive of violent and general recidivism than its emotional detachment scale. Moreover, three original studies indicate that the emotional detachment scale does not significantly predict future violence, independent of its association with the antisocial behavior scale.

Psychopathy explains the predictive utility of the PCL–R less than do two other factors. First, indices of past violent and criminal behavior naturally are linked with future, like behavior. Information about criminal behavior determines one's ratings of some PCL–R items and heavily affects one's ratings of many others. Second, ratings of past violent and criminal behavior appear to capture something traitlike that is clinically useful but not specific to psychopathy. The PCL–R (antisocial or total scores) manifests some incremental utility in predicting future violence and crime, beyond indices of past, like behavior. Recent research suggests that the PCL–R may tap constructs of antagonism or "externalizing" that place individuals at high risk of involvement in violent situations. Antagonism involves suspiciousness, hostility, combativeness, and irritability. Externalizing weaves together traits of aggression and behavioral disinhibition, antisocial behavior, and substance use. Neither construct is specific to psychopathic personality disorder. Both are related to violent and antisocial behavior.

Treatment Amenability

Practical interest in psychopathy revolves around its implications for assessing both violence risk and treatment amenability. The prevailing assumption is that psychopathy cannot be effectively treated. In fact, the results of one early study led many to opine that treatment only "made psychopaths worse"—that is, more likely to re-offend than if they had not been treated. This study was a retrospective matched trial that compared the recidivism rates of mentally disordered offenders released from either a prison or a radical therapeutic community program. The treatment program was active in the 1960s and involved unconventional interventions such as extended nude encounter groups and administration of psychedelics, alcohol, and other drugs to psychopaths to disrupt their defenses, increase their anxiety, and generally make them more accessible to treatment.

Therapeutic pessimism about psychopathy is so deeply entrenched in clinical and forensic circles that it rarely has been subjected to empirical evaluation.

To date, no randomized controlled trial has compared the outcomes of psychopathic individuals who do, or do not, receive treatment. Moreover, no published study has examined treatment programs developed particularly for those with psychopathy; instead, treatment for other conditions (mental disorder, substance abuse, or recidivism risk) has been administered "as usual" to those with psychopathy.

Nevertheless, a mounting body of recent quasi-experimental evidence challenges the assumption that individuals with psychopathy do not respond to conventional treatment. This research suggests that psychopathy, like many other personality disorders, complicates the first-line treatment of mental and substance abuse disorders. Simply put, individuals with psychopathy tend to have low treatment motivation, to misbehave in treatment, and to respond more slowly to treatment. However, when provided sufficient "doses" of treatment, those with psychopathy are as likely as anyone else to manifest reduced risk of violence and recidivism.

Three nonexhaustive examples will be provided here. First, a meta-analysis of 44 studies indicated that (a) therapeutic communities were the most common and least effective form of treatment for those with psychopathy and (b) across treatment modalities and definitions of psychopathy, treatment was moderately successful in reducing recidivism for psychopathic individuals (a 62% success rate). Second, a prospective study of approximately 900 civil psychiatric patients indicated that psychopathy did not moderate the effect of outpatient treatment on future violence. Of those who received relatively intensive treatment during one 10-week period, those with psychopathic traits were as likely as those without such traits to show significantly reduced violence potential in the next 10-week period. Third, a prospective study of 381 offenders mandated to substance abuse treatment indicated that treatment involvement significantly reduced risk of recidivism during the year after release, regardless of the effect of psychopathic traits. In the latter two studies, propensity scores were applied to control for the nonrandom assignment of individuals to less versus more intensive treatment. The effects remained moderate and significant. Together, this research suggests that individuals with psychopathy should be recast as high-risk (not hopeless) cases in need of intensive treatment. Correctional research indicates that focusing intensive resources on the highest-risk cases maximizes reduction in recidivism.

Basic Nature and Manifestations of Psychopathy

The relatively recent surge of interest in applying measures of psychopathy has affected our conceptualization of the construct itself. To be certain, use of the PCL–R has advanced the field's understanding of the nature and manifestations of psychopathy. The ever-increasing momentum of research on psychopathy is largely attributable to the PCL–R's ability to assess reliably traits such as callousness, facilitate comparison of results across studies, and clarify communication among practitioners and researchers. However, referring to the PCL–R as the "gold standard of psychopathy" signals that the field has mistakenly conflated a *measure* with a *construct*. A PCL–R score is no more psychopathy than a Wechsler Adult Intelligence Scale (WAIS–R) score is intelligence.

As research on the PCL–R's utility in predicting violence has accumulated, the dominant view of psychopathy itself has shifted. Most modern views of psychopathy may be traced to Hervey Cleckley's influential book *The Mask of Sanity* (1941). Based on a series of case studies, Cleckley articulated 16 criteria for psychopathy that emphasized traits of emotional detachment. Although the PCL–R is based on Cleckley's conceptualization, it omits some features that Cleckley viewed as central to psychopathy (e.g., low anxiety) and emphasizes tendencies toward violent and antisocial behavior. Cleckley viewed these tendencies as largely "independent" of the more fundamental manifestations of psychopathy. As the field has come to equate psychopathy with the PCL–R, there has been slippage toward the notion that psychopathy is a violent variant of antisocial personality disorder. Now, psychopaths are called "intraspecies predators," and criminal behavior has been held up as the "ultimate criterion" for measures of psychopathy.

Notably, this entry focuses on the nature and manifestations of psychopathy among those for whom measures of psychopathy are best validated: adult, Caucasian, male offenders. Questions have been raised about the applicability of the psychopathy construct to juveniles, African Americans (who do not manifest some deficits on laboratory tasks thought prototypic of psychopathy), and women (who do not yield a clear factor structure for measures of psychopathy).

Validation Hierarchy

Predictive utility (which seeks clinical utility) cannot be mistaken for construct validity (which seeks construct identification). To increase the PCL–R's predictive utility, one could go beyond criminal behavior to include items that assess young age and male gender. This would not, however, necessarily enhance the measure's validity in assessing psychopathic personality disorder. To advance understanding of the construct, psychopathy must be evaluated against a validation hierarchy dictated by a theory of the disorder.

There are two major groups of theories about psychopathy. The first group begins with Cleckley, who posited that psychopathy is a largely inherited affective deficit that results in self-defeating behavior. Similarly, Robert Hare hypothesizes that this affective deficit involves impaired processing of emotional meanings related to language and may be based on reduced lateralization of verbal processes. The second theoretical group begins with the Fowles-Gray model of psychopathy, which references two constitutionally based motivational systems that influence behavior. The behavioral inhibition system (BIS) regulates responsiveness to aversive stimuli and is associated with anxiety, whereas the behavioral activation system (BAS) regulates appetitive motivation and is associated with impulsivity. According to the Fowles-Gray theory, primary psychopaths possess an intact BAS and a weak BIS, so they do not experience anticipatory anxiety that causes most people to inhibit activity that leads to punishment or nonreward. In a related sense, David T. Lykken's primary psychopath is fearless. Without the experience of fear to facilitate learning to avoid conditions associated with pain, the primary psychopath has difficulty with avoidance learning. Rather than fearlessness, Joseph P. Newman's conceptualization emphasizes a lack of anxiety. Specifically, Newman postulates that a cognitive processing or "response modulation" deficit lies at the core of Cleckleyan psychopathy. These individuals are unable to suspend a dominant response set to accommodate feedback from the environment.

Despite the differences among them, most of these theories describe psychopathy as a largely inherited affective or cognitive processing deficit. These theories dictate a validation hierarchy that places pathophysiologic and etiological mechanisms at the top, as they offer the greatest potential for explaining the disorder and potentially altering its course. Although unmodulated, unrestrained, or self-defeating behavior is symptomatic of the disorder, and may be found at lower levels of the validation hierarchy, there is nothing specific to criminal or violent behavior. Indeed, several theories explicitly omit criminal behavior. The question is whether the diagnostic criteria for psychopathy identify a homogeneous group of individuals with clearly delineated deficits and largely genetic pathophysiology.

Deficits and Etiology

The PCL–R has been most thoroughly evaluated in laboratory experiments as comprising the diagnostic criteria for psychopathy. Although these criteria do appear to identify a group of individuals with theoretically relevant deficits, they could be refined to do this better. On the one hand, PCL–R scores are associated with diminished startle response to negative or aversive emotional cues, less autonomic arousal during fear and distress imagery, and greater recall for the peripheral details of aversive images. On the other hand, the PCL–R omits key features of psychopathy, such as low anxiety. Among offenders with high PCL–R scores, only those who also manifest low anxiety show response modulation deficits on a passive avoidance learning task or reduced sensitivity to cues of punishment when a reward-oriented response set is primed. Moreover, the PCL–R overemphasizes antisocial behavior. When PCL–R scale scores are examined, performance on many of these laboratory measures is more strongly linked with the emotional detachment scale than the antisocial behavior scale. Integrating across studies, the core of psychopathy seems to involve emotional detachment, including low anxiety, not antisocial behavior.

Although one might interpret the results of these experiments as evidence that psychopathy is genetically influenced, caution should be exercised in drawing premature inferences because the heritability of these laboratory variables is unclear. To date, no behavior genetic studies of PCL–R psychopathy have been conducted. Nevertheless, several survey studies indicate that childhood maltreatment is more strongly associated with the PCL–R's antisocial behavior scale than its emotional detachment scale. In keeping with the experimental data, this suggests that emotional detachment is a more theoretically valid indicator of psychopathy than antisocial behavior.

To date, only one behavior genetic study of psychopathy has been conducted with adults or adolescents. In this twin study of more than 600 17-year-olds drawn from the community, a measure of normal personality was used to estimate scores on a promising self-report measure of psychopathy, the PPI. Although

the PPI has "Fearless Dominance" and "Impulsive Antisociality" scales that appear somewhat like the two scales of the PCL–R, the PPI is not saturated with indices of violent and antisocial behavior. The study yielded moderate heritability estimates for both scales (h = .45 to .49). The extent to which these results will generalize to the context in which psychopathy is typically studied (i.e., direct assessment of PCL–R psychopathy with offenders) is unclear.

In summary, the criteria for diagnosing psychopathy can identify individuals with clearly delineated deficits, particularly if they are modified to include low anxiety and de-emphasize antisocial behavior. At present, it is unclear whether these deficits are largely genetically determined. However, as shown next, the present criteria clearly do not identify a homogeneous group of individuals as psychopathic.

Homogeneity

Although psychopathy usually is treated as a unitary construct, Ben Karpman's seminal theory posits that there are two variants: primary psychopathy is underpinned by an inherited affective deficit, whereas secondary psychopathy reflects an acquired affective disturbance. Primary psychopathy is consistent with classic conceptualizations of psychopathy as a deficit, whereas secondary psychopathy represents a more psychopathological, hostile, and violent variant.

Although the etiological distinctions between them have not been rigorously investigated, there is evidence that primary and secondary variants of psychopathy can be identified. Despite differences in their methodology, three studies have identified—among offenders with PCL–R scores in the range deemed psychopathic—primary and secondary variants. In the first study, model-based cluster analysis was applied to 96 inmates' scores on a measure of general personality to identify two groups of psychopaths: one emotionally stable (primary) and the other aggressive (secondary). Although the two groups were difficult to distinguish in their psychopathic traits, secondary psychopaths reported more fights, greater alcohol abuse, lower socialization, and higher trait anxiety than primary psychopaths. In the second study, model-based cluster analysis was applied to 124 inmates' scores on the PCL–R and a measure of trait anxiety to reveal two groups. Relative to primary psychopaths, secondary psychopaths had greater trait anxiety, fewer psychopathic traits, and comparable levels of antisocial behavior. Across validation variables, secondary psychopaths manifested more borderline personality features, poorer interpersonal functioning (e.g., withdrawal, lack of assertiveness), more symptoms of major mental disorder, and greater treatment responsivity than primary psychopaths. A similar approach was used in the third study of 116 juvenile offenders, which also yielded primary and secondary variants. Secondary variants were more likely than primary variants to endorse early childhood abuse.

These recent findings raise fundamental questions about the nature of psychopathy. Are secondary psychopaths still "psychopaths" if the mechanisms that underpin their traits differ from psychopathy as classically construed? The findings may also have substantial practical implications for risk assessment and risk management. Relative to primary psychopaths, secondary psychopaths theoretically are both more prone to violence and more amenable to treatment. The next generation of research holds promise for addressing these key questions, ideally while distinguishing between the practical enterprise of clinical prediction and the pursuit of understanding the psychopathy construct.

Psychopathy, Treatment of

The treatment of psychopathy is a controversial and underinvestigated area of study. Many researchers and clinicians have suggested that the pervasive and manipulative nature of the disorder makes it unlikely that psychopathic individuals can benefit from treatment. It is of concern that the primary characteristics of psychopathy (e.g., manipulation, deceit, and shallow affect) result in low treatment compliance and efficacy. To elaborate on this point, Ivan Zinger and Adelle Forth (1998) contend that the pessimistic views of treating the psychopath derive from three primary sources. First, Hervey Cleckley's description of the psychopath's inability to form affective relationships considered necessary for effective treatment was influential. Second, psychopaths who cause substantial harm to society tend to decrease the compassion of clinicians, thereby reducing therapist motivation. Third, serious personality disorders have often been considered intractable by many clinicians. Zinger and Forth also argued that these views are entrenched in the minds of both mental health and legal professionals, resulting in few objective efforts to examine treatment amenability in psychopaths. Despite these early concerns, recently there has been renewed interest in examining the treatment of psychopathy, as some researchers believe that treatment gains are possible if the modality and dosage of treatment are suited to the disorder. Recent advances in the treatment of other personality disorders also spurred a renewed interest in the treatment of psychopathy. Although contemporary research suggests that the field has been overly pessimistic about the prognosis for treating psychopathy, there are few well-controlled studies on the topic. It is therefore difficult to draw firm conclusions either way with respect to treatment outcomes.

Randy Salekin first shed light on the psychopathy-treatment relation by conducting a meta-analysis on 42 studies. The results of that study indicated that psychopathic individuals could show some benefit from psychotherapy; however, the treatment had to be intensive and typically involved both the psychopath and family members. Although the quality of the studies in the meta-analysis was somewhat limited, the review underscored two important points: (1) there was no evidence for psychopathy being considered an untreatable disorder and (2) there was a need for a second generation of research on the topic. Salekin's review and meta-analysis also highlighted several problematic areas that would need resolution before the field could move forward with a more informative generation of research. These problems included definitional concerns, an unclear etiology of psychopathy, and few controlled treatment-outcome studies. Each of these concerns is reviewed in further detail below.

Defining Features

Most problematic has been disagreement about the conceptualization and defining features of psychopathy. Hervey Cleckley offered a well-accepted early version of psychopathy. However, this version was replaced in the *Diagnostic and Statistical Model* (*DSM*) with a behavioral model for antisocial personality disorder. Lee Robins and Robert Cloninger suggested that antisocial personality disorder (i.e., psychopathy) might be best measured by examining behavior rather than personality because the assessment of personality was less reliable. Robert Hare offered a two-factor model for psychopathy that incorporated both Cleckley's personality model of psychopathy and behavioral aspects similar to those outlined in Robins and Cloninger's work. While these theorists purport to be assessing the same construct, the items of each model differ significantly, complicating the psychopathy (antisocial personality) treatment-outcome question. That is, depending on the model used, psychopathy might be more or less treatable. However, there is little in the way of systematic research to shed light on the treatment potential for each of the different models.

Whatever the chosen model, current diagnostic systems (e.g., *DSM-IV-TR* [fourth edition, text revision], *International Classification of Diseases*, 10th revision [*ICD-10*]) use cutoff points for diagnosing disorders, resulting in various permutations for a given disorder. This is pertinent to psychopathy research and practice because certain characteristics might be more resistant to treatment. For instance, "absence of nervousness," "manipulation," "deceitfulness," or other factors might be of most concern for treatment. To elaborate on this point, absence of nervousness, a cardinal feature of early definitions, may generate the hypothesis that psychopathy is difficult to treat; however, because the cutoff scores are set low on some measures (*DSM*-APD [antisocial personality disorder]) and moderate to high on others (PCL–R), it might mean that some individuals classified as having the disorder do not exhibit the trait that would make them less amenable (absence of nervousness). Of

equal concern, because few contemporary measures of psychopathy incorporate this feature, it is possible that newer indices may identify individuals who are amenable to treatment, even though they might be labeled as psychopathic. Thus, the mix of psychopathic characteristics could be very important in making determinations of amenability (unamenability).

Even if all symptoms were to be accorded equal weight in the amenability question, it is difficult to know at what point individuals become unamenable to treatment. It is also not clear from other disorders (e.g., depression) that endorsing all possible symptoms results in a more untreatable condition. Even assuming that higher-scoring individuals are less amenable to treatment, there are no data to suggest that individuals scoring more than 30 on the PCL–R (the cutoff score most often used for adults) are the worst candidates for treatment. Assessment with such instruments rests on the assumption that all criteria carry equal weight (and this may not be the case as noted above) and that any combination of items that exceeds a predetermined cutoff score is sufficient to warrant diagnosis (and presumably a conclusion that the individual is unamenable to treatment). Thus, even the use of dimensional scores that may reflect degrees of treatment amenability (or unamenability) is not well tested. And, as mentioned, if items are not of equal weight in answering amenability queries, such a perspective would not alleviate the potential for particular symptoms to have more or less effect on treatment amenability.

Etiology

The etiology for psychopathy is not well understood. Even for proposed theories, the specific linkage between etiology and treatment is not always well developed or articulated. What we do know is that the majority of prominent theories suggest a predisposition to the disorder. Specifically, temperamental style, low fearfulness, deficiency in psychopathy constraint, or a similar deficit, are frequently mentioned. Psychopathy researchers have also begun to show a genetic link to the disorder. Other theories suggest that psychopathy develops through a specific set of environmental conditions (e.g., poor attachment due to maltreatment). There is little in the theories themselves, however, even those emphasizing genetic factors, that could rule out the potential for treatment.

In sum, theories regarding the etiology of psychopathy suggest that psychopathy may develop through predisposition, harsh environmental conditions, or the interaction of temperament and environment. Even individuals with a particular temperamental style interact with others in ways that can foster either detachment and aggression or attachment and prosocial behavior. Moreover, the acceptance of linear deterministic theories that ignore the potential multiple factors that affect the development of psychopathy and are unable to account for the complexity of psychopathy symptoms will not be helpful in designing treatment programs. Specifically, theories that focus on only one component, or aspect, of psychopathy (e.g., frontal lobe dysfunction, deficiency in serotonin, response modulation) without explicating other manifestations (e.g., superficial charm, good intelligence, manipulation) are overly simplistic. Theories will have to be more encompassing when accounting for the symptoms of psychopathy because theory hints at methods and targets for intervention. For example, many of the current theories point toward parental practices and contextual factors as targets for potentially successful intervention. Or some theories suggest notifying psychopaths of their deficits in therapy so that they can begin to try to alter them.

Treatment-Outcome Studies

Another area of concern with respect to the treatment of psychopathy is that there are not many well-controlled treatment-outcome studies. The meta-analysis mentioned earlier showed that there may be some treatment effect for psychopathic individuals. Specifically, treatment may be beneficial if it is intensive and of long duration. This meta-analysis also found that youths evidenced the most gain from psychotherapy and that incorporating family and other support groups into treatment appeared to be helpful. This review and meta-analysis suggested that, like individuals with other disorders, psychopaths probably show moderate and incremental change over time rather than a complete transformation. Although this study suggested that a second generation of research was needed on this topic, few subsequent studies have been conducted. Specifically, very few studies have systematically examined the treatment response differences between psychopaths and nonpsychopaths. In those that have, psychopathic traits tend to be seen as

predicting early termination or poor treatment performance rather than targets for intervention themselves. This is particularly evident in the substance abuse literature, where the primary intervention target is substance use rather than psychopathy or psychopathic traits, even after numerous studies have demonstrated that psychopaths show fewer treatment gains using traditional interventions for substance use. Despite the limitations, these studies have a few hopeful findings that deserve greater attention. First, several programs found some positive benefits from treatment, even for individuals with high levels of psychopathy. Second, longer, more intensive treatments generally showed better effects, consistent with the view of psychopathy as a pervasive and destructive personality disorder.

The primary conclusion we can draw from past work in this area is that much more intensive and thoughtful research is needed if we are to further facilitate practice with psychopathic individuals. At present, there are few specific programs designed for treating psychopathy itself, and there are mixed findings regarding behavior and compliance while in treatment. It would be naive to conclude that treatment would not be difficult, particularly given what we know about the treatment of other severe forms of psychopathology; however, it is equally naive to conclude that psychopaths cannot benefit from treatment simply because of the complexity of the disorder. Working between these two extremes, the literature reviewed above indicates that more research is needed to study the risk, protective, and causal factors of psychopathy as well as to begin intervention development. Ultimately, the goal should be to test the efficacy and effectiveness of informed treatment programs.

Directions for Future Studies

In many clinical settings, psychopaths are seen as untreatable despite a lack of scientific support for this claim. Three problem areas are clear from the research that exists on the topic. First, classification is a critical issue with regard to treatment. Further clarity regarding the features of the disorder is necessary to accurately assess treatment amenability. This clarity can be gained in part by specifying the conceptualization of psychopathy used in treatment-outcome studies as well as the specific symptomatology present that makes it difficult (or easy) to treat them. Also necessary for understanding treatment effectiveness is work on the temporal stability of psychopathy. Few studies have examined the psychopathy-treatment relation from contemporary concepts of the disorder or compared treatment effects across broad models. In a meta-analysis by Salekin, the Cleckley psychopath was the most frequently investigated conceptualization of psychopathy in treatment-outcome studies, yet most current research uses Hare's conceptualization of psychopathy. Given that his definition differs from Cleckley's, treatment-outcome studies that employ this definition are necessary, particularly if psychologists are to make statements about treatment amenability based on the PCL–R.

Third, to better understand the psychopathy-treatment relation, several issues should be addressed in future studies. Treatment programs specifically aimed at reducing psychopathic characteristics should be developed and ought to be based on theory regarding the etiology and maintenance of psychopathy. These studies should be controlled and systematic to determine the effectiveness of different treatment modalities. For example, researchers should use psychopathy instruments pre- and posttreatment to examine the changes in symptom level, and raters should be blind to previous scores or intervention group membership. These studies should also investigate whether external criteria, such as recidivism and conduct problems, are reduced following treatment. This type of information would inform psychologists whether there is evidence that psychological change implies reduced risk of reoffending. In addition, in light of the characteristics of psychopathy, research needs to evaluate the possibility that clients are "faking good" rather than showing evidence of substantive changes in psychopathic traits.

In sum, the literature on the treatment of psychopathy has changed from pessimistic to cautiously optimistic with the notion that carefully designed and focused interventions may be able to produce measurable change in psychopathic individuals. Through careful design and evaluation of treatment intervention programs, it is hoped that the second generation of research on treatment outcomes will allow for earlier, more effective intervention with psychopathic individuals to reduce the high societal cost of persistent offending. The eventual goal should be to use theories of etiology to initiate prevention and intervention efforts before the development of the disorder causes the individual, and society, substantive harm.

Psychotic Disorders

The term *psychosis* was first used in the medical literature by Ernest von Feuchtersleben in his textbook *Principles of Medical Psychology* (1847). Originally, the concept was defined broadly to include any impairment of the higher mental functions. Starting in the late 1800s, psychopathologists such as Emil Kraepelin, Eugen Bleuler, and Kurt Schneider began to differentiate specific psychotic disorders on the basis of their symptomatology and course. According to contemporary views, psychotic disorders are psychopathological conditions characterized primarily by profound disturbances in cognition, perception, emotion, and volition that result in severe psychosocial dysfunction, including inability to meet the demands of daily life, and impaired reality testing.

Symptomatology

Psychotic disorders comprise literally scores of symptoms, many of which have a variety of distinct manifestations. The symptoms are not specific and occasionally can be observed in other disorders, including cognitive disorders and mood disorders. Psychotic symptoms can be categorized into four broad categories, according to functional domain.

Disturbances of Cognition. These can be divided into disturbances of thought content (i.e., what a person thinks or talks about) versus disturbances of thought form (i.e., the way in which a person thinks or speaks). Symptoms related to thought content include delusions (beliefs held with certainty that are demonstrably false and culturally abnormal) and ideation (overvalued beliefs). Specific symptoms that occur with some frequency include thought insertion (others are placing thoughts in the person's head), thought withdrawal (thoughts are being taken out of the person's head), thought broadcasting (others can hear the person's thoughts), misidentification (others are impersonating the person's loved ones), and thoughts of reference (ordinary occurrences have a special meaning or were arranged just for the person). Disturbances of thought content are often characterized according to thematic content (e.g., persecutory, grandiose, erotomanic, jealous, somatic, or nihilistic) or according to whether they are bizarre (strange and impossible, totally implausible), fixed (stable over time), and systematized (complex and internally coherent).

Symptoms related to thought form include loose associations (jumping quickly from topic to topic), tangentiality (keeps wandering off the topic), circumstantiality (speech is only indirectly relevant to the topic being discussed), derailment (loses track of the topic completely), perseveration (keeps returning to the same topic), thought blocking (abruptly stops talking), neologisms (makes up new words), clanging (speech is full of rhymes), pressured speech (talks quickly and loudly), incoherence (speech is unintelligible), and echolalia (repeating words spoken by others).

Disturbances of Perception. These also can be divided into two major types. First, hallucinations are sensations in the absence of an external stimulus. They may occur in any sensory modality. The most common are auditory (e.g., hearing voices that other people can't hear, often several people conversing in negative terms with or about the person or telling the person what to do) and visual (e.g., seeing things that other people can't see, such as lurking strangers, ghosts, or visions). Second, depersonalization and derealization are abnormalities in perception of self and the environment, respectively. Depersonalization often involves "out-of-body" experiences (e.g., people perceive that their minds have left their bodies and are floating around the room or that they no longer have control over the movement of their own bodies). Derealization, in contrast, often involves the perception that the outside world is unreal or a sham (e.g., other people are automatons).

Disturbances of Emotion. These involve either the absence of normal affect or the presence of abnormal affect. Symptoms of the first type include blunted affect or poverty of affect (a restricted range and depth of emotional displays), anhedonia (loss of feelings of pleasure), and flat affect (near-complete absence of emotion). Symptoms of the second type include perplexity (confusion or uncertainty about what is going on), stormy affect (intense and labile emotions), incongruity (emotional displays that are apparently opposite to the tone of the topic being discussed), and silly affect (emotional displays that are unrelated to the topic being discussed and are often perceived as immature or juvenile).

Disturbances of Volition. These involve difficulties with voluntary, purposive behavior. Symptoms related to problems making plans and carrying out goal-directed activity include abulia or avolition (inactivity), apathy (ambivalence or loss of interest), anergia (loss of energy), autism or social withdrawal (failure to interact with other people), self-neglect (neglect of one's own health and hygiene), negativism (ignoring the directions of others, resisting attempts to be moved by maintaining a rigid posture), and alogia or mutism (not speaking at all). Symptoms related to disturbance of behavioral tone, also known as catatonic symptoms, include hypertonia (overactivity, such as moving a lot or moving quickly) and hypotonia or catalepsy (underactivity, such as moving rarely, moving slowly, and waxy flexibility). Disturbances of purposeful activity include mannerisms (strange gestures or movements, such as walking on tiptoe or wiggling the fingers), stereotypies (repetitive, tic-like movements or vocalizations, such as constantly rubbing one's head or barking like a dog), grimaces, posturing (assuming strange poses, such as standing with one leg in the air or sitting with arms extended), echopraxia (repeating the movements of others), and bizarre behavior (e.g., masturbating in public, eating inedible substances, playing with feces).

Symptom Clusters. Clinical observation and research have found that certain psychotic symptoms frequently co-occur. There are at least three distinct syndromes (i.e., symptom clusters). *Positive symptoms* are pathological by their presence—things such as delusions, hallucinations, stormy affect, and mannerisms. *Negative symptoms* are pathological by their absence; examples are poverty of speech, poverty of affect, and social withdrawal. *Disorganization symptoms* reflect impairment in the regulation or coordination of basic psychological functions—for example, incoherence, silly affect, and bizarre behavior.

Contemporary Classification

The classification of psychotic disorders is based on symptomatology, course, and etiology. In the fourth edition of the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders,* or *DSM-IV,* psychotic disorders are grouped under the heading "Schizophrenia and Other Psychotic Disorders" and comprise a number of specific conditions.

Schizophrenia is characterized by a progressive or insidious onset (the prodromal phase), during which

negative symptoms predominate presentation. This is followed after a period of months or even years by a period of acute exacerbation (the active phase) lasting a month or longer, during which positive and disorganization symptoms predominate. In the majority (about 80%) of cases the course is chronic, characterized by at least some persistent negative symptoms (the residual phase) as well as the occasional recurrence of positive or disorganization symptoms. The total duration of symptoms (prodromal plus active plus residual phases) should be at least 6 months. The symptoms should occur in the absence of prominent symptoms of depression or mania and should not be the result of substance intoxication or withdrawal or of general medical conditions. A number of commonly occurring subtypes of schizophrenia have been identified based on their primary symptomatology, including Paranoid Type (prominent delusions or hallucinations), Catatonic Type (prominent disturbances of volition), Disorganized Type (prominent disorganization symptoms), Residual Type (prominent negative symptoms), and Undifferentiated Type (doesn't fit one of the other types). Age of onset is typically between 15 and 45 years; onset is about 5 years earlier in males than in females. Schizophrenia can have a debilitating affect on social adjustment, including impaired occupational functioning; failure to establish intimate relationships and reduced fertility; increased mortality owing to suicide, accident, and illness; and elevated risk of serious violence. In about 50% of cases, there is little or no improvement in social adjustment over time; in about 30%, there is substantial improvement; and in about 20%, there is good recovery or remission. Good prognosis is associated with having achieved adequate social functioning prior to onset of the disorder (e.g., absence of premorbid personality disorder), acute onset (e.g., short prodromal phase, onset following experience of a major life stressor), the presence of abnormal affect (e.g., stormy affect, perplexity, confusion), the absence of blunted or flat affect, and the absence of a family history of schizophrenia. Early detection and treatment may also be associated with good prognosis.

Schizophreniform Disorder. This differs from schizophrenia only with respect to its course. Whereas the total duration of symptoms in schizophrenia is at least 6 months, in schizophreniform disorder it is at least 1 month but less than 6 months. Two subtypes are recognized, With or Without Good Prognostic Features; the former may be associated with a full return to premorbid social functioning, whereas the latter may develop into full-blown schizophrenia (if psychotic symptoms persist or recur).

Brief Psychotic Disorder. This differs from schizophrenia and schizophreniform disorder in that the total duration of symptoms for all phases is less than 1 month, followed by a full return to premorbid social and occupational functioning. Three subtypes are recognized: Two subtypes, With and Without Marked Stressors, are diagnosed according to whether symptom onset occurs shortly after and apparently in response to stressful life events; the third, With Postpartum Onset, is diagnosed in women when symptom onset occurs within 4 weeks of giving birth.

Schizoaffective Disorder. This differs from schizophrenia only in that at some point during the active phase of the illness, the person also suffers from prominent symptoms of depression or mania (i.e., meets criteria for a major depressive, manic, or mixed episode) but has had a period of at least 2 weeks in which delusions or hallucinations were present in the absence of mood symptoms. Two subtypes are recognized, based on the nature of the mood symptoms: Bipolar Type, if the mood disturbance includes at least some symptoms of mania, and Depressive Type, if the mood disturbance is limited to symptoms of depression. Schizoaffective disorder is associated with a better long-term prognosis than schizophrenia, although with a worse prognosis than mood disorders such as major depressive disorder or bipolar I disorder.

Delusional Disorder. This is characterized by prominent nonbizarre delusions that persist for at least 1 month. The person may also exhibit prominent olfactory or tactile hallucinations related to the content of the delusions. The delusions should occur in the absence of prominent auditory or visual hallucinations and the absence of prominent mood symptoms, and they should not be the result of substance intoxication or withdrawal or of general medical conditions. Seven subtypes are recognized, based on the predominant theme of the delusions: Erotomanic, Grandiose, Jealous, Persecutory, Somatic, Mixed, and Unspecified Type. Delusional disorder may cause only limited or restricted disturbance of psychosocial functioning.

Shared Psychotic Disorder. This is diagnosed when the person develops delusions similar to those exhibited by a close acquaintance who suffers from a psychotic

disorder. The delusions should occur in the absence of prominent mood symptoms and should not be the result of substance intoxication or withdrawal or of general medical conditions.

Psychotic Disorder Due to a General Medical Condition. This is characterized by prominent delusions or hallucinations that arose during or shortly after and apparently in response to the physiological result of a general medical illness, which has been confirmed by history, physical examination, or laboratory findings. The symptoms should not occur only during periods of clouded consciousness (i.e., delirium). Two subtypes are recognized, With Delusions and With Hallucinations, based on which psychotic symptoms are predominant.

Substance-Induced Psychotic Disorder. This is identical to Psychotic Disorder Due to a General Medical Condition, except that history, physical examination, or laboratory findings indicate that the symptoms arose during or shortly after and apparently in response to substance intoxication or withdrawal. Two subtypes are recognized, With Onset During Intoxication and With Onset During Withdrawal.

Epidemiology

The lifetime prevalence of psychotic disorders in the general population is about 3% to 4%; the most common psychotic disorder is schizophrenia, with a lifetime prevalence of about 1% to 2%. Psychotic symptoms occur with much greater frequency; the lifetime prevalence of isolated delusions of hallucinations may be as high as 4% to 8%, and the lifetime prevalence of any psychotic symptom may be as high as 10% to 20%. The prevalence of psychotic disorders apparently varies little across nations, although within various nations, they may be diagnosed more often among members of ethnocultural minority groups and among recent immigrants. There is evidence of a small gender difference, with slightly higher rates among men than among women.

Etiology

Considerable research indicates the importance of neurobiological factors in the etiology of psychotic disorders, most likely as vulnerabilities or predisposing factors. Behavioral genetic studies indicate that psychotic disorders, and especially schizophrenia, are substantially heritable; however, molecular genetic studies have not been successful in isolating which genes, or even which chromosomes, are involved. The strength of the genetic contribution seems to vary as a function of the type of schizophrenia, with the strongest genetic loading associated with negative and disorganization symptoms. Many behavior geneticists agree that a polygenetic model is most likely, although there is also some support for a multifactorial model in which specific genes produce major effects and polygenes potentiate or insulate against the effects of the specific genes. Other studies have found that psychotic disorders are associated with a history of pregnancy and birth complications, including increased rates of maternal influenza in the second trimester, smoking and nutritional deprivation, and mother-child Rh incompatibility during pregnancy; obstetrical complications during delivery; and congenital abnormalities evident following delivery. Neuroimaging and postmortem studies have found an increased rate of structural brain abnormalities in people with psychotic disorders, as well as in their first-degree biological relatives, including enlarged ventricular and sulcal spaces; decreased brain volume, especially in the frontal and temporal regions, thalamus, amygdale, and hippocampus; reduced interregion connectivity; cytohistological abnormalities in the prefrontal and temporal regions, thalamus, hippocampus, and parahippocampal gyrus; and changes in regional activity during performance of cognitive tasks. Pharmacological studies indicate that disturbances of the dopaminergic neurotransmitter system in the brain (e.g., elevated frequency and activity of dopamine receptors) may be related to positive psychotic symptoms, whereas the serotonergic and glutamate systems may be related to both positive and negative symptoms.

Psychosocial factors may also be important in the etiology of psychotic disorders, most likely as triggers or precipitating factors. Life event studies indicate that active phases of psychotic disorders—both first episodes and recurrences—may occur shortly after, and apparently in reaction to, major life stressors. Also, a high level of negative expressed emotion in close personal relationships is associated with increased risk for development of psychotic disorders, as well as the recurrence of active phases. Both these factors, however, may be of limited importance in the absence of a neurobiological vulnerability or predisposition.

Treatment

Pharmacological treatments have been used for more than 50 years during the active phase of psychotic disorders. In the 1950s through the 1970s, the mechanism

of action of antipsychotic agents (e.g., phenothiazines, butyrophenones, thioxanthenes) was blockade of D_2 dopamine receptors. These "typical" antipsychotics resulted in a substantial reduction of positive symptoms (and, to a lesser extent, disorganization symptoms) in about 60% of cases, limited reduction in about 30% of cases, and no response in about 10% of cases. Maintenance doses also helped reduce the recurrence of active phases. But typical antipsychotics had a minimal effect on negative symptoms and were associated with a high rate of serious side effects, including sedation and movement disorders. In the 1980s, "atypical" antipsychotics (e.g., clozapine, amisulpiride) were introduced. Their mechanism of action is more widespread than that of typical antipsychotics; they affect the serotonergic and adrenergic systems, in addition to the dopaminergic system. Atypical antipsychotics are at least as effective as typical antipsychotics in reducing positive symptoms (even in cases where typical antipsychotics are ineffective), and they may also reduce negative symptoms. They also have serious negative side effects, however, and are very expensive. The effectiveness of pharmacological treatment has greatly reduced the use of other, more invasive somatic treatment, such as electroconvulsive therapy and prefrontal lobotomy; it has also greatly reduced the frequency of long-term institutionalization.

Psychosocial interventions are frequently used to manage active symptoms, reduce active symptoms that are refractory to pharmacological treatment, improve social functioning following an active phase, and reduce the risk of recurrence. Institutionalization or respite care is used when it is difficult to deliver appropriate services in the community and when risk of suicide or violence is acute. Psycho-educational programs for patients and their families are used to improve compliance with other treatments and to reduce the rate of relapse. Cognitive behavioral therapy is used to manage active psychotic symptoms, such as delusions and hallucinations, as well as to improve compliance with other treatment. "Dual disorder" or "co-occurring disorder" programs are used to treat symptoms of substance use disorders in people who also suffer from psychotic disorders. Rehabilitation and social skills programs are used to improve interpersonal and occupational functioning.

Most often, treatment of psychotic disorders is long-term and multimodal: Pharmacological interventions are used in combination with one or more psychosocial interventions. Delivery of services may be most effective when coordinated using assertive case management techniques.

Forensic Relevance

In the law, competency to make important decisions typically requires that the person can accurately perceive the environment, rationally manipulate information about the environment, and communicate desires and intentions to others. These specific decision-making capacities may be impaired by the presence of psychotic symptoms, especially positive and disorganization symptoms. For this reason, psychotic disorders are particularly important in psycholegal evaluations of adjudicative competencies (e.g., stand trial, waive the right to counsel, confess) and culpability in criminal settings and evaluations of other competencies (e.g., consent to treatment, testify, make wills, sign contracts) in civil settings. For example, research on adjudicative competencies and culpability indicates that as many as 80% to 90% of people who are found legally incompetent, or nonculpable, may suffer from psychotic disorders or from other disorders (e.g., cognitive or mood disorders) with prominent psychotic symptoms.

With respect to the ability to control one's behavior, the law typically requires that the person can freely form goals or intentions appropriate to the situation; develop plans to achieve those goals; and implement, evaluate, and modify those plans as necessary. These specific capacities also may be impaired by psychotic symptoms of all types. In criminal settings, psychotic disorders may be important in psycholegal evaluations of culpability and in civil matter evaluations of other competencies (e.g., consent to treatment, testify, make wills, sign contracts) in civil settings. In both criminal and civil settings, an issue of particular concern is serious violence associated with psychotic symptoms, particularly positive and disorganization symptoms. In some cases, the nature of the psychotic symptoms is directly related to the violence (e.g., a person with persecutory delusions assaults someone he believes is trying to poison him); in others, the psychotic symptoms interact with other factors (e.g., substance use) to generally destabilize social adjustment and increase interpersonal conflict that may result in violence. Research suggests that psychotic disorders cause a twofold increase in the odds that a person will engage in serious violence.

Public Opinion About Crime

Hundreds of research studies that have examined a wide range of topics on public perception about crime support the conclusion that citizens generally are not well-informed about this issue. For example, the public perceived that crime rates for several different types of crime were increasing during times when in fact those crime rates were decreasing or remaining stable. The public also overestimates the proportion of crime that is violent and makes incorrect generalizations about the types of crimes most commonly committed by specific ethnic groups. Furthermore, people hold many stereotypes about specific crimes that are inconsistent with the types of cases that come through the courts and with how those crimes are defined in statutes. Jurors with these misperceptions often acquit atypical cases or recommend less severe charges.

There is consensus across different cultures and countries that violent crimes are more serious than property crimes, which in turn are perceived as more serious than drug or victimless crimes. Despite public consensus on relative seriousness, criminal laws in Canada and the United States provide higher maximum jail sentences for some property crimes, such as grand larceny, than for violent crimes, such as fondling a child or inflicting moderate injuries on a person with the intent to harm. All social groups also attributed greater importance to environmental factors than to individual dispositional or mental factors as general explanations for why crimes occur.

Given the potential influence of public perceptions, this entry reviews research addressing the following questions: (a) To what extent are the public's general beliefs about crime consistent with the nature and severity of reported crime? (b) How much agreement exists in the public's views about the seriousness of specific criminal acts, and how well does the criminal law mirror public views about the seriousness of different crimes? (c) Based on the accumulated research, what are the nature of the public's stereotypes and the extent to which these stereotypes are consistent with the caseload of the criminal justice system and with how laws are defined?

Public Views of the Severity and Amount of Crime

Systematic national survey research in several countries, including the United Kingdom, Canada, Australia, Spain, and the United States, has shown that the public is not well-informed about the nature of crime. In the 1990s, when reported violent crime showed a significant decrease, the majority of the public believed that violent crime was increasing. Studies that have compared citizens' estimates of crime rates with police data have repeatedly found that the public overestimates the amount of theft, fraud, burglary, rapes, and violent crime. The majority also overestimates the proportion of crime that is violent; for example, violent crime comprises about 10% of the crime reported to the police, but the majority estimated that violent crime accounted for 30% or more. The majority also indicated that specific crimes, such as murder or burglary, were increasing during times when the system actually showed a decline. Most people also substantially overestimate the percentage of offenders released from prison who commit another serious crime. Whereas 30% to 40% of offenders released are arrested again for another serious crime, the majority of the public believes that about 60% to 75% commit additional serious crimes. The gap, of course, between public estimates and official police data is quite large, and the difference between reported crime and the actual commission of serious crimes may not entirely account for the difference. The news media's reporting of serious crimes and released prisoners committing new serious crimes also may contribute to the public's overestimates of the amount and severity of crime.

Public's Ranking of the Seriousness of Offenses

Researchers and professionals often assume that criminal laws and their associated punishment match public opinion concerning the relative moral wrongfulness and harmfulness of different crimes. This model, called the consensual model, assumes that societal members of different gender, social class, and ethnicities agree about what values should be protected and

the wrongfulness of certain acts. This model assumes that the public should determine what is and is not a crime or a serious crime, and public support and compliance with the law will be ensured if the laws mirror public views. Research on crime seriousness has been conducted for more than 40 years. This research started with the belief that a scale of seriousness of different crimes could inform police, prosecutorial, and judicial responses to crime, and by matching public and professional responses to crime, the public's confidence in the system would be warranted.

To determine whether the consensual model could describe how crimes are defined and justice administered in society, researchers tested whether the public agreed about the seriousness of different acts. Much research has found that the public perceives violent crime as more serious than property crimes, which in turn were perceived as more serious than public-order and victimless crime. Moreover, comparisons across Great Britain, Canada, Denmark, Finland, Holland, Kuwait, Norway, and the United States indicated that people from different cultures generally agree about which crimes are more serious than other crimes. Americans and Kuwaitis, however, perceived rape to be more serious than robbery or aggravated battery, whereas respondents from the Scandinavian countries and Great Britain indicated that these offenses had the same level of seriousness. Overall, there is more agreement than disagreement across countries in the relative seriousness of different offenses. Men and women, individuals of different social classes and ethnicities, victims and nonvictims, and incarcerated offenders and nonoffenders also agree on the relative ranking of different crimes, with the exception of murder and rape. Women generally have rated rape as more serious than murder, whereas men rated murder as more serious than rape.

Though the public demonstrates high consensus about the relative ranking of different categories of crime, there is considerably less consensus about which specific types of white-collar, victimless, and minor property crimes are more serious within each of these crime categories. For example, there is less consensus about, and changes across time in, the relative seriousness of different forms of white-collar crimes, such as tax fraud and price fixing. The public shows more agreement about the relative ranking of different acts of violence, which may partly be due to its greater familiarity with violent acts. In ranking the seriousness of different criminal acts, the public considers the seriousness of physical injuries, offenders' intent, and offenders' prior criminal record; crimes that are intentional and committed by repeat offenders are perceived as more serious.

Do members of the public, legislators, and criminal justice professionals hold similar views about the relative seriousness of different crimes? Research has found that even though the public ranks all forms of violence as more serious than property crimes; criminal laws in Canada and the United States provide higher maximum punishments for some property crimes, such as car theft and grand larceny, than for violent crimes such as fondling a child and punching an intimate partner. Legislators in enacting criminal laws thus have not mirrored the public's views of crime seriousness and give greater priority to protecting property than to personal dignity and freedom from injury, whereas the public has the opposite priorities. Studies also have found that the public, compared with police officers, agreed on the relative seriousness of different crime categories but differed in the absolute seriousness of specific crimes. For example, the public, compared with police officers, provided a higher seriousness rating to white-collar crimes and statutory rape (i.e., an adult having sex with a consenting minor) and a lower seriousness rating to residential burglary. Both the police and the public regarded street crimes as very serious, but the public also was concerned with white-collar crimes and statutory rape.

Public's Stereotypes of Crimes and Criminals

People tend to believe that crime is committed by a small, easily identifiable group of criminals who are very likely to commit further crimes in the future. The majority of the public blame society, unemployment, neighborhood problems, and lack of parental supervision as the major causes of crime, whereas about one third perceive individuals as solely responsible for their criminal acts and explain crime in terms of lack of morals, drug use, and mental or personality problems. More highly educated and self-identified liberal individuals and younger individuals generally attribute more importance to societal inequities, such as unemployment and discrimination, in explaining the high crime rates than do conservatives and older respondents. Despite these differences across backgrounds, all social groups assigned greater importance to environmental factors than to individual dispositional or mental factors as explanations for why crimes generally occurred.

Stereotypes of specific offenses are widespread and influence (a) public responses as to how to control crime, (b) jurors' interpretation of evidence and verdicts, and (c) eyewitnesses' accounts and recall of crimes. Stereotypes consist of visual images and detailed information about how the crime happens; the harm done; appropriate sanctions; and offenders' motives, dangerousness, intent, and social background.

Respondents are agreed on which pictures of men look like criminals and often describe criminals as young, unattractive males. Race also is often part of the public's stereotypes. When the public thinks of violent criminals, it often imagines young African American adults who have quit high school, are associated with gangs, and are unemployed or work in unskilled jobs. The public imagines that African Americans generally commit violent street crimes and Caucasians commit white-collar crimes; swindlers are pictured as intelligent male professionals in their thirties. In accordance with probation data, the public and probation officers agreed that the typical burglar is single, unemployed, and a high school dropout. Respondents also agree on the facial features of rapists, murderers, battered women who kill their abusers, and robbers, suggesting that many people may have visual images associated with their stereotypes about specific crimes. These distorted stereotypic images of specific types of offenders may interfere with witnesses' accurate recall of specific crimes.

Jurors often rely on information in stereotypes to draw inferences from evidence that is presented at trials and to decide whether defendants should be acquitted or convicted. The public obtains information about crime from the media, personal experiences, and interpersonal conversation. For many citizens, the news and entertainment media are the primary source of information about different crimes, and cultural stereotypes of specific crimes provide exaggerated information about the severity of the typical crime. For example, research shows that the public's stereotype of the typical burglar is a man who carries a weapon, steals valuables worth several thousand dollars, and ransacks the place, which is not consistent with the characteristics of burglary cases that come to the attention of the police. Research demonstrates that individuals holding exaggerated stereotypes often acquit offenders who commit atypical burglary, such as forced entry into a building with the intent to commit another felony but without taking any property. The public also incorrectly labels the forced entry into a home to take property when victims are not present as a robbery rather than a burglary. Based on experimental studies using detailed cases and open-ended questions, the majority of the public also holds misconceptions about robbery, assault, rape, and kidnapping, which may affect verdicts. The public also holds several misconceptions about battered women and rape victims, which calls for introducing expert testimony to correct jurors' misconceptions. For example, jurors were not well-informed about battered women's emotions, the batterer's propensity to make promises to change and persuade the victim to stay, and the victim's propensity to self-blame or to predict when she is about to be attacked. Individuals often hold many myths about rape. Consistent with media stories, the majority of the public agreed that the most credible rape involves a stranger accosting a woman on the street with a weapon and inflicting injuries, and the least credible were marital rape or instances in which the victim willingly left with the acquaintance and the rape involved no weapon.

Individuals, however, may differ in their personal stereotypes about crime through acquiring information from interpersonal conversations and direct experience. Research shows that when individuals acquire information about burglaries and muggings from interpersonal conversations and direct experience, their stereotypes about these crimes are more consistent with the caseload handled by the criminal justice system. This research thus suggests that the public's distorted stereotypes about specific crimes may be corrected through education and media campaigns that provide the public with a more representative sample of stories about crimes and criminals. Much research supports the influential role of public views about crime on verdict and punishment decisions; such influence is problematic given the misconceptions that the public holds.

Public Opinion About Sentencing and Incarceration

Two contrasting images of the public have emerged from the literature on public attitudes toward sentencing: a punitive public that demands long prison terms and a merciful public that supports community-based sanctions after considering the seriousness of the offense and the perceived character and blameworthiness of the offender. Although politicians and the media insist that the public wants to impose tougher and longer prison sentences, research shows that public views about appropriate sentences are much more complex. For example, although the majority of the public claims courts are too lenient, research using detailed cases consistently finds that the public imposes less severe punishment than judges or sentencing statutes. This disjuncture in attitudes occurs because the public relies on easily recalled violent crimes to answer general questions about its satisfaction with the court's sentencing. Moreover, the public wants more severe sentences for violent offenders but prefers community-based sanctions that can restore and rehabilitate nonviolent offenders.

Thus, politicians and scholars must examine how the public arrives at sentencing attitudes to obtain a more accurate view of the public's demands. This entry describes the findings from numerous studies that have examined whether public judgments about appropriate sentences are consistent with sentencing laws and practices. To fully understand the public's conception of justice, this entry examines the inferences and beliefs that contribute to citizens' views: their knowledge about sentencing options and prisons, their views of the primary goals of sentencing, and the effects of context and information on their decisions.

Public Knowledge About Sentencing, Parole, and Prisons

Misperceptions of criminal justice statistics abound. The average member of the public tends to underestimate the severity of the sentencing process as well as the parole system. When asked to estimate the average sentence for a particular crime, many people provide a response that is lower than the actual level. This finding has emerged from research conducted in the United States, England, Canada, and Australia. The public also is unaware of which crimes require prison time and of the minimum or maximum prison time required by criminal statutes. These underestimates underlie public attitudes that there should be more congruency between the assigned sentence and the actual number of years served. In those countries that have parole, most people assume that almost all offenders get parole, when in fact only a small fraction are released from prison early. Although offenders sentenced to life often are released on parole after serving on average a decade or more in prison, the public overwhelming agrees that a life sentence should mean that the offender serves his or her natural life in prison.

Since only a small percentage of the public has ever visited a prison, perceptions of prison life tend to be inaccurate, and the majority of the uninformed public indicated that prisons are too easy on offenders. Based on perceived public desires, several states have reduced many amenities for prisoners. However, when the public is informed about a variety of amenities and asked whether each specific amenity should be retained or eliminated, a different picture of public attitudes emerges. The majority of the public wants to retain educational, vocational, and psychological programs and also supports supervised visits with families, telephone calls, and air conditioning. The public is more selective in providing entertainment and recreational amenities. About 62% to 75% of the public would retain arts and crafts, basic television, basketball, conjugal visits with spouses, and college education programs. The majority of the public, however, supports eliminating boxing or martial arts, cable television, condoms, cigarettes, and pornography, including magazines such as *Playboy.* The public supports amenities that have rehabilitation potential or are useful for managing inmate behavior. The public, however, does not want prisoners to have amenities

for free that law-abiding, low-income citizens cannot afford.

The public is not well-informed about community-based sanctions. Research conducted in several countries, including England, Canada, Australia, the United States, and Germany, found that the majority of the public can provide a correct definition of community service but knows little about other community-based alternatives such as conditional sentences, probation, house arrest, and electronic monitoring. The public performed at chance level in identifying the correct definition of a conditional sentence. When asked about community-based sentences, over two-thirds of adults mentioned restitution, while only one-third spontaneously mentioned probation as an alternative. Moreover, about one-quarter is completely unaware of probation as an alternative. Furthermore, research shows that the majority of respondents who were informed about the alternatives chose community-based sanctions, whereas uninformed respondents chose imprisonment. Thus, when the public is informed of the existence of alternatives to incarceration, support for imprisoning offenders declines considerably. These findings indicate that the public is unfamiliar with community-based sanctions but supports such sanctions, especially for nonviolent felonies. This lack of familiarity is not surprising given that community-based sanctions are not well publicized in the media and that prisons are much more salient, especially with the growth in the number of prisons and prisoners in recent decades.

Impact of Information on Crime and Justice

Though the public lacks much knowledge about sentencing, research suggests that educating the public may change its top-of-the-head punitive responses. Based on deliberative polling after participants took part in a televised weekend event on the nature of crime and justice, the more punitive respondents, after receiving accurate information about crime and the justice system, became much less punitive and more supportive of community-based alternatives, and this attitude change lasted over a 10-month period. Researchers found that respondents who initially lacked knowledge about crime and justice were more likely to change their attitudes than those who were better informed.

General Versus Specific Questions About Sentencing

How the question is asked also affects the public's response. Opinion polls conducted in all Western nations over the past 25 years have routinely shown that approximately three quarters of the public says that sentences should be harsher. Research shows, however, that people recall atypical violent crimes when answering this abstract question. When asked about specific crimes, public views change. It is important, therefore, to pose specific rather than general questions to the public. This can be clearly illustrated with respect to the "three strikes" laws in the United States. Researchers have found strong general support for this law, which would mandate a lifetime prison sentence for an offender convicted of a serious felony for the third time. When specific cases are examined, the strong support for the "three strikes" statute remains only for offenders with three violent felony convictions. The public generally prefers a more flexible approach to sentencing that allows individualized judgments for each specific case and is uncomfortable with the mandatory lifetime prison sentence for repeat felony offenders.

An examination of the public's responses to detailed cases rather than general questions also is useful in understanding what goals the public wants to achieve in sentencing offenders. When asked to choose between punishment and rehabilitation, at least two thirds of Americans chose rehabilitation and prevention programs. At least two thirds of the public, when asked general questions that do not force a choice, assigned substantial importance to all five of the major goals of sentencing: retribution, rehabilitation, individual deterrence, general deterrence, and incapacitation (prevention of future crimes during the time in prison). Deterrence is achieved by providing offenders with severe enough punishment so that convicted offenders (individual) or potential offenders in society (general) refrain from committing future crimes. Thus, general questions do not provide sufficient information about what the public wants sentences to achieve.

When specific, detailed cases are used, support for sentencing goals varies by offenders' criminal history; offenders' social, substance abuse, and employment history; and the type of crime. Much research suggests that the public supports proportional justice, in

which the severity of the sanction matches the severity of the harm done and the culpability of the offender. Research shows that retributive justice is the main goal that the public wants to achieve for serious violent crimes. However, felony murder laws and other laws that hold offenders who committed the crime (principals) and those who helped in less direct ways (accessories) to the same punishment also are incongruent with public views of justice. The public prefers that principals receive longer prison terms than accessories and thus negates the law's equality principle in favor of proportional retributive justice.

At the same time, for nonviolent offenders, the public supports restorative justice, which now is part of several countries' sentencing schemes. Restorative justice emphasizes community-based sanctions that allow offenders to be reintegrated as productive, law-abiding citizens more easily but that require offenders to accept responsibility and make amends for the harm done, express sincere remorse, and provide restitution to the victims. Thus, community service and restitution that are directly related to the harm done are examples of restorative sanctions. Combinations of community-based sanctions can be used to achieve restorative justice. Both restorative justice and retributive justice are based on fairness, though restorative justice considers fairness toward the victim, the offender, and society. Evidence for support of restorative justice is quite consistent throughout the world. For example, numerous studies have asked respondents to choose between community-based alternatives and prison in sentencing specific nonviolent criminal offenders; the majority of the public across European and North American countries chose community-based alternatives. Of the community-based sanctions, restitution and community service orders have the most support because these sanctions address the needs of the victim and allow close monitoring of the offender in the community, whereas standard probation is the least supported. For several years, from 1989 to 2000, the International Crime Victimization Survey asked respondents to sentence a repeat 21-year-old burglar. Almost three fourths of New Zealanders; about two thirds of residents of Australia, Britain, Canada, Finland, and the Netherlands; about half of U.S. citizens and Latin Americans; 40% of residents of Asian countries; and about 30% of residents of Africa recommended community-based alternatives (typically a community service order). In 15 Eastern European countries, endorsement of community service rather than imprisonment for the repeat burglar has increased across time, with a divided public in 1992, but by 2000, about 72% of the public endorsed community service. These findings show widespread support for restorative justice for the serious property crime of burglary and suggest that Europeans have the strongest support, whereas less industrialized countries have the least support, for community-based alternatives.

Mandatory Minimum Prison Terms and Retributive Justice

In recent decades, politicians have enacted statutes that provide longer mandatory minimum prison terms for many offenses or longer prison terms for repeat offenders. These statutes are based on the goal of retributive justice—providing punishment that is proportional to the seriousness and harmfulness of the offense. The public shows strong support for punishing adult offenders based on seriousness of the crime, particularly those convicted of serious crimes of violence. However, based on vignette and video studies, the public prefers more flexibility in meting out justice than retributive justice systems allow. The majority of the public attends to individual characteristics, such as the offender's potential to be rehabilitated, employment status, criminal history, and so forth. For example, in response to realistic videotaped sentencing hearings, laypersons, compared with judges (and with statutorily required mandatory minimum prison terms), gave less severe sentences and were less likely to choose prison sentences for a repeat residential burglar, a cocaine dealer, and a mugger who caused an elderly woman to fall and break her hip when he stole her purse. Moreover, when offenders had a substance abuse problem and asked for treatment, laypersons overwhelmingly recommended court-mandated substance abuse treatment, whereas judges were more likely to recommend prison terms to achieve retributive justice or deterrence. Thus, researchers have characterized the public as supporting "individualized proportionality" in that the public assigns harsher punishment to more severe crimes but also considers the individual circumstances surrounding the crime in meting out justice.

In the past three decades, the U.S. government has engaged in a "war on drugs"; national survey data indicate that the public is quite skeptical that this government effort will reduce crime rates and believes that the sentences are too severe. For example, the U.S. federal sentencing guidelines' mandatory minimum prison time for drug possession is incongruent with the

public's rehabilitation orientation and preference for probation for marijuana possession. Public leniency is shown in both hypothetical and real cases; many cases of defendants charged with possession of cocaine, crack, or marijuana have resulted in jury nullification. Interviews with jurors who acquitted defendants despite proof beyond a reasonable doubt indicate that these jury nullifications occurred because jurors believed that the federal sentencing guidelines imposed an unjust, too severe punishment. The majority also is willing to recommend treatment programs to small-time drug dealers but want prison terms for major drug dealers or small-time drug dealers who fail a second time. Americans also disagree with the provision in U.S. sentencing guidelines that adds a mandatory 9 years to drug-trafficking sentences when the drug is crack cocaine; they believe that drug traffickers should receive similar prison terms regardless of whether they are selling heroin, cocaine, or crack cocaine. The public supports punitive penal policies only when violence is associated with the drug trafficking and in these cases wants longer sentences than the U.S. sentencing guidelines allow.

Although a strict retributive justice approach provides sanctions that are proportional to the amount of harm done and does not consider the offenders' criminal history or background, the public supports harsher sentences (e.g., prison time) for recidivists than for first-time offenders. At the same time, the public is more forgiving than federal sentencing guidelines. When the guidelines' recidivist premiums are compared with the public's sentences assigned to detailed cases with a different number of prior convictions, the public appears to recommend shorter prison terms for recidivists than the guidelines allow. Moreover, the public overwhelmingly does not support life in prison without parole for an offender whose third strike is a felony property crime. The public clearly wants recidivists to receive more severe punishments, but its response is more tempered than recidivist-sentencing statutes.

Public Opinion About the Courts

The study of public opinion about the courts is closely tied to concerns that date back to the Constitutional Convention. Then, and subsequently, it has been noted that while the executive branch has the power of the sword and the legislative branch the power of the purse, for compliance with its orders, the judiciary uniquely must rely on the public's belief in its legitimacy.

Public opinion today about the U.S. Supreme Court is different from public opinion about the other, "lower" courts; the U.S. Supreme Court enjoys consistently higher levels of confidence, support, and loyalty. This is often explained by reference to political and legal socialization, which inculcates loyalty to the Supreme Court. Other courts do not appear to benefit from such socialization. For the trial courts, with which the public can have direct contact, the public has modest levels of confidence, loyalty, and support. The lower courts need to continually demonstrate that they deserve the public's compliance by making decisions through procedures that the public perceives as fair. African Americans are less likely than members of other groups to be persuaded that fair procedures are being used.

The Public's Image of the Courts

The level of public support for and confidence in the courts is best assessed in comparison with other public institutions. Both the U.S. Supreme Court and the lower courts tend to be ranked higher than the executive or legislative branches of government. The relative advantage is considerable for the U.S. Supreme

Court and modest for other courts. Other courts tend to be rated lower than the police and similar to local schools and executive bodies but higher than legislative bodies and the mass media. The public is most critical of how courts handle juvenile and family cases and generally of the processing of cases in high-volume court venues such as traffic and small claims. The jury system is the most highly rated component of the courts. Former jurors, in turn, are the group most likely to hold positive views about the courts.

The public, in general, knows very little about how the courts work and is not attentive to issues regarding the courts. Many public opinion surveys about the courts, virtually all concerning trial courts, have been carried out at the national and state levels over the past 30 years. What emerges from the accumulation of confidence survey findings is a national stereotype that does not vary greatly from state to state or from one decade to the next. A stereotype is the shorthand description of "courts" that comes up in people's head—images that are commonly held, some positive and others negative.

On the positive side, people tend to believe that judges are well qualified and honest, defend people's rights, and treat people with dignity and respect. In recent years, it has become clear that people like alternative dispute-resolution methods, such as arbitration and mediation, and are highly positive about the features of problem-solving (drug and domestic violence) courts.

On the negative side, the list is longer. People report that courts are slow, difficult, and costly to access; do not allow people to participate meaningfully in court proceedings; and are out of touch with community sentiment. The presumed leniency of judges in sentencing offenders is another negative characteristic but one that may now be declining in significance. The majority of the public believes that the courts produce less favorable outcomes if you are a member of a minority group, on a low income, or a non–English speaker. Finally, studies indicate that African Americans have less confidence in the courts, on average, than do other Americans. This does not extend to all minority groups; Asian Americans generally have a positive view of the courts, while the position of Latinos depends on the specific context and topic under consideration.

In an important sense, the lower courts have two publics. One consists of the slightly more than half of all adults with one or more direct experiences of the courts. The most common form of such experience is serving as a member of a jury, applicable to about one adult in four. That proportion has been rising in recent decades in response to jury source list reform and the reduction in occupational exemptions.

The public with direct court experience tends to remember those encounters for decades, no matter how trivial objectively, and draw heavily on them when evaluating the courts. Among those with court experience, the extent of exposure to media representations of the courts, perceptions of judicial leniency in sentencing, and political ideology are poor predictors of confidence in or support of the courts. The opposite is true for people without direct experience, who appear to draw on a national rather than a locally formed image of the courts.

The evidence points to a slightly negative general impact of court experience per se, but one that varies according to the role a person played in a case. Individuals serving on a jury (as opposed to the essentially neutral impact of being summoned but not seated as a juror) are the most positive, while civil litigants tend to be the most negative.

Explaining Opinions About the Court

Those interested in explaining the sources of support for the U.S. Supreme Court rely primarily on legitimacy theory, which emphasizes institutional loyalty. Research on the U.S. Supreme Court sought to explain the sources of two types of support and their interrelationship. *Diffuse support* is a willingness to accept the decisions of the Court as legitimate, a belief that the Court has the right to decide questions of constitutional interpretation. *Specific support*, the other aspect, refers to responses to individual decisions issued by the Court.

Specific support rises and falls as individuals react to well-publicized decisions. Diffuse support tends to vary little. Even the polarizing decision in *Bush v. Gore* (2000) did not diminish the reservoir of goodwill for the Court. In the immediate aftermath of the decision, support for the Court among the Democrats sharply declined and that of Republicans increased just as sharply. Over time, people return to the loyalty or diffuse support that they had for the U.S. Supreme Court prior to a controversial decision. Research suggests that the U.S. Supreme Court is more effective than other parts of government in leveraging its perceived legitimacy into compliance with unpopular

decisions and presumably more so than the lower courts.

Early studies of public opinion about the lower courts focused on the influence of socioeconomic and demographic backgrounds on satisfaction with the outcomes of specific cases and with the courts generally. Opinions were predicted to vary according to a person's educational level, gender, race and ethnicity, political ideology, and knowledge of the courts.

Starting in the mid-1970s, social psychologists took a different direction by focusing on perceptions of the fairness of court procedures. A substantial body of research applying a variety of methodologies in a wide range of adjudicatory contexts, and in many countries, established that the perception of procedural fairness is the most important influence on a court user's satisfaction with the courts. People who lose in the courtroom can nonetheless leave satisfied with their day in court, confident in the courts, and likely to comply with the court's decisions.

The work of Tom Tyler and his colleagues provides the theoretical basis for anticipating such a finding. They argued that the public's concerns had more to do with "relational" issues than with "instrumental" factors such as the absolute or relative outcome. Group value theory explains this expectation: People value their membership in social groups and seek evidence that they are indeed valued by those groups. The behavior of the judge, or other decision maker, provides the confirmation.

Procedural fairness consists of various "symbolic criteria" that people can look for as they assess how they are being treated:

- *Respect:* Being treated with dignity and having one's rights respected
- *Neutrality:* Decision makers who are honest and impartial and who base decisions on facts
- *Voice:* Having the opportunity to express one's viewpoint to the decision maker
- *Trustworthiness:* Benevolent and caring decision makers, who are motivated to treat you fairly, are sincerely concerned about your needs, and consider your side of the story

Voice is the element of procedural fairness on which the courts tend to score the lowest relative to the executive and legislative branches; neutrality is where they tend to score the highest. People with direct experience tend to focus on what they can use to decide on the judge's trustworthiness. In the absence of such experience, the focus is on clues about neutrality.

The significance of procedural fairness is that when measured and placed in a predictive model of satisfaction with the courts, sociodemographic characteristics, including race, and political ideology tend to be statistically insignificant. In other words, if African Americans are less satisfied with the courts, it is because they perceive less procedural fairness in the courts than do other groups. Factors related to the practical side of court performance, as in cost and case delay, also tend to be far less consequential than perceptions of fairness. This is particularly true among people who had experience of a court case. People with no court experience give greater attention to the practical side of court operations, but their perception of procedural fairness still is the primary factor influencing their support for the courts. Researchers are more successful in predicting the opinions of people with court experience than of those without such experience.

There is an important exception to this general pattern. Judges and lawyers generally tend to attach greater importance to the fairness of outcomes than to procedural fairness. There may be a practical dimension to this reverse of the pattern found in the public at large. Judges are able to evaluate the fairness of legal decisions and are less concerned about confirming their value to the group. The public, however, is poorly equipped to assess legal decisions and therefore focuses on whatever clues it can find on how it and others are being treated by the decision maker.

Thus, perceptions of procedural fairness assume an overwhelming importance in shaping public responses to specific court decisions or broader opinions on the courts in general. Procedural fairness can be used to explain reactions to U.S. Supreme Court decisions. The majesty and mystery with which the Court surrounds its decision-making process appears to conform to the symbols people associate with a fair process. Consequently, some observers have questioned whether the public is being too generous in its esteem for the Supreme Court.

Public Opinion About the Polygraph

The public is routinely informed that suspects have been administered a polygraph test and have either failed or passed the test. In some cases, this information is provided during the trial. Consequently, how the public judges the polygraph test is of interest to those in the legal community. A number of studies have addressed how the public responds to polygraph tests, and these studies generally suggest that people react to polygraph test results much differently than the courts assume they do.

As used in criminal investigations, the polygraph test consists of a series of questions administered to a suspect by a polygraph examiner, who measures the suspect's physiological responses to each of the questions. In most instances, the pattern of questioning of suspects involves a variant of the Control Question Test (CQT), in which suspects are asked both relevant questions and control questions. A pattern of higher physiological responses to the relevant questions results in a failed test.

The courts have been largely unwilling to admit polygraph test evidence into trials. Much of this reluctance stems from the concern that the polygraph test cannot reliably determine when someone is truthful or deceptive. This concern was first articulated in 1923 in *Frye v. United States*, in which it was ruled that the lie detector had not gained general acceptance in the scientific community. Today, courts routinely cite the 1993 case of *Daubert v. Merrell Dow Pharmaceuticals*, which did not concern the polygraph specifically but rather any scientific evidence. More important to the present discussion, a second concern surrounding the polygraph test is that the public may see the test as infallible and place unwarranted trust in the results. Because the polygraph test gets directly to the heart of the matter—whether the suspect is truthful or deceptive in denying the crime, there is the fear that jurors will simply disregard all other evidence and place their trust entirely in the results of the polygraph test. This belief on the part of the court was articulated in the 1975 case of *United States v. Alexander.*

Polygraph test results typically are entered into trial evidence either as a result of prior stipulation (i.e., prior agreement between the parties) or as a result of a separate hearing. Presently, approximately one third of the states allow polygraph tests into evidence under prior stipulation. Stipulated tests arise in instances where the prosecutor asks a defendant to submit to a polygraph test and agrees to drop the charges if the test is passed but will introduce the test results into evidence if the test is failed. In instances where the defense wants to admit the results of a passed test over the objection of the prosecution, a hearing typically called a *Kelly-Frye* or a *Daubert* hearing is conducted to determine the admissibility of the polygraph evidence.

Several studies have investigated whether jurors are likely to place unwarranted trust in polygraph test results. Here, the findings have been consistent in showing that the public remains rather skeptical about the validity of polygraph tests. These findings have come about from jury simulation studies, in which the participants are given information about a criminal trial and asked to render judgments. The cases in these studies have varied the crime in question from burglary to rape to murder. The manner in which the trial information was presented to participants has varied from videotaped trial simulations, audiotaped information, and lengthy trial transcripts, to brief summaries of trial facts. Moreover, the characteristics of participants have also varied, from college undergraduates to samples of community members.

In these studies, when evidence that the defendant failed a polygraph test is introduced into the trial, it consistently has failed to affect verdicts or measures related to verdicts (e.g., confidence ratings, strength of evidence ratings). In comparison, in studies in which other forms of equally suspect evidence are also introduced—such as eyewitness testimony, participants have tended to rely heavily on this information when rendering judgments. Moreover, participants fail to draw a distinction among the different types of polygraph test evidence. For example, research has consistently shown that the Guilty Knowledge Test (GKT) is much less likely to result in false positives (i.e., truthful suspects misclassified as deceptive) than is the CQT. Yet when studies have varied the type of polygraph test admitted in instances where the defendant failed the test, again no differences were found. That is, participants are no more trusting of the GKT than they are of the CQT. When researchers have varied whether the polygraph test results indicated that the defendant had passed the test or failed the test, there were again no differences in verdicts when compared with a control group that did not receive polygraph test results in the trial. Finally, because it is possible that participants are less apt to rely on polygraph evidence when other, more reliable forms of evidence are present than when it is the sole evidence against the defendant, researchers have varied the presence of failed polygraph evidence both with and without other corroborating evidence. Again, no differences were found for guilty judgments, as participants were no more likely to rely on polygraph evidence when it was the chief evidence against a defendant than when it was one of many pieces of evidence against the defendant.

However, whereas jurors are rather reluctant to use polygraph evidence in their decisions, the general public appears to be less skeptical of the test than are experts. That is, surveys of experts in areas such as psychophysiology suggest that compared with the general public, they are more uniformly condemning of the value of polygraph tests. The general public tends to be more varied in its beliefs. Moreover, the general public is less inclined to perceive subtle differences in the techniques (e.g., CQT vs. GKT) but rather holds a generally skeptical attitude toward all polygraph tests. What is clear, then, is that despite the opinions of many within the legal community who fear that polygraph evidence may be overly probative in the minds of jurors, the research thus far is consistent in demonstrating that neither are polygraph test results highly valued by jurors nor do jurors place unwarranted trust in the test when rendering judgments concerning the defendant.

Race, Impact on Juries

The relationship between race and the decision making of juries is complex and controversial. Media and public discussions of the topic often focus on anecdotal evidence in the form of recent high-profile cases in the United States. Researchers, on the other hand, have begun to generate a wide-ranging empirical literature regarding the influence of a defendant's race on jurors, between-race differences in juror tendencies, and the effects of jury racial composition on verdicts and deliberations. The findings of these studies are not always consistent, and the psychological processes through which race influences decision making merit additional investigation. Nonetheless, this body of research clearly indicates that race has the potential to affect trial outcomes—a conclusion that is noteworthy from a practical standpoint and carries important implications for ongoing debates regarding jury representativeness, peremptory use during jury selection, and racial disparities in capital sentencing.

Researchers who investigate these issues typically do not seek to provide definitive conclusions concerning whether race was influential in any particular case. Rather, this research attempts to identify—through a variety of methodologies—general tendencies and statistical trends regarding race. Some researchers conduct archival analyses, selecting a sample of actual cases from a particular jurisdiction over a particular time period and using regression analysis to determine whether a variable such as defendant race reliably predicts verdicts. Other researchers conduct interviews with former jurors to assess perceptions of the role played by race at trial or to compare the experiences of jurors of different races. Social scientists tend to use mock juror experiments and jury simulations in which judgments are compared across slightly different versions of the same case or between juries of different racial compositions. Each of these research strategies has unique strengths and limitations, emphasizing the importance of converging empirical findings from multiple study types.

Race of Defendant

From a historical perspective, the question of whether the race of defendants influences legal decision making can be answered with a straightforward "yes." In the pre–Civil War United States, for example, statutes mandated that certain behaviors were illegal when practiced by Blacks but not by Whites; different punishments were also on the books for White versus Black perpetrators. Even well into the 20th century, "Jim Crow" laws not only facilitated racial segregation in the U.S. South, but also criminalized behaviors and established punishments that disproportionately targeted Blacks. A long litany of anecdotal examples indicates that such overtly disparate treatment was not confined to legislative bodies and law enforcement but was also apparent in jury verdicts and appellate court rulings.

In the past half-decade, in the wake of the Civil Rights Movement and the end of statutory discrimination, it has become more difficult to provide unqualified answers to questions regarding defendant's race. As fewer individuals become willing to endorse overtly prejudicial attitudes or to admit to racial discrimination,

researchers have come to focus on behavioral measures in the effort to assess the influence of race. This development mirrors more general trends in social science research: Many theorists have described contemporary manifestations of racial bias as more subtle and ambiguous than in previous eras, and few empirical investigations today rely on self-report measures to identify the influence of race.

Much current research on the issue of defendant's race addresses the question of whether White jurors render different judgments in cases involving White versus Black defendants. Presumably, this focus reflects both the historical context reviewed above (in which Black defendants have often received disproportionately harsh treatment at the hands of a predominantly White legal system) as well as a more general tendency in social science research to consider racial bias in terms of the dichotomy of White perceivers and Black targets. Literature reviews and meta-analyses of experimental research report mixed findings regarding the influence of race on White mock jurors, but a general tendency emerges such that Whites, often, are more conviction-prone and recommend harsher sentences for Black versus White defendants. A smaller number of archival analyses provide converging evidence for this conclusion.

A great deal remains unknown regarding the influence of a defendant's race, however. The case-by-case variability of these effects suggests the importance of determining precisely when and why a defendant's race colors legal judgments. Studies have identified a range of factors that render defendant race more likely to influence jurors, including when the evidence at trial is ambiguous, when the crime in question is violent, and in the face of incriminating inadmissible evidence or inflammatory pretrial publicity. Further exploration of these and other variables is needed, as are future examinations involving defendants of races other than White and Black. The race of the victim is another important consideration because archival research on capital sentencing indicates that the influence of a defendant's race is often greater for interracial versus same-race murders; indeed, the "Baldus study," an extensive archival investigation discussed in the U.S. Supreme Court's *McCleskey v. Kemp* (1987) decision, indicates that victim race is an even stronger predictor of capital sentencing outcomes than defendant race.

Efforts to combat disparate legal treatment by race would also be facilitated by a better understanding of the psychological processes through which a defendant's race affects jurors. To the extent that hostile attitudes toward defendants of particular groups, in-group/out-group effects, or overt motivations for race-based jury nullification are responsible for such effects, accurate identification of biased jurors during jury selection becomes of paramount importance. But a defendant's race may influence even those jurors who do not harbor explicit racial prejudices or motivations. Cognitive associations between race and crime likely impact legal judgments, either because jurors personally endorse the belief that individuals of particular racial groups are more likely to commit certain crimes or through mere awareness of the race-relevant crime stereotypes endemic to society and perpetuated by popular culture. The processes through which a defendant's race influences decision making merit additional empirical attention.

Race of Juror

As mentioned above, the majority of experimental research regarding defendant race has focused exclusively on the individual judgments of White jurors. A smaller subset of studies has examined the judgments of jurors of other races. The objective of such studies, typically, is not to identify general between-race differences in juror verdict tendencies (e.g., non-White jurors are more acquittal prone than Whites; Black jurors are particularly skeptical of police testimony), despite the fact that many legal practitioners and laypeople harbor such across-the-board assumptions. Rather, most studies examining juror race seek to determine whether particular factors—such as defendant race—have different effects on jurors of different backgrounds.

On the question of the intersection between defendant and juror race, many experiments have converged on the conclusion that jurors are likely to be lenient toward same-race defendants. In other words, the finding that Black defendants tend to be judged more harshly than White defendants is likely specific to studies involving White jurors; the opposite pattern is often expected for Black jurors. In fact, more than one mock juror experiment has indicated that the influence of a defendant's race is more pronounced or consistent among Black jurors than among White jurors. However, the interaction between juror and defendant race is complex, and a notable exception to this "same-race leniency" tendency can be found in what some researchers refer to as the "black sheep effect." Studies have demonstrated that in some instances, jurors tend to be harsher in their judgments of a same-race defendant, such as when the evidence against the defendant is

unambiguously strong, the crime in question is particularly heinous, or the victim is also of the same race as the juror.

Studies using actual trials have examined juror race by comparing the subjective jury service experiences of individuals of different races. Interviews with jurors from capital cases, for example, have revealed that White jurors report greater satisfaction with their jury experiences than do non-White jurors, that Black jurors are more concerned that the jury may have made a mistake than their White counterparts, and that Black jurors are sometimes concerned that the Whites with whom they served failed to understand Black defendants' personal circumstances. Again, though, most of these studies only examine White and Black participants, and much remains to be learned regarding the ways in which the experiences and decision making of jurors varies and converges across different racial groups.

Jury Racial Composition

Although the title of this entry refers to "juries and race," the research described to this point has focused not on the decision making of juries but rather on the private judgments of individual jurors. Most research examining race and legal decision making at the group level is archival in nature. One finding to emerge from this literature parallels the between-race juror effects reported above: The greater the proportion of Whites to non-Whites on a jury, the harsher a jury tends to be toward non-White defendants. This group-level variation on the same-race leniency phenomenon has been observed for Whites and Blacks on capital juries as well as for Whites and Latinos on nonfelony juries. A smaller number of experimental studies have produced comparable findings among investigations of White and Black jurors, White and Latino jurors, and jurors of African versus Indian descent.

Whereas archival analyses demonstrate that a jury's racial composition is associated with its verdict tendencies, only experimental data reveal the causal link between composition and decision. But even experiments rarely shed much light on the processes through which such influence occurs. There are multiple possible explanations for why a jury's composition sometimes affects its decision making, and these possibilities are not mutually exclusive. First, the relationship between a jury's composition and its verdict may simply be the group-level manifestation of the same-race leniency effect found among individual jurors. That is, to the extent that generalized differences exist between, for example, the tendencies of White and Black jurors for a given case, the racial makeup of a jury is likely to shape the predeliberation jury vote split and, therefore, also likely to have an impact on verdict tendencies. In this manner, more Black jurors in a trial involving a Black defendant might render a guilty verdict less likely because Black jurors tend to be more lenient toward Black defendants than are White jurors.

There are additional explanations for the effects of a jury's racial composition beyond a simple demographic, vote-split account. Indeed, archival and experimental investigations have found that a jury's racial composition can predict not only verdict tendencies but also the process and content of its deliberations. Many legal scholars and judges have argued that a diverse jury composition leads to a diversity of information exchanged during deliberations. The assumption underlying this proposition is typically that jurors from racial minority groups tend to bring to the jury room different perspectives and life experiences than would otherwise be heard during deliberations of homogeneously White juries. Though few empirical jury studies have tested this prediction, research from nonlegal domains has demonstrated a link between a demographic diversity and the breadth of perspectives with which a group approaches a decision. But the effects of jury composition need not be wholly attributed to the informational contributions of racial minority jurors. Recent research—set in both legal and nonlegal contexts—suggests that a diverse group composition also affects the judgments and cognitive performances of White individuals. Specifically, experimental research indicates that the racial composition of a jury can affect White mock jurors' verdict preferences, evidence processing, and performance during deliberations; even the mere expectation of deliberating on a diverse jury has been found to influence the private judgments of White as well as Black mock jurors.

In sum, research on jury racial composition—like research on race and legal decision making more generally—has provided compelling evidence that race can exert a causal effect on trial outcomes. The precise mechanisms that account for this influence of racial composition remain in need of additional empirical investigation, as do a variety of questions regarding the generalizability of these findings across different types of cases and racial groups. Moreover, published research on this topic does not allow for definitive assessment of whether a jury's racial composition was

influential in any particular case or whether a different verdict would have been reached by a jury with a different composition. Nonetheless, jury racial composition appears to be more than a constitutional consideration; it is a variable with the potential for performance effects related to intragroup dynamics, deliberation content, and final verdict.

Racial Bias and the Death Penalty

The issue of racial bias in death sentencing has long been a significant concern in the system of capital punishment. Many studies across the United States have found the race of the defendant (combined with the race of the victim) to be a salient predictor of juror decision making in capital cases, with Black defendants convicted of killing White victims to be most likely to receive the death sentence. Racial bias in capital trials appears to be correlated with the following: (a) the ethnic background of the district attorney pursuing the death penalty; (b) the racial breakdown of the jurors in capital cases; (c) jurors' failure to understand jury instructions in death penalty trials; and (d) jurors' attitudes toward the death penalty and their death qualification status. Research also suggests that whether Blacks' physical appearance resembles racial stereotypes may be a factor in jury decisions.

In the United States, 38 states use capital punishment as the ultimate penalty for defendants convicted of crimes such as first-degree murder, capital sexual battery, and treason. The United States is the only country in the Western world to employ the death penalty and, along with China, Iran, and Saudi Arabia, is responsible for 94% of the world's executions.

Clearly, capital punishment is an extraordinarily controversial issue. The debate about the death penalty appears to be several fold, involving issues such as its lack of financial feasibility, its questionable deterrent value, the execution of innocent persons, diminishing public support for capital punishment, increasing public support for the alternative penalty of life without the possibility of parole, and lethal injection constituting "cruel and unusual punishment." One of the most salient controversies surrounding capital punishment is the fact that it appears to be arbitrarily and capriciously applied, with the majority of capital defendants and death row inmates being men of an ethnic minority charged with/convicted of killing a member of the ethnic majority.

Legal Background

The issue of racial bias was addressed by the U.S. Supreme Court 20 years ago in *McCleskey v. Kemp* (1987), in which the Court was forced to take a realistic look at the issue of social injustice in the application of the death penalty. In a brief submitted to the Court, social scientists concluded that prosecutors were 70% more likely to seek the death penalty against a Black person accused of killing a White person than in cases with any other racial composition.

In addition, the study found that when Black defendants were convicted of killing a White victim, they were 22 times as likely to receive the death penalty as Blacks convicted of killing Blacks and 7 times more likely to receive the death penalty than Whites convicted of killing Blacks.

In spite of the conclusions brought forth by the data, the Court said that the overall pattern of discrimination

did not mean that racial issues actually entered into sentencing decisions in Georgia. The Court also argued that the study's reliance on statistical probabilities was an inherent weakness in the data (as opposed to its greatest strength). The Court insisted that researchers must provide "exceptionally clear proof" that racism is a factor in jury decision making in capital cases. Because research has indicated that people with the most prejudices are often the least likely to admit them, this standard has proven to be difficult, if not impossible, to meet.

Statistical Analysis of Racial Bias

Although recent findings have suggested that racial bias appears to permeate the system of capital punishment, the issue is more complex than previously imagined. For example, roughly half the death row inmates in the United States are Black, Hispanic, or Asian. Although only 34% of defendants who have been executed have been Black, 80% of murder victims in capital cases in which the defendant was subsequently executed were White (while only 50% of murder victims are White). As of January 2007, 213 Black death-row inmates were executed for killing a White victim, whereas only 15 White defendants were executed for killing a Black victim.

In addition, research has found that in 96% of the states that have conducted systematic reviews of the correlation between race and the death penalty, there was a pattern of race-of-defendant or race-of-victim discrimination, or both. A recent study in North Carolina suggested that people who killed White victims were 3.5 times more likely to receive the death penalty. Another study found that capital defendants in California were 3 times more likely to receive the death penalty if their victims were White than if they were Black and 4 times more likely to receive the death penalty than if their victims were Hispanic. Another report released in New Jersey by the state Supreme Court found that the state is more likely to pursue capital charges against defendants who kill White victims. Indiana, Maryland, and Virginia have conducted similar studies and concluded that the race of both the defendant and the victim is a controlling factor in most capital cases.

Causes of Racial Bias

One possible cause of the aforementioned bias is the race of the person who decides to pursue capital charges at the outset. For example, in most states, the vast majority (by some counts, 98%) of chief district attorneys are White, whereas only 1% are Black.

Another probable explanation of the bias is that jurors make decisions based on their race and that of the defendant rather than on the evidence in the case. For example, a recent study found that White jurors were more likely to sentence Black defendants to death.

Failure to understand jury instructions may also lead to death penalty decisions in which race appears to be a factor. For example, research conducted by Mona Lynch and Craig Haney suggested that when instructional comprehension was poor, Black defendants were even more likely to receive the death penalty.

Certain juror characteristics also appear to affect racial bias in the system of capital punishment. For example, a study by Brooke Butler found that both attitudes toward the death penalty and death qualification status (i.e., jurors' eligibility to hear a capital case based on their attitudes toward the death penalty and whether they would be able to disregard personal convictions that the capital punishment is wrong and consider the death penalty as an option) correlate with various forms of prejudice. Specifically, as support for the death penalty increased, venirepersons (i.e., jurors who are eligible to hear a capital case) were more likely to believe that discrimination against Blacks is no longer a problem in the United States; that Blacks have more influence in school desegregation plans than they ought to have; that Blacks are getting too demanding in their push for equal rights; that Blacks have gotten more economically than they deserve; and that, over the past few years, the government and news media have shown more respect toward Blacks than they deserve.

The same study also revealed that death qualification status was significantly related to jurors' beliefs that racism remains a problem in the United States today. Specifically, death-qualified venirepersons were more likely to believe that discrimination against Blacks is no longer a problem in the United States.

It also appears that simply looking "more Black" affects the way jurors make sentencing decisions in capital cases. For example, recent findings suggest that in cases involving White victims, the more stereotypically "Black" a defendant is perceived to be, the more likely that person is to be sentenced to death.

Rape Trauma Syndrome

Rape trauma syndrome (RTS) is a topic about which experts testify in legal cases. It is most often used by prosecutors in sexual assault cases to counter a defendant's claim that the sexual contact in question was consensual. The specific nature of the testimony varies from case to case but often includes a description of the common effects of rape and an opinion that a particular complainant's behavior is consistent with—or not inconsistent with—having been raped. Judicial decisions regarding the admissibility of RTS testimony have varied because of differences in the specific nature of the testimony given as well as changes over time and across jurisdictions in rules regarding the admissibility of expert testimony. Nonetheless, expert testimony on RTS generally is admissible, particularly when it is offered to educate the jury (versus to prove that a rape occurred).

Definition of Rape Trauma Syndrome

The term *rape trauma syndrome* was first coined by Burgess and Holmstrom in 1974 to describe a two-stage model of reactions to rape among adult rape victims. Their model was a description of symptoms observed in a sample of 92 adult female rape victims seen in a hospital emergency room. Based on interviews with these women, Burgess and Holmstrom described an acute phase of the recovery process, which was characterized by a great deal of disorganization in the victim's lifestyle. Physical (e.g., muscle tension) and emotional (e.g., fear, self-blame) symptoms were common during this phase. The second (reorganization) phase began 2 to 3 weeks after the rape. Victims often moved during this phase, and trauma symptoms (e.g., nightmares, fears) were still common. Although the term RTS continues to be used in legal decisions and commentary, subsequent research has conceptualized rape trauma in terms of specific diagnoses and symptoms rather than stages of recovery.

RTS is sometimes referred to as a specific type of posttraumatic stress disorder (PTSD) in expert testimony, case law, and legal commentary. Indeed, rape is an example of a traumatic event that can lead to PTSD as defined in the *Diagnostic and Statistical Manual* (*DSM*) of the American Psychiatric Association. The *DSM* outlines very specific criteria that must be met for individuals to be diagnosed with PTSD: (a) They must have experienced a traumatic event that involved actual or threatened death, serious injury, or threat to physical integrity and react to that event with intense fear, helplessness, or horror; (b) they must report a specified number of symptoms involving reexperiencing the event, avoidance, and heightened arousal; and (c) the symptoms must last for at least 1 month and cause clinically significant distress or impairment in functioning. Studies suggest that the vast majority of rape victims meet the criteria for PTSD immediately postrape and that approximately 50% continue to meet the criteria at 1 year postrape. Current PTSD prevalence rates among victims raped several years previously range from 12% to 17%. Several studies have found that rape victims report more symptoms of PTSD than nonvictims and victims of other types of traumas.

Although case law tends to focus on PTSD, several other symptoms are also common following a sexual assault, including fear, anxiety, depression, health

problems, and substance abuse. These symptoms are both common in rape victims and more common in victims than in nonvictims. Some argue that only evidence that symptoms are more common in victims than nonvictims is relevant to whether a rape occurred. Evidence that symptoms are common among rape victims is not relevant if the symptoms are equally common among nonvictims. However, evidence that a symptom is not common following rape, but is consistent with having been raped (i.e., is a possible consequence), is relevant if the defense claims that the symptom is inconsistent with having been raped.

In summary, RTS has been used to refer to the description of the effects of rape in Burgess and Holmstrom's 1974 study, research on rape-related PTSD, and research on other effects of rape. This can be very misleading because the RTS symptoms described by Burgess and Holmstrom are not the same as those described in the *DSM* criteria for PTSD. In addition, unlike PTSD, RTS is a description rather than a diagnosis with specific criteria. Some of the symptoms described by Burgess and Holmstrom have been found to be more common in victims than in nonvictims in subsequent research, but this research has not replicated Burgess and Holmstrom's stage model. The term RTS will be used here to refer to the entire body of research on the effects of rape.

Expert Testimony on RTS

Most often, the purpose of expert testimony on RTS is to counter a defendant's claim that the sexual contact in question was consensual. It can be difficult to prove nonconsent because there are often no witnesses or other physical evidence, and the complainant often knows the defendant. Expert testimony regarding psychological trauma experienced by a complainant is considered to be the strongest evidence available in consent defense cases.

Expert testimony on RTS was first introduced in U.S. courts in the early 1980s. Most states that have ruled on its admissibility have found it to be admissible although decisions vary depending on the specific nature and purpose of the testimony in a particular case. For example, the testimony offered can differ in terms of whether the expert provides only a general description of the common aftereffects of rape or whether the expert also provides an opinion regarding whether a particular complainant is suffering from RTS. Testimony also differs in terms of whether the expert refers to RTS or to PTSD.

Several criteria determine whether expert testimony is deemed admissible. First, the expert has to be qualified. Various kinds of professionals (e.g., psychologists, psychiatrists, crisis workers) have provided testimony, but their qualifications have rarely been an issue in determining the admissibility of RTS evidence. The second criterion is that the evidence should be scientifically reliable and valid. RTS evidence generally is seen as reliable if it focuses on whether RTS is a generally accepted response to sexual assault and is not seen as reliable in determining whether a rape occurred. The third criterion is that the evidence should be helpful to the jury. In general, the testimony is seen as helpful in educating jurors about the common effects of rape and particularly common misconceptions about rape and rape victim behavior. The final criterion is that the testimony should not be unfairly prejudicial to the defendant. This has been the most controversial aspect of the testimony, but the degree of prejudice depends on the nature of the testimony. The testimony is generally viewed as less prejudicial if the expert uses the term PTSD versus RTS, if the testimony is used to rebut a defendant's claim that a complainant's behavior was inconsistent with having been raped, and if the testimony concerns victims as a class versus the specific complainant. The testimony is viewed as unfairly prejudicial and as invading the province of the jury if it is used to prove that a rape occurred (e.g., if the expert states that he or she believes that the victim was raped or definitely has RTS).

Although RTS evidence was initially introduced in sexual assault cases to corroborate the complainant's claim that sexual contact was nonconsensual, defendants have also sought to use the testimony to support their version of the facts. For example, a defendant may try to offer expert testimony that, because a complainant does not have RTS, she must not have been raped. Compelling complainants to be examined by defense experts undermines protections introduced by rape shield laws and could deter reporting. Nonetheless, concerns about complainants must be balanced against the rights of the accused. The admissibility of RTS evidence by the defense depends on several factors. For example, expert testimony offered by the defense is more likely to be admissible if the prosecution first offered the testimony. Some argue that it should only be admissible in these circumstances. In addition, some

argue that the defense should be allowed to compel an examination of a complainant if the prosecution expert did an examination but not if the prosecution expert only provided general testimony about the effects of sexual assault.

Rapid Risk Assessment for Sexual Offense Recidivism (RRASOR)

The Rapid Risk Assessment for Sexual Offense Recidivism, abbreviated as the RRASOR (pronounced like the cutting tool), is an actuarial scale designed to assess different levels of sexual recidivism risk for convicted sexual offenders. This scale was the first empirically validated actuarial instrument specifically designed for the assessment of sexual offense recidivism. As such, it served both to change the manner by which people conducted risk assessments and as the stepping stone for the development of second-generation actuarial instrumentation, though it is still being used because of its unique contribution to risk assessment technology. This overview describes the instrument's development, summaries of tests of reliability and validity, how it has been used in furthering risk assessment knowledge, and the reason why it is still used despite the availability of newer instruments.

Development of the RRASOR

R. Karl Hanson was the sole developer of the RRASOR. He started (in 1997) with a set of seven empirically derived correlates to sexual recidivism selected from the findings of a then recently completed meta-analytic study. These seven risk factors were selected based both on their correlation with sexual recidivism and the presumed ease in finding the relevant information in prison records. A regression analysis using measures of these seven variables across six aggregated samples found that a subset of four of the seven variables accounted for nearly all the relevant variance of sexual recidivism. These four risk factors (prior sex offenses, offender age being younger than 25 years, ever having a male victim, and ever having an extrafamilial victim) were then combined to form an instrument called the RRASOR. A cross-validation test of the new scale with an independent seventh sample documented supportive evidence of the scale's utility.

Scoring for 3 of the items is dichotomous, while scoring for the "prior sex offense" item involves four levels, with higher item scores always representing high recidivism risk. Each additional sign of risk is scored 1 point. The total scale score for the instrument is computed through simple addition across the 4 item scores. The final form of the instrument offers recidivism rates for each of six rank-ordered score levels (i.e., scale total scores of 0 through 5) for 5- and 10-year follow-up periods.

Although scores of 6 were possible, no one with that score was found among the nearly 2,600 subjects used to develop the instrument. Offenders with RRASOR scores of 6 have been found since by other researchers and risk evaluators, though that score is so rare that its associated degree of recidivism risk is still unknown.

The developmental study found the RRASOR to have an ROC (Receiver Operating Characteristic) ranging from .62 to .77 (relative to sexual recidivism) across the seven samples used to develop it. This range of ROCs is very much similar to the ROCs found from cross-validation tests of the instrument.

Reliability and Validity Findings

There have been between two and three dozen empirical tests involving the RRASOR to date. These have occurred using samples across at least eight countries

(Belgium, Canada, England, the Netherlands, New Zealand, Sweden, the United States, and Wales). Interrater reliability tests have typically found the instrument's reliability to fall in the .90 to .94 range—very high, though not surprising given the small number of items on the scale.

The RRASOR's predictive accuracy (as measured by the ROC) is regularly found to be equal to that of other actuarial instruments when tested with individual samples. When viewed across a host of samples in a meta-analytic test by R. Karl Hanson and Kelly Morton-Bourgon, the RRASOR showed a lesser degree of relationship with sexual recidivism than did a second-generation actuarial scale called the STATIC–99 (described briefly below). The RRASOR's predictive validity relative to sexual offenders' nonsexual violent recidivism, however, has regularly been found to be poor, indicating the instrument's effectiveness is specific to sexual recidivism.

Use of RRASOR in Furthering Risk Assessment Technology

As a first-generation instrument, the RRASOR served to demonstrate that actuarial procedures could be effective in assessing sexual re-offending risk. The development of a second-generation risk assessment instrument, the STATIC–99, was completely based on combining the 4 items from the RRASOR with the items from one other scale, for a total 10-item scale. Given that the STATIC–99 has become the most widely used actuarial instrument for assessing sexual recidivism risk, the RRASOR served well toward its own improvement.

The RRASOR has also served as a covariate in analyses to scale out the possible effect of different a priori recidivism risk levels (such as relative to the effect on sexual recidivism rates of aging, of the inability to suppress deviant responding on the penile plethysmograph, and of sex offender treatment). These occasions represented the first time researchers could statistically control for different risk levels in an empirically validated way.

Why the RRASOR Is Still Used

Research involving dimensions of risk (i.e., risk driven independently by offenders' sexual deviance, their general antisociality, and other dimensions) has documented the utility of the RRASOR and fueled its continued use. The 3 nonage items from the RRASOR appear regularly as correlates to measures of sexual deviance and as not correlating strongly with measures of general criminality. Advocates of multidimensional risk assessment procedures often still use the RRASOR when assessing sexual recidivism risk to address risk driven by subjects' sexual deviance, while assessing general antisociality-driven risk with other instruments.

Reconstructive Memory

Reconstructive memory refers to a class of memory theories that claim that the experience of remembering an event involves processes that make use of partial fragmentary information as well as a set of rules for combining that information into a coherent view of the past event. These theories provide a powerful way of understanding how witnesses remember crimes, how reliable recovered memories of abuse are, and how jurors remember testimony. According to reconstructive theories of memory, ordinary memory is prone to error. Errors in remembering can be broken down into *errors of omission,* in which information is

left out of a memory report, and *errors of commission,* in which inaccurate information is added to a memory report. Errors of commission are more typically referred to as *false memories* or *memory illusions.* Reconstructive theories of memory generally hold that errors of omission and errors of commission are related to one another. In fact, according to reconstructive theories of memory, errors of commission occur because reconstructive processes are used to fill in gaps in our memory reports.

History of the Concept of Reconstructive Memory

Pioneering work on the development of reconstructive theories of memory was conducted by Bartlett and described in his classic volume entitled *Remembering.* According to Bartlett, remembering involves an active attempt to make sense out of the historical past—what Bartlett referred to as an "effort after meaning." Bartlett studied the memories of English participants by asking them to repeatedly attempt to recall an unfamiliar folktale called *The War of the Ghosts.* Bartlett found that as participants attempted to recall the event, their recall was systematically distorted by their world knowledge. In particular, with repeated recall attempts, the unfamiliar folktale was recalled in an increasingly conventional manner. Details that were difficult to integrate with the participants' world knowledge tended to drop out. Details consistent with world knowledge tended to be added. Unfamiliar words were replaced with more familiar words. Bartlett concluded that memory does not simply passively record or retrieve facts. Instead, memory combines fact and interpretation in a reconstructive way such that the two become indistinguishable.

In his pioneering text *Cognitive Psychology,* Neisser offered the analogy of a paleontologist reconstructing what a dinosaur must have looked like. According to Neisser's analogy, paleontologists begin their reconstruction based on fragments of bone found in the fossil record. Based on this partial fragmentary information, the paleontologist makes use of his or her knowledge of finds at other sites, anatomy and physiology of current animals, and so on, to make a best guess of what the animal must have looked like, how it must have lived, what it likely ate, and so on. This best guess can be seen as a reconstruction of the past. Similarly, reconstructive theories of memory argue that people make use of partial fragmentary information, world knowledge, inferential processes, and so on, to reconstruct a memory of the past event.

The Process of Memory Reconstruction

Event Details

According to most reconstructive theories of memory, the process of reconstructing a memory is based on a variety of different types of information. First, reconstruction relies on fragmentary pieces of information from the event itself. If one were to witness a bank robbery, details from that event would be stored in episodic memory. Over time, these details would become increasingly less accessible following the exponential forgetting curve first described by Hermann Ebbinghaus. Some time later, the witness would be interviewed about the bank robbery. Although many of the details would be inaccessible, the witness would probably be able to retrieve some key pieces of information that made a special impression on him or her.

Schemas and Scripts

The stored details of the event provide partial evidence on which witnesses can base their memory reconstruction. However, this record of details from the event is likely to be incomplete. To help reconstruct the memory, witnesses would also likely rely on their prior knowledge about bank robberies in general. Memory psychologists have proposed that this type of prior knowledge is stored in long-term memory in the form of *schemas* and *scripts.* A schema is a general term we have for knowledge structures that represent typical instances of categories. Scripts are knowledge structures that represent the typical sequence in which a stereotypical event unfolds. For instance, a witness to a bank robbery likely has a schema representing the layout of a typical bank. They know that banks usually have offices or cubicles where loan officers, new account managers, and the like work. They know that banks typically have guards. They know that banks typically have tellers who work behind a counter. They know that banks typically have safes. This organized body of knowledge is thought to be stored in a "bank schema" that resides in memory. A witness to a bank robbery also likely has a bank robbery script, which includes information about the typical

sequence of actions in a bank robbery. For example, a bank robbery script may include information like the robbers take out weapons, they disarm the guards, they demand money, the tellers provide them with money, the robbers make their escape, and so forth.

Schemas and scripts are thought to guide our understanding of events as they unfold and guide our recall of events as they are being remembered. Reconstructive theories of remembering suggest that schemas and scripts have two effects on our ability to remember events. They make actions that are inconsistent with the schema especially easy to remember because these actions require extra processing at the time of study to reconcile them with the schema. Schemas can also lead to false memories because they are used to fill in gaps in our memory for the event. If you cannot remember what happened in an event, the schema provides the *default value* you should expect.

In one classic study of the role of scripts on memory, participants were presented with a story about a young woman. Some of the participants were told that the story was about Helen Keller. Other participants were told that the story was about someone else. Participants who heard that the story was about Helen Keller falsely remembered facts from the story that were consistent with their world knowledge about Helen Keller (e.g., a book was written about her life). Other research has shown that participants are especially likely to correctly recall information that violates their expectations. For instance, when reading a story about a restaurant, one may remember unexpected events—such as the waiter spilling water—especially well.

Recently, researchers have shown that similar effects occur in forensically relevant settings. In one recent study, participants were shown a videotape of a bank robbery. The video included consistent and inconsistent schema, and irrelevant actions. Consistent with prior research on reconstructive memory, participants falsely recalled many details that were consistent with the robbery schema. In addition, the researchers found that participants used their bank robbery schema to interpret ambiguous information in the video.

Postevent Information

Reconstructive theories of memory also claim that people rely on information obtained after the event to reconstruct their past. Information obtained after an event is known as *postevent information.* For instance, if one were to witness a bank robbery and then later saw a news report about the robbery, details from the news report may become incorporated into one's memory for the event. Classic work on the role of postevent information was conducted by Loftus in the 1970s. In one study, participants watched a videotape of an auto accident. Some participants were asked to estimate how fast the cars were going when they "collided." Other participants were asked to estimate how fast the cars were going when they "smashed" into each other. When tested 1 week later, participants who had been asked the "smashed" version of the question were more likely to remember seeing broken glass, when in fact no broken glass had been shown in the film.

The mechanisms by which postevent information influence memory became a subject of debate in the 1980s. Loftus proposed a theory whereby postevent information overwrites memory for the original information in storage. Other researchers argued that postevent information does not overwrite memory for the original event but rather interferes with the retrieval of the original event. Still other researchers argued that postevent information only influences memory reports in those participants who would not have remembered the detail in the first place. Later attempts to understand the influence of postevent information conceptualized it as an error in source memory. In other words, participants remember the information but have difficulty determining whether that information is from the original event or the postevent information (e.g., was it from the bank robbery or from the newspaper account?).

Work on postevent information has been extended in a wide variety of forensically important settings. Some research has examined the role of the interviewer in moderating the effects of postevent information. Social psychologists have shown that witnesses tend to discount postevent information when it is presented by a noncredible witness and to accept postevent information when it is presented by a credible witness. Also, in the 1980s, considerable research began to examine the role of postevent information in children. After some initial controversy, researchers reached a consensus that preschool-age children are more likely to be influenced by postevent information than are older children or adults. During this same time period, researchers came up with a number of clever research designs to examine children's false memories in contexts with considerable ecological validity. For instance, researchers conducted a number of studies of children's memories for stressful events by embedding postevent information experiments into children's visits to their pediatrician.

The postevent information paradigm was further extended to examine adult memories for childhood events implanted by suggestion. The first of these studies involved implanting a childhood memory of being lost in a shopping mall in college students. Later researchers extended these findings using what has been termed the *familial informant false narrative procedure.* In this procedure, family members first complete a questionnaire about events from the participant's childhood. Later, participants are interviewed about actual childhood events obtained from the cooperating family members and one invented childhood event (e.g., spilling punch on the parents of the bride at a family wedding). Participants are asked to repeatedly think about or imagine these invented events. Research has shown that false memories for childhood events can be created in 20% to 40% of participants using this technique.

Self-Serving Memories

In addition to fragmentary information from the event itself, prior knowledge in the form of scripts and schemas, and postevent information, some theories of reconstructive memory also assume that self-concept can influence how events are reconstructed. According to these theories, one's self-concept can distort how events are remembered. One intriguing case study compared John Dean's testimony at the House Watergate Hearings with taped transcripts of White House meetings involving Dean, Richard Nixon, H. R. Haldeman, and other White House officials. The study revealed that Dean's memory appeared to show systematic distortions that tended to exaggerate his own role in those meetings. Thus, Dean's memory showed a kind of self-serving bias. Later research on autobiographical memory showed that people's memories could be distorted by their current self-concept.

Current Trends and Forensic Implications

Reconstructive theories of long-term memory provide a powerful way of understanding important forensic issues such as how witnesses remember crimes and accidents, how adults remember childhood experiences, how children remember events, and even how jurors remember evidence. These theories stand in sharp contrast to reproductive theories of memory, which view memory as more like a videotape recorder. Research on reconstructive memories currently emphasizes the subjective experience of memories produced by reconstructive processes, whether true and false memories can be distinguished, how errors of commission can be avoided, and the individual differences that influence the use of reconstructive processes.

Reid Technique for Interrogations

Law enforcement personnel use a variety of procedures to elicit confessions from suspects. The Reid Technique uses psychological methods to elicit confessions from those who are believed to be guilty, without the need to resort to physical force to extract a confession. The technique, initially developed in the 1940s and 1950s, was first published in 1942 by Fred Inbau and was called "Lie Detection and Criminal Interrogation." The technique has evolved over the years into what is now known as the Reid Technique. The nine-step process for effective interrogation has been used in police-training programs nationally. The Reid Technique or similar methods are routinely used

by law enforcement in structuring interrogation. Unfortunately, the Reid Technique is sometimes misapplied by law enforcement. Another problem is that the underlying theories behind the Reid Technique have not been empirically validated. The Reid Technique also has the potential to produce false or inaccurate confessions.

Assumptions Underlying the Reid Technique

The Reid Technique makes a distinction between an *interview* and an *interrogation.* These two terms are often used interchangeably as if they refer to the same process. An interview is ostensibly conducted when an officer does not have a lot of evidence to implicate the suspect. It is used to get evidence that may or may not establish guilt. An interview is not accusatory and may be conducted relatively early during a police investigation. An interview can also be conducted in a variety of environments (e.g., home, office, back of a police car), not necessarily at a police station. The interview can be free-flowing and relatively unstructured. The investigator should take written notes throughout the entire interview process.

According to the Reid Technique, an interrogation should be used only for suspects whom the police are reasonably certain committed the offense. The tone of the interrogation is accusatory because it is presumed that guilty individuals are not likely to make incriminating statements unless law enforcement is certain of their guilt. The interrogation involves actively persuading the suspect to admit his or her guilt. The interrogation takes place in a controlled environment. The officer does not take notes until the suspect has told the truth about his or her involvement with the crime, and the defendant is fully committed to that position.

The assumption behind interrogation procedures, according to the Reid Technique, is that most criminal suspects are reluctant to confess because they are ashamed of what they have done. Also, they fear the legal consequences associated with a confession. With most interrogation practices, according to the Reid Technique, it is believed that a certain amount of pressure, deception, persuasion, and manipulation is needed for the truth to be revealed. The U.S. Supreme Court has recognized that all custodial interrogations are, to a certain extent, inherently coercive because of the power and control inherent in law enforcement.

The Reid Technique assumes that guilty individuals experience greater nervousness than innocent individuals when questioned by law enforcement. It also assumes that the anxiety of innocent people diminishes as the interrogation progresses, while the opposite holds true for the guilty party. Both the innocent individual and the guilty individual may display anger directed toward law enforcement during the interrogation. Guilty feigned anger and real innocent anger look almost the same. Yet unlike the anger from the innocent party, it is presumed that the guilty party has difficulty maintaining that anger over time. There is no research to support any of those suppositions.

The Reid Technique proposes three distinctly different channels through which people communicate: the verbal channel (word choice and arrangement of words to send a message), the paralinguistic channel (characteristics of speech falling outside the spoken word), and the nonverbal channel (posture, arm and leg movements, eye contact, and facial expressions). A behavioral analysis approach is recommended by the Reid Technique to help assess behaviors associated with telling the truth and telling lies. Although mental health professionals routinely observe many aspects of both verbal and nonverbal behavior in assessing psychological functioning, these specially trained professionals are not human lie detectors and are unable to tell by a subject's verbal or nonverbal behavior (such as a defensive-type posture while sitting) whether a particular statement is the truth or a lie. Nevertheless, investigators using the Reid Technique claim to be able to analyze verbal, paralinguistic, and nonverbal behavior to determine whether a suspect is telling the truth. Critics argue that the technique is based on unfounded assumptions.

These assumptions have not been subject to scientific scrutiny and may result in law enforcement personnel making erroneous assumptions regarding a suspect's guilt, based on how that suspect sits in his or her seat, the tone of voice the suspect uses, and how denials are worded.

The Nine-Step Process

The Reid Technique involves a nine-step process. The first step, *direct positive confrontation,* involves directly confronting the suspect with a statement that it is known that he or she committed the crime. Often, the police lie and describe nonexistent evidence that points to the suspect as the offender.

The second step, *theme development,* is the step in which the police present a hypothesis about the reason for which the suspect committed the crime. This theme minimizes the moral implications of the alleged offense or allows a suspect to save face by having a morally acceptable excuse for committing the crime. While the Reid Technique states that in no situation is an officer to state that punishment will be lessened by admitting to guilt, in fact, quite often, the officer states just that. If the suspect becomes emotional, the interrogator displays an understanding and sympathetic demeanor toward the suspect. If the suspect does not become emotional and the interrogator does not detect remorse about the offense, various other techniques are used, such as attempting to catch the suspect in a lie, playing one co-offender against another, or behaving more confrontationally such as by stating that there is no point in denying involvement in the crime because all the evidence points toward guilt.

The third step, *handling denials,* involves interrupting a suspect's denials of guilt. The fourth step, *overcoming objections,* involves rejecting a suspect's excuses or explanations. Once the guilty suspect feels that objections are not getting him or her anywhere, he or she becomes quiet and shows signs of withdrawal from active participation. When the suspect becomes withdrawn, the interrogator acts quickly so as to not lose the psychological advantage. In the fifth step, *procurement and retention of the suspect's attention,* the interrogator reduces physical and psychological space between himself and the suspect to get the suspect's full attention. This prevents the suspect from emotionally withdrawing or tuning out from the remainder of the interrogation.

The sixth step, *handling the suspect's passive mood,* is a continuation of the fifth step. The police continue to get into the theme of the crime, expressing both sympathy and understanding of the suspect and emphasizing the need for the suspect to tell the truth. When encouraging the suspect to tell the truth, the interrogator might emphasize "the sake of everyone concerned," "the stress on the victim's family," or "decency and honor."

The seventh step, *presenting an alternative question,* takes place when the interrogator gives two possible alternatives for why the crime was committed. Both alternatives are incriminating but one is presented as face-saving, more acceptable, or more morally blameless than the other. Although proponents of the Reid Technique adamantly state that at no time should an officer state that the morally acceptable option will be less severely punished, many suspects believe that the more morally justified explanation will indeed meet with more lenient treatment.

The eighth step, *having the suspect orally relate various details of the offense,* involves a one-on-one interrogation with no other officers in the room. It is for the purpose of getting the suspect to give a detailed account of the crime that would establish legal guilt. The ninth and final step, *converting the oral statement to a written statement,* is done as quickly as possible after the eighth step. Sometimes, the confession will be videotaped, audiotaped, or recorded by a stenographer rather than written by the suspect or interrogator.

Use of the Reid Technique With Innocent Suspects

Although Fred Inbau and his coauthors stress that the Reid Technique should not be used unless law enforcement is certain the confession is being extracted from a guilty subject, often, this technique or others like it are used on innocent suspects. The police may erroneously believe that a suspect is guilty because of faulty police work or bad evidence, or because a suspect engages in suspicious behavior during the initial interview. For example, there are many reasons why a suspect may lie about details to the police even if he or she is innocent. The suspect may have information that he would like to remain hidden (e.g., drug use or an extramarital affair). An innocent suspect may appear overly nervous because of past experiences with law enforcement or because of the intrinsically anxiety-provoking situation of being accused of a crime.

Police interrogation tactics and techniques, particularly with highly suggestible and/or compliant suspects, may produce false confessions. Also, the interrogation tactics may produce statements from the suspect that, although incriminating him or her in some aspect of the crime, may also exaggerate the actual involvement or criminality of the offense.

Unfortunately, very few jurisdictions require law enforcement to record all interactions with the suspect—from the first encounter following an offense to the completion of a memorialized confession. Often, there are discrepancies in the accounting of what transpired. The defendant has one version, but the police have a different version.

Expert Testimony About Interrogation Techniques and Confessions

Even if the confession has previously been determined to be admissible, there is case law to support expert testimony about interrogation techniques that heighten the risk of false, retracted, or distorted confessions. This expert testimony can focus on individual characteristics of a defendant such as psychological vulnerabilities (e.g., low intelligence), interrogative suggestibility, and compliance. The expert testimony can also describe the methods used by law enforcement to extract confessions and how such methods may increase or decrease the reliability of the statements obtained. It can also focus on the interaction between defendant characteristics and the interrogation methods employed by law enforcement.

The Reid Technique and similar methods have been deemed legally permissible interrogation procedures. Although law enforcement and proponents of this methodology attest to its effectiveness in producing confessions in guilty suspects, many mental health professionals specializing in this field believe that these methods increase the likelihood of false confessions with certain types of suspects. A confession, or self-incriminating statement to law enforcement, carries great weight with the jury. There is disagreement in the field as to what percentage of defendants actually produces false confessions. In fact, most people realize that no scientific estimates can be presently made. It is currently impossible to accurately assess the number of false confessions or the percentage of confessions that are false. Nevertheless, false confessions do occur and there are individuals who are at a higher risk for producing false confessions when encountering the Reid Technique.

Religion and the Death Penalty

Religion has the ability to affect death penalty trials in numerous ways. The most studied include the effects of jurors' religiosity and religious appeals used by lawyers during trial. Religion also affects judges' decisions. Although the study of how religion affects legal decision making is still in its infancy, religion has the potential to affect voir dire, trial presentation, and trial outcomes.

Use of Religion in Voir Dire

Before a trial begins, lawyers have the opportunity to exclude a set number of potential jurors who they believe will not favor their client. Lawyers often exclude potential jurors on the basis of personal characteristics such as religious beliefs or affiliation. For example, lawyers have excluded potential jurors because they were Jewish, Islamic, Jehovah's Witnesses, Catholic, or Pentecostal. Other potential jurors have been excluded because they had strong religious beliefs, had acted as a missionary, or had served as a pastor.

State courts are divided on whether the exclusion of potential jurors based on religion is legally permissible. Some state courts have held that lawyers can exclude potential jurors based on any religious variable, while others have determined that lawyers cannot exclude a potential juror for any factor related to religion. Still other courts have created rules that govern the exclusion of jurors. For instance, the court in *United States v. DeJesus* (2003) stated that it was permissible to exclude a juror because of his or her degree of religiosity (e.g., how often the juror prayed) but not because of his or her religious affiliation. The Indiana Supreme Court in *Highler v. State* (2006) held that lawyers cannot exclude a juror because of religious affiliation but that it is permissible to exclude a juror because his or her occupation is religious in nature. The U.S. Supreme Court had the chance to settle the controversy but declined to do so (*Davis v. Minnesota,* 1994). Thus, state courts can generally develop their own rules.

Because few states prohibit using religious factors to exclude potential jurors, most lawyers are able to do so. Psychologists can provide information about how religious variables may affect jurors' decisions, although the research has been sparse and sometimes contradictory. Conflicting findings likely represent the strong relative influence of individual case facts, the type of trial (e.g., capital or noncapital trial), and different measurements of religious variables.

Studies have investigated the relationships between religion and guilt verdicts, sentencing verdicts, and punishment in nontrial settings. Early research shows that jurors who believe in a divine plan and life after death tend to be more likely to find a defendant guilty. Other research has found that individuals who believe in a punitive God or could be categorized as religiously moderate or fundamental/conservative were more punitive. Religious affiliation may influence attitudes toward punishment, as a few studies have found that Protestants are more supportive of the death penalty than Catholics; other studies have found Catholics to be more punitive than Jews. Several studies have found a positive relationship between punitiveness and a belief in a literal interpretation of the Bible. Religious fundamentalism has sometimes been linked to punitiveness and support for the death penalty. Evangelist individuals (i.e., those who actively encourage others to accept Jesus) in one study were less likely to support the death penalty, though other studies have failed to replicate the finding. Devotionalism (i.e., the amount of time one spends in religious activities) has also produced mixed findings.

A more current study found that individuals who support the death penalty were more likely to be Protestant, have fundamentalist beliefs, believe in a literal interpretation of the Bible, believe that God supports the death penalty, believe that God requires the death penalty for murderers, and believe that their own religious groups support the death penalty. All these relationships except literal interpretism also existed among jurors who were death qualified. A mock jury simulation revealed that various religious factors influenced sentencing verdicts. Specifically, a death penalty verdict was related to high scores on the fundamentalism scale, belief in a literal biblical interpretation, belief that God requires the death penalty for murderers, and a belief that one's religious group supports the death penalty. Although research has sometimes produced conflicting results, many individuals do rely on their religious beliefs when making decisions, including death-penalty-sentencing decisions.

Use of Religion by Lawyers During Trial

Both prosecutors and defense attorneys have presented religious appeals and testimony about a defendant's religiosity to influence capital jurors' sentencing decisions. Appeals typically are presented in the closing arguments of the sentencing phase; testimony and evidence can come from a variety of sources, including pastors and relatives. Some courts have objected to these uses of religion (especially appeals), determining that religion improperly influences jurors' decisions.

Prosecutors have used several types of appeals during trial. First, attorneys have quoted biblical passages that support retribution, such as the "an eye for an eye and a tooth for a tooth" passage and the "Whoso sheddeth man's blood, by man shall his blood be shed" passage. Prosecutors in child murder cases have quoted the passage, "It were better for him that a millstone were hanged about his neck and he were cast into the sea, than that he should offend one of these little ones." Such appeals communicate that a person who murders should also be put to death.

Second, prosecutors have told jurors that God has given them the authority to make the life-and-death decisions. Other attorneys have claimed that the state legislature, the prosecutor, or the court is acting under God's authority. Such an instruction implies that God supports, or at least does not object to, the jury giving the defendant the death penalty.

Third, prosecutors have made comparisons between the defendant and biblical characters such as Judas Iscariot and the devil. Attorneys also tell biblical stories of Cain and Abel, David and Goliath, and the Apostle Peter. These stories provide recognizable metaphors for jurors to use in their decisions.

Defense attorneys have also used a variety of religious appeals to persuade jurors. For example, they have quoted biblical passages such as "Do not take revenge, my friends, but leave room for God's wrath, for it is written: 'It is mine to avenge; I will repay,' says the Lord" or argued generally that life-and-death decisions belong to God, not to man.

Defense attorneys have countered the prosecution's use of the "eye for an eye" argument by presenting quotes from Jesus that advocate "turning the other cheek." Such appeals promote forgiveness rather than retribution. They have also argued for the importance of forgiveness by telling biblical stories such as the one in the book of John about the woman who is caught

committing adultery and is about to be stoned to death. Jesus tells her would-be executioners that only a man who is without sin should throw a stone. After freeing the woman, Jesus forgives her. The purpose of telling the story is to illustrate that no one is without sin, and thus, no one should condemn another person to death. Because Jesus stopped an execution in favor of mercy and forgiveness, jurors should do the same. Another biblical story involves the crucifixion of Jesus. The attorney tells the jury that Jesus asked God to "forgive them for they know not what they do." Thus, jurors are told that they should forgive the defendant, just as Jesus forgave the people who were killing him.

Finally, defense attorneys have presented evidence of the defendant's religiosity in an attempt to evoke jurors' mercy. For example, a lawyer may tell the jury that the defendant deserves mercy because he is a Christian or has converted to Christianity while in prison. The defendant may present evidence or testimony that establishes that he has formed a prison Bible study, has written Christian books, or spends much time in prayer.

Courts have issued a variety of opinions concerning whether it is permissible for attorneys to use religion during trial. Generally, defendant can present evidence of their character that would convince a jury that they do not deserve the death penalty. Thus, evidence of a religious conversion would typically be allowed.

There has been much more controversy over religious appeals by prosecutors and defense attorneys. Some courts have forbidden all religious appeals, while others have provided guidelines for determining what kinds of appeals are allowable—for instance, excluding religious appeals that are excessive, are not related to the character of the defendant, prejudice jurors, or prevent a trial. Still other courts have allowed all appeals. Such courts have determined that appeals are appropriate because they are merely part of lawyers' theatrics.

Courts have forbidden religious appeals for a variety of reasons. Some courts have determined that such appeals violate the Eighth Amendment prohibition on cruel and unusual punishment. In a death-penalty-sentencing trial, a defendant is allowed to provide evidence of mitigating factors (i.e., evidence that the defendant does not deserve the death penalty). Biblical appeals allegedly do not allow jurors to consider mitigating factors; for instance, the "eye for an eye" command instructs jurors to give murderers the death penalty and does not provide jurors with any reasons to deviate from this biblical principle. Courts have rejected defense appeals as well. Some courts have found defense appeals to be improper because they suggest that jurors deviate from the state law. For instance, a lawyer tells jurors that God forbids them from giving a death sentence, while state law allows a jury to sentence a man to death.

Only a few studies have investigated the effects of religious appeals and testimony. In general, research indicates that appeals used by the prosecution are ineffective. That is, biblical quotes do not encourage jurors to give death sentences. Defense appeals used in one study were influential; however, they actually had the opposite effect from what was intended. Specifically, a defense attorney's biblical appeal led jurors to be more likely to give a death sentence. On the other hand, the study found that evidence of a religious conversion led jurors to be less punitive. Evidence that the defendant has always been a Christian has either backfired or had no effect.

Use of Religion in Deliberation

In several recent capital trials, jurors have used a Bible during deliberation. Jurors in at least one trial admitted looking up passages such as the "eye for an eye" passage before sentencing the defendant to death. While judges have generally declared the practice impermissible, it is difficult to completely remove religion from the deliberation room. Even without a Bible, jurors can cite scripture from memory or privately rely on their religious convictions during deliberations. The effects of religion in deliberation have not been studied.

Use of Religion by Judges

Judges can also rely on religion in their decisions. They may be persuaded by their religious beliefs when deciding whether to uphold or reverse a death sentence. They may also allow religious factors to determine whether a lawyer has misused religion in a specific trial. Very little research has been conducted on this issue, although one study found that evangelical judges were more likely to uphold a death sentence than their counterparts. This finding opposes another study that found that evangelical individuals were less punitive.

In sum, religion can affect a death penalty trial in various ways, though these effects remain largely unstudied.

Repeated Recall

Eyewitnesses to a crime or other incident often recall that event dozens of times while waiting for a trial that may take place months or even years later. These recall episodes are often in response to questioning by arresting officers, police detectives, district attorneys, friends, other witnesses, private investigators, and defense attorneys, among others. Even in the absence of direct questioning, witnesses often recall what they have seen on their own, sometimes to prepare themselves for testimony at trial and other times simply because the event was frightening, disturbing, or otherwise vivid. The effects of such repeated recall on eyewitness accuracy and confidence are complex. Although repeated recall can occasionally yield new information, it may also cause memory distortions due to postevent misinformation effects, imagination inflation, increases in witness confidence, and retrieval-induced forgetting.

Generally speaking, repeated recall helps strengthen memory associations and can make the practiced information easier to retrieve in the future. In some circumstances, repeated recall can even lead to hypermnesia, which is the recall of additional information that was not recalled initially. Hypermnesia is most likely to occur when the repeated recall involves multiple retrieval cues. One prominent method of interviewing witnesses—the *cognitive interview*—is designed to elicit as much information as possible by encouraging witnesses to recall an event from multiple perspectives. If administered properly, the cognitive interview can yield increases in the total amount of information as compared with straightforward questioning.

Given that repeated recall can help strengthen memory associations and may even lead to the production of additional information, one would think that an eyewitness should recall the target event as often as possible. However, recalling information repeatedly is not without potential costs; repeated recall can actually alter a witness's memory of the target event.

One well-known side effect of repeated recall is the *postevent misinformation effect.* When a witness is exposed to inconsistent or misleading information that is embedded in questions posed to that witness, the misleading postevent information can impair later memory reports of the original target event. For example, if a witness is asked how fast the car was going when it went through the stop sign (when in fact the car went through a yield sign), that witness is more likely to report later on that there was a stop sign than is a witness who was not exposed to the misleading information. The effects of postevent misinformation are especially strong when the witness is exposed to the misinformation multiple times.

A related phenomenon is *imagination inflation.* When someone repeatedly recalls an imagined event that did not actually occur, eventually she or he will come to believe that the event really did occur, often with great confidence. As is the case with postevent misinformation, the magnitude of the imagination inflation effect generally increases with multiple imaginings (i.e., with repeated recall).

There are other equally troublesome side effects of repeated recall that can occur even in the absence of misleading information or imagined events. For example, repeated questioning of eyewitnesses can lead to *increases in witness confidence* without corresponding changes in witness accuracy. This effect

occurs independent of the content of the questions; in fact, just asking a witness to think repeatedly about an event can lead to later increases in witness confidence. Such increases in confidence are problematic because trial jurors place a great deal of weight on witness confidence when judging the accuracy of a witness's testimony.

Repeated recall of portions of an event can lead to *retrieval-induced forgetting.* Many studies in the cognitive literature, some using eyewitness memory paradigms, have demonstrated that the act of recalling certain information about an event can actually impair a person's performance on a future memory task for other previously unretrieved items. That is, repeated questioning about some details of an event (e.g., the male robber in a bank heist) may make it more difficult for the witness to recall other details about the robbery later on (e.g., the female robber who was waiting outside). Because interviews of eyewitnesses conducted by the police, investigators, and attorneys often constitute incomplete retrieval tasks, repeated questioning of witnesses can lead to retrieval-induced forgetting that may impair recall later at trial.

Finally, it should be noted that young witnesses, particularly children, are generally *more suggestible* than adult witnesses, and they are especially susceptible to all the effects of repeated recall discussed here. In addition, some studies have shown that children will change their answers to questions that are asked multiple times, simply because they assume that their original answers must have been wrong.

Reporting Crimes and Victimization

Almost all crimes become known to the police because citizens, usually victims, report them. In this role as gatekeeper, victims weigh their concerns about injustice, their own security, and the security of the community against the costs of reporting the crime, which may include a belief that the police are unlikely to arrest the offender or return stolen property and the notion that involvement in the criminal justice process is time-consuming and possibly humiliating. Typically, victims are more likely to report more serious crimes. The information and advice that victims solicit and receive from others are, often, also important. Just as in the case of victims, bystanders' decisions to report criminal events are frequently subject to the social influence of others.

In the United States, there are more than 23 million crimes annually—more than 18 million property crimes and more than 5 million violent crimes. Since 1993, rates of crime have generally been declining, in part due to changing demographics (i.e., fewer people in the most crime-prone ages) but also due to the decline in the use of some drugs and to improved law enforcement practices. Although victims are stereotyped as being disproportionately female, White, and older, in fact, there is an overlap between offenders and victims, such that both offenders and victims are disproportionately male, Black, and young. Males are more likely to be victimized by a stranger, whereas females are more likely to be victimized by someone they know.

Absolute Reporting Rates

Reporting is generally considered by psychologists to be a type of help-seeking behavior. Most victims of crime seek help from others, although, depending on the crime, most do not call the police. Typically, victims seek help from family and friends, and some may also seek help from mental health professionals.

Less than half of all crime is reported to the police—about 47% of violent crimes and about 40% of property crimes. The biggest single predictor of whether a crime will be reported is the severity of the offense. About 60% of aggravated assaults, about 40% of simple assaults, about 55% of burglaries, about 80% of motor vehicle thefts, and about 30% of thefts are reported to the police. More generally, reporting is more likely for

violent rather than property crimes, for completed than attempted crimes, for crimes in which the victim suffered more serious injury, for crimes that involved greater loss of property, and for crimes that involved a weapon.

Attitudes toward the police and the criminal justice system are generally not strong predictors of the decision to report or not to report a crime, although there is some evidence that satisfaction with how the police acted in prior cases is related to the reporting of subsequent victimizations. Moreover, although demographic characteristics are not strong predictors of reporting, there are small but consistent findings that females are more likely than males to report, especially violent crimes, and that older individuals are more likely than younger individuals to report them.

In general, crimes against strangers are more likely to be reported to the police than crimes against nonstrangers. Several reasons might account for this difference, including fear of retaliation from the known offender, greater difficulty in determining whether the event really was a crime, a belief that the victim might be seen as partially responsible for the crime, and a belief that events occurring between nonstrangers, particularly intimates, are private matters.

Since the early 1990s, the rates of reported crime have generally been increasing, most markedly with regard to the reporting of sexual assault. This increase in the reporting of sexual assault is the result, in part, of statutory changes that make it easier for victims to report (e.g., victim shield laws that protect victims' identity in the media) and for district attorneys to prosecute these cases (e.g., the elimination of the need for corroborating evidence beyond the victim's statement).

More generally, victims might be more likely to report because of the increasing concern for victims since the establishment of the President's Task Force on Victims of Crime in 1982. This report resulted in statutes or constitutional amendments in all 50 states that give victims the right to testify at criminal sentencing and to be notified about other stages of the criminal justice process (e.g., plea bargaining, parole hearings). Other victim-related legislation includes making restitution mandatory, making offenders pay fines that go to a fund that provides compensation to victims, establishing victim-witness-services offices (generally within the district attorney's office) that give aid to victims, and providing funding for agencies that specifically support victims of sexual assault and domestic violence.

Reasons for Reporting or Not Reporting

According to the National Crime Victimization Survey, a continuing survey of about 75,000 nationally representative individuals who are interviewed biannually, the most common reasons for reporting crimes are to stop or prevent the specific reported crime, to recover property, to prevent further crimes by the offender against the victim, to prevent crime by the offender against anyone, and because the event was a crime. The most common reasons for not reporting a crime are because it was reported to someone else, because it was a private or personal matter, and because the offender was unsuccessful. These reasons suggest that victims use a cost-benefit analysis to determine whether to report the crime.

Process of Reporting

If a crime is to be reported to the police, then, based on a model by Martin Greenberg and Barry Ruback, the victim must label the event a crime, determine that it is serious enough to report, and then decide that reporting the crime to the police is the appropriate action to take. In terms of the first stage—labeling the event a crime—in most cases, the process is relatively straightforward. That is, the person determines whether the event matches his or her definition of what constitutes a crime (although the victim's definition may or may not be the same as the legal definition of the crime). In some cases, the labeling process is more complex. For example, with property crime, individuals might decide that they had lost or misplaced an item rather than that the item had been stolen. For violent crimes, the issue is generally not whether the act occurred but whether the violent act is considered to be a crime. For example, a wife who suffers a physical beating from her husband may not define the event as a crime if she is part of a culture that thinks it is appropriate for men to beat their wives.

After the victim determines that an event is a crime, he or she must determine the seriousness of the crime. This determination of seriousness, which is important because it is related to the amount of distress and arousal the victim experiences, is based on how unfairly treated and on how vulnerable to future crime the victim feels. These two judgments are related to the magnitude of the physical, material, and psychological harms the victim experienced, the magnitude of the harms that the victim could have experienced, and the

degree to which the crime was unexpected. Greater harm, greater potential harm, and greater unexpectedness lead to higher ratings of seriousness and to more arousal and distress.

After determining the seriousness of the crime, the victim must then decide what to do. Victims have four options. First, they can seek a private solution, such as seeking compensation from or retaliating against the offender if he or she is known or, in some cases, from third parties who may have been negligent in failing to take actions that would have prevented the crime from occurring. Second, victims can cognitively reevaluate the situation, by either reconsidering whether the event really was a crime or by reevaluating its seriousness. The most common form of cognitive reevaluation is for victims to blame themselves for the crime, at least in part. Third, victims may report the crime to the police based on their judgment after their weighing of the costs and benefits that reporting is likely to reduce their distress from being unfairly treated and being vulnerable to future victimizations. Finally, some victims might choose to do nothing, in the belief that nothing can reduce the injustice and make them feel safe.

Importance of Social Influence

Studies in the 1970s designed to determine why there was such a long delay before the police arrived at a crime scene came to the conclusion that the delay was due not to the police taking a long time but to victims talking to relatives, friends, and strangers before calling the police. These discussions with others make sense in that, for most people, being the victim of a crime is an unusual event and victims are likely to turn to others for help in understanding and coping with the crime.

According to social comparison theory, individuals are likely to rely on others for information and advice concerning perceptions and judgments that have no objective standard. That reliance on others is particularly likely when the individuals are aroused (as in an emergency situation) and are unsure of what to do. Consistent with this theory, crime victims often talk with others, generally friends and relatives, before deciding whether or not to call the police. And interview studies with rape, burglary, robbery, and theft victims indicate that these others are likely to give victims advice.

These other individuals can influence victims' judgments about whether an event is a crime, how serious the crime is, and whether the crime should be reported. Their influence comes from providing victims with information about the crime and the criminal justice system, from applying normative pressure concerning what they (and the group that they belong to) believe to be appropriate, and from providing support (or sometimes nonsupport) in the form of sympathy, emotional support, and tangible help. Furthermore, experimental research by Martin Greenberg and Barry Ruback indicates that victims are likely to follow that advice, even if it comes from a stranger. Their experimental research found that victims would be especially likely to call the police if the bystander gave specific advice to call the police (rather than diffuse advice to do something), was physically present when the call to the police was made, and offered to be of help in the future.

Investigations of norms among several ethnic groups in the United States suggests that victims are more likely to be advised to call the police if they are female, if they are older, and if they have not been drinking. Females are more likely than males to advise calling the police. In addition, research across countries suggests that the closer the relationship between the offender and the victim, the less likely people are to advise reporting.

Bystander Reporting

In most cases, it is the victim who reports the crime to the police. However, bystanders sometimes report, and work by Bibb Latane and John Darley indicated that the more the number of bystanders present the less likely any one of them is to report the crime. According to their research, the presence of others can affect whether an individual bystander notices the incident, interprets it as an emergency, assumes personal responsibility, and then reports the event to the police. The presence of others can lead to *pluralistic ignorance,* if for example, everyone believes that someone else has already reported the crime, and to *diffusion of responsibility,* if people realize that they have some blame for not reporting but that this blame is shared by everyone else who also did not report. Bystanders are often reluctant to report because of a fear of looking foolish. Also, bystanders may be reluctant to report crimes involving domestic situations because of their belief that personal relationships should be kept private.

For most crimes, bystanders who do not report are not subject to legal sanction. The one exception is for crimes of child abuse. All states mandate that when, in the course of their employment or professional practice,

certain individuals (e.g., physicians, nurses, school teachers, mental health professionals) come across what they believe to be child abuse, they must report the abuse to the proper authorities. Despite the fact that failing to report can lead to criminal penalties, many individuals who are required to report, including therapists, do not do so. Their decision not to report is often based on the fact that most cases do not involve serious abuse, and such cases, if reported, are unlikely to result in prosecution. Thus, reporting the abuse is likely to lead to a lengthy and expensive legal process that will probably result in some action to encourage the family to seek treatment. If the family were already in therapy, mental health professionals may judge that reporting produces no positive outcomes. Moreover, because reporting violates confidentiality, undermines the therapeutic relationship, and is intrusive and likely damaging to the family, mental health professionals are likely to believe that reporting is, on balance, not worthwhile. Thus, many clinicians have, at some time, chosen not to report suspected child abuse.

Repressed and Recovered Memories

While one cannot deny that repressed and recovered memories have had an effect on individuals, their families, and our legal system, little credible evidence exists for massive repression. Moreover, most claims of repression and recovered memories have alternative explanations such as ordinary forgetting or exposure to suggestive situations. This entry examines issues relating to claims of repressed and recovered memories, the role of these claims in the legal system, research that bears on these claims, and alternative explanations for what might appear to be repressed and recovered memories.

At the end of the 19th century, Sigmund Freud popularized the term *repression* to describe a mechanism by which horrifically traumatic events are pushed into some inaccessible corner of the unconscious. Later, they may return to consciousness. The process is thought to involve something other than ordinary forgetting and remembering, and is sometimes called massive repression or robust repression. Since Freud's day, the term "repression" has had a nebulous meaning for many in the field of psychology, often being used interchangeably with dissociation and traumatic amnesia and subject to great controversy. Some have suggested that repression has never been proven to exist. Because of the controversy, some writers now refer to an umbrella term *recovered memories*—memory experiences that someone is conscious of after not thinking about them for a long time. This experience happens commonly and need not be controversial unless one assumes it involves more than ordinary forgetting and remembering.

The topic of repressed and recovered memories has been a hotly debated issue within the mental health profession for almost two decades. Although there is no credible scientific support for massive repression, many individuals who claim to have recovered repressed memories of childhood abuse have subsequently pressed those claims in civil and criminal courtrooms. Most of the repressed and recovered memory reports involve claims of childhood sexual abuse (CSA). Some have involved claims of recovered memories of murders and satanic ritual abuse. Many claims of recovered CSA memories have been made by individuals accusing family members, former neighbors, or other family friends. Often, but not always, these memories are recovered in individual or group psychotherapy.

Surge in Recovered Memories and Their Effects

Media Contribution

During the late 1980s and early 1990s numerous individuals claimed to have recovered memories of CSA. During this period, accusations of CSA and satanic ritual abuse escalated and peaked in the 2-year

period of 1991 to 1992; since that peak, the number of accusations has steadily declined. Many recovered memory cases appeared in the media, which may have contributed to the surge in repressed memories that were recovered in therapists' offices throughout North America. As a result of media coverage of an unusual murder case, repressed memories were brought into the public eye.

In a landmark case that went to trial in 1990, George Franklin was accused of a murder that occurred more than 20 years earlier. The victim, 8-year-old Susan Nason, was a friend of Franklin's daughter, Eileen. Eileen was 8 at the time of the murder; however, it was she who provided the only evidence against her father. Eileen claimed that she had repressed the memory of witnessing her father murder Susan, a repression that lasted for 20 years. When her "memory" returned in the late 1980s, she brought these allegations to the police. George Franklin was found guilty of murder based solely on Eileen's testimony of her recovered memory. It was the first time that a U.S. citizen had been tried and convicted of a murder on the basis of a recovered memory.

Around this time, *The Courage to Heal,* a self-help book by Ellen Bass and Laura Davis, was written to assist victims of CSA. Even in the absence of memory, the purported victim was encouraged to recover memories of abuse and to confront alleged molesters. Critics of *The Courage to Heal* contended that it caused widespread harm to many innocent people—both the alleged perpetrators and the accusers whose lives may have been negatively affected by false revelations. Bass and Davis have no formal training in psychiatry or psychology, and some critics have argued that their book encourages the recovery of memories that may not be true. Given that their book has sold more than 800,000 copies, *The Courage to Heal,* some felt, contributed greatly to the surge in the number of recovered memory cases by encouraging people to embrace their recovered memories.

Statute of Limitations

Concurrently, the legal implications of recovered CSA memories were propelled into the limelight particularly in the United States. In 1989, Washington State became the first state to toll the statute of limitations for repressed memory cases. People with newly recovered memories of abuse had 3 years from the time of remembering to sue their parents, other relatives, or any alleged molesters. Many states followed, and thousands of lawsuits were filed.

Most provisions applicable to victims of CSA fall into the categories of *minority tolling* and *delayed discovery doctrine.* A tolling doctrine is a rule that postpones the date from which a statutory period begins. In the case of minority tolling, it is a statute that might run 3 years from when the child turns 18, the legal age of majority. This is in recognition of the problem that some children may not feel secure enough to confront abusers while still in childhood.

The delayed discovery doctrine has historically been used in different types of cases, for example, in cases of medical malpractice. To give a medical example, the statute of discovery would be extended for a patient who undergoes surgery and only much later realizes that subsequent abdominal pain is due to the doctor failing to remove a sponge during surgery. Such a patient's statute of limitations to sue for medical malpractice begins to accrue at the time the sponge is determined to be the cause of the abdominal pain. Those in support of applying the delayed discovery doctrine in recovered memory cases purport that such a medical malpractice claim is analogous to an individual who alleges recovery of CSA memories, in that the source of their pain would be realized when the memories are recovered. Such an individual would have some number of years (say, 3) from the date on which they assert that the memory was recovered in which to pursue legal action.

As a result of the tolling of the statute of limitations in repressed memory cases, a large number of victims began to sue their alleged abusers for compensation. But these were not the only ways in which repressed memories entered the courtroom. In an ironic twist, a few of those accused of CSA began to sue their accusers' therapists for planting false memories of childhood abuse. A somewhat larger group who also sued call themselves "Retractors."

False Memory Syndrome and Retractors

There have been a number of adverse effects of recovered memory therapy, especially when there has been no history of sexual abuse. Devastating effects can occur, for example, when a daughter accuses her father of child abuse. Many such accusations have resulted in litigation that often forces other family members to choose sides, causing great strain and often separation within the family.

Another adverse effect is the development of new symptoms unrelated to the primary concern for which the patient went to the therapist in the first place. These symptoms include false beliefs and memories of having been abused—a syndrome now referred to as *false memory syndrome.* These symptoms may take the form of flashbacks, which include detailed memories and even hallucinations and delusions of the abuse. Thus, the patient believes that she has specific recollections of abuse that may not have occurred.

The False Memory Syndrome Foundation was formed in 1992 by a group of families and professionals who saw the need for an organization to determine and prevent the spread of false memory syndrome and support and attempt to reconcile families who were torn apart by claims of repressed CSA. In recent years, there have been a number of CSA accusers who have reestablished family relationships and acknowledged that their accusations were false. These "retractors" typically blame their therapists for suggesting to them that they were victims of CSA and for encouraging memory recovery that led to the false memories of abuse.

In 1997, a remarkable legal case was settled in which a retractor sued her therapist. Ms. Burgus, a patient of Dr. Braun's, originally sought treatment for postpartum depression but was diagnosed as having multiple personalities. Dr. Braun believed that her symptoms resulted from sexual and ritual abuse including cannibalism and torture; in other words, the purported sexual and ritual abuse was what led her to be diagnosed with having multiple personalities. Although Ms. Burgus had no recollection of the sexual and ritual abuse, Dr. Braun encouraged her to try and remember these instances of abuse through hypnosis. Ms. Burgus eventually realized that these allegations were not true and subsequently retracted her previous abuse accusation. She sued her former therapists, including Dr. Braun and the hospital, for negligence, breach of the standard of care for uncritical acceptance of a clinical diagnosis, and the use of hypnotic techniques without first advising her of the risks involved. The lawsuit was settled for $10.6 million.

Research in the Field of Repressed and Recovered Memories

Research on repressed and recovered memories has primarily involved women victims of CSA. There are three primary resources of information in the extant field: retrospective studies, prospective studies, and case histories. Retrospective studies rely on individuals whose initial disclosure of abuse happens years after the supposed abuse took place. Prospective studies use cases documented by social workers or the police to establish abuse, while case histories consist of data collected from an individual.

In one of the first retrospective studies, more than half of the participants (mostly women who were referred to the study by their therapists) stated that they did not remember their first incident of sexual abuse at some point in the past. Compared with those who remembered the abuse continuously, individuals who reported a lapse in memory also reported that they were abused at a very young age. Regrettably, it is difficult to construe this research as evidence of massive repression in CSA victims, because the main question posed to participants was complex and the answers uninterpretable. In another retrospective study, researchers tried to probe what people meant when they claimed to have forgotten abuse at some point in the past. In a large sample of people who were questioned about their sexual, physical, or emotional abuse, more than a quarter reported some form of abuse. Of the participants who claimed to have forgotten their memories of abuse, just less than half also claimed that they had avoided thinking about the instances of abuse. The researcher noted that lack of continuous memory for an event does not necessarily constitute repression and suggested that therapists should proceed with caution when dealing with patients who claim to have recovered memories of abuse.

Retrospective studies rely on an individual's self-report of sexual abuse at a much later date. Such studies are not ideally designed because the initial disclosure and subsequent recovered memories of abuse cannot be verified and, therefore, may be inaccurate or altogether false. Prospective studies, on the other hand, rely on documentation of CSA at the time of the incident (e.g., by police report). Individuals are later contacted to see what they can remember.

In one often-cited prospective study conducted by the sociologist Linda Meyer Williams, 38% of participants failed to report documented abuse when interviewed 17 years after the reported abuse occurred. Williams found that the younger a participant was at the time of the documentation, the less likely she was to report the specific incident. Some of these cases may be accounted for by a phenomenon known as childhood amnesia, which is discussed in the following section. Critics of the study also point out that just because a woman didn't report the abuse did not mean she did not

remember it; perhaps she simply did not want to tell the interviewers about it. Also complicating the picture, a more recent prospective study showed that only 8% of people with documented abuse failed to report it to interviewers much later.

Case Histories

Perhaps the least reliable research from which to draw generalizable results is the single case history. An example of a case history in the field of repressed and recovered memories is the case of Jane Doe. When Jane Doe was 6 years old, she was the subject of an intense custody battle and, therefore, underwent psychological evaluation to determine who should retain custody of her. A psychiatrist videotaped a particularly emotional session in which Jane accused her mother of sexually abusing her. After the psychiatrist concluded that Jane was abused by her mother, the mother was forced to relinquish custody of Jane and all visitations.

Years later, the psychiatrist-evaluator captured on video Jane first not remembering and then remembering abuse by her mother. This case was put forth as proof of repression; however, it is questionable as to whether it was truly evidence of repression. Subsequent investigation of Jane's case history revealed new important information that had been left out of the original account. The later investigation revealed that Jane had discussed the alleged abuse many times between the time of the first videotaped session and when she claimed to have recovered the memories of abuse, casting doubt on the case history's support for the concept of total repression. Additionally, documentation and interviews raised significant doubt that the sexual abuse of Jane by her mother had ever occurred in the first place. Thus, it is necessary to be skeptical of case histories when attempting to use their findings to make generalizations about repressed memories.

Alternative Explanations for Repression

Many scholars believe that virtually no good evidence for repression exists. There are several other possibilities where these richly detailed memory reports may have come from. The reports could reflect true memories that have simply been forgotten by normal memory processes and are triggered by a retrieval cue. They could, of course, reflect out-and-out lies. Another explanation is that these memories are the result of therapists' suggestions and other activities that planted false beliefs.

True Memories

In any given case in which a person reports recovering a memory, the statement could be an accurate reflection of the individual's experience; however, it may be an instance of ordinary forgetting. For example, an adult who was abused as a child may not think about the abuse for a given period of time. In this case, ordinary forgetting would occur, and the person may forget the abuse altogether until a trigger reminds him or her of the abuse. This is not a case of repression; rather, it is a case of ordinary forgetting.

False Memories

In most cases, it is not possible to tell a true memory from a false one without independent corroboration. There are a few situations, however, where we can say with some confidence that the memory report is probably false. Some individuals have claimed to remember abuse that allegedly occurred to them before the age of 2 years—even as early as 6 months in some case reports. But as adults, we do not have concrete and reliable episodic memories for events that occurred in the first couple of years of our lives—a phenomenon known as childhood amnesia. Some adults' earliest childhood memories are even later. Thus, these very early "memories" are almost certainly false.

One must still consider the instances where individuals claim to recover memories for events that occurred after the offset of childhood amnesia. Research on human suggestibility and the malleability of memory has revealed that individuals are susceptible to forming false memories and believing them to be true. In research where rich false memories have been planted, a significant minority of subjects have been led through a suggestion to believe they had experiences like being lost in a shopping mall or being attacked by a vicious animal. These studies have shown that people are highly susceptible to embracing false memories as their own. Once planted, the individual can report the false event with a great deal of detail, confidence, and even emotion.

Response Latency in Eyewitness Identification

An important issue for the police and courts is the extent to which an eyewitness's decision about a lineup can be trusted as accurate. Consequently, psychologists have searched for variables associated with the witness's decision that help distinguish correct from incorrect decisions. One such variable is response latency (or response speed). Response latency is measured as the time elapsed from the witness's first view of a lineup or photo array to their indication of a decision. A consistent relationship has been identified between the response latency and accuracy of positive identifications, but not of lineup rejections. Thus, fast identifications are more likely than slow identifications to be correct, while rapid and ponderous lineup rejections are equally likely to be accurate.

The rationale behind the investigation of response latency as a marker of accuracy is that witnesses who have a good memory of the offender should be able to determine whether any of the lineup members match their memory more rapidly than witnesses with a poor memory. Furthermore, response latency is compelling as a potential marker of accuracy for two reasons. First, unlike other potential markers of identification accuracy (e.g., confidence or self-reported decision strategy), response latency is a direct product of the identification task. Consequently, it is objectively measurable and not subject to the same influences as self-report measures. Second, response latency is correlated with other markers of accuracy (e.g., faster responses tend to be made with more confidence) without being identical to them. Thus, the combination of response latency and confidence may discriminate correct from incorrect decisions more effectively than either marker alone.

Although it has not been the focus of an overwhelming amount of research attention, investigations of response latency in eyewitness identification and face recognition have produced very consistent results. Specifically, a relationship is consistently observed between the response latency of positive identifications and the accuracy of those identifications, with the likely accuracy of an identification declining as the response latency increases. In contrast, studies equally consistently find no evidence for a relationship between the response latency of lineup rejections (i.e., responses that the offender is not present in the lineup) and the accuracy of those rejections. Interestingly, this pattern of a significant relationship with accuracy for choosers (i.e., positive identifications), but not nonchoosers (i.e., lineup rejections), parallels the findings regarding the confidence-accuracy relationship in face recognition and eyewitness identification.

Despite the consistency of the relationship between the speed and accuracy of positive identifications, this knowledge does not necessarily translate into a practically useful discrimination tool. For example, is a witness who takes 30 seconds to identify the suspect from a six-person photo array fast, and therefore likely to be correct, or slow, and likely to be incorrect? Researchers have attempted to address this challenge in two major ways. One involved the direct manipulation of response latency. However, attempts to produce high

accuracy rates by forcing participants to make a fast identification were unsuccessful. Thus, it appears that the relatively short latency of accurate witnesses is the result, not the cause, of the decisions processes that produce accurate decisions. The other involved the suggested use of a specific time (i.e., 10–12 seconds) as the cutoff for distinguishing fast (i.e., reported in less than 10–12 seconds), and consequently accurate identifications, from slow (i.e., reported after more than 10–12 seconds) identifications, which were less likely to be correct. Despite the apparent early success of this rigid rule, subsequent studies demonstrated that the boundary between fast and slow decisions is not constant but varies from situation to situation as a result of changes in variables such as the target and lineup, the nominal size of (i.e., the number of members in) the photo array, and the retention interval between viewing the offender and attempting to make an identification from the lineup. The demonstrated instability of the border that separates fast from other identifications rules out the practical use of a universal response latency boundary to discriminate identifications with a high probability of being correct. However, subsequent analyses using this type of static response latency boundary (i.e., 10 seconds) in combination with a confidence criterion (e.g., identifications made with 90% or 100% confidence) have shown some promise. Although few decisions met both the response latency and confidence criteria, those decisions observed a very high accuracy rate across a number of stimuli and viewing conditions. Consequently, the most encouraging use for response latency appears to be in combination with other markers of identification accuracy—most notably confidence.

Response latency is often inappropriately referred to as decision latency (or decision speed). Although this may seem a pedantic, semantic distinction it underscores an important point about the measurement and use of response latency in the eyewitness identification domain. Specifically, an eyewitness, particularly a conscientious eyewitness, may not make a response immediately on arriving at a decision. For example, the attention of one witness with an excellent memory for the offender may be drawn to a specific lineup member as soon as he or she sets eyes on a photo array, and the witness could feel certain that the perpetrator has been found. However, to ensure that they have not made a mistake, these conscientious witnesses may continue to carefully examine each of the other lineup members before identifying the lineup member to whom their attention was initially drawn as the offender. In contrast, the attention of another witness with a relatively impoverished memory may not be drawn to any specific member of the lineup. Consequently, that witness may conduct a careful and deliberate examination of the lineup before making and indicating their identification decision. In other words, the observed response latency may be affected by factors other than the amount of time it took the witness to arrive at a decision (e.g., their conscientiousness or their confidence in their ability to make the correct decision).

At present, despite the consistent relationship between latency and identification accuracy, these findings do not lead to any practically useful methods for reliably discriminating correct from incorrect decisions, but the combined use of response latency with confidence judgments appears to be a potentially fruitful area of investigation.

Retention Interval and Eyewitness Memory

Retention interval refers to the amount of time that elapses between the end of a witness's encounter with a perpetrator and any subsequent testing of the witness's memory for that encounter. Testing of a witness's memory for a perpetrator's identity is obviously important whenever the prosecution seeks to prove that the

perpetrator and the defendant are indeed the same person. When eyewitness testimony is provided, the trier of fact must decide whether the testimony is accurate. Unless the trier of fact believes that human memory operates with the fidelity of a video camera, he or she will need to estimate the strength of the witness's memory at the time of his or her memory being tested. To increase the precision of the estimate, the trier of fact needs three pieces of information: An estimate of the original strength of the witness's memory representation of the perpetrator's face, the length of the retention interval, and the nature of the *forgetting function.* The forgetting function is the curve that describes the strength of the memory trace over the course of the retention interval.

Inasmuch as the trier of fact ordinarily has access to a relatively precise measure of the length of the retention interval, with both the time of the incident in question and the time of the memory test being well established, the problematic pieces of information are an estimate of the original strength of the witness's representation of the perpetrator and knowledge of the course of the forgetting function during the retention interval. Let us first consider what is known about the nature of the forgetting function. Researchers interested in how memory for the human face is affected by the retention interval have conducted several dozen published studies wherein they have assessed memory accuracy after two or more different retention intervals. Assessments of the average effect size for the retention interval (measured in standard score units) taken across all these published studies have revealed that, statistically speaking, one can safely conclude that memory traces of human faces encountered but once previously will be weaker at longer retention intervals than at briefer ones. However, simply knowing that memory for unfamiliar faces is less accurate at longer retention intervals does not specify the time course of the forgetting function. The trier of fact would like to know just how rapidly memory strength declines for an unfamiliar face.

Published surveys of the opinions of psychologists who qualify as experts in the science underlying the psychology of testimony have shown that more than 80% of them believe that the nature of the forgetting function for the human face follows the same form as that of the forgetting function first described by the early experimental psychologist, Hermann Ebbinghaus, and reproduced in introductory psychology texts. That is, the experts believe that the forgetting curve declines rapidly right after viewing of a perpetrator's face and then levels off over time. It turns out that when theoretical forgetting functions are fit to retention interval data from studies wherein three or more retention intervals were tested, theoretical functions that fit the data very well describe a forgetting function that is mathematically quite similar to that of Ebbinghaus.

Given that there are theoretical forgetting functions that make relatively accurate predictions regarding the memory accuracy of the typical witness in a laboratory or field experiment, memory accuracy at any particular retention interval, it should not be surprising that one can "work backward" from the earliest tested retention interval to make a prediction as to what the original strength of the witness's memory representation was. When this estimate is translated into a proportion correct measure of accuracy, one then has a reasonable estimate as to the maximum level of accuracy expected for the typical witness under the conditions prevailing in the experiment—or in more realistic situations, to the extent that conditions are the same as in the experiment in question. The expectation is that memory accuracy will only decline from this level at forensically typical retention intervals. Interestingly, the retention interval most frequently encountered by the British police has been reported as 1 month. One theoretical forgetting function that fits empirical data well makes the prediction that the strength of the memory trace for an unfamiliar face at a 1-month retention interval, depending on a number of factors, would likely be in the range of 40% to 60% of its original memory strength.

Researchers have identified a number of factors that affect initial memory strength and, therefore, the amount of strength remaining after any retention interval. Longer exposures to an unfamiliar face, better lighting, and greater facial distinctiveness (as compared with the typical face) have all been shown to increase initial memory strength. Estimates of witness memory accuracy when tested with a lineup or photo spread have also been shown to be a function of how distinctive (or similar) the unfamiliar target face is relative to the other faces presented. A high degree of similarity will produce a lower estimate. Events occurring during the retention interval can also seriously affect witness memory accuracy. For instance, exposure to mug shots before the ultimate memory test, followed by a memory test that includes one of the faces from the mug shots, increases the probability of erroneously selecting the face seen in the mug shots rather than at the crime scene.

Return-to-Work Evaluations

A worker may be required to leave the workplace because of the experience of an extreme stressor on the job, disability, discipline, or concern about threat. That same worker may wish to return to the job, raising questions about whether the worker may effectively resume functioning. This entry deals with several kinds of evaluations conducted by forensic psychologists to determine if a worker is fit to return to the job. The first, the fitness-for-duty evaluation (FFDE), is a specialized evaluation that occurs in safety-related or "high-risk" jobs such as fire fighting, police work, or security. The second, the return-to-work evaluation (RTE), occurs in more general situations in which the worker has been removed from the job because of disability.

Fitness for Duty in High-Risk Occupations

High-risk occupations, such as police or security work, have much less tolerance for emotional or behavioral dysfunction than other positions. In situations in which the worker's very life, the lives of others, or the security of the nation depend on the worker being fully functional, the anxiety disorder or impulse control problem that would cause some problems in an office job or trade, effectively disables the worker. This heightened standard requires that the employer take greater care when making decisions about returning the worker to the job.

In high-risk occupations, two kinds of concerns would prompt an FFDE. The first is when there is a reason to believe that the worker may pose a significant danger to himself or others. Concerns about the worker's ability to function safely may arise from a number of sources, which must usually be directly observed or derive from credible third-party information. For example, a police officer may have demonstrated poor judgment or impulse control on the job and used excessive force in detaining or arresting a suspect. Or a security guard may have failed to intervene when an unidentified individual entered the secure area of an airport. These behaviors may result in disciplinary action such as suspension or consideration of permanently removing the officer from duty.

The second concern focuses on whether the worker may have symptoms of a mental or substance abuse disorder that would significantly interfere with the worker's ability to perform essential job functions. Of course, this focus is not mutually exclusive from the first, in that a mental illness or substance abuse problem may very well underlie a safety-related issue. For example, a police officer who is dependent on alcohol may arrive on the job in a hung-over condition, which would result in impaired alertness and reduced effectiveness in a dangerous situation.

IACP Guidelines

The International Association of Chiefs of Police (IACP) Police Psychological Services Section ratified the *Psychological Fitness-for-Duty Evaluation Guidelines* in 2004. These constitute widely accepted considerations and procedures for these evaluations. These guidelines lay out the qualifications for examiners and remind the examiner that the client in an FFDE is the employer, not the employee. In addition, the guidelines indicate that the evaluator should be properly qualified and should obtain sufficient background information concerning the employee's relevant work history and the issues that raised the question of fitness for duty. The examiner must obtain proper informed consent and written authorization to release the findings from the evaluation to the referring agency. The guidelines also include recommendations for the elements of the evaluation and the structure and content of the evaluation report. For professionals conducting FFDEs with police officers, the IACP guidelines are usually the best guidance, and adherence to them may be required by the referring agency.

FFDE Procedures

Prior to the evaluation, the psychologist should request information concerning the evaluee from the referral source. Particularly, the referral should include the officer's work history, including details concerning prior incidents of concern. These may not be exactly like those prompting the evaluation and should be put into context by balance of the officer's personnel file, which may reveal positive aspects of the worker's past performance. If the officer has been in treatment, these records are invaluable and may be a basis for the psychologist's later discussions with the therapist. Medical records are essential as they may reveal treatment by the officer's primary care physician. The incident reports surrounding the incident or incidents of concern are critical reading. If it is an officer-involved shooting, the evaluating psychologist should attend to details concerning the observations of other officers or of the department's internal investigation.

The psychologist should also have a clear idea of the duties of the officer and the skills necessary to perform those duties. Consultation with the agency's human relations department or commanding officer should help in putting together this listing. If possible, the duties should be prioritized so that the psychologist would have an idea of which of the skills to be assessed are most critical to the performance of the officer's job.

Although informed consent is necessary for any forensic evaluation, in the case of an FFDE, thorough informed consent is essential. In this case, the officer must understand that the agency is the psychologist's client. Although it is commonly the case that forensic psychologists evaluate individuals who are not their clients, in this case, the interests of the officer and the interests of the agency may diverge sharply. The evaluation may have one of four outcomes for the officer: fit for duty; fit for duty with mandatory treatment; temporarily unfit for duty with mandatory treatment; or permanently unfit for duty. The officer should be presented with these four options at the onset of the evaluation so that he or she fully understands the gravity of the assessment.

The officer should be informed of the parameters of confidentiality. In most cases, the evaluation report is closely held within the referring agency. However, depending on the agency's policies, it is often the case that the officer himself or herself may never see the evaluation report. The informed consent procedure should include the officer signing a release to allow the evaluator to release the results of the evaluation to the referring agency. In some cases in which the officer's union is involved, it may be appropriate to forward the written consent and releases of information to the officer prior to the date of the evaluation so that the officer may confer with the union representative or counsel before signing them.

Psychological testing is required for these evaluations. The use of the Minnesota Multiphasic Personality–2 (MMPI–2) test with workers in high-risk occupations is well documented in the literature and provides a basis for comparing the examinee with other individuals. Some testing services offer specific scoring and reports for this population. The Personality Assessment Inventory (PAI) test also has personnel-oriented report formats. If the issue raised in the referral has to do with failures of attention and concentration, a full cognitive battery, including the Weschsler Adult Intelligence Scale–III test, may be appropriate. Specialized testing that has been standardized on populations of police officers, such as the Hilson or Inwald Scales, may also be appropriate.

A face-to-face interview is essential. This interview should cover the officer's family history, school history, and work history. A legal history, including driving violations and domestic violence, should be obtained. A medical history, including any hospitalizations or broken bones is part of this interview. Mental health issues, such as prior counseling or psychiatric hospitalizations, should be covered. Another critical issue is substance abuse history, focusing most often on alcohol (as officers are prohibited from using illegal drugs). Prescription drug use may be an issue, especially if the FFDE is prompted by a physical injury, perhaps from an on-duty auto accident or shooting.

Collateral interviews are critical for most forensic evaluations, but in FFDEs, they are essential. The officer's current immediate supervisor should be among those interviewed. Past supervisors are also important to determine if the behavioral problems prompting the evaluation antedated the incident that necessitated the FFDE. Discussions with the officer's spouse or a critical other are also important as this person may provide additional information about the problems that led up to the incident. The officer's past or current therapists are also important collateral sources and may provide information concerning the officer's participation in therapy and the degree to which therapeutic efforts proved fruitful.

The evaluation report should include a listing of the data relied on for the evaluation. The officer's history should include information critical to the agency's understanding of the officer's path to the current state of affairs, including no more of the officer's personal history than necessary to achieve this goal. The report should include a clear statement of the officer's current status, complete with ongoing symptoms and problems. The officer's status should be discussed in light of the critical aspects of the officer's current position. For example, if the officer has become paranoid, it may no longer be appropriate for him or her to evaluate the performance of subordinates. If the officer has developed a generalized anxiety disorder, it may be inappropriate for the officer to serve "on the street," where critical minute-to-minute decisions must be made.

A clear statement of the officer's fitness for duty status in light of the four alternatives listed above is essential. This should be followed with recommendations for the next step in the process. If the recommendations include modified duty, the nature and extent of the job modifications should be outlined. If the recommendations include counseling, the kind and duration of that treatment should be specified. If the recommendation is that the officer is unfit for duty, the report should include a discussion of how the departure from duty should be accomplished. In particular circumstances in which the officer is a danger to himself or others, the report should include procedures to minimize the probability of harm to either the officer or others. This may include a recommendation for an extended period of medical leave while the officer receives both treatment and a paycheck. Such periods allow for the "cooling down" of the officer's condition to reduce the probability of a dangerous outcome.

As has been noted in one of the recommended readings, particular attention should be paid to situations of officer-involved shootings. Both shooting another person or witnessing the shooting of a fellow officer are rated as being among the most traumatic experiences that an officer may have while on duty. As in other cases of trauma, the range of responses of affected individuals varies widely. A good understanding of posttraumatic stress disorder and its particular manifestations among workers in high-risk occupations is necessary so as not to unduly burden an officer who is doing well with months of treatment or of allowing an officer who is brittle but "looking good" to return to work prematurely.

Return-to-Work Evaluations

Although most FFDEs are RTEs, not all RTEs involve workers in high-risk occupations. In almost any work setting, a worker may develop a mental illness or substance abuse problem that results in temporary disability. In many cases, it makes sense for the employer to get the employee back to work as soon as possible. If the position requires extensive training or if the employee is a long-time incumbent in the position, the employer has a significant financial investment in the employee. Likewise, the employee has an investment in the job and the relationships and income that come from it.

RTEs are carried out very much in the same way as FFDEs. The psychologist must have an understanding of the worker's duties and work setting. A clear history of the events that led up to the worker leaving the workplace must be developed, both from the employer's perspective and from the history of the worker. Informed consent is also essential in this setting, including the worker knowing whether a copy of the report will be made available. Testing may be used as appropriate, although for most other occupations specialized test reports are usually not available. The report should include the same elements, with a well-developed recommendation section.

RTEs may often be conducted with individuals with chronic illnesses, such as a major depressive disorder or a substance dependence disorder, which would eliminate a security or police officer from consideration for employment. Because of considerations of the Americans with Disabilities Act, employers may be required to provide reasonable accommodation for these chronic conditions. An RTE may be part of this process and may include recommendations for specific accommodations for the worker to be able to function in the workplace.

Conclusion

Both FFDEs and RTEs assess the worker's fit with the job duties and job setting. In the case of workers in high-risk occupations, the FFDE often occurs at a critical juncture in the officer's career. For the RTE, this may also be the case, but it may also occur in situations with more chronic illnesses or recurring problems than would be tolerated in high-risk jobs.

The psychologist should be aware that the ramifications of an FFDE are serious. An officer who has demonstrated a history of problems on the job is going to be returned to duty, a situation that may place not

only the officer but his or her fellow officers and members of the public in danger. This makes essential the performance of these evaluations within the highest professional standards.

Risk Assessment Approaches

Violence risk assessment is relevant to the field of law and psychology because it occurs at numerous junctures in the legal system, and it is one of the key areas of research and clinical practice in forensic psychology. This entry reviews two primary approaches to risk assessment: unstructured and structured. The former approach, sometimes also called clinical prediction or judgment, imposes no rules on the decision-making process, whereas the latter approach does. Two primary approaches to structured risk assessment include (1) actuarial and (2) structured professional judgment (SPJ). Although both structured approaches impose rules in terms of which risk factors are considered and defined, actuarial risk assessment uses an algorithm to combine risk factors into a final decision, whereas SPJ does not. This entry will describe these approaches, along with their attendant strengths and weaknesses.

The Relevance and Context of Risk Assessment

Risk assessment informs decisions about future violence. In numerous legal and clinical practice areas, such decisions are required by statute, professional ethics, or common law. For instance, in most jurisdictions, a person must pose, inter alia, a risk of harm to others (or to self) to be involuntarily civilly committed. The release of prisoners from institutional to community placement is typically contingent on whether they constitute an undue risk to public safety. Risk assessment is the basis for decision making in these situations. Depending on jurisdiction in the United States, psychologists and other mental health professionals have common law and ethical duties to protect third parties from the violence posed by their patients. Correspondingly, risk assessment is used to determine whether a sexual offender will be subjected to postsentence involuntary commitment under sexual predator laws. Analogous "indeterminate sentencing" provisions exist in non-U.S. jurisdictions as well, for example, Canada and the United Kingdom. As such, risk assessment plays a pivotal role in balancing public safety with constitutionally protected rights and freedoms such as liberty.

Approaches to Risk Assessment

Contemporary approaches to risk assessment have been heavily influenced by Paul Meehl's distinction between actuarial and clinical prediction. The former refers to decision-making procedures that involve the formal combination of variables or pieces of information, by way of equations or other algorithmic processes, to reach a decision. The latter is defined by a lack of such rules. In contemporary risk assessment, approaches may be generally classified as structured and unstructured. As described below, unstructured risk assessment is, in essence, the clinical prediction to which Paul Meehl referred. Structured risk assessment includes actuarial prediction as well as a more recent approach termed *structured professional judgment.*

Unstructured Risk Assessment

Conventionally, *unstructured clinical judgment* is the most common approach to appraising an individual's risk for violence. By definition, it is based primarily on professional opinion, intuition, and clinical experience. Assessors have absolute discretion in terms of selecting risk factors to consider, how to conceptualize them, how to synthesize case material, and how to interpret this information to render decisions. As such, this method is inherently informal and subjective. Although clinical judgment is a routine and necessary component within many clinical decision-making contexts, the defining

feature of clinical judgment *in terms of prediction* is the lack of rules to integrate case information. Although this permits flexibility, ostensible widespread applicability, and relevance to the individual patient, there are numerous problems with this approach.

First, because of the lack of rules, critics contend that the technique generally lacks consistency because independent clinicians may focus on dissimilar sources of information and subsequently form disparate conclusions (low interrater reliability). Second, clinicians may or may not attend to variables that actually relate to violent behavior (low content validity). Third, either failing to attend to important risk factors, attending to irrelevant variables, or giving improper weight to risk factors, will inevitably decrease the accuracy of decisions (low predictive validity). Fourth, detractors argue that unaided clinical decision making precludes transparency of decision making, which is essential in a legal forum (low legal helpfulness). Other factors leading to low (or at least inconsistent) accuracy include susceptibility to decisional biases and heuristics, failure to consider base rate information, failure to integrate situational information, and a lack of specificity about the criterion variable. Research bears these weaknesses out: The accuracy of unstructured risk assessment has been shown (a) to vary considerably across different clinicians and (b) though predictive of violence, to be less strongly related to violence than more systematic approaches.

Structured Risk Assessment

In response to the shortcomings of the unstructured clinical approach and the disquieting implications these held for important legal decisions, researchers started to investigate structured approaches. Contemporary structured risk assessment approaches share common features such as (a) inclusion of a fixed set of risk factors, (b) operational definitions of risk factors, (c) scoring or coding procedures for risk factors, and (d) direction for how to integrate risk factors to reach a final decision about risk. As described below, however, there are important differences between the two primary approaches to structured risk assessment.

Actuarial Prediction

The first structured approach that was investigated was *actuarial prediction.* Technically, a prediction approach is said to be actuarial when it uses formal rules to combine variables or risk factors to make a decision. This process, therefore, involves the formal application of a predetermined set of explicit and formulaic decision rules to make a decision about the likelihood of violence. The actuarial approach has been described as algorithmic, mechanical, well specified, and completely reproducible. An associated, though not defining, feature of actuarial prediction is the use of empirical item selection; that is, the variables that comprise risk factors on an actuarial risk assessment measure are often selected because they demonstrated statistical associations with violence in one (or, more rarely, two or more) specific construction or calibration sample. Another associated feature of actuarial prediction is that the risk factors that are derived empirically are typically weighted according to the strength of association with violence observed in the construction sample(s).

The primary argument in support of actuarial prediction techniques is that they facilitate interrater reliability and predictive validity, especially in comparison with unstructured approaches. Because actuarial procedures use explicit rules for combining risk factors, they yield the same decision regardless of who uses them (high interrater reliability), and given the presence of the same risk factors across cases, they yield the same outcome. Furthermore, they are transparent (reviewable and accountable). Many actuarial prediction techniques are statistically optimized because they weigh variables according to their relationship with violence. Hence, *at least in the samples in which they were developed,* they tend to have high predictive validity in comparison with unstructured approaches.

There is general agreement that the actuarial approach to risk assessment yields higher predictive accuracy than does the unstructured approach when the two are compared for group-based (nomothetic) predictions within the same sample. Perhaps the best evidence of this stems from a meta-analysis of 136 studies conducted by William Grove and colleagues that directly compared actuarial prediction with unstructured clinical prediction. Actuarial prediction was more accurate than clinical prediction in approximately one-third to half of the studies. In approximately half the studies, there was no difference in predictive accuracy. In a small minority of studies, unstructured clinical prediction was more accurate. On average, actuarial prediction was more accurate than clinical prediction by an approximately 10% increase in hit rate.

Despite the important advantages of enhanced interrater reliability and predictive validity that actuarial prediction possesses, commentators have noted several

weaknesses. Perhaps most important, the predictive properties of actuarial models tend to be optimized within the sample of development, with no guarantee that these properties will apply to novel settings or samples (generalizability). For this reason, the precise numerical probability estimates, or bright-line classification cut scores, that tend to be used in actuarial prediction are in crucial need of cross-validation and replication prior to use.

Second, some actuarial techniques may have limited clinical applicability, in that decision makers may be concerned about violence in a context (e.g., imminent violence) that is incongruent with existing actuarial protocols constructed with a specific set of conditions (e.g., a long-term follow-up period). Third, actuarial approaches tend to ignore low base rate factors that failed to enter nomothetically derived statistical equations because of their rarity or their case-specific nature, even if they may be important in individual cases. Under the strictest actuarial approaches, any extraneous information not contained on the instrument cannot be considered. Fourth, some actuarial models have been criticized for not being helpful in terms of risk management, treatment, or risk reduction more broadly because they tend to focus on static risk factors as opposed to dynamic (changeable) risk factors that may be better suited to treatment efforts.

Structured Professional Judgment

To contend with these weaknesses, a more recently developed risk assessment approach, termed structured professional judgment, has been forwarded. Like most actuarial approaches, the SPJ approach specifies a fixed set of operationally defined risk factors with explicit coding procedures. The purpose of this structure is to facilitate both interrater reliability and comprehensive domain coverage, or content validity. It has three primary differences compared with most actuarial approaches. First, SPJ approaches use logical or rational item selection as opposed to empirical item selection procedures to select risk factors. This process involves extensive consultation of the scientific and professional literature to select risk factors with broad support across contexts. In theory, this approach fosters generalizability as well as comprehensiveness of the set of risk factors.

Second, SPJ approaches do not require algorithmic combinations of risk factors to derive risk estimates, and hence they are not actuarial. There are four primary reasons why SPJ approaches do not adopt algorithmic item combinatory procedures. (1) Such procedures are susceptible to degradation of predictive accuracy across contexts, meaning that a cutoff score in one sample cannot be assumed to apply to another context. (2) While combination rules promote consistency, they may do so at the expense of individual relevance; that is, certain risk factors will be more relevant for one person's violent risk than for another's risk, and a risk assessment process should be able to account for this differential individual relevance. (3) Decisions based on fixed algorithmic procedures presume that the future is fixed as well; if circumstances change, the actuarial estimate may be invalid. (4) There may be cases with only a few risk factors present, but their salience compels a conclusion of high risk.

SPJ approaches attempt to optimize the relevance of nomothetically derived risk factors to the individual—which, whether for legal or clinical purposes, is the level of decision making. Final decisions of low, moderate, or high risk are formed by decision makers after consideration of the number and relevance of risk factors present in the case and the intensity and urgency of any necessary intervention or management strategies to mitigate risk. The SPJ model does not provide estimated numerical probability levels of future violence for the individual case, because it is assumed that it is not actually possible to do so given the problems with lack of stability of such procedures, as reviewed above. Furthermore, actuarially derived numerical probability estimates are *group-based estimates* (i.e., 53 of 100 persons in X risk group were violent); their applicability to what *an individual who was not in this group* might do in future is tenuous.

Critics of the SPJ approach have argued that it lowers reliability and validity through the allowance of discretion at the variable integration phase of decision making. Though this is a controversial aspect of SPJ, research to date suggests that the reliability and predictive validity of the SPJ approach are at least comparable with the reliability and predictive validity of the actuarial approach—and in some studies, exceed them.

Researchers continue to study the strengths and limits of both actuarial and SPJ approaches to risk assessment. Both have promise, and both have limitations. The field would benefit from research on how to increase individual relevance, treatment relevance, and cross-validated generalizability of actuarial procedures. In terms of SPJ research, questions in need of research include whether additional structure can be

added to the final decision without introducing the problems associated with actuarial decision making.

Risk-Sophistication-Treatment Inventory (RSTI)

The Risk-Sophistication-Treatment Inventory (RSTI) is a semistructured interview and rating scale that is designed to help clinicians assess Risk for Dangerousness, Sophistication-Maturity, and Treatment Amenability as well as treatment needs. The RSTI demonstrates reliability and validity and can assist mental health professionals with the assessment and development of treatment plans for juveniles in forensic settings.

Description

Each of the three scales (Risk for Dangerousness, Sophistication-Maturity, and Treatment Amenability) of the RSTI contains 15 items that represent both static and dynamic factors. Additionally, each scale of the RSTI consists of three clusters, thus providing psychological information on nine subconcepts. Specifically, the Risk for Dangerousness Scale consists of Violent and Aggressive Tendencies, Planned and Extensive Criminality, and Psychopathic Features clusters. The Maturity Scale is composed of Autonomy, Cognitive Capacities, and Emotional Maturity clusters and allows for the assessment of whether youths are using their maturity prosocially or antisocially. The Treatment Amenability Scale consists of the Psychopathology—Degree and Type, Responsibility and Motivation to Change, and Consideration and Tolerance of Others clusters. These clusters are dynamic, although some types of psychopathology might be more difficult to treat than others.

The RSTI materials include the Professional Manual, the Semi-Structured Interview Booklet, and the Rating Form and are available from Psychological Assessment Resources. The professional manual describes the reliability and validity of the instrument and includes case studies that provide examples of appropriate scoring and interpretation of the results. The interview booklet provides guidance for obtaining background, clinical, and historical information and a sample of the juvenile's behavioral and psychological functioning. Optional probes are provided throughout the interview to garner further information if needed. The rating form enables the clinician to score the items by reviewing and synthesizing information from collateral sources. Each item is rated on a 3-point scale reflecting the extent to which the individual demonstrates the specific characteristic (0 = *absence of the characteristic/ability,* 1 = *subclinical/moderate,* 2 = *presence of the characteristic/ability*).

Development

The RSTI was developed according to conventional scale construction procedures and involved three primary steps. First, item generation entailed an extensive search for items in case law and psychological literature. Descriptions of juveniles and their families were drawn from relevant statutes pertaining to transfer criteria, appellate cases (both successful and unsuccessful), and research (both psychological studies and law reviews) related to the primary constructs and transfer decisions.

The second step involved two separate prototypical analyses. Clinical child and adolescent psychologists were asked to rate the items they considered to

be central to Dangerousness, Sophistication-Maturity, and Treatment Amenability. Forensic diplomates were asked to provide ratings of juveniles they had evaluated who had subsequently been transferred to adult criminal courts. Next, National Council of Juvenile and Family Court judges were asked to rate core characteristics for the three loosely defined concepts. Prototypical items for each of the constructs aligned across the raters, indicating that there was general agreement regarding the central components of Risk for Dangerousness, Sophistication-Maturity, and Treatment Amenability.

Structure of the RSTI

Exploratory and confirmatory factor analytic (CFA) procedures were used to examine the structure of the prototypical ratings. CFA results formed the basis for the development of the RSTI scales. Assignment of items to scales relied heavily on consideration of prototypical ratings and factor structures. Items with low prototypical ratings were not included on scales, even though they might have loaded on a factor. For example, reckless and hyperactive characteristics were loaded on the dangerousness factor but were excluded because they received low prototypical ratings and produced inadequate model-fit indices in the CFA.

Internal Consistency and Reliability

Alpha coefficients for the three RSTI factors range from .78 to .83. Intraclass correlations for the RSTI scales range from .74 to .94, indicating good interrater reliability across types of raters and scoring methods. Comparing interview-based RSTI ratings between clinicians and trained graduate student raters resulted in slightly higher reliability, ranging from .81 to .94, indicating that interviews may increase the reliability of ratings.

Validity

Several studies have reported evidence for the RSTI's concurrent validity using other measures of psychological constructs to which the RSTI constructs should be related. The RSTI Risk for Dangerousness Scale correlated positively with Conduct Disorder, Violent Conduct Disorder, Psychopathic Traits, and both Reactive and Total Aggression. The Treatment Amenability Scale was associated with older ages of onset of conduct disorder and negatively associated with conduct disorder symptoms.

Criterion validity of the Treatment Amenability Scale was examined by testing the association between file-based RSTI ratings and later treatment compliance and other criteria among male juveniles at a juvenile treatment center. The scale was associated with positive interactions with staff and maintenance of appropriate boundaries, both of which are important to the therapeutic relationship. The Dangerousness Scale was negatively associated with maintenance of appropriate boundaries, and the Maturity Scale was associated with excellent classroom behavior. Criterion validity was assessed in two studies of retrospective outcomes among youths facing transfer to adult court. Relative to youths not transferred to adult court, transferred youths received, on average, significantly higher dangerousness and maturity scores and lower treatment scores.

Application

The RSTI manual is available from Psychological Assessment Resources. The RSTI is copyrighted and can be purchased as a kit, which includes a manual, 25 structured interview booklets, and 25 rating scales. Mental health professionals with experience in juvenile justice settings can administer the RSTI. The RSTI can be administered in court evaluation units, detention centers, and by consulting clinicians in outpatient settings. The RSTI can be used in evaluations related to recommendations for general disposition decisions, commitment and transfer to adult court and reverse transfer hearings, treatment recommendations, and most important, development of individualized treatment plans.

Rogers Criminal Responsibility Assessment Scales (R–CRAS)

The Rogers Criminal Responsibility Assessment Scales (R–CRAS) is a structured decision model for quantifying relevant psychological variables that are salient for the retrospective evaluation of insanity. The R–CRAS was validated to address specifically the American Law Institute (ALI) insanity standard that requires an assessment of a defendant's cognitive and volitional impairment at the time of the alleged offense. In addition to the ALI standard, the R–CRAS provides clinical data relevant to the M'Naghten insanity standard and the Michigan-based guilty but mentally ill (GBMI) standard.

The R–CRAS decision process combines an appraisal of general diagnostic categories with an assessment of cognitive and behavioral (i.e., volitional) abilities at the time of the offense. Three rationally constructed scales evaluate diagnostic issues: (1) Patient Reliability, which includes malingering or involuntary interference with accurate recall; (2) Organicity, which addresses the likely effects of brain damage or mental retardation; and (3) Psychiatric Disorders, which examines the effects of key Axis I symptoms. Two scales address legally relevant impairment: (1) Cognitive Control, which evaluates impairment in verbal abilities, awareness of the criminal behavior, and capacity for planning; and (2) Behavioral Control, which considers level and focus of criminal activity, as well as the defendant's capacity to control criminal behavior and engage in responsible behavior. Finally, the GBMI items address general domains of impairment that are not specific to criminal behavior.

Description and Development

The R–CRAS was developed by a study group of five experienced forensic psychologists and psychiatrists who reached consensual agreement for the inclusion of core psychological and situational variables relevant to insanity. This operationalization of the ALI standard requires forensic experts to make a series of professional judgments based on anchored ratings. These ratings provided descriptions of impairment for each level that typically ranged from "none" and "slight" to "moderate," "severe," and sometimes "extreme."

The primary standardization sample was drawn from two well-established outpatient forensic centers: the Isaac Ray Center in Chicago and the Court Diagnostic and Treatment Center in Toledo. Using eight forensic psychologists and eight forensic psychiatrists, R–CRAS data were collected on a total of 157 insanity evaluations with test-retest reliability on 76 cases. A secondary sample of 103 insanity referrals was collected from two inpatient and two outpatient forensic facilities.

Reliability

The reliability of the R–CRAS is challenging to establish, given the retrospective nature of insanity evaluations. As a rigorous test of its reliability, the R–CRAS was administered by independent evaluators on separate occasions with an average interval of 2.7 weeks. For individual variables, the mean reliability coefficient was .58, which is very acceptable given the rigorousness of the retrospective test-retest design.

One critical issue is the reliability of the ALI decision model to demonstrate the reproducibility of R–CRAS decision variables by independent experts at separate times. Average agreement between experts was very high with values ranging from 85% to 100% (M = 91%). Kappa coefficients were generally excellent with an average of .81. Because kappas are affected by low base rates, the kappa for malingering was modest (.48) despite the high level of agreement (85%). For the final decision regarding insanity, the agreement between independent experts was almost perfect (97%; k = .94).

Validity

The R–CRAS used Loevinger's model of construct validation, which is conceptualized in terms of substantive, structural, and external validities. The development of the R–CRAS addressed substantive validity in its selection and operationalization of key variables relevant to insanity. The structural validity used a formulation of insanity that could be tested as a series of hypotheses. In comparison with sane defendants, clinically evaluated insane defendants would manifest (a) a relative absence of malingering, (b) greater psychological impairment (i.e., organicity and mental disorders), and (c) greater impairment (i.e., cognitive and volitional). Marked differences were observed in the predicted direction. For

example, very large effect sizes were found for the role of hallucinations (Cohen's $d = 1.80$) and delusions (Cohen's $d = 3.15$) in criminal behavior. Discriminant analyses were also used to demonstrate differentiating patterns between sane and insane defendants on calibration and cross-validation samples. As evidence of external validity, R–CRAS decisions were compared with legal outcomes. The primary samples yielded high concordance rates that were nearly identical—88.5% for the Isaac Ray Center and 88.1% for the Court Diagnostic and Treatment Center.

Forensic Applications

The R–CRAS is the only well-validated decision model for the assessment of criminal responsibility. Its model requires forensic psychologists and psychiatrists to quantify key variables related to the severity of Axis I symptoms and elements of criminal behavior. This model appears to be generalizable to defendants with different sociodemographic (e.g., gender, race, age, and education), criminal (e.g., prior arrests and delinquency), and clinical (e.g., prior diagnoses and hospitalizations) variables.

Forensic psychologists may prefer to use the R–CRAS for insanity evaluations as a structured guide rather than a formal test. This use appears warranted, especially in jurisdictions that do not use the ALI insanity standard. For GBMI consultations, the Michigan-based R–CRAS criteria are used in many jurisdictions. However, forensic clinicians should carefully check its relevance to their particular jurisdiction. Finally, experts are likely to be divided on whether to render conclusory opinions with insanity cases. Forensic psychologists avoiding conclusory opinions should use the final decision point for sanity as simply advisory and not document it in their forensic reports.

Scientific Jury Selection

Scientific jury selection (SJS) is the use of a survey to decide which jurors to favor in a trial. Prior to the 1970s, jury selection was done by attorneys based on their hunches. The new quantitative method was welcomed enthusiastically by trial attorneys. Social scientists were more reserved. SJS led to the employment of social scientists as trial consultants. This entry describes traditional jury selection as conducted by attorneys, reviews the origin of SJS, presents an example of a 2003 survey used in Florida to implement SJS, and examines evidence on the utility of SJS.

Voir dire is the process at the beginning of a trial when prospective jurors, called *venirepersons,* are examined verbally to determine their fitness for service as jurors in a particular trial. An unlimited number of venirepersons can be excused *for cause*—that is, found unfit by the trial judge for reasons of incompetence or prejudice. Venirepersons are also excused *peremptorily,* that is, by the attorneys without stated reason. The rules for using peremptory excusals vary by jurisdiction and preferences of trial judges. Judges differ widely in the questions they ask or allow the attorneys to ask. Some judges allow venirepersons to complete trial-specific questionnaires constructed by the attorneys. The information about venirepersons available to the attorneys varies greatly, given the court's voir dire practice. Nevertheless, in U.S. courts, the parties (prosecution, plaintiff, and defendant) have a right to a certain number of peremptory excusals. These peremptory excusals are determined and used during the jury selection process.

Traditional Attorney-Conducted Jury Selection

How do attorneys evaluate venirepersons and decide whom to favor or oppose? Lawyers are sometimes influenced by the published preferences of famous colleagues—the idols of the tribe. These famous trial lawyers have published preferences mainly based on ethnic, religious, gender, and occupational stereotypes that may often conflict with each other. These stereotypes were formed long ago and have no application to modern jurors or cases. Many attorneys hold other stereotypes that may have some limited value, for example, that nurses are unsympathetic to pain and suffering or that people who use newspaper coupons give stingy monetary awards. In addition, a trial attorney's experience with a particular type of juror may result in prejudice for or against such jurors in future trials. Attorneys also evaluate venirepersons on the basis of "vibes"—their impression of the venireperson's nonverbal behavior and deportment. Generally, the attorney has a limited profile of good and bad jurors derived from advice from other attorneys, prejudices, speculation, and experience.

Origin of Scientific Jury Selection

In the 1972 Harrisburg Seven trial of Vietnam War resisters, Jay Schulman and colleagues decided to evaluate venirepersons on the basis of a survey. Schulman surveyed 840 respondents in the trial venue, recording diverse attitudes possibly related to juror view of war resisters. Respondents indicated what they thought of various antiwar activities, which historical figures they

admired, their level of trust in government and the establishment, and many demographic features such as age, sex, education, occupation, media preference, and residence. Demographic variables were then statistically correlated with attitudes suggesting support for the government and the Vietnam War. Schulman reported that respondent sex, education, religion, and media preference distinguished "good" from "bad" jurors. In principle, jurors at the trial who had features that were bad (male, better educated, Protestant, attended to local media) would be excused peremptorily. Despite the apparently scientific approach, it is clear from Schulman's article that the Harrisburg Seven jury was chosen by a mishmash of survey findings and old-fashioned practice (including informant information on certain venirepersons; speculation about how a given juror was likely to relate to other jurors; speculation on racism; and deliberation among the multiple lawyers, social scientists, and defendants about the desirability of prospective jurors).

If it is unclear how SJS was employed in the Harrisburg Seven trial, it was abundantly clear to the litigation profession that a promising new tool was available to assist in jury selection. While Schulman's academic colleagues continued pro bono work on political trials, some of his followers formed the National Jury Project in 1975. In 1979, in the wake of success in the MCI/ATT antitrust case, Donald Vinson founded Litigation Sciences. In 1987, he founded Decision Quest, which was employed by prosecutor Marcia Clark in the 1995 trial of O. J. Simpson. Today, trial consultation is a billion-dollar enterprise, with practitioners in all metropolitan areas.

An SJS Survey

The following survey was conducted in 2003 in preparation for a trial with charges of vehicular homicide while driving under the influence of alcohol, a felony punishable by as much as 50 years in a Florida state prison. The sample in this SJS survey consisted of 211 Miami-Dade county residents whose sex, age, family income, marital status, education, and race/ethnicity closely paralleled those of registered voters, from among whom state court venirepersons are subpoenaed. These people's responses should be similar to those of people who show up for duty at this trial.

The survey begins with the case summary, a one-page description of the most essential features of the case, to wit, that an elderly lady was hit and killed by a speeding BMW. The driver failed to stop. A witness with a cell phone described the driver as a black or dark-skinned male. A police BOLO (be on the outlook for) broadcast this description. The police found the abandoned, damaged car within 20 minutes at a distance of 1.5 miles from the accident. About 1 hour after the accident, the police went to the apartment of the registered owner of the car, who lived 8 miles away. He was a light-skinned White man who was wearing his bathrobe. He had been in bed and in the shower and appeared intoxicated. There were glass shards in his robe and in the shower. He admitted having been out drinking all night at two gay bars. He claimed his car was parked below in the garage. When it was not found there, he agreed with the police that it must have been stolen. He was interrogated at the police station and continued to deny guilt. He claimed to have blacked out in a bar and to be unable to remember anything thereafter. His blood alcohol level 4 hours after the accident was 0.17, far above the legal limit. At that point he was arrested. The summary concludes with a statement of a defendant's right to be presumed innocent and stresses that the entire burden of proving guilt rests with the prosecution.

The summary is followed by a 9-point verdict scale asking the respondent to indicate the likelihood of guilt based on what he or she knows. This verdict scale is repeated after each separate additional fact introduced in the second section. A final verdict scale comes after the respondent has heard the case summary and all eight additional facts. This is the most important measure of the verdict.

The second section of the survey records the respondent's verdict after hearing specific critical facts. These verdicts determine trial themes and are the most important information in an SJS survey. They tell the attorney which facts fly and which crash, what to leave in the argument at a trial, and what to leave out. It is no simple matter to know which evidence and which themes to emphasize in a trial.

Recall that respondents indicated verdicts after hearing eight specific bits of evidence or argument. In terms of the prosecution's case, respondents did not increase their guilt ratings on the basis of evidence stressing that the defendant's car was involved or that he was out drinking all night without an alibi. However, evidence that the glass spray pattern in the damaged auto proved that no one other than a driver was in the car at the time of the accident resulted in a sharp increase in guilt ratings. These findings identify the critical defense problem that must be successfully addressed.

Two defense themes proved most helpful. First, the police BOLO identified the driver as a dark-skinned

male. Second, sloppy police work such as failing to fingerprint the steering wheel led to lower guilt ratings. The defense was on notice to focus on these points and ignore certain other evidence such as a doctor's testimony that the defendant had no memory of postblackout events under hypnosis.

The third section of the survey consists of open-ended items answered in the respondent's own words. Respondents are asked for the best reasons for convicting and acquitting, and for any suggestions they might have. The responses confirmed that the best reasons for acquittal were the legal ground rules favoring the defendant, sloppy police work, and the BOLO. Responses to free-response questions often produce useful articulations. These can be used to make a point in argument.

The fourth section consists of opinion items. Respondents used rating scales to indicate their opinions about alcohol and driving, sloppy police work, eyewitness accuracy, and conventionality. The results indicated that opinions about convicting when the police work has been sloppy, not convicting on strong suspicion but only on proof, and concern about irresponsibility and sexual immorality predicted the verdict. The defense would focus on these opinions in voir dire.

Experience has shown that demographic predictors emphasized in the original SJS research are usually less predictive of the verdict than are experiences and/or opinions. Nevertheless, as in the current case, they are sometimes predictive. This is extremely helpful when court procedure limits voir dire as in the federal courts. The current study indicates Cuban Whites reach verdicts similar to those of married jurors, jurors with lower incomes and less education, male jurors, and jurors who never drink even moderate amounts of alcohol when driving. These characteristics are associated with conviction.

In the current case, the survey has distinguished critical and less significant evidential issues. Nine opinion and demographic predictors have been identified. In juror selection, venirepersons with more of these features will be favored for defense peremptory excusals.

The disposition of this case is instructive in evaluating the utility of SJS. Preparation for jury selection is only one aspect of trial outcome and usually far from the most important. In this case, as noted, the defense knew from the survey that the police BOLO indicating that the driver was a dark-skinned male was crucial to introducing doubt that the fair-skinned defendant was driving the car. The prosecution argued that the BOLO was in error because the eyewitness in fact told the police that it was the car that was black. Unfortunately for the defense, the judge disallowed mention of the BOLO. Faced with 50 years in prison if convicted, the defendant agreed to plead guilty and serve 12 years in prison. In this case, SJS succeeded in identifying crucial evidence and juror features predictive of the verdict.

Utility of SJS

Informed opinion differs, but most academic reviewers are skeptical that SJS improves attorney-conducted jury selection. Eight traditional published studies of the statistical utility of SJS indicate that on average only 11% of the factors that determine a juror's verdict are explained by SJS opinion and demographic predictors. This is, however, better than it may sound as it suggests an improvement of 17% in the accurate prediction of a venireperson's verdict. If, for the sake of argument, we assume that attorney jury selection is no better than guesswork—50% accurate (it is unknown but probably better on average)—then SJS improves this to 67% accurate prediction. Eleven (nine unpublished) additional SJS studies at Florida International University in recent years suggest that verdict prediction accuracy can be further improved (up to 76% accuracy). SJS is of no value if the evidence makes conviction inevitable. SJS is more frequently used in civil trials, where the evidence is more likely to be balanced. Finally, it must be recognized that the survey must capture the essence of the evidence to be presented at the trial as well as case-relevant opinions, which are known to predict juror verdicts better than demographic characteristics or general attitudes do.

Sentencing Decisions

The sentencing decision is typically the last court decision made in a case. This decision has attracted the most attention from researchers studying legal decision making. After being convicted of a crime, a defendant may be sentenced to, for example, imprisonment, a community penalty, fine, restitution or compensation, or probation. A sentence may have one or more goals, including to deter, rehabilitate, and incapacitate the offender. Crimes may have maximum and minimum penalties attached to them. However, in between these penalties, sentencers have discretion as to the sentence they pass. Efforts have been made to curb this discretion through the introduction of sentencing guidelines. Past research on sentencing has largely been conducted in the American and English criminal justice systems. Researchers have aimed to describe and explain sentencing practice. They have found that guidelines do not necessarily reduce sentencing disparity. Sentencing decisions are associated with earlier decisions in a case. In addition, sentencers may be influenced by myriad individual-level factors such as offender, victim, and case characteristics as well as higher-level factors related to the sentencer, court, and area or jurisdiction.

Sentencing Theory and Policy

Once a defendant has been convicted of a crime, he or she will be sentenced. This sentencing decision is typically made by a judge or magistrate (depending on the sentencing court). Several sentencing options are available to sentencers; common ones include incarceration (prison or jail), community sentences, fine, restitution or compensation, and probation. Of these, incarceration is usually the most severe sentence, although some crimes carry the death penalty in some jurisdictions. Defendants convicted of more than one crime may be given consecutive or concurrent sentences. Sentencing statistics indicate trends in sentencing such that the relative use of different options changes over time, largely in response to changes in sentencing policy or public opinion.

A sentence may be justified on one or more of several theoretical grounds. In their simplest forms, desert or retributive theories propose that those who commit crimes deserve punishment and should receive sentences proportionate to the seriousness of the crime. Deterrence theories state that a sentencing should aim to deter specific people, or people in general, from committing crimes and that doing so requires that a sentence be certain and severe. Rehabilitative approaches also suggest that a sentence should aim to prevent further reoffending but hold that this should be done by means of treatment. The incapacitative approach advocates that a sentence should aim to protect the public by detaining persistent or dangerous offenders. Finally, restorative and reparative theories state that sentences should aim to repair the harm done by crime and encourage social integration.

Research on public opinions of sentencing has found that support for the purposes of punishment varies by the nature and seriousness of the offense. Nevertheless, studies have consistently reported that people perceive sentencing policies and practices as being too lenient. In fact, public opinion has been a driving force behind several sentencing policies such as the "three strikes" policy in the United States. However, evidence also suggests that the public may be ill informed or misinformed about current sentencing policy and practice as well as crime rates. Studies indicate that the public are less likely to favor imprisonment when they are made aware of the range of sentencing options available, and they support alternatives to imprisonment under certain circumstances.

Most offenses have fixed maximum penalties assigned to them, usually in the form of a length of incarceration or fine amount, and some offenses also have mandatory minimum sentences. In addition, the sentencing options may differ for offense type. Finally, sentencing options may differ for adults and youths (juveniles and young offenders). Despite this, the sentencer is afforded considerable discretion in the sentence passed. When making a sentencing decision, sentencers are expected to use legal factors such as the nature and seriousness of the offense and the defendant's criminal history. The sentencer is also obliged to take into account any aggravating factors, such as the vulnerability of the victim, whether the victim was racially/religiously targeted, the offender's leading role in the offense, his or her profit from the offense, as well as mitigating factors, such as whether the offender was provoked, the offender's minor role in the offense, and his or her acceptance of responsibility or show of remorse. Finally, sentencers may also have access to sentencing recommendations provided by a probation officer in what is called a presentence report.

Sentencing guidelines have been introduced in some jurisdictions to focus sentencers' attention on

legal factors and to promote predictability, consistency, transparency, and accountability in sentencing. For example, in the United States, since the 1980s, there have been both state and federal guidelines that employ a grid structure. State guidelines vary in their use of the axes of criminal history and offense seriousness, as well as the sentence ranges proposed. Some guidelines are advisory/optional (voluntary), and others are legally mandated (presumptive); some are based on past sentencing practices, while others offer a new sentencing goal or philosophy. In the English system, optional sentencing guidelines are being produced for all criminal courts since 2004. Although these guidelines are much less structured than in the United States, they are informed by public consultation and data on the effectiveness of sentences in reducing re-offending, as well as the financial cost of different sentences. However, commentators are pessimistic about the extent to which objectivity in sentencing can be achieved by the English guidelines. Research evaluating guidelines in the American system suggests that while successful in reducing extralegal disparity in sentencing in some jurisdictions, the guidelines have sharply increased such disparity in other jurisdictions.

Research Describing and Explaining Sentencing Practice

Much of the past research has investigated sentencing decisions in the American and English criminal justice systems. Studies have been conducted by psychologists, sociologists, criminologists, and legal scholars using methodologies such as experiments involving sentencers being presented with simulated cases, interview and questionnaire surveys of sentencers, analyses of sentenced case records and sentencing statistics, and analyses of sentencing policies. Researchers have examined both sentencing decisions generally as well as the choice of specific sentencing options. They have documented the influence of legal and extralegal factors on sentencing, variations in sentencing practice across areas or jurisdictions, and disparities in the sentences passed on subgroups of defendants.

Sentencers are often required to give reasons for their sentencing decisions. The reasons given in court or in self-report studies typically do not concur with the findings of research that is based on an analysis of sentencing behavior.

Evidence from studies of sentencing behavior suggests that sentencing decisions are associated with earlier decisions made in a case such as the bail-setting decision and the defendant's plea. In particular, defendants who were denied bail or remanded in custody are more likely to receive a custodial sentence than those who are given bail, after controlling for some legally relevant variables such as offense type. Furthermore, sentencing discounts may be given to those defendants who plead guilty. Some of the relations between the sentencing decision and earlier decisions are supported by policies such as the guilty plea discounts in the English system and plea agreements in the American federal system. However, the association between the bail-setting decision and the sentencing decision are not mandated by sentencing policy.

Studies have examined the extent to which sentencers may be influenced by myriad individual-level factors such as offender, victim, and case characteristics as well as higher-level factors related to the sentencer, court, and area or jurisdiction. With regard to individual-level factors, there is evidence that in addition to legally proscribed factors, sentencers may use extralegal factors such as the race or ethnicity and gender of the defendant. In particular, Black defendants have been reported to be treated more punitively than White defendants, and females have been shown to be treated more leniently than their male counterparts, even after controlling for the defendant's offense and criminal history. However, there may be other legally relevant case variables that covary with these extralegal factors that also need to be controlled, and the impact of extralegal factors on sentencing may also be partly accounted for by the impact of these factors at earlier stages of the criminal justice process such as at the bail-setting stage.

With regard to higher-level factors, criminological research in America shows that the decision to incarcerate as well as the length of incarceration can be predicted by sentencer characteristics, such as age, and court and area factors, such as court size, availability of custodial spaces, and proportion of ethnic population. For instance, minority judges have been found to be more lenient than their White counterparts. Sentences have been found to be more severe in small courts than in large courts. The availability of custodial spaces has been found to increase the likelihood of incarceration. In some areas, it has been found that as the proportion of the population belonging to an ethnic minority increases, so does the length of incarceration. Criminological research

in the English system similarly reports that, for offenses of similar levels of seriousness or for similar types of offenders, sentences appear to vary by area, court type, and sentencer. Here, sentences given in the Crown court tend to be more severe than those given by the magistrates' (lower) court for similar offenses, and sentences by professional judges tend to be more severe than those given by lay judges (magistrates).

Although psychologists have generally not studied the impact of higher-level variables on sentencing decisions, they have demonstrated how the personal characteristics of the sentencer, such as his or her attitudes and experience, may influence the sentencing decision. Psychological research has also pointed to the types of heuristic decision-making strategies that sentencers may use.

More recently, criminologists such as Brian Johnson have begun to argue for the importance of studying sentencing decisions using multilevel theories. These allow the researcher to simultaneously examine the relative (direct) impact of individual- and higher-level factors on sentencing decisions and to measure the interactive effects of individual- and higher-level factors. Therefore, theories of sentencing can better consider how sentencers are influenced by the individual offender, case, or victim and how sentencing behavior is affected by the characteristics of the sentencer and his or her environment such as court or area.

Sentencing Diversion Programs

Sentencing diversion programs are formal, institutionalized programs for people with mental illness that were created to reduce the volume of and frequency with which this population is involved in the criminal justice system as defendants. Their primary purpose is to divert persons with mental illness (PMIs) from the criminal justice system (including jail and prison) into community, outpatient mental health, and substance abuse treatment. Diversion, which can occur at any point in the criminal justice process (from prearrest to postconviction), has several defining features. These features include sharing a common goal of reducing recidivism rates of PMIs, relying on a therapeutic jurisprudence model, having predefined target populations, using a carrot-and-stick approach to achieve compliance, maintaining collaborations across multiple systems of care, and sometimes mandating treatment. Preliminary research on the effectiveness of the programs is equivocal but promising, in that diversion can improve the lives of PMIs involved in the criminal justice system.

The Purpose of Diversion Programs

Diversion has always been an informal option for the police and prosecutors, but the development of formalized programs is relatively recent. Diversion is an attempt to stem the tide of PMIs who enter the criminal justice system. An estimated 900,000 persons with serious mental illness are booked into U.S. jails annually. (Serious mental illness is typically defined as having a schizo-spectrum, bipolar, or major depressive disorder.) Approximately 10% to 15% of jail and prison inmates have a serious mental illness compared with about 3% of the general population. Moreover, PMIs who are involved in the justice system tend to have repeated, "revolving-door" contact with law enforcement and the courts. It has been said that U.S. jails and prisons have become de facto mental health institutions. Because of

the volume of PMIs involved in the criminal justice system and the associated problems (e.g., behavioral problems while incarcerated, access to medication), formal diversion programs have been developed to help reduce the number and frequency with which PMIs pass through the criminal justice system. Typically, diversion programs are premised on the notion that PMIs who access and engage in community treatment will be less likely to have police contact and less likely to be charged with crimes, thereby reducing the repeated cycling.

Timing of Diversion

There are two main forms of diversion programs: prebooking (or prearrest) and postbooking (including mental health courts). Although diversion can occur at any point along the criminal justice continuum, including probation and parole, one goal of diversion is to identify potential participants as early as possible. The timing of diversion, however, can depend on awareness of the mental illness and of the diversion program itself. For example, an inmate may not be recognized as having a mental illness (or as being a suitable candidate for the program) until after several months of pretrial detainment. Additionally, in larger urban communities, many criminal justice personnel with whom the PMI interacts may not even know a diversion program exists in their locale.

The timing of the referral and whether the program is pre- or postbooking also influence the diversion process itself. Specifically, prebooking programs divert the PMI from being arrested and charged and, thus, from criminal justice involvement entirely. That is, for PMIs involved in prebooking diversion programs, law enforcement has used their discretion to not arrest them. Currently, there are an estimated 120 prebooking diversion programs. A growing form of prebooking diversion programs are crisis intervention teams (CITs). The CIT model is primarily concerned with de-escalating crisis situations between police officers and PMIs in the field, but it also involves making informed decisions about when to arrest PMIs rather than taking them to treatment settings.

Postbooking diversion occurs after the person has been charged. Two critical points for this type of diversion to occur are when making decisions concerning pretrial release and deferring prosecution. Usually, the decision to release a defendant occurs soon after the arrest. If the arraignment judge is aware that the person has been accepted into a diversion program that is partially responsible for community supervision, the judge may be more inclined to release the person from jail. Similarly, when the prosecutor is deciding whether to go forward with a case, knowing that the defendant is involved in a diversion program, and is thus likely to be getting treatment and supervision, can affect that decision. To date, there are approximately 150 postbooking U.S. diversion programs that are not mental health courts.

Mental health courts, while a form of postbooking diversion, are distinct. Mental health courts are criminal courts with typically one judge presiding. Clients are supervised by the judge (in periodic status review hearings) and in the community by mental health and/or criminal justice professionals. Often, communities that have instituted successful drug courts will form mental health courts as well. The courts are part of a growing field of specialty courts, which include domestic violence, DUI, and even teen smoking cessation courts. The first two mental health courts were formed in 1997. In 2006, there were more than 130 U.S. mental health courts.

Features of Diversion Programs

Diversion programs are most often created by individual communities and thus meet the needs of that specific jurisdiction. As such, diversion programs can appear quite distinct from one another, especially when examined at a micro level. However, at a macro level, there are several shared and defining aspects of diversion programs.

Common Goal

Diversion programs have the shared goal of reducing the frequency with which PMIs become justice involved. They also aspire to linking their clients with community treatment services and, quite often, with other services such as vocational training, housing, and accessing government funds. Generally, diversion personnel are concerned with what is in the best interests of their clients, and many programs are paternalistic in their nature.

Therapeutic Jurisprudence

Therapeutic jurisprudence is defined as an outlook that views the law as a system for social change (either in a therapeutic or nontherapeutic direction). Diversion programs strive to improve the lives of their participants. The programs, particularly mental health courts,

are also less adversarial and less formal than traditional criminal court processing. In mental health courts, often, defendants can approach and speak to judges directly, and sometimes clients and judges will hug. Most programs are also lenient, have realistic expectations, and understand that the population they are serving is prone to relapse and instability. For example, if a client in a mental health court misses a scheduled court hearing, the immediate response is not to issue a bench warrant but rather to use a gradated list of sanctions that increase in intensity as noncompliance increases. Expulsion from the program and incarceration, while possible, are usually the last resorts. Finally, diversion program clients tend to report high levels of procedural justice, in that they feel they have a "voice," are respected, and heard.

Target Populations

Diversion programs set criteria for who is allowed entry into the program. Mental health screening and assessment procedures are important components necessary to diversion. Most programs have both clinical and criminal eligibility criteria. Clinical criteria can be specific or broad and can include, for example, accepting only persons diagnosed with Axis I (*Diagnostic and Statistical Manual of Mental Disorders,* fourth edition [*DSM-IV*]) disorders or requiring a link between the commission of the crime and the person's mental health problem. Criminal criteria can include limiting the program to misdemeanants or requiring victims' assent to be involved. For the most part, diversion programs exclude violent felons for public safety reasons. Finally, some communities have developed women-only diversion programs, recognizing that male and female defendants with mental illness have different treatment needs (such as trauma-based services) and routes to recovery.

Carrot-and-Stick Approach

All diversion programs offer some end benefit, whether it be avoiding an arrest, avoiding a jail or prison sentence, and/or having the charges dropped or reduced. However, in exchange for not being charged or sentenced, the person agrees to go to mental health and substance abuse treatment in the community, to take prescribed medications, and sometimes to attend periodical status review hearings before a judge. If the person is not compliant on a repeated basis, the charges or sentences that were held in abeyance can be instated. Alternatively, some programs require participants to plead guilty and only after successful completion reduce the original charges (e.g., from a felony to a misdemeanor) or expunge the conviction from their criminal record. Thus, like drug courts, diversion programs use this carrot-and-stick approach to induce cooperation and compliance. As mentioned above, this is generally not done in a coercive manner but rather with an eye toward the person's best interest.

Cross-System Collaborations

Almost by definition, diversion programs need to involve professionals from the criminal justice and mental health systems who work collaboratively. Very often, a group of key stakeholders in the community come together to form the program. These stakeholders can include a judge, state and/or county mental health and substance use officials, attorneys, pretrial service personnel, correction officers, advocates for mental illness, and the police. Elements identified as being essential to the success of diversion programs are (a) ongoing and active cross-systems collaboration, (b) written memorandums of understanding between the systems, (c) strong leadership, and (d) a "boundary spanner." A boundary spanner is a staff member who bridges across the mental health, criminal justice, and substance abuse systems and who serves to coordinate cross-systems collaborations.

Mandated Community Treatment

Many, but not all, diversion programs can be considered a form of mandated community treatment, in that they require the person to go to treatment and to take prescribed medications and will impose consequences when the person is nonadherent. Typically, prebooking diversion does not mandate treatment or have long-term follow through with divertees. In contrast, mental health courts, while voluntary to enroll, exemplify the concept of mandated community treatment.

Effectiveness of Diversion Programs

In regard to the effectiveness of diversion, preliminary research has shown mixed but promising results. On one hand, there is research demonstrating that diversion programs can be successful in achieving their goals of reducing recidivism and linking clients with treatment. For example, a research study examining nine pre- and postbooking diversion programs found that in comparison with a group of similar but nondiverted individuals,

divertees spent more days in the community than in jail, received a higher number of treatment services, and showed improved mental health symptoms. On the other hand, the same study also showed that divertees had higher rates of emergency room usage and hospitalizations, and a similar number of new arrests compared with nondivertees. Additionally, a study on clients from one mental health court found reductions in the number of arrests and increases in the number of treatment services used, but no change in mental health symptoms over the course of court participation.

Studies have also shown that there are individual characteristics that influence whether diversion is successful. That is, diversion is not a "cure-all" that works equally well for every participant. The exact characteristics (such as gender, criminal charges, diagnosis) that lend themselves toward success are still being explored. Major research studies of all forms of diversion programs are now underway.

Future of Diversion Programs

In the years to come, diversion programs are likely to continue to proliferate. President George W. Bush's New Freedom Commission on Mental Health recommended the wide adoption of these programs, and the federal government has provided millions of dollars in financial support to create new, and sustain existent, programs. The number of persons with serious mental illness involved in the criminal justice system is a significant and complex problem. Diversion can play an integral role in the solution to this problem.

Serial Killers

People are fascinated by violent crime, and serial murder may be the most fascinating crime of all. Books, newspapers, television shows, and movies recount the destructive paths of those who kill repeatedly. Many of these accounts leave the impression that serial killers are distinct from other types of criminals and from the public at large. However, current knowledge on serial killers is based almost exclusively on a small number of case studies and a handful of moderately sized archival investigations. Thus, our current level of knowledge on serial murder is, at best, sketchy, and this knowledge may not stand up to more rigorous empirical testing. This entry reviews the definition of serial killing, demographics of serial murder, results of research on serial killers and their motivations, and typologies that have been used to classify serial killers.

Definition

Serial murder is defined by three key elements: number, time, and motivation. Most murderers have only one victim; serial killers, by definition, have multiple victims. The minimum number of victims listed in various definitions of serial murder proposed in recent years range from 2 to 10, with a modal value of 3. The time element in serial murder is designed to distinguish serial killers from mass murderers and spree killers. Whereas mass murderers have multiple victims in a single episode and spree killers have multiple victims in several separate but related episodes, in neither case is there an emotional cooling off period between murders. In contrast, in serial murder, there is a cooling off period of several days, weeks, months, or years. Finally, to differentiate serial killers from professional hit men, political terrorists, and military combatants, most definitions of serial murder omit individuals who kill exclusively for financial, political, or military gain.

Demographics

Men are responsible for the vast majority of crimes committed worldwide. An even greater percentage of men engage in serial murder. The ratio of male to female criminals, including those who commit single-incident homicides, is 9:1; the ratio of males to females who commit serial murder is somewhere in the neighborhood of 19:1. Although rare, female serial killers do exist and are more likely to work in pairs than male serial killers. In the United States, as many Blacks as Whites commit single-incident murder; the ratio of White to Black serial killers, on the other hand, is 5:1, which is roughly comparable with each group's representation in the general population. Single-incident murders are normally committed by individuals in their early to mid-20s, while the initial murder in a series is normally committed by an individual in his or her late 20s to early 30s.

The victims of serial murder are just as likely to differ from the victims of single-incident homicide as the perpetrators of serial murder differ from the perpetrators of single-incident homicide. Young adults are the most common targets of serial murder, but victims could be anywhere from their early childhood to late adulthood. Some serial killers prefer male victims, others prefer female victims, and still others have no gender preference. According to recent estimates, females are more likely to be victimized by a serial killer than males, a pattern that runs counter to what has traditionally been observed in single-incident homicide, where male victims predominate. There are also single-serial differences in the victim-perpetrator relationship. Whereas the victims of single-incident murder are often family members, friends, and acquaintances, the victims of serial murder are nearly always strangers.

Research on Serial Murder

The research that has been conducted on serial murder has been largely descriptive in nature. Most serial killers work alone, although in 10% to 37% of cases serial killers work in pairs. When serial killers operate as a pair, one member ordinarily assumes the dominant role while the other member assumes the submissive role. Serial killers generally select their victims, and the victims they find most appealing are those that seem preoccupied, distracted, or vulnerable and those whose disappearance would be least likely to be noticed. Hence, single women, transients, runaway teenagers, and prostitutes are prime targets for serial murder. With respect to the method of murder, serial killers prefer to strangle, stab, or beat their victims rather than shoot them (the staple of single-incident murder). It has been speculated that "hands-on" murder techniques such as strangulation, stabbing, and beating offer the serial killer greater personal control over the victim than killing from a distance. Once the crime has been committed, the serial killer is more likely than the single-incident killer to try and deceive law enforcement by burying the body, moving the body to another location, or altering the crime scene.

There is no single psychological or personality profile that all serial killers fit, but there are certain characteristics that have been observed on a fairly regular basis in serial killers. First, serial killers are more likely to have a history of criminal involvement, often in the form of petty criminality, than a history of psychiatric treatment. Second, some serial killers exhibit tell-tale signs of a psychopathic personality. In several small-scale studies, approximately half the serial killers satisfied criteria for psychopathy as measured by Hare's Psychopathy Checklist. This may explain why some serial killers are adept at disarming their victims without coercion and avoiding apprehension for an average of 4 to 5 years. Third, many serial killers have a rich fantasy life capable of fueling their appetite for murder, with or without the aid of additional facilitative conditions such as pornography and alcohol or drugs. Objects the serial killer collects from the crime scene or takes from the victim, commonly called trophies, not only help the killer relive the murder but can also trigger future killings. Several studies indicate that it is not unusual for an individual to entertain murder fantasies for several years before acting on them.

Motivation of Serial Killers

Research on the motivation behind serial homicide is complicated by the fact that motivation is often used to define serial murder and distinguish it from other categories of multiple murder (i.e., political terrorism, organized crime, military combat). It has traditionally been assumed that serial murder is driven by sexual motives, and in more than half of the serial killers interviewed, a clear sexual motive has been identified. Furthermore, in comparison with the emotional and social issues that frequently motivate single-incident homicide, serial

homicide is more often motivated by sexual fantasies and desires. Having said this, the relationship between serial murder and sexual motivation may be an artifact of how serial murder is defined. Future researchers must consequently avoid confounding the criteria used to define serial murder (i.e., motivation) with the presumed motivation for serial murder by defining serial murder using variables other than sexual motivation.

Whether sexual motivation is an artifact of how serial murder is defined, nearly half of the serial killers who have been interviewed deny that there was a strong sexual component to their crimes. A small portion (4–5%) of serial murders appear to be motivated by psychosis, and slightly more are motivated by a strong profit motive. Revenge, on the other hand, may be a more powerful motive for serial murder than either psychosis or profit. There is preliminary evidence, for instance, that some serial killers target victims who display characteristics symbolic of a group or person they despise. Ted Bundy targeted young women with long dark hair parted down the middle because these were prominent features of a woman who had spurned him years earlier. John Wayne Gacy preyed on young males as a way, perhaps, of venting hatred toward his own homosexuality. An even stronger motive for serial murder is the power a person can derive from taking control of another person's life. Forcing a stranger to submit to their every demand and then killing the person with their bare hands, a knife, or a piece of rope can be highly reinforcing to a serial killer.

Typologies

Several typologies have been advanced in an effort to classify serial killers into discrete categories. One of the more popular typologies, the organized/disorganized typology, was developed at the FBI's Behavioral Science Unit in Quantico, Virginia. The organized serial killer is said to be of average to above-average intelligence, with good social skills, and a reasonably stable employment history. The murders enacted by an organized serial killer are usually well planned and typically involve the use of a weapon. Such individuals are said to leave an organized crime scene. A disorganized serial killer, on the other hand, possesses below average intelligence, weak impulse control, and poor social skills, leading to an unplanned attack that often results in a disorganized crime scene. The organized/disorganized typology was developed and validated on a group of 36 serial killers and other offenders who volunteered to be interviewed by the FBI. Recent empirical research has failed to support the organized/disorganized dichotomy, showing instead that most serial killers are organized and that they vary along a continuum of increased organization rather than splitting off into two groups.

Another popular typology of serial murder was proposed by Holmes and DeBurger. This typology consists of four categories: (1) visionary type; (2) mission-oriented type; (3) hedonistic type, which is broken down further into the lust killer, the thrill killer, and the creature-comfort killer; and (4) power/control type. Separate descriptions and motives are listed for each category in the typology. For instance, the visionary type is alleged to be motivated by delusions and hallucinations, is opportunistic in selecting victims, and leaves a messy crime scene, whereas the hedonistic type is motivated by personal enjoyment, pleasure, or gain, carefully selects victims based on predetermined criteria, and generally leaves a tidy crime scene. The problem with the Holmes and DeBurger typology is that because the four types are so poorly defined and the boundaries that separate them so indistinct, there is a high degree of overlap between types—a fatal flaw in any typology. Furthermore, there is no empirical support for the typology either as an effective shorthand in describing serial homicide or as a mechanism for predicting future behavior.

Future Research

Serial murder is a rare event, thereby making it difficult to research. At present, nearly all of what we know about serial murder is based on a few case studies conducted on individuals who agreed to be interviewed by law enforcement and a handful of archival studies using information gleaned from newspapers, police files, and court documents. Consequently, there is a need for more empirical research on serial murder. First, a generally accepted definition of serial murder must be found so that it can serve as the standard for future research on serial homicide. The use of divergent definitions of serial murder and confounding definitions with variables (e.g., motivation) have thus far hindered progress in the field. Second, theoretical models, such as Hickey's Trauma-Control Model, need to be created, tested, and refined. A good theory could reap tremendous benefits by advancing research and practice in the field. Third, alternatives to the traditional serial killer typologies need to be found. One such alternative is the

instrumental-affective dimensional approach in which instrumental and affective motives for serial murder are allowed to coexist. Finally, more research needs to be devoted to prediction—not just as a way of narrowing down the field of suspects in a series of seemingly related murders but also as a way of understanding the factors that lead to serial murder and how some of these features can be ameliorated, altered, or changed.

Sex Offender Assessment

Although clinical psychological assessment is generally expected to be specific to particular interventions with demonstrated efficacy, there is insufficient empirical evidence on which to prescribe clinical assessment practice with sex offenders. The best strategy is to examine interventions that target personal and circumstantial characteristics empirically related to commission of sex offenses or to recidivism among sex offenders. The most reliable and robust empirical differences between sex offenders and other people pertain to sexual preferences. The best available assessments of the risk of recidivism are provided by actuarial systems that include indicators of deviant sexual preferences and of persistent antisociality across the life course. The Hare Psychopathy Checklist is the best available measure of such antisociality. Equivocal evidence supports the use of some assessments of specific attitudes and symptoms. This entry discusses the psychological assessment of men who have sexually assaulted women and children; much of the discussion also applies to assessment of adolescent male sex offenders.

Forensic Psychological Practice With Sex Offenders

At the time of this writing (early 2007), crucial lacunae affect clinical practice with sex offenders. Despite several decades of research, there are no generally accepted scientific explanations for sex offending. There is also no empirically conclusive evidence about what specific interventions, if any, reduce the likelihood of subsequent offending among sex offenders. Regarding psychological treatment, the most authoritative and comprehensive meta-analysis concluded in 2002 that the available evidence *suggested* that some psychological therapies were effective, but a firm conclusion could not be drawn. A glaring problem highlighted by meta-analyses is the absence of useful data pertaining to which specific changes in psychological or clinical constructs induced by therapy were responsible for reductions in recidivism (if indeed any had occurred). The intervening 5 years has seen no improvement. Most of the experts' efforts over the past several years appear to have been devoted to debating, with no evident resolution, whether existing evidence convincingly demonstrated treatment effects. Although novel therapies were recommended and tried, no new effects of sex offender treatment were demonstrated. Consequently, forensic psychologists planning interventions are not in a strong empirical position to know what clinical constructs ought to be assessed for sex offenders. The most appropriate course for psychologists in such circumstances is to implement interventions that specifically target those ostensibly changeable characteristics that distinguish men who commit sex offenses from those who do not or that distinguish those sex offenders who recidivate from those who do not. The intensity of intervention (including supervision and, in the very highest risk cases, incapacitation) should be related to the measured risk of recidivism. Assessment would generally then give greatest priority to assessing this risk of recidivism and the measurement of those constructs selected for intervention.

Some historical and sociodemographic variables are clearly related to offenders' status as sex offenders or to sex offenders' risk of recidivism but will mostly be

addressed in the later section on risk assessment because their unchangeable nature means they are unlikely to form the basis of clinical psychological intervention (e.g., past sex offending history, past history of other criminal conduct, having experienced abuse, neglect, or abandonment as a child, etc.). Similarly, recent research has strongly suggested that various neurophysiological and neuroanatomical measures are related to sexual offending against children, but again, it would currently be unclear what could be done about such problems in clinical intervention, and therefore, they would be expected to have lower priority in typical clinical assessment with sex offenders. Conversely, other psychological constructs, especially intellectual ability as one example, do not distinguish sex offenders and are very unlikely to be a target for intervention but would usually be assessed because they are probably relevant to program assignment and design. Acute symptoms of psychosis might be another rarer example in this category.

What are the psychological characteristics that distinguish sex offenders from other men or are related to recidivism among sex offenders? There is no doubt that the two most important domains are sexual preferences and life-course-persistent antisociality; these are discussed at greater length in the next two sections. Several other variables are clearly relevant, especially the age and sex of victims and the victim–offender relationship. Sex offenders who target males and adults represent greater than average risk, while those who have targeted only children in their own families represent lower than average risk. Thus, thorough investigation of such details pertaining to all victims, involving collateral sources is probably essential. Although not specific to sex offending, it is probable that assessment for substance abuse problems is relevant to clinical services with all sex offenders. Evidence supports efforts by forensic psychologists supervising sex offenders under conditional release to assess fluctuations in hostility, anger, and noncompliance, and to monitor (via direct observation and collateral reports) access to potential victims.

Much more equivocal evidence relates to the assessment of several other domains including attitudes, beliefs, and symptoms. In this category are assessments of specific justifications and excuses for sexually coercive behavior (e.g., endorsing the idea that victims deserve or enjoy being sexually assaulted) or attitudes supporting generally exploitative and selfish conduct. Similarly, lack of social competence and clinically significant depression have been reported to be relevant in some studies but disconfirmed by others. Polygraphy has been recommended as an adjunct assessment for sex offenders, but evidence to support its use is sparse and equivocal. Some clinical constructs can, on the basis of available evidence, be ruled out as worthwhile assessment concerns among sex offenders. Based on available evidence, self-esteem, anxiety, specific victim empathy, loneliness, denial, and insight would be difficult to support as targets for assessment and intervention among sex offenders. Novel theories about the causes of sex offending might imply new approaches to intervention that would, in turn, imply new ways of assessing these constructs or the measurement of psychological characteristics not yet entertained among sex offenders. Such novel interventions could be ethically attempted as a test of such novel explanations but only in the context of a rigorous outcome evaluation. Comprehensive discussions of the psychometric and other properties of the many formal assessment tools for these characteristics as well as advice about sources of information and interviewing tactics are provided in the recommended readings and related entries.

Assessment of Sexual Preferences

The only assessment shown to reliably distinguish sex offenders from other men (especially offenders without sex offenses) and also to predict recidivism among adjudicated sex offenders is phallometrically evaluated sexual preferences. Phallometry is the measurement of penile tumescence in response to controlled stimuli. Research clearly shows that, on average, men who have sexually assaulted prepubescent children exhibit relatively greater erectile responses to stimuli that sexually depict children (versus adult stimuli) compared with men without such sexual histories. Such "pedophilic" sexual test results are also related to the likelihood of recidivism among such sex offenders. Similarly, several meta-analyses have demonstrated that men who have committed coercive sexual assaults against women exhibit relatively greater erectile response to depictions of rape and violence (vs. depictions of consensual sex) compared with men without such sexual histories, and there is evidence that such test results are related to recidivism. Although the theoretical meaning of these robust and reliable relationships pertaining to sexual preferences has not been fully settled, it seems inescapable that the scientific explanation of sex offending will at least partly depend on them.

There are no fully standardized phallometric assessment packages, but several procedural, instrumentation, and interpretation issues have been worked out. Most important, validity is enhanced with relative measurement—for example, comparing each man's greatest mean response to a prepubescent child category with his response to his largest adult category or comparing his largest response to a violent category with his mean response to consenting sex. Responses to a single stimulus or category are much less informative. Validity is also improved by having multiple stimuli in each category, using ipsative scoring to remove between-subject variability in overall response magnitude, using stimuli in which the brutality of the deviant sexual behavior is emphasized, and including sexually neutral stimuli to aid in the detection of attempts at dissimulation. Validated stimuli include still pictures and aural stories; video materials have not been shown to be valid in forensic assessment. Other strategies to detect and foil faking have also been reported. Phallometry is probably more specific than sensitive—a deviant result is more informative than a nondeviant profile. There have been reports of low test-retest reliability for phallometric testing, but the well-established discriminate and predictive validity implies that test-retest is probably an inappropriate index of reliability for this form of assessment. Comprehensive discussions of the best ways to conduct phallometric measurement for research and clinical evaluation have been provided elsewhere (see the Further Readings and related entries).

Obviously, phallometric assessment requires specialized techniques and might not be suitable in all forensic practice with sex offenders. In nonclinical populations, self-reported sexual preferences can be valid, but self-report is unlikely to be trusted in most forensic work. There is evidence that a simple count of relevant characteristics of past sexual victims (a male victim, multiple child victims, a victim under the age of 12, and an unrelated victim) is closely related to pedophilic sexual preferences. Of course, by definition, such a measure, though a valid index of preferences, cannot detect changes in such interests. Also, there is no parallel index for sexual interest in coercive and violent sex directed toward adults.

Researchers have attempted a variety of other cognitive-behavioral techniques to detect deviant sexual interests. For example, a picture of a naked person in a man's most sexually preferred category causes maximal interference (compared with pictures from nonpreferred categories) in some speeded concurrent mental tasks. As another example, when men can control how long they look at pictures, covertly recorded viewing times have also been found to be related to sexual preferences—for example, heterosexual men spend the most time viewing pictures of adult women. Some of these latter measures are still in the development stages, while others have been marketed to forensic clinicians. However, the empirical basis to support their ability to detect sexual interest in children is scant in the context of forensic assessment, and there are no data to support their use to detect interest in the sexual coercion of adults or in the assessment of sex offenders' risk of recidivism.

Risk Assessment Among Sex Offenders

Many forensic psychologists take on the task of assessing the risk of recidivism represented by sex offenders. Much of this work occurs under the aegis of statutes mandating preventative detention for "sexually violent persons," "dangerous offenders," or "dangerous people with severe personality disorders" in various English-speaking jurisdictions. This form of assessment is frequently undertaken outside any other clinical responsibility to provide psychological interventions or services. In this context, the assessment of recidivism risk among sex offenders has been controversial, with some commentators saying that psychologists' participation is unethical. This condemnation has been partly based on the inaccurate assertion that sex offenders are generally very unlikely to recidivate. In fact, the best long-term data indicate that approximately 40% of adult male sex offenders released from secure custody will be apprehended for subsequent sexually violent crime. Most forensic psychologists would probably espouse the view that assessing the risk of sex offenders can be ethically conducted as long as psychologists' practice is in accord with the best available empirical evidence. In that regard, and in contrast with the scientifically less fruitful field of sex offender therapy, there has been clear recent progress in empirically based risk assessment among sex offenders.

This recent empirical progress has occurred in the context of a much larger literature on assessment, in general establishing (beyond any responsible debate) the superiority of actuarial assessment over informal, intuitive, subjective methods. The latter approach occurs when the assessor makes the decision about what information to select, combine, and process. In contrast, the

actuarial method eliminates human judgment about the selection of relevant assessment information and about how to combine that information—assessment results depend only on empirically measured relationships between data and the outcome of interest. Several well-validated and replicated actuarial assessments have been developed for use among adjudicated adult sex offenders—men in custody for sexual assaults against women or children. Consequently, psychologists could not defend failing to use such a tool in assessing the risk of recidivism for such sex offenders.

A few psychologists have claimed that instructing clinicians to insert an idiosyncratically determined amount of unaided clinical intuition at the end of the assessment process confers an advantage in predictive accuracy, and they have promulgated nonactuarial schemes for doing so with sex offenders. This promulgation was accompanied by no evidence in support of these claims. The few studies that have since examined these claims among sex offenders show little evidence overall of an improvement due to the addition of unaided clinical intuition, which rather appears to worsen assessment reliability when applied to offenders in general. Because of the overwhelming evidence against the use of unaided clinical intuition in general and the ready availability of actuarial systems for sex offenders, use of such schemes could not be recommended. It should be noted that no actuarial systems have been developed specifically for juvenile sex offenders. However, some of the samples on which the existing actuarial assessments are based included sex offenders who were adolescents at the time of their referral offenses, even though they were adults when followed up. Structured schemes for juvenile sex offenders have been published with some evidence of predictive accuracy.

The available actuarial assessments for sex offender recidivism are moderately to highly intercorrelated, meaning that they do not rank order sex offenders identically. Some of this apparent disagreement is due to differences in the operational definition of recidivism. That is, some researchers have designed actuarial systems to predict only those recidivistic sex offenses labeled as such on police rap sheets. This research strategy is known to miss some officially detected sex offenses, especially the most serious ones (i.e., those involving homicide). It is clear, nevertheless, that the predictive accuracy of all these actuarial systems derives principally from two domains. The first of these was discussed earlier—deviant sexual preferences assessed phallometrically or as indicated by aspects of sex offenders' offending history (prior sex offenses, multiple sexual victim categories, unrelated and stranger victims, clinical evidence of other paraphilias, etc.).

The second and even more powerfully predictive domain is life-course-persistent antisociality. The best single measure of this for forensic practice is the Hare Psychopathy Checklist (PCL–R), which is an item in some of the available actuarial systems for sex offenders. Other characteristics (some of which are also evaluated in the PCL–R) indicative of this crucial forensic risk assessment construct are a history of criminal and violent offending; parents' criminality and substance abuse; early age of onset for sexually aggressive, violent, and criminal conduct; aggression and antisocial behavior as a child; disrupted and disturbed family background; failure on prior conditional release; substance abuse; antisocial friends and associates; poor employment stability; hostile and selfish attitudes; quitting or being ejected from sex offender treatment; and meeting the diagnostic criteria for conduct disorder or antisocial personality disorder. Considerable clinical skill is required to assess some of these, but the manner of the assessment and the combination of individual measures should be determined entirely by an actuarial system. Note that these constructs are somewhat redundant, so that an optimal actuarial system need only capture some of them. Instructions on the scoring and interpretation of actuarial risk assessment systems for sex offenders are provided in the recommended readings or suggested related entries.

Conclusions

The sex offenders of greatest forensic concern are those men who sexually assault children and those who engage in sexually coercive offenses against women. There is no accepted scientific explanation of these criminal behaviors and no useful data on specifically what personal or circumstantial changes caused by intervention affect the likelihood of such behavior. As a result, forensic clinicians can rely on very little empirical data to guide assessment when designing treatment. Nevertheless, sufficient evidence exists to show that greatest priority in clinical assessment should be given to comprehensive information on the age, sex, and relationship to all victims; substance abuse; access to potential victims; deviant sexual preferences; and various measures indicative of life-course-persistent antisociality (especially the Hare PCL–R). Available actuarial

systems are the most appropriate way to select and combine individual assessment findings to make decisions about sex offenders' risk of recidivism.

Sex Offender Civil Commitment

During the past 15 years, sex offender civil commitment laws have emerged that require some dangerous sex offenders to receive involuntary treatment in a secure facility after their criminal incarceration. Following an assessment of risk, sex offenders who are considered likely to re-offend are entitled to a trial with a judge or jury, where evidence of their dangerousness is presented. If they are found to meet statutory criteria for civil commitment, they are detained, with yearly evaluations, until they are considered no longer dangerous to the community. Sexually violent predator (SVP) statutes seek to prevent the recurrence of sexual victimization by incapacitating potentially violent and dangerous sexual offenders. Though it is well established that a proportion of sex offenders are dangerous and likely to re-offend, the effectiveness of civil commitment in preventing re-offense has yet to be empirically determined.

Background

The first of these new SVP commitment laws was passed in Washington state in 1990 after a convicted sex offender who was recently released from prison abducted and brutally sodomized a 7-year-old boy. Washington's Community Protection Act of 1990 increased penalties for sex crimes and created stricter supervision for sexual offenders. It also contained the "Sexually Violent Predator Statute," the nation's first law allowing for the civil commitment of SVPs following their criminal incarceration.

Currently, 17 states have passed sex offender civil commitment statutes (Arizona, California, Florida, Illinois, Iowa, Kansas, Massachusetts, Minnesota, Missouri, New Jersey, North Dakota, Pennsylvania, South Carolina, Texas, Virginia, Washington, and Wisconsin). Texas allows outpatient commitment only, where offenders are treated in an intensely supervised program in the community, and Pennsylvania allows commitment only for juvenile sex offenders who are likely to go on to commit sex crimes as adults.

Sex Offender Civil Commitment Criteria

The constitutionality of sex offender civil commitment was upheld by the U.S. Supreme Court in the 1997 ruling in *Kansas v. Hendricks.* The Court ruled that states must require that a sex offender exhibit both a mental abnormality and a likelihood to re-offend in order to be committed. A second Supreme Court ruling, in the 2002 case of *Kansas v. Crane,* established that some degree of inability for a sex offender to control his or her behavior must also exist. This concept is called "volitional impairment" and implies "difficulty if not impossibility" in controlling one's behavior.

To meet criteria to be civilly committed, a convicted sex offender must display (a) a mental abnormality or personality disorder predisposing him to commit sexually violent offenses and (b) a likelihood of future sexual violence. The mental abnormality is generally

diagnosed as a disorder listed in the *Diagnostic and Statistical Manual of Mental Disorders,* fourth edition, text revision (*DSM-IV-TR*). Because the disorder must "predispose" the offender to sexually re-offend, sex offenders who meet criteria typically display a paraphilia (e.g., pedophilia) or personality disorder (e.g., antisocial personality). The likelihood of future sexual violence is usually determined through the use of actuarial risk assessment instruments, which estimate the probability of re-offense by using a formula incorporating risk factors statistically associated with recidivism. The most commonly used instrument for this purpose is the STATIC–99.

Determination of whether a sex offender meets criteria for civil commitment is a multistep process. In most states, the first step is a record review of sex offenders due to be released from prison. The screening identifies inmates who display a multitude of risk factors for sexual re-offense. These individuals are then referred for a more thorough face-to-face evaluation and risk assessment by a psychologist or psychiatrist. If the individual is found to meet the statutory criteria for commitment, a trial is held in which the state and the offender present evidence that is heard by a judge or a jury. Most states use a legal threshold of "more likely than not" to quantify re-offense risk. If found by the trier of fact to be an SVP, the individual is confined indefinitely for treatment in a secure facility, usually with yearly evaluations, until his risk to re-offend has diminished sufficiently to be returned to the community.

States differ somewhat in their implementation of sex offender civil commitment criteria. For instance, California requires that individuals evaluated for commitment have two or more sex crime arrests, while Florida allows commitment proceedings for any offender with a past conviction for a sexual crime—even if the sexual crime is not the offense for which the inmate is currently incarcerated. Other states, such as Illinois, Pennsylvania, Washington, and Wisconsin, allow juveniles to be considered for commitment. New Jersey requires a "pattern of repetitive, compulsive behavior" and Minnesota requires a "psychopathic personality," while other states require a history of "predatory behavior." Though the vast majority of civilly committed sex offenders are male, most states allow females to be considered for commitment.

Nationally, it is estimated that approximately 5% to 12% of sex offender inmates are referred for civil commitment proceedings. Child molesters account for the majority of individuals committed under SVP statutes (approximately 51% to 76%), with the remainder being rapists. Most state laws appear to exclude from their definitions those offenders who have had only incestuous victims or those who have not had physical contact with a victim (e.g., exhibitionists).

Mad or Bad?

The goals of sex offender civil commitment statutes have sparked controversy and debate among mental health professionals and legal scholars. Although the civil commitment of SVPs implies rehabilitation, some argue that punishment, isolation, and incapacitation are its primary purposes. Others question whether sex offender civil commitment criteria conform to the traditional concept of mental illness as established by courts to justify psychiatric civil commitment. The "mad or bad?" debate argues that if sex offenders are truly mentally ill, they should have qualified for an insanity defense or traditional psychiatric commitment in lieu of criminal sentencing. If sex offenders are responsible moral agents and were, therefore, appropriately tried and punished through the criminal justice system, then culpability and mental or volitional impairment should be mutually exclusive.

Sex Offender Community Notification (Megan's Laws)

Sexual assault is a serious social problem of great concern. The U.S. Department of Health and Human Services estimates that approximately 100,000 cases

of child sexual abuse are substantiated each year. In addition, according to the 2005 National Crime Victimization survey, there were nearly 192,000 victims of rape, attempted rape, or sexual assault. In an effort to prevent sex crimes, community notification laws (also known as Megan's Laws) allow information about convicted sex offenders to be disseminated to the public. Distribution of this information occurs through various means, including Internet registries, community meetings, media announcements, and distribution of flyers. The goal of community notification is to prevent sexual assault by warning potential victims that a convicted sex offender lives in the vicinity. Thus far, research has been limited in demonstrating the effectiveness of community notification in preventing sex crimes, in general, or sex offense recidivism more specifically. There is research to suggest that the collateral consequences of notification interfere with community reintegration for many sex offenders.

History and Development of Notification Laws

The Jacob Wetterling Crimes Against Children and Sexually Violent Offender Registration Act was passed by the U.S. Congress in 1994. This federal statute mandated that all 50 states pass laws requiring sex offenders to report their addresses to local law enforcement agencies. The police are required to maintain a registry of convicted sex offenders' current whereabouts. The law was named for an 11-year-old Minnesota boy who was abducted and remains missing to this day. The purpose of sex offender registration is to assist law enforcement agencies to track where sex offenders are located and to aid in the investigation of sex crimes by identifying a potential pool of suspects.

In 1996, the Wetterling Act was amended by adding a provision allowing states to distribute sex offender registry information to the public. This amendment is often referred to as Megan's Law, and was named for a 7-year-old New Jersey child who was murdered by a previously convicted sex offender. The purpose of community notification is to provide information about sex offenders living in the community so that parents and other concerned citizens can take steps to protect themselves.

About half of the states classify sex offenders according to risk levels and use more aggressive notification to warn of sex offenders who are assessed to pose the greatest threat to public safety. Other states use broad community notification, publishing information about all sex offenders without an assessment of risk. Community notification methods vary in each state, but media releases, door-to-door warnings, flyers, community meetings, and Internet access are the most common strategies.

The Wetterling Act was again modified under the PROTECT amendment in 2003 to require states to post information about convicted sex offenders on public Internet registries. The Adam Walsh Act, passed in July 2006, increased the amount of information that can be disclosed on public registries, created more stringent registration requirements for offenders, and provided further guidelines for the development and activation of a national sex offender registry by which information from various states can by integrated into one database.

Sex offender registration and community notification initially began as distinct social policies with different goals. Registration was intended to be a tool to assist law enforcement agents to track sexual criminals and apprehend potential suspects. The purpose of notification was to increase public awareness and provide communities with information to help them avoid contact with sex offenders and thus prevent victimization. Over the past decade, however, Internet-based registries have led registration and notification to become nearly interchangeable.

The constitutionality of community notification statutes has been challenged. In 2003, the U.S. Supreme Court ruled that a Connecticut statute was constitutional, allowing sex offenders to be placed on an Internet registry without first holding a hearing to determine their danger to the community. In an Alaska case, the U.S. Supreme Court ruled that registration and notification of sex offenders whose crimes were committed prior to the passage of the laws did not constitute ex post facto punishment.

Effectiveness of Community Notification

Community notification is a very popular social policy. However, little research has investigated the success of registration and community notification in reducing sex crime rates or preventing recidivism. One of the first studies of community notification was conducted by the Washington State Institute for Public Policy in 1995. No significant differences were found in the rearrest rates of high-risk sex offenders who were subject to community notification and those who were not. In Iowa, no significant differences were found in the

reconviction rates of registered and unregistered sex offenders. About 3% of registered sex offenders were convicted of a new sex crime after 4 years, compared with the 3.5% recidivism rate of unregistered sex offenders. In Wisconsin, it was found that high-risk sex offenders exposed to aggressive community notification actually had higher rates of recidivism (19%) than those about whom little information was publicly disclosed (12%). A multistate study examining the effect of registration and notification laws in 10 states found no systematic reduction in sex crime rates after registration and notification laws were passed. A more recent study conducted in Washington state did find substantial reductions in sex offense recidivism. However, it is unclear whether the changes can be directly attributed to notification or whether they are a result of more stringent sentencing and probation policies.

Unintended Consequences of Community Notification

Community notification laws have been criticized as creating unforeseen negative consequences for victims, communities, and offenders. For instance, victims may be discouraged from reporting sexual abuse, especially if the perpetrator is a family member, because of the potential for the crime to be publicly disclosed. Broad notification that disseminates information about all sex offenders regardless of risk may dilute the community's ability to determine who is truly dangerous if all offenders are similarly publicized. Finally, the high costs of community notification may take away funding from victims' treatment, protective services, and foster care programs.

A small but growing body of research has begun to investigate the experiences of sex offenders and the impact of notification on their community reintegration. Research in several states has found that community notification often leads to harassment, vigilantism, and migration for sex offenders. Sex offenders report that public disclosure interferes with their ability to secure housing and employment. Some scholars have speculated that public registries may not be advantageous to a goal of preventing recidivism, because they create obstacles to successful community reentry by limiting education and employment opportunities and by creating social environments marked by shame, loneliness, instability, and psychosocial stress.

The practical, legal, and social consequences of crime may be more severe for sex offenders than for other criminals. Obstacles such as maintaining housing and employment, social stigma, a sense of vulnerability, and relationship problems are recognized as factors that can facilitate recidivism. Criminological research has indicated that employment, positive social bonds, and stability increase the likelihood of successful reintegration for criminal offenders. Social policies that ostracize and disrupt the stability of sex offenders may increase their risk and, therefore, may not be in the best interests of public safety. States that assess risk and reserve more aggressive notification for high-risk offenders may minimize potential unintended negative consequences for lower-risk offenders, with little probability of compromising community safety.

Although each state prohibits harassment or violence toward registered sex offenders, community notification has been known to lead to vigilantism. Though extreme vigilante violence appears to be relatively rare, cases of arson, shootings, hangings, and severe property damage have been documented. Murders of registered sex offenders by vigilantes have occurred in Maine, Washington, and New Hampshire. A survey of sex offenders in Florida found that one third reported being threatened or harassed, 21% suffered property damage, and 5% said they had been physically assaulted or injured. In Kentucky, 16% of male sex offenders and 15% of female sex offenders said that they had been physically attacked. In Indiana and Connecticut, about 20% of sex offenders reported that they had experienced harassment, threats, or property damage, and 10% had been assaulted.

The accuracy of Internet registries has been criticized by the media. The validity of registries can affect their ability to protect the public. In 2003, the *Boston Herald* reported that the whereabouts of 49% of registered sex offenders in Massachusetts were unknown. Research regarding the accuracy of Kentucky's sex offender registry revealed that about one quarter of registered addresses might be incorrect. Newspapers in Florida reported that nearly half of the sex offenders on the state's Internet registry were incarcerated, dead, or missing.

Recidivism, Risk Assessment, and Community Notification Practices

Community notification is a very popular social policy, largely because of the belief that sex offenders have alarmingly high recidivism rates. In actuality, sex offense recidivism is lower than commonly believed. Studies by the U.S. Department of Justice and the Canadian governments suggest that 5% to 14% of sex

offenders are re-arrested for new sex crimes within a 3- to 6-year follow-up period. Longer follow-up studies have found that after 15 years, the vast majority (about three quarters) of convicted sex offenders had *not* been re-arrested for a new sex crime. All these studies involved very large sample sizes ranging from about 4,700 to 29,000 subjects.

There is also a widespread belief that sex offenders do not respond to psychological therapies. Early studies were unable to demonstrate that treatment reduced recidivism. However, more recent research indicates that contemporary cognitive-behavioral sex offender treatment can reduce recidivism by about 40%. A more recent meta-analysis found that 10% of sex offenders who received treatment were re-arrested for new sex crimes, while 17% of untreated sex offenders re-offended. This was a statistically significant difference. A recent experimental design was unable to detect general differences in recidivism between treated and untreated groups but did find that those sex offenders who successfully completed the treatment goals were re-arrested at significantly lower rates than those who did not.

Though most sex offenders do not re-offend sexually over time, and many do not meet the criteria for a paraphilia disorder as defined by the *Diagnostic and Statistical Manual of Mental Disorders,* fourth edition (*DSM-IV*), some subgroups of sex offenders are dangerous and likely to re-offend. Research consistently suggests that pedophiles who molest boys are at highest risk to re-offend and have the largest number of victims. Rapists of adult women are also among those sex offenders most likely to re-offend, and they are also more likely than other types of sex offenders to use weapons and physically injure their victims. Incestuous offenders consistently have the lowest recidivism rates. At the same time, research has found that many sex offenders have committed more sex crimes than those for which they have been arrested. So, official recidivism rates are likely to underestimate true offense rates. Also, some sex offenders abuse multiple types of victims (i.e., adults and children, or both boys and girls), and official documents may not fully reflect an offender's patterns and risk factors.

Those challenges notwithstanding, great progress has been made in the ability to assess risk for future sexual violence and estimate the likelihood that a sex offender will commit a new sex crime in the future. Researchers have identified factors statistically associated with recidivism and have combined those factors into risk assessment instruments. In general, the more risk factors a person displays, the more likely he or she is to re-offend. Risk factors most highly correlated with sex offense recidivism include sexual attraction to children, sexual deviance in general, previous arrests and charges for both sexual and nonsexual offenses, male victims, extrafamilial victims, stranger victims, variety of offending behavior, intimacy deficits, noncontact offenses, and age under 25.

Some states use this knowledge of risk factors to assess the likelihood of recidivism and classify sex offenders into categories (i.e., high, low, and moderate risk) for community notification purposes. States that use risk assessment often provide a different amount of information to the public depending on the danger an offender poses to the community. For example, high-risk offenders (for instance, a child molester who victimized multiple prepubescent boys in a cub scout troop) might have their address, photo, and information about their crimes displayed on a public Internet registry, while lower-risk offenders might be subjected to less aggressive community notification. Using risk classification systems benefits states in several ways. They are a more efficient use of resources because more aggressive notification procedures are reserved only for higher-risk individuals. They also allow the public to better identify who poses the most severe threat to women and children in the community. Broad notification policies, on the other hand, weaken citizens' ability to tell who is truly dangerous, use vast resources to warn communities about sex offenders who may pose very little risk, and can interfere with successful community reentry.

Recent federal policies (i.e., the 2006 Adam Walsh Act) have enhanced registration and notification requirements, so it is likely that community notification will become more inclusive. There is a need for continued research to investigate the effectiveness of community notification in preventing sexual assault.

Sex Offender Needs Assessment Rating (SONAR)

Now primarily of historical interest, the Sex Offender Needs Assessment Rating (SONAR) was the first focused attempt to assess change in sexual offenders based on dynamic risk factors. Dynamic risk factors are personal skill deficits, predilections, and learned behaviors correlated with sexual recidivism that can be changed through a process of "effortful intervention" (i.e., treatment or supervision). It was theorized that if such intervention reduced these risk-relevant factors, there would be a concomitant reduction in the likelihood that the offender would recidivate with another sexual crime. The SONAR demonstrated adequate internal consistency and a moderate ability to differentiate sexual recidivists from nonrecidivists (r = .43; ROC [receiver operating characteristic] area of .74).

As the 1990s drew to a close, the profession was making ever increasing use of actuarial risk assessments for sexual and violent offenders. The debate about the utility of such measures and their ability to reliably rank offenders according to risk of re-offense had, for the most part, been decided in favor of actuarial assessment. General acceptance of actuarial assessment grew as a number of tools (Violence Risk Appraisal Guide [VRAG], Sex Offender Risk Appraisal Guide [SORAG], Rapid Risk Assessment for Sexual Offense Recidivism [RRASOR], Minnesota Sex Offender Screening Tool–Revised [MnSOST–R], STATIC–99) gained acceptance in the courts and were used in most jurisdictions. However, those assessing risk in actual sexual offenders had no reliable technology for assessing change in risk status subsequent to treatment or other intervention. Actuarial measures, listed above, are based almost totally on the assessment of historical, nonchangeable (static) factors that are insensitive to clinical change. There had been previous attempts to measure dynamic or "changeable" factors, most notably in Don Andrews and Jim Bonta's LSI–R; but prior to SONAR, there were no focused attempts to delineate changeable risk factors for individual types of crimes such as sexual crimes or violent crimes.

Using a group of 409 sexual offenders on community supervision, the SONAR authors assessed by both file review and interview of the supervising community parole or probation officer the antecedents of sexual recidivism in a group of Canadian sexual offenders from nine Canadian provinces. Half of these sexual offenders had sexually recidivated while on community supervision, and half had not sexually recidivated while on community supervision. The sample was also roughly divided into equal numbers of incest offenders, child molesters, and rapists. Offenders were matched on offense history, type of index victim, and jurisdiction; nonrecidivists had an average of 24 months of supervision in the community, while recidivists had, on the whole, re-offended within 15 months. The interview and the file review sought data on 128 individual items from within 22 risk-relevant domains.

Comparison of these two groups of sexual offenders on this number of risk-relevant factors revealed a subset of those factors that were seen to change for the worse in the recidivistic group during the period of community supervision. Often, deterioration in the assessed areas of functioning preceded a sexual re-offense. These factors were divisible into two categories, each of which had an attending temporal association. Labeled *Stable* factors, the following five risk-relevant factors—intimacy deficits, social influences, antisocial attitudes, sexual self-regulation, and general self-regulation—seemed to be amenable to clinical intervention or treatment but on an intermediate term. These behavioral influences were seen as more "stable" in the personality and requiring sustained effort to change. The other four factors seemed to change on a much faster basis and to be a reaction to rapidly changing environmental stresses, conditions, or events. Labeled *Acute* risk factors, substance abuse, negative mood, anger/hostility, and opportunities for victim access were seen as transient conditions that would only last hours or days. As such, these factors were seen as more strongly related to predicting the arrival of imminent re-offense. Statistical analysis provided a scale, showing moderate predictive accuracy, that was able to assess ongoing changes in risk in sexual offenders.

An important limitation of the study flows from this data having been collected retrospectively, with everyone involved knowing, a priori, the recidivism/nonrecidivism status of the offender. In addition, the same sample was used both to develop the instrument and to test it. The potential for retrospective recall bias, the retrospective nature of the study, and the lack of cross-validation called urgently for a truly prospective study of dynamic risk factors in sexual offenders.

Karl Hanson and Andrew Harris responded to these shortcomings, splitting the SONAR into two parts, manualizing the assessment, and expanding on the first 5 items of the SONAR to form the STABLE–2000 and the final 4 items of the SONAR to form the ACUTE–2000. The STABLE–2000 and ACUTE–2000 were subsequently tested in a truly prospective study using more than 1,000 sexual offenders on community supervision. Both tests showed predictive ability above that available to static assessment alone. That study led to the development of two new tests with even better predictive validity: the STABLE–2007 and the ACUTE–2007. These two measures have demonstrated predictive validity beyond that available to static assessment alone and beyond that of the SONAR and the STABLE–2000/ACUTE–2000 packages. The authors do not support or recommend the use of the SONAR but recommend the STABLE–2007 and ACUTE–2007, both available from the authors, for assessing dynamic changes in risk in sexual offenders.

Sex Offender Recidivism

Sex offender recidivism refers to the commission of a subsequent offense by a sex offender on release. The base rates of sexual offending have been found to range anywhere from 4% to 71% across studies. Some research findings suggest that the risk of re-offending may differ according to the sex offender typology. Furthermore, there is some research that suggests that there are various static and dynamic risk variables that can increase the likelihood of re-offense. However, there has been a considerable amount of debate in the literature about how sex offender recidivism should be operationalized. These debates center on the definition of a subsequent re-offense, how to handle unreported crimes, and the duration of the follow-up period.

Sex Offender Recidivism

Although there have been numerous individual studies assessing recidivism rates of sex offenders, Hanson and his colleagues have conducted two seminal meta-analyses examining recidivism rates of sex offenders. In studying sex offender recidivism, meta-analyses are superior to individual studies as they can statistically combine results from several studies, thus increasing the generalizability of the findings.

Hanson and Bussière conducted a meta-analysis of 61 recidivism studies, which provided information on 28,972 sexual offenders. They found that, on average, the sexual recidivism rate was 13.4% after between 4 and 5 years. When they examined sexual recidivism by the type of sex offender, they found a recidivism rate of 18.9% for rapists and 12.7% for child molesters. When they examined recidivism rates for nonsexual violent recidivism, they found an overall recidivism rate of 12.2%, with child molesters re-offending at a rate of 9.9% and rapists at 22.1%. Finally, when they defined re-offending as any re-offense (sexual, violent nonsexual, or nonviolent nonsexual), Hanson and Bussière found an overall recidivism rate of 36.3%, with 36.9% for child molesters and 46.2% for rapists.

In 2005, Hanson and Bourgnon conducted another meta-analysis of 82 recidivism studies providing information on 29,450 sex offenders over an average of 5 to 6 years postrelease. This time they found an average sexual offense rate of 13.7%, a violent nonsexual re-offense rate of 14.3%, and a general (including sexual, violent nonsexual, or nonviolent nonsexual) re-offense rate of 36.2%.

Factors to Consider in Defining Sex Offender Recidivism

Factors such as the definition of recidivism, unreported sex crimes, and the length of follow-up can have an impact on the determination of recidivism rates.

The definition of what constitutes sexual recidivism is a hotly contested topic. While almost all researchers agree that recidivism should be defined as a subsequent offense, the nature of the re-offending has been contested. In some studies, recidivism is defined as a subsequent charge or arrest, while other studies specify that the subsequent charges or arrests must result in a conviction. Furthermore, some researchers argue that among sex offenders, recidivism should refer only to new sexually based crimes. However, other researchers define recidivism as any subsequent crime, regardless of its nature. Finally, some studies define recidivism as re-incarceration.

These differences in the operational definition of recidivism have serious implications when considering the prevalence of sex offender recidivism. For example, studies in which subsequent arrests were used as the criterion would result in higher recidivism rates because being arrested or charged with a crime does not always result in conviction. Operationalizing recidivism as subsequent re-incarceration makes the definition more narrow thus decreasing recidivism rates. However, some researchers would argue that sex offender recidivism should encompass reconviction only for sexually based crimes and not crimes that are nonsexual in nature. Finally, using subsequent re-incarceration as the criterion could also erroneously inflate recidivism statistics as many sex offenders have long periods of parole following the completion of their sentence, and they could be re-incarcerated for technical parole violations such as drinking alcohol or failing to meet with their parole officer. Therefore, it is very important when examining rates of sexual recidivism to determine how the researchers have operationalized recidivism.

Another issue to consider when examining rates of sexual recidivism is the number of sex crimes that go unreported or undetected. For example, it is estimated that only 32% (or 1 in 3) of sex crimes against individuals older than 12 are reported to the police. Polygraph studies of convicted sex offenders found that sex offenders had committed significantly more sexual offenses than they were charged or convicted of and that, on average, sex offenders had been committing crimes for 16 years before being caught. Furthermore, even if an offender is charged with a sex crime, it may be harder to prove, so they may plead to a lesser nonsex crime.

Finally, when conceptualizing sex offender recidivism, it is also important to examine the length of the follow-up period. While recidivism may be considered to be a lifelong occurrence, many studies use discrete periods of 5 or 10 years postrelease, while some studies have followed sex offenders for up to 25 years. However, the duration of postincarceration follow-up could also influence recidivism rates as it is inevitable that the longer the follow-up period, the more likely it is that a sex offender will re-offend.

Static and Dynamic Predictors of Sex Offender Recidivism

Factors predicting risk for recidivism among sex offenders can be separated into static and dynamic risk variables. Static risk variables are risk factors that are unchangeable, such as age or ethnicity, while dynamic risk variables are factors that are amenable to change with treatment, such as anger.

In their 1998 meta-analysis, Hanson and Bussière found several static variables that were related to sex offender recidivism. They categorized them into four broad domains encompassing criminal lifestyle, psychological maladjustment, sexual deviance, and treatment motivation. Of those general categories, they found that the strongest predictor of sexual recidivism was deviant sexual interest. Specifically, they found that offenders who had sexual interest in boys and those who had any other sort of deviant interest were more likely to re-offend sexually. Additionally, they found that offenders who were young (under the age of 25) and single (never having been in a long-term relationship) were more likely to re-offend. The risk for recidivism was also increased if the sex offender had a prior sexual offense, had victimized strangers, had an extrafamilial victim, started offending at an early age, had male victims, and had engaged in diverse sexual crimes. Finally, they found that offenders who had failed to complete treatment or those who were exhibitionists were more likely to have committed another sexual offense. These findings were used as the basis for the development of the STATIC–99, an actuarial risk assessment tool used to assess the risk for future sex offender recidivism.

In a subsequent meta-analysis of 82 recidivism studies, Hanson and Morton-Bourgnon found that sexual deviancy and antisocial orientation (composed of antisocial personality disorder, psychopathy, antisocial

traits, and a history of rule violation) were the best predictors of sexual recidivism.

Few studies have focused on dynamic factors related to recidivism. In their meta-analysis, Hanson and Morton-Bourgnon found several dynamic factors that were related to sexual recidivism, including sexual preoccupation and general self-regulation deficits. However, it should be noted that they found no relationship between factors that have been commonly assumed to be related to sexual re-offending and subsequent sexual recidivism, such as psychological distress, denial of sex crimes, victim empathy, and motivation for treatment.

Hanson and Harris conducted another study looking specifically at dynamic factors related to sexual recidivism. They examined sexual re-offending in a sample of 400 sex offenders for a period of 5 years following release. The researchers found that sex offenders who had committed new sex crimes were more likely to be unemployed, have substance use disorders, engage in deviant sexual activities, demonstrate low levels of remorse for the victim, and report a more chaotic and antisocial lifestyle than those who had not committed new sexual offenses.

Sex Offender Typologies and Recidivism

Some evidence suggests that the risk of sexual recidivism may differ by sex offender typology (category of sex offender). One study found that rates of sexual re-offense for incest offenders (those who offend against family members) ranged between 4% and 10%; rates of sexual recidivism for child molesters with female victims ranged between 10% and 29%; rates of sexual recidivism for child molesters with male victims ranged between 13% and 40%; rates of sexual recidivism for rapists ranged between 7% and 35%; and rates of sexual recidivism for exhibitionists (those who expose themselves in public) ranged between 41% and 71%.

Numerous studies have examined recidivism rates for rapists. Rates of sexual recidivism for rapists have ranged between 11% and 28% over 5 years. Researchers have postulated that these discrepancies in recidivism rates could be attributed to the fact that there are different types of rapists (such as those who are mentally disordered vs. those on probation) and the differential length of follow-up.

When studying recidivism rates among sex offenders who commit sexual offenses against children, researchers generally separate the sex offenders into three categories: (1) those who molest girls; (2) those who molest boys; and (3) those who molest family members (incest offenders). Generally, it has been found that child molesters who have same-sex victims are at risk of higher rates of re-offending than those who offend against children of a different sex. A study of mentally disordered child molesters who offended against boys found a recidivism rate of 30% over 5 years, compared with a 25% recidivism rate for child molesters who offended against girls and a recidivism rate of 6% for incest offenders. However, other studies have found no differences between recidivism rates for child molesters with male or female victims.

It should be noted that there have been some contradictory findings regarding sex offender typologies and risk for re-offending in the recidivism literature. Many studies, including Hanson and Bussière's meta-analysis, have found higher sexual recidivism rates for rapists compared with child molesters, with incest offenders having the lowest rate of re-offense of all categories of sex offenders. However, one study found that over a 25-year period, child molesters had a higher rate of re-offense than rapists (52% vs. 39%). In this study, recidivism was recorded as any new re-arrest that could inflate recidivism statistics. Another factor that should be considered when examining sex offender typologies and recidivism is that there is some evidence that sex offenders may not be stable in their victim choice, and there could be crossover (e.g., a child molester with male victims could offend against a female) in victim age and gender.

Sex Offender Risk Appraisal Guide (SORAG)

The Sex Offender Risk Appraisal Guide (SORAG) is a 14-item actuarial scale designed to predict violent, including hands-on, sexual recidivism among men who have committed at least one previous hands-on sexual offense.

The items on the scale are the following:

1. Lived with both biological parents until age 16
2. Elementary school maladjustment
3. History of alcohol problems
4. Never been married at time of index offense
5. Criminal history score for nonviolent offenses
6. Criminal history score for violent offenses
7. Number of convictions for previous sexual offenses
8. History of sexual offenses only against girls below 14 years of age (negatively scored)
9. Failure on prior conditional release
10. Age at index offense (negatively scored)
11. Diagnosis of any personality disorder
12. Diagnosis of schizophrenia (negatively scored)
13. Phallometric test results indicating deviant sexual interests
14. Psychopathy Checklist (Revised) score

Each item is scored and then assigned a weight based on the relationship of that item to violent recidivism in the construction sample; the weights are then summed to obtain a total score. The score yields the percentile rank of the offender as compared with the construction sample and the estimated probability of violent recidivism based on a 7- and a 10-year period of opportunity to re-offend. The items can be scored from complete institutional files or from files and interviews (but note that external corroboration of offender self-report is important).

The initial construction sample used by Rice and Harris in 1997 comprised released child molesters and rapists who had been briefly assessed in a Canadian maximum security psychiatric hospital before transfer to corrections and offenders treated in the psychiatric institution. Outcome data were obtained from a variety of official sources, and criminal charges for violent or hands-on sexual crimes were the primary predicted outcome. Outcome data were collected by individuals blind to offenders' SORAG scores.

The SORAG is closely related to the Violence Risk Appraisal Guide (VRAG), an instrument designed to predict violent recidivism among serious offenders (not exclusively sex offenders), and it contains many of the same items. Accuracy of predicting recidivism is similar in the two instruments among sex offender samples, but the estimated probability of recidivism is higher for the SORAG (reflecting the fact that sex offender samples have higher violent and sexual recidivism rates than unselected samples).

Follow-up studies of sex offenders using the SORAG have examined variations in sample (correctional releasees, forensic psychiatric hospital releasees, offenders supervised in the community), jurisdiction (Canada, United States, Europe), and variations in average follow-up time. The SORAG has been robust to these variations, and SORAG scores are consistently linearly related to an offender's probability of violent recidivism. In replication studies, the accuracy of prediction as indexed by the area under the curve of the receiver operating characteristic or, equivalently, the common language effect size is about .75, meaning that 75% of randomly selected violent recidivists have higher SORAG scores than randomly chosen men who are not violent recidivists. Accuracy is degraded when recidivism is measured poorly, when data are missing for SORAG variables, and when the length of the follow-up period varies widely across offenders. In 2003, Harris and colleagues found that, under optimum conditions, an accuracy of about .85 can be achieved. Scores on the SORAG correlate with both the speed and severity of recidivistic offenses.

The SORAG has also been used to estimate the likelihood that an offender will recidivate with a specifically sexual offense, although these offenses are a subset of the violent offenses that the SORAG was designed to predict. In 2006, Rice, Harris, Lang, and Cormier found,

using actual behaviors involved in offending, that sexually motivated offenses are frequently labeled as violent (nonsexual) offenses in official police "rap sheet" records: For example, sexually motivated homicides were recorded as homicides. It was argued on the basis of these data that a tabulation of violent offenses corresponds more closely to the number of sexually motivated offenses than a tabulation of officially recorded sexual offenses. The prediction of violent offenses rather than sexual offenses appears on the basis of this work to better capture the intent of legislation dealing with the risk sex offenders present to society.

Descriptions of the items, scoring criteria, the method of derivation of the scale, and the results obtained with it in follow-up studies can be found in the 2006 book *Violent Offenders: Appraising and Managing Risk* (see Further Readings below). Updated information on the SORAG is maintained at www.mhcp-research.com/ragpage.htm.

Sex Offender Treatment

Given the rising concern about the problem of sexual violence, increased attention has been given to the evaluation of existing treatment interventions and the exploration of new treatment models that aim to prevent or reduce future sexual violence. Because the rehabilitation of sex offenders might curb future sex offending and thus enhance overall public safety, the importance of research that examines the efficacy of sex offender treatment interventions cannot be overstated. To date, the majority of research has been directed at examining whether suitable treatment interventions exist, whether sex offenders are amenable to such treatment, and most important, whether such treatments "work."

Numerous treatment models have been used to rehabilitate sex offenders. While some forms of treatment were developed specifically for use with sex offender populations, most have been adopted from the larger class of treatment techniques developed for use with wide-ranging clinical populations. Moreover, while some of these sex-offender-specific treatment approaches have received at least modest empirical support, others have only limited support or have not yet been subject to any form of systematic evaluation. Indeed, because of the many difficulties in evaluating treatment outcome with this population, considerable work remains with regard to understanding what works for whom and whether this treatment success actually translates into reductions in recidivism.

Treatment Models

The cognitive-behavioral therapy (CBT) approach, which involves an integration of both cognitive and behavioral therapy techniques, has been adapted for use with sexual offenders. The central tenet of CBT is essentially that our thoughts, behaviors, and emotions interact with one another in a cyclical manner, such that changing thoughts about a situation or event might change subsequent behaviors that ultimately change our emotions. Purely cognitive interventions used with sex offenders include cognitive restructuring, which is aimed at challenging rationalizations, minimizations, or other offense-supportive beliefs involved in the initiation or maintenance of sexual offending behavior. For example, a therapist using a cognitive restructuring technique might challenge an offender's minimization that "no one was hurt," by having the offender examine the veracity of such belief.

Behavioral approaches have also been used in the treatment of aberrant sexual behaviors. Behavioral therapies are premised on the idea that deviancy is a learned behavior that can be unlearned. Thus, inappropriate (or deviant) sexual desire might be reduced if associated with negative consequences, while appropriate sexual

desire might be enhanced if paired with rewards or other positive consequences. Masturbatory satiation, for example, involves having an offender masturbate to deviant fantasies for an extended amount of time through the sexual refractory (i.e., postorgasm) period, with the idea that this unrewarded and perhaps aversive masturbatory experience will reduce or eliminate deviant arousal. Although procedures might vary, verbal satiation similarly aims to reduce deviant interest by having an offender repeat aloud deviant sexual fantasies during the postorgasm period. Aversion techniques similarly aim to reduce the deviant sexual response by pairing aversive stimuli (such as mild electric shock or foul odors) with deviant arousal. When the arousal is followed by a shock or other aversive stimuli, the resulting behavior (deviant arousal) is, again, expected to decrease. Just as behavioral strategies might be used to reduce deviant arousal, they are also used to reinforce or enhance "normal" sexual arousal. While there is some limited support for the use of these pure behavioral techniques, these approaches have generally fallen out of favor in preference of more integrative and comprehensive treatment interventions.

Cognitive-behavioral interventions thus combine elements of the pure cognitive and pure behavioral camps. Covert sensitization, for example, relies on the behavioral technique of pairing negative stimuli with deviant arousal, but instead of a physical stimulus uses an imaginal (or cognitive) negative stimulus. In a typical use of the technique, an offender might be asked to masturbate to a deviant fantasy, pairing with that fantasized act an imagined unpleasant negative consequence. For example, the offender might fantasize about committing a deviant offense but then interrupt that fantasy with a vivid and highly personalized negative consequence, such as the offender's wife discovering the act and reporting it to the police.

Relapse prevention (RP), a model adopted from the substance abuse literature, aims to help sex offenders identify the emotional and situational precursors to sex offending. In emphasizing the importance of cognitive states and decisional processes, RP often employs a CBT framework. RP operates under the assumption that by identifying the emotional or contextual states that precede offending, an offender can intervene in the cycle and prevent a recidivistic sexual offense from occurring. RP might typically incorporate a wide range of treatment components, such as anger management, social skills training, empathy enhancement, or the aforementioned CBT techniques. Indeed, the general focus is on giving offenders the skills to manage their offending behavior once they return to the community. Thus, offenders learn their "offense cycles" and are taught how to use this knowledge to recognize high-risk situations, with the aim of preventing relapse (or re-offense). Although RP is one of the most widely used models for treating sexual offenders, there have been mixed findings with regard to its utility in reducing sexual recidivism. More research is needed to examine whether there is sufficient empirical support for the continued use of this model.

Because evidence suggests that the suppression of sexual drive will reduce sexual offending, there is general support for a combined psychological and pharmacological approach to treating sexual deviancy. Such pharmacological treatment (at times referred to as "chemical castration") includes anti-androgens and hormonal agents that work to reduce sex drive, sexual arousal, and/or sexual fantasizing. These drug interventions, which diminish or alter testosterone levels, have been shown to be related to reduced rates of re-offending. Additionally, there has been support for the use of selective serotonin reuptake inhibitors (SSRIs) in reducing deviant sexual behavior. The class of SSRIs, which have generally been used in treating obsessive-compulsive tendencies, may have specific utility in reducing the intrusive or obsessive sexual thoughts often associated with sexual offending.

Finally, some mention of surgical castration deserves mention. Although rarely used, surgical castration involves the removal of the testes, which has the effect of reducing circulating levels of testosterone and thereby diminishing sexual drive. While some have expressed concern regarding the ethical merits of this form of intervention, surgical castration has been associated with reductions in sexual recidivism.

Risk, Need, and Responsivity

Some have maintained that treatment should be based on the principles of risk, need, and responsivity. Risk refers to the notion that treatment should be matched to the risk level (typically assessed through actuarially derived risk assessment tools such as the STATIC–99/STATIC–2002 or RRASOR) of the offender, with higher-intensity treatment services reserved for the highest risk offenders. The need principle distinguishes between criminogenic and noncriminogenic needs, with criminogenic needs referring to those factors that directly relate to recidivism, that is,

those factors that have a direct relevance to reducing re-offending. Noncriminogenic factors include treatment needs that do not directly relate to re-offense risk but that may improve the overall adjustment or quality of life of the offender, which may thereby indirectly reduce sexual recidivism. Finally, the responsivity principle maintains that treatment interventions should be delivered in a way that is compatible with the ability, treatment readiness, or cognitive capacity of the offender. The strength of this risk, need, and responsivity model lies in its consideration of the heterogeneity of sexual offending. Indeed, this model advocates for the use of differential treatment strategies for offenders with varied criminogenic and noncriminogenic needs, thus renouncing a "one size fits all" approach to treatment.

Does Treatment Work?

Despite the early notion in the sex offender academic community that "nothing works," recent research has been more optimistic with regard to the value of sex offender treatment. Indeed, recent evidence seems to suggest that there are small but important differences in the recidivism rates of offenders who do and do not receive sex-offender-specific treatment interventions. Indeed, researchers have found that sex offender treatment is effective in reducing both sexual and general recidivism.

A meta-analysis of sexual offender treatment outcome studies found that, on average, sex offenders who had completed treatment had a 12.3% sex offense recidivism rate compared with the 16.8% recidivism rate seen for offenders who did not complete treatment. In support of more recent (typically CBT) interventions, those who completed treatment demonstrated a sexual recidivism rate of 9.9%, while those who did not receive one of these newer interventions had a 17.4% recidivism rate. While more research may shed light on the particular strategies that work for particular types of offenders, one can reasonably conclude from the existing research that treatment does indeed reduce recidivism. Given this research evidence, some contend that effective treatment programs should target offenders who are deemed to be at highest risk to recidivate and, moreover, that best practices suggest that such programs must target the offender's criminogenic needs and be based on a combined CBT and psychopharmacological model.

Critics charge, however, that the overwhelming majority of sex offender treatment studies use too weak a methodology to draw any firm conclusions. As a result of practical constraints and the many impediments to implementing sound research methodologies in criminal justice or treatment settings, treatment outcome studies typically fail to use rigorous research designs that use, for example, random assignment or lengthy follow-up periods. Sex offenders typically cannot be randomly assigned to treatment or no-treatment groups in these settings. Instead, researchers tend to examine differences between treated and untreated groups where assignment has been based on need, resulting in a selection bias. That is, offenders selected for treatment are typically different in important respects—either being viewed as amenable to treatment or more dangerous and, therefore, more in need of treatment. Thus, the groups being compared differ in risk level or motivation or other important respects that affect conclusions. Unfortunately, researchers are seldom able to use rigorous, tightly controlled designs, because they must do this research in real-world settings that allow for less sophisticated methodologies.

Moreover, there is often divergence with regard to what sort of outcome should be measured. While some studies might consider outcome very narrowly to include only sexual reconvictions, other studies consider outcome much more broadly, including for example, any arrests (even for nonsexual offenses), probation violations, and/or informal reports of re-offense. Some attention has also been given to the measurement of in-treatment change. Indeed, some research has examined pre- and posttreatment scores on dynamic variables related to sexual recidivism. Thus, treatment providers or researchers might focus on changes in attitudes tolerant of sexual offending or intimacy deficits as a function of treatment interventions. More research is needed to establish the direct relationship between these within-treatment gains and actual reductions in recidivism.

In sum, while meta-analytic research has generally supported the value of treatment for sex offenders, the research studies on which these meta-analyses were based have typically employed suboptimal methodological designs. Despite this, the weight of the research does show some support for cognitive-behavioral and psychopharmacological interventions. Thus, while there is room for optimism, especially with regard to certain techniques, firm conclusions about the utility of sex offender treatment await further research.

Sex Offender Typologies

Sex offenders are a heterogeneous group. While there is no standardized system for the taxonomy of sex offenders, they are generally classified into various typologies based on their offense characteristics, motivations for offending, and likelihood of recidivism. Typologies are important in that they capture the characteristics of sex offenders, and they can be useful for treatment intervention and risk assessment. However, it should be noted that these typologies do not always coincide with criminal justice classifications of sex offenders. Sex offenders are generally separated into those that commit contact sex offenses and those that commit noncontact sex offenses. Contact sex offenders include child molesters, incest offenders, and rapists. Noncontact sex offenders include exhibitionists, voyeurs, and frotteurs.

Child Molesters

Child molesters are sex offenders whose victims include minors (under the age of 18). Child molesters can be further categorized by their sexual preferences. Those child molesters who are sexually attracted to children under the age of 13 (i.e., prepubescent children) are referred to as pedophiles, while child molesters whose sexual preference is for teenagers or those between the ages of 13 and 18, are considered hebophiles. However, it should be noted that neither pedophilia nor hebophilia are considered crimes, as they relate only to sexual interest and not to the commission of any sexual act.

Child molesters generally report attraction to children of a certain age that are not related to them. Some child molesters have only male victims, some only female victims, while other child molesters offend against both boys and girls. Child molesters who offend against boys have been found to have higher rates of recidivism.

Child molestation can involve a variety of inappropriate sexual activities and behaviors. These include undressing the child, exposing themselves to the child, masturbating in front of the child, or touching and fondling the child. They could also include more serious sexual offenses, including performing fellatio or cunnilingus on the child or penetrating the child's vagina, mouth, or anus with their fingers, foreign objects, or penis. Physical force, coercion, or threats may be used to compel the child into the sexual act.

To gain access to their victims, child molesters often engage in relationships with the child or with the adult guardians of the child. This is referred to as grooming behavior. The sex offender appears to be very interested in the child's needs to gain the child's affection and loyalty and the guardian's confidence so that the molestation will not be reported. Some child molesters may also use threats to prevent the children from reporting the abuse.

Child molesters often believe that their victims want to be involved in a sexual relationship. When a child responds positively to the grooming behavior, the child molester interprets this as the willing participation of the victim. As a result, the child molester can believe that the molestation is not damaging to the child. This is referred to as a cognitive distortion.

Incest Offenders

Incest offenders are sex offenders who offend against minors (children) who are related to them by blood. Additionally, offenders are also considered incest offenders if they abuse a child that they have quasiparental authority over, such as a stepfather or the boyfriend of the child's mother.

The most common form of incest is sexual contact between a father and daughter or a stepfather and stepdaughter. Perpetration of inappropriate sexual contact may occur only once, but more often, it takes place over several years. It is not uncommon for incest offenders to offend against several children in the same family. Unlike child molesters, the majority of incest offenders have female victims and their victims tend to be older. While they may start offending against a prepubescent child, the offending may continue after the child hits puberty.

Unlike a child molester, the incest offender is generally sexually attracted to adult females. Most incest offenders have had consensual, age-appropriate partners at some point in their lives. While by definition they would be considered pedophiles as they are engaging in sexual acts with a minor, they often view the victim as a surrogate for an age-appropriate partner. Incest offenders often only start abusing children as a way to cope with the stress they are experiencing. Stressors reported by incest offenders include dysfunctional relationships, sexual problems or dissatisfaction, and social isolation. Often alcohol and drugs are involved in the commission of the offense. However, once identified, incest offenders have the lowest rates of recidivism compared with other sex offenders.

Rapists

Rape is generally defined as forced sexual intercourse without consent against adult victims. Rape is a violent crime. Rapists engage in behaviors such as threats, hostility, and physical violence to overpower the victims and force them into sexual activity against their will. Rape does not always result in overt physical injury to the victim. Rapists' primary interests are self-gratification, dominance, and control. Unlike child molesters and incest offenders, rapists generally offend against the same victim only once. Rapists have been found to have high levels of deviant sexual arousal and impulsivity. Additionally, they are more criminalized than child molesters and incest offenders. Rapists who use violence in the perpetration of the rape and who have a history of violent behavior recidivate at higher rates than rapists who do not use physical violence in the commission of the crime.

In 1979, Nicholas Groth identified three different kinds of rapists: anger rapists, power rapists, and sadistic rapists. According to Groth, anger rapists are angry about a variety of issues in their lives and are unable to cope with them in a prosocial manner. While their anger may be directed at women, this is not always the case. Anger rapists tend to use excessive physical and verbal violence in the commission of the rape, thus leaving the victim battered and bruised. In addition, anger rapists may use weapons to hurt their victims. The offenses are generally not planned and are short in duration. The anger rapist tends to choose victims who are perceived to be vulnerable when the rapist becomes angry. It is believed that between 25% and 40% of all rapes are committed by anger rapists.

Groth describes power rapists as offenders who use power and control to dominate their victims. Contrary to anger rapists, power rapists tend to use the threat of violence, rather than violence, to force their victims into submission. While a power rapist may use a weapon in the commission of the rape, the weapon is used primarily to gain compliance from the victim. Victims of power rapists are often not physically harmed during the perpetration of the crime. These rapists seek out women who are both physically and emotionally vulnerable and who will require little force to be dominated. Groth estimates that the majority of all rapists fall into the power rapist category.

The third type of rapist is the sadistic rapist. According to Groth the sadistic rapist derives sexual gratification from the physical and psychological suffering of his or her victim and often engages in ritualized sexual behavior involving degradation and torture of the victim. Activities may range from restraint, beating, and punching, to stabbing, strangulation, torture, and murder. Sadistic rapists frequently have psychiatric difficulties that may have a direct relationship to the offense behavior. Sadistic rapists often continue offending until they are apprehended, and the severity of sadistic acts increases over time. It is estimated that only between 2% and 5% of all rapes are committed by a sadistic rapist. Due to the violent and sadistic nature of their attacks, sadistic rapists often receive long prison sentences.

Exhibitionism

Exhibitionism is the most common form of sexual offending behavior. The exhibitionist is typically a male, and the victim is usually a female. Exhibitionists derive sexual pleasure and arousal from the exposure of their genitals or entire naked body to unsuspecting

strangers. Exhibitionism is considered a paraphilia in the *Diagnostic and Statistical Manual of Mental Disorders,* text revision (*DSM-IV-TR*). On occasion, exhibitionists will masturbate while exposing themselves. While exhibitionism is sometimes considered a humorous topic, it often causes the victims a significant amount of fear and distress. Exhibitionists will rarely seek physical contact with their victims. Generally, they become aroused by the reaction of the victim. In other cases, the exhibitionist may fantasize that the victim becomes sexually aroused following the exposure. Exhibitionists frequently have high rates of recidivism. It is speculated that exhibitionism generally starts by the age of 18; however, very few arrests for exhibitionism are documented in adults over the age of 40.

Voyeurism

Voyeurism is the act of becoming sexually aroused by observing unsuspecting individuals who are naked, in the process of disrobing, or engaging in sexual activity. Voyeurism is considered a paraphilia in the *DSM-IV-TR.* Masturbation usually occurs during or shortly after voyeuristic activities. There is usually no relationship between the voyeur and the victim. Individuals who engage in voyeurism are often referred to as "Peeping Toms." In most cases, the voyeur observes the victim to become sexually aroused and does not desire any contact with the victim. However, on occasion, voyeurs suffer from delusional disorders and thus truly believe themselves to be in a relationship with the victim. In these cases, the voyeur could pose a danger to the victim.

Voyeurism generally begins before the age of 15 years and tends to be a chronic behavior. Many voyeurs have consensual age-appropriate relationships in addition to the voyeuristic behavior. However, in its extreme form, voyeurism constitutes the only form of sexual activity.

Frotteurism

Frotteurism involves touching and rubbing against a nonconsenting person to achieve sexual gratification. Frotteurism is considered a paraphilia in the *DSM-IV-TR.* The behavior usually takes place in crowded areas in which the frotteur can more easily escape arrest or detection (e.g., on busy sidewalks and on crowded trains or buses). Frotteurs are generally male, and their victims are usually female. During the assault, the frotteur generally rubs his genitals against the victim's thighs and buttocks or fondles the victim's genitalia or buttocks with his hands. Some frotteurs will grab a woman's breast as they are walking by. While engaging in frotteurism, the frotteur usually fantasizes that he is in a consensual sexual relationship with the victim. However, the frotteur recognizes that he must escape following the assault to avoid prosecution from the authorities. Some acts of frotteurism are very overt (such as grabbing a breast), while others are less so (rubbing against someone in a crowded shopping mall). Therefore, victims may not always be aware that they have been assaulted. Usually, this paraphilia begins by adolescence. Most frotteurs are between the ages of 15 and 25; however, frotteurism has also been noted in older, shy individuals.

Sexual Harassment

Law and psychology scholars have studied judgments of sexual harassment for several decades and have reported a number of findings that add to and draw from the literatures in social, clinical, and industrial organizational psychology. This entry discusses some of the more important variables such as sex of the observer, complainant, and alleged harasser; organizational structure; and individual differences in observers, complainants, and alleged harassers. While not all psychological studies of sexual harassment follow the contours of

discrimination law, all the scientific literature eventually comes into contact with the law either as a starting point that shapes judgments of responsibility or as an ending point to address issues of discrimination. Therefore, it is helpful to organize the literature around the law.

Federal Sexual Harassment Law

Title VII of the Civil Rights Act of 1964 (amended in 1991) prohibits an employer from discriminating with respect to compensation, terms, conditions, or privileges of employment because of race, color, religion, sex, or national origin. With respect to sex, Title VII prohibits employers from exacting sexual contact in exchange for compensation or advancement (quid pro quo harassment) and from subjecting workers to abusive or hostile working environments because of their gender. In 1986, in *Meritor Savings Bank v. Vinson,* the U.S. Supreme Court upheld a liability finding against an employer who subjected a worker, because of her sex, to unwelcome misconduct that was "sufficiently severe or pervasive to alter the conditions of employment and create an abusive working environment." After the Court heard *Harris v. Forklift Systems, Inc.* in 1993, hostile work environments required subjective (the victim actually experienced abusive conduct) and objective tests (a reasonable person would have found the conduct abusive). More recently, in its 2001 term, the Supreme Court affirmed in *Clark County School District v. Breeden* limits for the "severe or pervasive" test, holding that a comment and a chuckle were insufficient to define a hostile work environment. However, going the other way (increasing Title VII protection), the Court prohibited intragender harassment: "Nothing in Title VII necessarily bars a claim of discrimination 'because of . . . sex' merely because the plaintiff and the defendant (or the person charged with acting on behalf of the defendant) are the same sex" in its holding in *Oncale v. Sundowner Offshore Services, Inc.* (1998). In recent times, the majority of cases brought to the Equal Employment Opportunity Commission and the courts are hostile work environment theories of liability. Psychologists find these cases most interesting to study as well.

To determine whether unwelcome social sexual conduct reaches the threshold of a hostile work environment, most courts adopt the reasonable person test, which according to *Rabidue v. Osceola Refining Co.* (1986) is "the perspective of a reasonable person's reaction to a similar environment under essentially like or similar circumstances." Other courts emphasize differences in how men and women view social sexual conduct. Specifically, in *Ellison v. Brady* (1991), the Ninth Circuit held that "a female plaintiff states a prima facie case of hostile environment when she alleges conduct which a reasonable woman would consider sufficiently severe or pervasive to alter the conditions of employment and create an abusive working environment." In *Fuller v. City of Oakland* (1995), the Ninth Circuit clarified this standard, holding that "whether the workplace is objectively hostile must be determined from the perspective of a reasonable person with the same fundamental characteristics" as those of the plaintiff. After the intragender holding in *Oncale,* the reasonable victim test looks to the background (e.g., gender, race, and age) of the complainant as well as the context of the conduct (e.g., persistence, status, and sexual orientation of the participants). Thus, the reasonable victim standard is a semisubjective test, which is concerned with whether a reasonable person with the same key attributes and in a situation similar to the complainant would find the offensive conduct sufficiently hostile to violate Title VII. While the issue of appropriate legal standard remains open today, after *Harris* there has been movement in most (but not all circuits) toward a more objective reasonable person test.

In *Burlington Northern v. White,* a recent 2006 case defining retaliatory action in hostile work environment sexual harassment, the Court reiterated that there are two types of hostile work environment claims. One type involves a tangible work action (e.g., hiring, firing, promoting, changing work assignments) in which defendants are strictly liable (if their supervisors were responsible for the tangible actions), and the second type creates abusive conditions through other conditions of employment (such as sexual comments, pornography in the work place, unwanted requests for dates). Interestingly, Justice Samuel Alito's dissenting opinion in *Burlington Northern* pointed out confusion about whether the reasonable person is an objective test (ignoring plaintiff attributes) or a subjective test that takes into consideration the complainant's individual characteristics (i.e., age, gender, race, family relations). Justice Alito's opinion in *Burlington* suggests that the issue of objective versus subjective standard may soon become an important concern in this area of jurisprudence. There is need for more work that examines the power of the reasonable victim test to sensitize workers to gender, racial, and sexual orientation differences. Knowledge about how legal standards influence workers' judgments should be of interest to social scientists,

lawyers, legislators, and judges as they grapple with sexual harassment in a multicultural workforce populated with large numbers of members of both sexes.

Psychological Research on Sexual Harassment

Despite a plethora of empirical research efforts, few theories explain the production of sexually harassing conduct or the evaluation of sexual harassment allegations at work. With regard to the production of sexually harassing conduct, Barabara Gutek proposed and successfully tested sex-role spillover theory as one of the earliest models of workplace misconduct resulting from gender-based interactions. Data collected in a telephone survey of Los Angeles workers supported a tendency for male workers to invoke sex-based stereotypes, which sometimes produced inappropriate sexual conduct, especially in male-dominated occupations and work groups. In male-dominated settings, gender became highly salient and activated social stereotypes that were inappropriate guides for workplace conduct. Later tests of the theory have not been as successful. Other researchers presented vignettes of ambiguous incidents and found that participants rated the behaviors more harassing when they occurred in *integrated* or *nontraditional* occupations. Sex-role spillover theory has successfully explained how workers label only some forms of harassment and only with certain stereotypes of women workers. Thus, the literature supports a role for gender distributions (i.e., the ratio of men to women in the workplace) in explaining harassment, but the exact form of that relationship is not at all clear.

Focusing on the situational side of the workplace, Louise Fitzgerald and colleagues theorized that sexual harassment is a function of both gender distribution and the extent to which the organization communicates tolerance of harassment. In one study examining women in a large West Coast utility company, these researchers report that workers who perceived the organizational climate to be tolerant of harassment and who participated in nontraditional gender occupations reported higher levels of harassment, job dissatisfaction, and psychological distress. Data from another organizational survey suggested that women who self-report harassment and those who experience behavior that others find harassing suffer from similar psychological harms.

Relying on traditional social psychological theory, John Pryor and his group posited that sexual harassment is the joint product of situation *and* person variables. In one study, they found that men who scored high on the Likelihood to Sexually Harass Scale (LSH) overestimated the co-occurrence of words *power* and *sex* on a paired-associates memory test. Other studies using subliminal primes found evidence for an automatic power and sex link in high LSH men. In still other research, men high in LSH and men primed with sexist ads, such as those seen on television, asked sexist questions of a female confederate during an ostensible job interview. Together, these studies showed how stimuli commonly encountered by workers can trigger uncontrollable cognitive responses in some men that produce harassing behavior.

Gender Differences

One area in which a great deal of psychological research exists concerns judgment differences between men and women in cases of alleged harassment. With few exceptions, experiments, field studies, and surveys show consistent gender differences in judgments of harassment against women, with women using broader definitions and being more likely to label specific incidents as harassing. To explain the extant gender effects, one group of researchers presented scenarios to evaluators and produced a path analysis in which hostile sexism, observer self-referencing, and complainant credibility explained gender effects in harassment judgments. However, others found gender effects on harassment tolerance and on harassment judgments even after they controlled for hostile sexism.

Despite these findings, some authors have questioned the size and consistency of gender effects, and one meta-analysis of 83 investigations found significant but small effects for gender. Richard Wiener and colleagues suggested that the severity of the unwelcome conduct might explain the seemingly small effects. Researchers using experimental (scenario) methods with undergraduate participants reported that women rated ambiguous conduct more harassing, but perceived severe and benign instances similarly to men, while others surveying workers found gender effects with ambiguous, but not with severe or innocuous cases. A subsequent meta-analysis completed in 2001 took type and severity of harassment into account and found a moderately large overall gender effect (i.e., women found a broader range of behaviors harassing) and even stronger gender effects in studies using moderately severe hostile work environments. Furthermore, when Wiener and colleagues presented evaluators scenarios based on *Ellison v. Brady* and *Rabidue v. Osceola Refining Co.* and two video

reenactments, women found more evidence of legally defined harassment.

With regard to intragender harassment, early work found that male workers experience at least as many potentially sexual harassing behaviors from other men as from women, but reacted less negatively to encounters with women. Furthermore, one study reported that men experience cross-gender social sexual conduct at work as seductive but same-gender behavior as harassing. Expanding on this work, Margaret Stockdale and colleagues showed that male-on-male harassment results, in part, from men's motivation to enforce strict gender role norms on less masculine men. Data from a 1995 Armed Forces survey showed intragender harassment occurred mostly among men who treat other men harshly. That is, these male workers reject other men as too feminine and do not approach them sexually. While others have begun to study intragender harassment, the influence of sexual orientation of men in intragender cases remains largely untested.

Following up on their earlier work, Margaret Stockdale and colleagues presented approach and rejection scenarios in which males experienced unwanted sexual attention from women or other men. In the rejection scenarios only, female as compared with male observers rated higher sexual harassment using their own personal definitions of harassment. These results supported Richard Wiener and colleagues' self-referencing hypothesis that people use themselves as reference points to judge the abusiveness of harassment complaints. Other research using vignette studies found that subjective ratings of how evaluators would perceive the egregious conduct if they were the object of the unwanted behavior explained the effects of observer gender. There is also support in the literature for self-referencing in another scenario study in which women (compared with men) found more evidence of male-on-male harassment.

Unlike the gender literature, a smaller and much less organized literature attests to the importance of cultural factors. Most interestingly, one cross-cultural scenario study involving eight nations conducted by Janet Sigal and colleagues found participants from individualist countries (e.g., the United States and Germany) were less likely than those from collectivist countries (e.g., Taiwan and the Philippines) to find a professor "guilty" of sexually harassing a female student. Other research manipulated a litigant race in a mock jury study of sexual harassment to find jurors (especially White males) more sympathetic to litigants of their own race.

While several studies have examined race and ethnicity as factors that qualify the way in which workers experience sexual and ethnic harassment, the results of those investigations are inconsistent, sometimes supporting conditional findings and sometimes not supporting the effects of these qualifying factors. Louise Fitzgerald and colleagues empirically developed and successfully tested an organizational model to explore the effects of race and ethnicity as explanations for outcomes of sexual harassment. Others have also built empirical models to identify some of the correlates of gender that help explain its effect on harassment judgments. Approaching the problem from a theoretical perspective, Richard Wiener and colleagues offer a social cognitive model of liability decisions to account for gender, race, and sexual orientation effects.

Social Cognitive Model of Sexual Harassment Judgments

The social cognitive model tries to integrate the law and psychology in this area. According to this model, sexual harassment judgments emerge from a two-stage model, with a preliminary judgment based on well-rehearsed and easily retrievable rules of categorization (i.e., sexual assault is harassment, telling dirty jokes is not). The initial judgment compares the complained after conduct to existing standards of behavior. If the conduct exceeds an offensiveness threshold, people perceive it as harassment with little cognitive activity (e.g., quid pro quo harassment, assault, and rape). If the conduct falls below a minimum offensiveness, people perceive it as nonharassing, again with little cognitive activity (e.g., compliments and personal talk). If the conduct falls between these norms, or if the observer is motivated to engage in further efforts, then a second, deliberative process ensues.

The model anticipates a second stage that triggers self-referencing to analyze more carefully the complained after incident(s). Here, the effects of the gender, race, and sexual orientation of the observer, alleged harasser, and complainant come into play. Because of prior experiences in and out of work, men and women, as well as people with different racial/ethnic backgrounds, cultural backgrounds, and sexual orientations, use different standards to judge harassment complaints. Women, ethnic minorities, and homosexuals use a broader definition because their vulnerable positions in society make them more sensitive to the role of social underdogs.

This model and prior research argue that people informed of the law and motivated to do so will test the unwelcomeness, severity, and pervasiveness of the incident(s) to evaluate the accuracy of their initial harassment judgments. Observers use themselves as reference points to determine whether ambiguous social sexual conduct at work is unwelcome, severe, and/or pervasive. If the perceivers think that the unwelcome behavior would have seemed sufficiently pervasive or severe to themselves as targets, then they will conclude that it was harassing for the complainant, to the extent to which they perceive themselves to be similar to the complainant.

Findings from several studies by Richard Wiener and colleagues support the two-stage approach. In one study, 50 male and 50 female workers completed semi-structured interviews with card sorting and rating tasks. The resulting mental concept maps showed that women evaluated male harassers with attributes (i.e., intimidation, arrogance, and popularity) related to the harassers' power and social aptitude, but men evaluated male harassers around the dimensions of responsibility and psychological adjustment attributes (i.e., strength, confidence, and being a bully). Women grouped female victims along dimensions of blameworthiness and assertiveness, relying heavily on security, upward mobility, and gullibility as victim attributes. Men used attributes of attractiveness, shyness, and anger to differentiate between helpless and blameful victims who were sexually aggressive or physically alluring. Statistical analyses (logistic regression) produced accurate gender classification for 86% of the sample using these attributes.

In another study, this research team presented videotapes of equal employment opportunity officers interviewing ostensible workers based on *Rabidue v. Osceola Refining Co.* and *Ellison v. Brady* fact patterns. Two hundred full-time workers applied either the reasonable person or reasonable woman legal standard and rated the complained after conduct on unwelcomeness, severity, pervasiveness, and harassment likelihood. The main effect for gender was significant across cases. However, self-referencing questions that asked respondents how they would have perceived the conduct had they been the complainant completely explained the gender effects. Several additional studies replicated the gender and self-referencing findings. In other results, participants who applied the reasonable person (as opposed to the reasonable woman) standard and those high (as opposed to low) in hostile sexism found less evidence of sexual harassment, regardless of gender or case. Most notably, use of the reasonable person legal standard offset the effects of hostile sexism so that the difference in harassment judgments between high and low hostile sexists disappeared under the reasonable woman standard.

In more recent efforts, this research team presented respondents with two scenarios (videotaped reenactments of *Rabidue v. Osceola Refining Co.* and *Faragher v. City of Boca Raton,* 1998), which depicted independent cross-gender allegations. A female complainant in the first set of allegations displayed aggressive, submissive, mixed, or neutral conduct. Most interestingly, perceptions of complainant aggressiveness in the priming sequence lowered likelihood of harassment judgments in the target sequence. The fact that hostile attitudes toward women triggered by one sequence of behavior influenced harassment judgments of later new facts supports the automatic internal standard component of the social cognitive model. Finally, hostile and benevolent sexism influenced judgments under the reasonable person but not under the reasonable woman standard. Current efforts are under way to examine the implications of the two-stage model for judgments that men and women make when males accuse other males of harassment in multicultural workplace scenarios. These efforts are looking more closely at the effects of ethnicity and sexual orientation as precursors to sexual harassment and other forms of discrimination in the workplace, schools, and housing markets. The extension of the social cognitive model of discrimination in these settings is important in our increasingly multicultural work, education, and living environments.

Sexual Harassment, Jury Evaluation of

Research examining juror decisions in sexual harassment has generally found a relationship between juror gender and liability decisions, in that women are more likely than men to consider sociosexual behavior sexual harassment. This relationship is mediated by several variables, including attitudes of hostile sexism, juror self-referencing, juror ratings of the credibility of the plaintiff, and the story constructed by the juror. Using a "reasonable woman" standard as opposed to a "reasonable person" standard has not been successful in attenuating the gender gap in decision making in sexual harassment cases. However, some research suggests that expert testimony addressing these issues may help jurors make better decisions. Expert testimony addressing the "abuse excuse" has been suggested by some experts as a defense strategy, but researchers have demonstrated that this defense is not only flawed but also ineffective with jurors. Some research suggests that jurors may need an expert to testify about the harms experienced by targets of sexual harassment because they underestimated those harms. In addition, researchers have begun to examine how jurors award damages in sexual harassment cases, and a preliminary study has demonstrated that they award compensatory damages incorrectly but are correct in their allocation of punitive damages.

Sexual harassment in the workplace is a serious legal problem that has only gained attention in the legal arena in the past few decades. There are two types of sexual harassment that are actionable in the U.S. legal arena: (1) quid pro quo sexual harassment, that is, behavior in which an employee directly threatens a subordinate employee with a sexual request that the subordinate must comply with to maintain employment, and (2) sexual harassment caused by a hostile work environment (HWE), that is, unwelcome behavior from any employee that is gender-based and that is severe and pervasive enough to negatively affect the victim's working environment. Research investigating juror decisions in sexual harassment cases has focused on how jurors perceive different types of sexual harassment and has examined several different factors that affect jurors' decisions in sexual harassment cases (e.g., juror gender, the legal standard used, the use of expert testimony). Researchers have also begun to examine how jurors award damages in sexual harassment cases.

Gender Effects on Juror Decisions in Sexual Harassment Cases

Research on jurors' decisions in sexual harassment cases has consistently demonstrated that women are more likely than men to perceive more types of sociosexual behavior in the workplace as sexually harassing. This effect has been consistent across several levels of ecological validity (e.g., participants acting as jurors, participants judging workplace scenarios), types of stimuli (e.g., written summaries of workplace situations, videotaped trials), and participant types (e.g., students, community members) and has been confirmed by two meta-analyses. In addition, researchers have found that the magnitude of the gender difference is moderated by the type of harassment perceived. Specifically, men and women make similar judgments about cases of clear-cut sexual harassment (e.g., quid pro quo, sexual coercion), but women are more likely than men to make judgments in favor of the plaintiff in cases in which the behavior is more ambiguous (e.g., HWE sexual harassment).

Mediating Variables in the Relationship Between Gender and Verdict

Researchers have also examined mediating variables in the relationship between gender and verdict in sexual harassment cases. Several studies have shown a mediating effect of juror self-referencing (i.e., jurors imagining how they would have acted or what they would have done in the same situation) on the relationship between juror gender and verdict. In these studies, women were

more likely than men to self-reference and, therefore, were more likely to find for the plaintiff. Research expanding on this relationship found that attitudes of hostile sexism mediated the relationship between gender and self-referencing, in that men were more likely than women to hold attitudes of hostile sexism, and therefore, men were less likely to self-reference than women. In addition, those jurors who were higher in self-referencing (typically women) also rated the plaintiff's credibility higher than those who were low in self-referencing; those who rated the plaintiff's credibility higher were more likely than those who rated the plaintiff's credibility lower to render a judgment in favor of the plaintiff.

Further research replicated and extended this model to show that the content of expert testimony may affect jurors' tendencies to self-reference. In this study, self-referencing was a significant mediator for jurors who heard traditional forms of expert testimony but not a significant mediator for jurors who heard expert testimony from a traditional plaintiff expert and a defense expert who included information about the plaintiff's history of childhood sexual abuse (CSA) as a possible cause of the harassment. Thus, jurors were most able to relate to the plaintiff who had no history of CSA rather than to the plaintiff with a history of CSA and, therefore, only self-referenced in those conditions with no claims of prior CSA.

Other researchers used the story model for juror decision making as a basis for explaining jurors' decisions in sexual harassment cases and accounting for the gender difference in juror decisions. These researchers showed that the story endorsed by the jurors (either proplaintiff or prodefense) mediated the relationship between juror gender and juror decisions. Women were more likely to endorse a proplaintiff story than men (who were more likely to endorse a prodefense story), and therefore, women were more likely than men to render a verdict for the plaintiff.

The Effect of Legal Standard on Juror Decisions

To find an employer liable for HWE sexual harassment, jurors are instructed that not only must the plaintiff show that she experienced discrimination based on gender, but she must also show that the behavior must have been so severe and pervasive that a reasonable person would believe that the conditions of employment were altered or that the working environment was hostile. This reasonable person standard is reflective of the unique nature of sexual harassment compared with most other tort claims—namely, that it involves a subjective component. Because of the gender differences in perceptions of sexual harassments, some courts have adopted a "reasonable woman" standard instead of the reasonable person standard traditionally used in sexual harassment cases.

The thought behind using a reasonable woman standard is that men and women differ in their perceptions of sexual harassment, so the decision maker should adopt the perspective of the victim (who is most likely a woman) when deciding whether the behavior in question is sexual harassment. Despite these good intentions, researchers have found little to no effect of legal standard on juror decisions in sexual harassment cases. Researchers have conducted several studies, varying in ecological validity and with different types of participants and have found little to no evidence that using a reasonable woman standard as opposed to a reasonable person standard diminishes the gender effect. It is possible that using the reasonable woman standard is ineffective in attenuating the gender gap in juror decisions because jurors may not notice the difference in standard. Scholars have also postulated that jurors may not understand the differences between a "reasonable person" and a "reasonable woman" or may ignore the reasonable woman standard in their decision making.

The Effect of Expert Testimony on Juror Decisions

Experts have suggested that perhaps expert testimony addressing the differences between the reasonable woman and reasonable person standards and/or expert testimony addressing gender differences in juror decision making about what behavior constitutes sexual harassment may help reduce the gender gap in decision making in sexual harassment cases. Some research suggests that this may be a successful strategy. In one study, researchers examined the effect of expert social framework testimony, addressing the effects of gender stereotyping on juror judgments. The expert testimony did not affect women's judgments, but men were more likely to find for the plaintiff in conditions with expert testimony than in conditions without expert testimony. The gender gap was not completely eliminated, but this research shows the potential of expert testimony to aid juror decisions.

In addition to using expert testimony to help jurors make good decisions in sexual harassment trials, some researchers have suggested that experts should examine plaintiffs in sexual harassment cases for evidence of prior sexual abuse (which these experts have suggested may have caused the sexual harassment), termed the *abuse excuse.* Most scholars have rejected this hypothesis, demonstrating that it is based on flawed logic and is fundamentally false according to the empirical literature in the area. In addition to its flawed basis, testimony based on the abuse excuse does not have the expected effect on juror judgments in sexual harassment cases. In one study, jurors were less likely to find in favor of the defense if an expert testified using the abuse excuse argument compared with if the defense expert testified more traditionally (with an opposing expert) or did not testify at all.

Jurors' Common Understanding of the Consequences of Sexual Harassment

Some experts have argued that plaintiffs should claim ordinary or garden variety damages (e.g., sadness, loss of enjoyment) rather than claiming injuries in sexual harassment cases (e.g., Posttraumatic Stress Disorder), so that the plaintiff's mental health does not become a subject of controversy. Claiming an injury could result in a compelled mental health examination by a defense expert. However, claiming garden variety damages assumes that jurors have a general understanding of the harms experienced by targets of sexual harassment. Research comparing jurors' and experts' perceptions of the harms experienced by sexual harassment targets in several different workplace scenarios suggests that jurors consistently underestimate the amount of harm experienced by targets in both sexual harassment scenarios and other stressful workplace situations. Thus, such litigation strategies may be more detrimental than helpful to the plaintiff's case.

Damage Award Decisions

If the defendant is found liable for sexual harassment, victims of sexual harassment may also recover both compensatory damages (designed to restore the victim to the state prior to the injury) and punitive damages (designed to punish the defendant for behavior that was particularly egregious and deter others from acting similarly). Thus, in addition to determining liability, the jury is also given the task of determining damages. Generally, jurors award damages appropriately in civil cases. However, given the difference between the psychological nature of the harm in sexual harassment cases and the physical harm alleged in most other civil cases, there may be a discrepancy in how jurors award damages, and researchers have just begun to investigate juror allocation of damages in sexual harassment cases. In one study, researchers demonstrated that jurors inappropriately awarded compensatory damages in a sexual harassment case, confusing harassment severity with pain and suffering. However, jurors did correctly award punitive damages as a function of the behavior of the organization. In addition, juror gender did not have an effect on damage award amounts, counter to the robust gender effect found in liability decisions.

Sexual Violence Risk–20 (SVR–20)

The Sexual Violence Risk–20 (SVR–20) is a set of structured professional judgment guidelines for conducting sexual violence risk assessments in criminal and civil forensic contexts. The SVR–20 is not a quantitative test that yields norm-referenced or criterion-referenced scores. Rather, it was developed as an aide mémoire to help systematize the risk assessment of individuals who (allegedly) have committed an act of sexual violence. More important, the concept of risk assessed by SVR–20 is not limited to likelihood of a new offense, as is commonly the case in actuarial (i.e., statistically based) tests. Other aspects of risk, such as level of victim harm, victim specificity, frequency, imminence, and likelihood are also addressable by this instrument.

Development

The SVR–20 comprises 20 items or factors considered to be minimally comprehensive in a sexual violence risk assessment. These items were gleaned from a systematic review of the scientific and professional literature in the area of sexual violence, sex offender recidivism, and sexual offender treatment. The guidelines for assessment and treatment of sexual offenders proposed by many different jurisdictions were also examined. The 20 factors selected for inclusion in the SVR–20 are divided into three domains: Psychosocial Adjustment, Sexual Offenses, and Future Plans.

The Psychosocial Adjustment section comprises factors that are primarily historical in nature but also relate to current functioning. These factors include sexual deviation, victimization as a child, psychopathy, major mental illness, substance use problems, suicidal/homicidal ideation, relationship problems, employment problems, past nonsexual violent offenses, past nonviolent offenses, and past supervision failures. Clearly, some of these factors are more stable than others (e.g., past offenses), and some of these factors are more related to current functioning (e.g., substance use problems).

The Sexual Offenses section comprises items that are all related to the person's historical and current sexual offenses. These factors include high-density sex offenses, multiple (types of) sex offenses, physical harm to victim(s) in sex offenses, use of weapons or threats of death in sex offenses, escalation in frequency or severity of sex offenses, extreme minimization or denial of sex offenses, and attitudes that support or condone sex offenses.

The Future Plans section comprises 2 items: lacks realistic plans and negative attitude toward intervention.

The assessor may also include "other considerations" unique to the individual case that are considered to be important to the determination of risk.

Administration

Administration of the SVR–20 begins with a gathering of relevant information. The manual contains recommendations concerning what information to gather and how to gather it. Evaluators then rate the lifetime presence of the 20 standard risk factors as well as any case-specific risk factors identified. A brief definition of each risk factor is included in the manual. Next, evaluators rate recent change in the risk factors to identify whether there has been any increase or decrease over time in the risks associated with each. After rating the presence of individual risk factors, evaluators make an overall judgment of risk that is meant to reflect the level of intervention required to manage risk in the case. For example, people are judged to be "low risk" when evaluators believe they require minimal intervention (e.g., monitoring), "moderate risk" when evaluators believe they require enhanced intervention (e.g., a high-intensity sex offender treatment group, frequent reporting to a probation officer), and "high risk" when evaluators believe the person requires urgent or extreme intervention (e.g., incapacitation, supervised residence, emergency treatment).

Critique

Content Validity. The SVR–20 has been criticized because its items vary greatly in terms of the extent to which they are associated with the probability of recidivistic sexual violence, according to meta-analytic research. For example, factors such as high-density sexual offenses, sexual deviation, and attitudes supportive of offending are reasonably well established as predictors of recidivism in sexual offenders, whereas physical harm to victim(s), extreme minimization or denial, and negative attitude toward treatment are not. But the latter factors were included because they can be very important in

helping professionals to assess aspects of risk other than likelihood (i.e., nature, severity, imminence, frequency) as well as to develop risk management strategies.

Interrater Reliability. Research indicates that judgments regarding the lifetime presence of risk factors and overall risk can be made with good interrater reliability. The interrater reliability of judgments regarding recent change has not been evaluated.

Predictive Validity. Research has provided good support for the use of the SVR–20 in sexual violence risk assessment. Individual studies and meta-analyses have demonstrated that the SVR–20 predicts sexually violent recidivism about as well as, and in some cases better than, commonly used actuarial tests. In studies that compared evaluators' overall judgments of risk with simple linear combinations of risk factors, typically, overall judgments have better predictive validity.

Recommendations

In the authors' experience, most assessors find that the inclusion of a locally normed actuarial risk assessment test alongside the SVR–20 allows for a more comprehensive appraisal of risk, and we support this practice. There is no convergence of opinion as to what is the best practice in this area; however, it is clear to most clinicians that the use of a single instrument is not necessarily the best manner in which to protect the public from future offending and that a more comprehensive and conservative approach is warranted.

Short-Term Assessment of Risk and Treatability (START)

The Short-Term Assessment of Risk and Treatability (START) is a concise clinical guide for the dynamic assessment of short-term (i.e., weeks to months) risk for violence (to self and others) and treatability. START guides the assessor toward an integrated, balanced opinion to evaluate the client's risk across seven domains: violence to others, suicide, self-harm, self-neglect, unauthorized absence, substance use, and risk of being victimized. This structured professional guide is intended to inform clinical interventions and index therapeutic improvements or relapses.

START represents a refinement in the risk assessment field, in that it comprises dynamic variables that are responsive to treatment and management efforts and because each of the 20 items is scored both as a vulnerability and as a strength, from 0 (no evident risk or strength) to 2 (high risk or strength). It also allows for the recording of historical and case-specific factors. Once the 20 items are coded, the assessor completes a summary judgment of risk (low, moderate, or high) on the seven domains (i.e., violence to others, suicide, etc.); other client-specific risks may also be added. A potentially useful aspect of START is that it facilitates the identification, recording, and communication of individually determined "critical" vulnerability items, "key" strengths, and "signature risks" (i.e., early but reliable, unique, and invariant signals of impending relapse and elevation in risk) deemed to be especially relevant to the particular client's functioning, responsivity to treatment, and the likelihood of adverse outcomes.

START is devoted to the systematic assessment of the strengths and vulnerabilities of the individual client with the ultimate goal of enhancing mental health functioning and preventing adverse events. It is intended to assist in day-to-day monitoring, treatment planning, and risk communication. Repeated administrations are a convenient method of tracking changes in mental health status, vulnerabilities, strengths, and violence potential (against self/others). START is anticipated to be an effective means of reducing the cycling of mentally disordered persons through the civil psychiatric and criminal justice systems. It was developed for use with adults with mental, personality, and substance-related disorders, with relevance to correctional, civil, and forensic clients in the community and institutional settings. This new scheme is particularly applicable to

forensic assessments requiring a consideration of violence risk. Where possible, START should be completed by multidisciplinary treatment teams.

Reliability

The interrater reliability of START has been assessed across multiple mental health disciplines. The interrater reliability for three assessor professions using the intraclass correlation coefficient was ICC2 = .87, $p = .001$. The internal consistency (Cronbach's alpha) of the total START scores for diverse raters is also good ($\alpha = .87$) and is relatively consistent across disciplines: psychiatrists ($\alpha = .80$), case managers ($\alpha = .88$), and social workers ($\alpha = .92$). Item homogeneity measured using the mean interitem correlation exceeds .20, generally agreed to reflect a unidimensional scale.

Validity

Content validity of START is demonstrated by the measure emerging from a perceived need by frontline mental health professionals. The items and content reflect the collaboration of a multidisciplinary group of researchers and mental health professionals. It grew out of repeated consultation with multiple treatment teams and reflects a comprehensive consideration of existing risk assessment devices and the literature. Professionals report that the items are easily applied to their clients' circumstances, that START provides a comprehensive risk summary, and that signature risk signs are useful when evaluating their patients. It is also noteworthy that assessors identify more strengths than vulnerabilities in their clients, suggesting that the inclusion of strengths in START is an important advance over previous instruments.

Construct validity has been demonstrated by prospectively examining the relationship between START item scores and Review Board hearing outcomes; results indicate a weak positive relationship. Further evidence of convergent validity has been demonstrated through an examination of START scores by ward security levels in a forensic psychiatric hospital. Findings demonstrated significantly lower total scores among patients in open units than among patients in closed and locked units ($F = 15.64$, $p < .001$). Patients in open units were also found to have lower risk scores and higher strength scores than patients in closed and locked units.

Predictive validity has been examined in prospective research, which demonstrates a moderate association between START total scores and future self-harm, aggression against others, and attempted unauthorized leave, as measured by a modified Overt Aggression Scale (e.g., physical aggression $r_{pb} = .23$, $p < .001$; $AUC = .65$, $CI = .57$-$.72$, $p < .001$). There is substantial overlap between the risk domains evaluated on START. For instance, patients who aggress against others are also significantly more likely to engage in self-harm ($\varphi = .37$). These findings suggest that joint assessment and treatment of these diverse needs is appropriate.

Future Research

Research examining the hierarchical organization and construct validity of START, as well as its utility for monitoring progress and planning for effective interventions, is needed. Prospective studies demonstrating START's capacity to measure change in offenders, forensic, and civil psychiatric patients are required, as are projects to demonstrate whether that change is reflected in decreased future risk. In particular, future research should examine to what extent START's dynamic variables add incremental validity to established static (more or less unchanging) risk markers and for what time frames static versus dynamic variables are most relevant. START research should focus on comparing and contrasting the importance of considering clients' strengths in combination with their vulnerabilities and the relevance of those variables for predicting and reducing risk. START has been translated into several languages, though a pressing need remains for studies demonstrating its utility in English- and non-English-speaking populations and across cultures and settings.

SHOWUPS

Showups are an identification technique in which a single individual, the suspect, is presented in a one-on-one confrontation with the victim or other witness of a crime. The witness is asked to indicate whether the suspect is or is not the perpetrator. Showup identifications are very common and even favored by the police as an investigative procedure. They are considered inherently suggestive because the witness views only one person and the identification requires only the assent of the witness. This entry describes the criteria used to justify the use of showups, compares the outcomes of showups and lineups, and reviews some of the dangers presented by the use of showups.

Although showup identifications may be viewed with disfavor by the courts, they are not per se considered violations of due process if there was an overriding need in light of the totality of circumstances. Showups may be justified when an immediate identification would facilitate an ongoing police investigation, a quick exoneration of the innocent could be made, the identification is completed in close proximity in time and place to the scene of the crime, and the witness's memory is strongest or in its freshest state.

Whether a crime scene showup is unduly suggestive and results in a misidentification is a mixed question of law and fact. If the prosecution can prove by clear and convincing evidence that the showup identification was reliable enough to be probative despite some suggestiveness, the witness's identification is admissible. Any suggestiveness in the process would go to the weight of the identification, not its admissibility. In contrast, if the defense can prove that the showup procedure was unduly and unnecessarily suggestive, the identification evidence based on an unfairly conducted showup would be suppressed.

Judges typically consider the following factors in determining whether pretrial suggestiveness unduly influenced the identification trial testimony of an eyewitness: (a) the opportunity of the witness to view the perpetrator at the time of the crime, (b) the witness's degree of attention at the time of the crime, (c) the accuracy of the witness's prior description of the perpetrator, (d) the level of certainty demonstrated at the time of the identification, and (e) the lapse of time between the crime and the identification procedure. Scientific research has shown, however, that only the opportunity to observe and the length of the retention interval are related to accuracy of identification. Most eyewitness researchers agree that the use of showups in contrast to many-person lineups increases the risk of misidentification, and the evidence in support of this conclusion is generally reliable.

It has been argued that showups, in principle, are less fair than lineups because they fail to protect the innocent suspect. That is, showups cannot distribute the probability of identification of an innocent suspect across lineup fillers, and thus, they increase the risk of an identification error. Also, it is assumed that showup procedures are high-pressure situations in which witnesses are encouraged to make an identification or situations that force witnesses to make an identification. Because a showup involves the single presentation of a suspect, it is hypothesized that a witness's decision is based on an absolute judgment in which the suspect is compared with his or her memory of the perpetrator. Viewing the showup may be similar to viewing the first person in a sequential lineup, where the witness must make an absolute judgment based on individual presentations of the suspect and a number of fillers. In contrast, simultaneously presented lineups of a suspect and fillers involve witnesses making relative judgments of who in the lineup most closely resembles the perpetrator. Sequential lineups have been shown to increase correct rejections of innocent suspects without significantly affecting the accuracy of identification (hit) rate compared with simultaneously presented lineups of a suspect and fillers. Thus, in theory, showups may be beneficial if they increase correct rejections; however, they may be dangerous if they fail to protect an innocent suspect from false identifications. Furthermore, if the procedure is suggestive, there will be increased pressure to choose, thereby generating an increase in both correct and incorrect selections.

Meta-analytic comparisons of showup and lineup presentations reveal that showups generate lower choosing rates than lineups. This suggests that witnesses may be more cautious with their identification in a showup situation. Unlike actual cases where the presence of the guilty suspect cannot be controlled, meta-analysis comparisons indicate that the correct identification (hit) rate is very similar in both conditions (approximately 46%)

when the target is present; correct rejection rates are significantly higher in showups when the target is absent; false identifications in target-absent conditions are about the same (16%); however, errors in target-absent lineups are spread across fillers rather than focused on the innocent suspect in a showup; and false identifications are particularly high in showups when the innocent suspect resembles the perpetrator, for example, when they wear similar clothing.

No significant differences in identification have been found between live and photographic showups. Witnesses are likely to be equally confident in showup identifications in their correct choices of guilty suspects and false selections of innocent suspects. Innocent suspects are at significantly less risk in being falsely identified in lineups than in showups, especially after 2- and 24-hour retention intervals. Comparisons of showups and lineups for voice identifications, either from tape-recordings presented in the field or over the telephone, indicate that lineups are significantly superior to showups in minimizing false identifications of a suspect who sounds very similar to the perpetrator.

Research on the effect of alcohol on identification from showups reveals that blood alcohol level is not related to accuracy of identification (hits) when the guilty suspect is present in the confrontation. However, if an innocent suspect is present, the higher the blood alcohol level, the greater the number of false identifications.

Simultaneous and Sequential Lineup Presentation

Simultaneous and sequential presentation refers to two styles of presenting a police lineup to witnesses of a crime. Research shows that patterns in identification decisions differ between these presentation styles. This entry reviews the components of each presentation method and the advantages and disadvantages of their use and mentions some unresolved issues.

Some crimes involve perpetrators who are strangers to the victims and to eyewitnesses. When a suspect is identified by a police investigator, the investigator may ask the witness to view that suspect in a lineup or photo array containing the suspect and others who are known to be innocent (referred to as *fillers, foils,* or *distracters*). Four outcomes are possible: The witness can select the suspect, select a filler, respond that the suspect is not in the lineup, or give a response of "don't know." Obviously, the accuracy of selections and rejections of suspects depends on whether the suspect is actually guilty.

Simultaneous presentation of a lineup involves showing a witness all the members of a lineup at once. Thus, witnesses decide whether the criminal is present while looking at the entire lineup. Traditionally, police investigators have used simultaneous lineup presentation.

Research suggests that simultaneous presentation encourages witnesses to choose the person in the lineup who looks most like the perpetrator. This comparative approach is referred to as a "relative judgment strategy." If the guilty person is in the lineup, using relative judgments should lead to correct identification. However, evidence can lead police officers to suspect an innocent person. In some portion of these occasions, the innocent suspect will look more like the criminal than other lineup members. This would make it likely that the innocent suspect would be chosen by witnesses using the relative judgment strategy. As evidence mounted that many innocent people were selected from lineups, the use of a relative judgment strategy was posited as a possible explanation for the frequency of such errors. One way to increase the accuracy of eyewitness decisions was to develop a lineup technique that decreased the likelihood that witnesses would use a relative judgment strategy when viewing the lineup.

Sequential presentation of lineups was proposed as a means to elicit fewer false selections than simultaneous lineups by reducing reliance on relative judgments. In its original formulation, sequential presentation involved the following five principles. First, each lineup member is individually shown to the witness. This discourages comparisons among lineup members and encourages witnesses to compare each lineup member only with his or her memory for the criminal (often referred to as an absolute judgment). Second, lineup

members are shown only once, discouraging comparisons between lineup members because individual lineup members cannot be viewed repeatedly. Third, witnesses are unaware of how many lineup members they will be shown. This is designed to prevent witnesses from feeling pressure to choose as they get closer to the end of the lineup. Fourth, witnesses are not permitted to change a decision once it has been made. Finally, the person showing the lineup to the witness should not know which lineup member is the suspect (double-blind testing), so that witnesses are not prompted or cued (intentionally or otherwise) to choose suspects for reasons other than recognizing them.

There is no doubt that the sequential lineup achieved its primary purpose. Sequential lineups consistently led to fewer false selections than simultaneous lineups. The effect of using sequential lineups on correct selections is less clear. Early studies reported little or no decline in correct selection rates. The pattern of large decreases in false-positive choices combined with relatively small losses of correct selections in comparison with simultaneous lineups has been termed the "sequential superiority effect." Later research produced mixed results with regard to correct selections, and meta-analyses support the conclusion that a real but smaller decrease occurs for correct selections than for false selections.

Several issues remain to be resolved concerning simultaneous versus sequential lineup presentation. The reason for the difference in correct selection rates has been attributed to a criterion shift, a multiple-choice selection strategy (relative judgment), and guessing. Both in the laboratory and in the police station, there is variance in the sequential procedure. Not all features of the sequential lineup have been used in every study or in the field. Sometimes witnesses are permitted to see all lineup members before making a decision. For example, in England, the mandated procedure for the police using a sequential lineup is to have witnesses go through the lineup at least twice before making their decisions known. Not all studies mask the size of the lineup. Practices vary in terms of whether the lineup is terminated after a selection is made. To date, there are insufficient data to determine the degree to which these methodological issues are crucial to the size or existence of the full "sequential superiority effect." What is clear is that simultaneous presentation, the traditional technique for presenting a police lineup, is not ideal because of high false-positive selection rates. Sequential lineups lead to dramatically fewer false selections than simultaneous lineups but also lead to somewhat fewer correct selections.

Source Monitoring and Eyewitness Memory

The source monitoring (SM) framework is an evolving set of ideas developed by Marcia Johnson and her collaborators regarding the cognitive processes by which individuals attribute mental events (thoughts, images, feelings) to particular origins (e.g., memory, perception, creativity, etc.). Most of the research motivated by the SM framework has had to do with how people identify the specific sources of mental events that they experience as episodic memories (e.g., how a witness differentiates between memories of a crime vs. memories of a cowitness's descriptions of that crime). "Source" is a multidimensional construct that includes (a) the environmental context in which a past event occurred (e.g., Did *X* happen at work or at home?), (b) an event's temporal context (e.g., Did *X* happen yesterday or last week? Before or after *Y?* In the morning, midday, or evening? Summer or fall?), (c) the agents involved in an event (e.g., Who said *X?*), and (d) the sensory modalities and media through which the event was encountered (e.g., Did I read the book or see the film? Did I see a knife or only hear mention of a knife?). People quite often experience difficulty in remembering the sources of their recollections. Moreover, they sometimes misremember aspects of a

source. As briefly summarized at the end of this entry, such SM failures are thought to play central roles in a variety of false-memory phenomena.

The core assumption underlying the SM framework is that memories do not include abstract tags or labels that identify their origins; rather, accessed memory information is said to be attributed to particular sources of past experience on the basis of its quantitative and qualitative characteristics. That is, the idea is that source is inferred from the content of the accessed memory information.

According to the SM framework, dimensions of source are recognized in the course of recollecting a past event much as dimensions of source are recognized in ongoing perceptual experience. When you answer the phone and your friend Yuji says hello, you immediately recognize the voice as Yuji's even though the sensory signal includes no abstract label designating the speaker's identity. Cognitive processing of the acoustic properties of the signal interacts with memory, cuing a wealth of information that enables you to recognize the speaker. Likewise, when you recollect something Yuji told you yesterday, the memory records of hearing that utterance likely do not include any abstract symbols naming the speaker (unless you happened to reflect about Yuji's name as you listened to the utterance), but they may include information about the sound of his voice and/or his appearance, the semantic content of the statement, information pertaining to the environmental and temporal context, and so on, all of which can serve as bases for identifying the speaker of the remembered utterance as Yuji.

Just as source attributions in ongoing experience are usually made quickly and without conscious reflection, so too are most memory attributions. But just as a bad cell phone connection can make it difficult to identify a friend's voice, weak or incomplete memory records may provide insufficient information to specify various aspects of a memory's source. When this occurs, the rememberer may make conscious, strategic efforts to retrieve more information and/or make deliberative inferences about the source of the recollection.

Even if fairly rich and detailed memory information about a past event is accessed, if two or more sources characteristically give rise to memory records highly similar to those accessed, the rememberer may be uncertain as to which of them gave rise to that recollection or may mistake a memory from one source as a memory from the other. Here again, the analogy to perception holds; if Don's voice is very similar to Yuji's, then you may mistake one for the other on the phone or when recalling their utterances. Such source-similarity effects are not limited to perceptual similarity; SM errors are also likely if the semantic content of a remembered event from source X is characteristic of the semantic content from source Y. If Don and Yuji are both psychologists who study eyewitness memory, for example, that may make it difficult to remember which of them made a particular comment on that topic.

Yet another parallel with perception is that SM judgments can be biased and distorted by expectations. Rememberers may, for example, be biased to attribute a recollection of a politically conservative utterance to a person who (they know) tends to say such things. As another example, people show systematic biases in the attributions they make when they mistakenly recognize a new foil (*foil* refers to an innocent person in a police lineup) on a memory test as an item presented earlier in the experiment. If the acquisition phase of the experiment involved participants reading some words aloud and listening to the experimenter say others, for example, then when participants falsely recognize a new test word as one presented in the study phase, they are likely to attribute that word to the experimenter rather than to themselves. This "it had to be you effect" presumably arises because participants expect memories of words the experimenter had said to be weaker and less detailed than memories of words they themselves had said; because "memories" of new words are likely to be weak and vague, participants tend to attribute them to the source of weaker memories.

SM confusions are thought to be involved in a wide range of memory errors and memory illusions. Early studies by Sir Frederick Bartlett, for example, demonstrated that individuals' knowledge and beliefs can bias and distort their reconstructions of past episodes. Bartlett's ideas were extensively explored and elaborated during the 1970s and 1980s by researchers studying various schema- and script-based memory errors. From an SM perspective, knowledge and beliefs provide a rich source of thoughts and images coming to mind during efforts to recollect past events and hence being mistakenly attributed to memory. Similarly, the last decade yielded a torrent of research on "false memories" for nonstudied words that are highly associated with studied words, and these errors too can be described as SM failures. Additionally, there is a large body of literature demonstrating that misleading suggestions regarding details in a witnessed event can lead

individuals to believe that they remember witnessing things that they really only read or heard about. These ideas are also relevant to the controversy regarding cases in which adults report "recovered memories" of childhood sexual abuse. Cryptomnesia (aka unconscious plagiarism), in contrast, is the opposite sort of SM confusion; here, individuals experience thoughts that arise from episodic memories of another's ideas as newly minted ideas of their own. These and other memory errors provide insight into the often unconscious inferential processes by which people attribute mental events to sources.

Spousal Assault Risk Assessment (SARA)

Given the increasing number of spousal assaulters coming before the justice system, there is a growing need for risk assessment instruments to assist in making appropriate decisions at various stages of the proceedings. The Spousal Assault Risk Assessment (SARA) guide is a manual that presents a set of recommendations for the assessment of spousal assault risk and includes a checklist of risk factors. Adequate reliability and validity for judgments concerning violence risk with adult male offenders has been established; however, there is a continuing need for further research with the SARA to advance knowledge and practice.

The SARA is a structured professional approach to risk assessment that bridges the gap between unstructured clinical judgment and actuarial approaches. Its purpose is to guide and enhance professional judgments about risk, not to provide absolute measures of risk using cutoff scores. It is composed of 20 items that were selected based on a review of empirical research and relevant legal and clinical issues. These items are both static and dynamic in nature. The first 10 items are associated with risk for general violence and include three criminal history factors and 7 factors assessing psychosocial adjustment of the offender. The next 10 items are directly associated with the offender's history of spousal violence and include 7 factors that relate to the offenders past assaultive behavior and 3 items that relate specifically to the current offense. Additional case-specific factors may also be considered.

Each of the 20 items is coded on a 3-point scale (0 = *absent,* 1 = *subthreshold,* 2 = *present*), according to detailed criteria. Each item is then evaluated as to whether it should be considered a critical item, defined as those items which, given the specific circumstances of the case, are considered sufficient on their own to compel the evaluator to conclude that the individual poses an imminent risk of harm. After evaluating the presence of each item, and assessing critical items, the evaluator makes a final risk rating of low, moderate, or high. As indicated above, there is no cutoff score for identifying those individuals considered as low, moderate, or high risk. Rather, these ratings are based on a review of the available information and represent the professional opinion of the evaluator.

Assessment procedures for completing the SARA make use of multiple sources of information and use multiple methods. A thorough assessment will include comprehensive interviews with the offender and victim; standardized measures of physical and emotional abuse and drug and alcohol abuse; a review of collateral records, which should include police reports, victim's statements, and a criminal record; and other psychological tests or procedures. After the SARA is completed using the procedures noted above, overall risk ratings should be communicated in a clear manner with justification accompanying each opinion. Any limitations on the opinions should be included in a report of the findings. Additionally, risk management strategies should be discussed as they relate to the underlying risk factors present for the offender.

Although there is a paucity of research examining the SARA, the available evidence suggests that the SARA has demonstrated adequate reliability and validity for judgments concerning violence risk with adult male offenders. Structural analyses of the risk factors

have yielded moderate levels of internal consistency and item homogeneity. Interrater reliability has been found to be high for judgments regarding the presence of individual risk factors and good for overall summary risk ratings. Research conducted by the instrument's authors showed that SARA ratings yielded good convergent and discriminant validity when compared with other measures of risk for general and violent criminality, and good concurrent validity when scores were compared with another domestic violence instrument.

Evidence of predictive validity with respect to future violence is only modest at present; however, this may be accounted for, in part, by the risk management and violence prevention applications of the instrument. Data concerning the SARA's ability to discriminate between spousal assaulters who re-offend and those who do not re-offend have been mixed. In some samples, SARA total scores have discriminated between recidivistic and nonrecidivistic spousal assaulters but have failed to distinguish between the groups in others. Current evidence supports the predictive validity of several individual items, and the SARA total score has demonstrated a modest, statistically significant improvement in predicting spousal violence over chance. However, some research has shown that the SARA does not add incrementally to the prediction of wife assault recidivism after controlling for alcohol abuse, severe psychological problems, and childhood abuse or neglect. It should be noted that SARA items were selected on the basis of their established association with interpersonal violence in the empirical literature.

Much of the published literature on the SARA has used offender interviews and file review data to make risk judgments, and it is difficult to ascertain the nature and depth of the information included in these ratings. It is possible that the full assessment procedures described earlier and recommended in the SARA manual have not been followed; this could include failure to conduct victim interviews or use standardized measures. As a result, the generalizability of these research studies to general clinical practice may be limited. Future research incorporating these multiple sources of information may prove informative. While prospective research on the SARA is also needed to further advance the use of this instrument in forensic decision making, additional research is required to evaluate the effectiveness of this risk assessment approach in preventing violence.

STABLE–2007 and ACUTE–2007 Instruments

Sexual offenders do great societal damage that causes justifiable public concern. Over the past 10 years, psychology has developed the ability to reliably classify male sexual offenders as low, moderate, and high risk for sexual recidivism (Minnesota Sex Offender Screening Tool–Revised, Risk Matrix–2000, Rapid Risk Assessment for Sexual Offense Recidivism, and STATIC–99) based on historical, static, nonchangeable risk factors. The "static" structure of these tests effectively precludes their ability to measure changes in risk. The STABLE–2007 and the ACUTE–2007 instruments are specialized tools designed to assess and track changes in risk status over time by assessing changeable "dynamic" risk factors. "Stable" dynamic risk factors are personal skill deficits, predilections, and learned behaviors that correlate with sexual recidivism but that can be changed through a process of "effortful intervention" (i.e., treatment or supervision). Should such intervention take place in such a way as to reduce these risk-relevant factors, there would be a concomitant reduction in the likelihood of sexual recidivism. "Acute" dynamic risk factors are highly transient conditions that only last hours or days. These factors are rapidly changing environmental and intrapersonal stresses, conditions, or events that have been shown by previous research to be related to

imminent sexual re-offense. These instruments should be used to inform correctional managers as to how much risk they are managing, inform decisions on levels of community treatment and supervision, and estimate changes in risk status pre- and posttreatment or other interventions.

In the late 1990s, Karl Hanson and Andrew Harris began to investigate the relationship between sexual recidivism and dynamic, changeable, risk factors that correlated with sexual recidivism. This work produced the Sex Offender Needs Assessment Rating (SONAR) assessment, which demonstrated adequate internal consistency and a moderate ability to differentiate sexual recidivists from nonrecidivists. Extending this work, Hanson and Harris broke the SONAR into two parts, creating a stable measure of dynamic risk, STABLE–2000 (16 items), and an acute measure of dynamic risk, ACUTE–2000 (8 items).

To test these new instruments, Hanson and Harris instituted a prospective study, the Dynamic Supervision Project, involving every Canadian province and territory and the states of Alaska and Iowa in a robust test of risk assessment methodologies. A total of 156 parole and probation officers completed repeated three-level (static, stable, and acute) risk assessments on 997 sexual offenders across 16 jurisdictions. All the probation and parole officers scoring risk of re-offense for these community-based sexual offenders were trained in sexual offender risk assessment by attending a 2-day training that focused on scoring actual case examples. Sexual, violent, and "other" recidivism information was gathered from official criminal histories after a median of 41 months of follow-up. Results showed that both STABLE–2000 and ACUTE–2000 added predictive validity above that demonstrated by STATIC–99 alone. The sexual recidivism rate for this widely disparate group of community-based sexual offenders was 7.6% after 3 years (n = 790). Empirically based changes in scoring were recommended, and this research led to the development of two improved dynamic risk measures, the STABLE–2007 and ACUTE–2007 instruments.

STABLE–2007 assesses 13 stable risk factors that have been shown to correlate with sexual recidivism: significant social influences, capacity for relationship stability, emotional identification with children, hostility toward women, general social rejection, lack of concern for others, impulsivity, poor problem-solving skills, negative emotionality, sex drive and preoccupations, sex as coping, deviant sexual preference, and cooperation with supervision. Each of these 13 items are scored on a 3-point scale (0 = *no problem evident,* 1 = *some problem evident,* and 2 = *significant problem evident*) for a total of 26 possible points. Emotional identification with children is not scored for those offenders who do not have a child victim, and the scale is subsequently scored out of 24 points for that group. The offender's STATIC–99 score is then combined with his STABLE–2007 score to produce percentage estimates of sexual recidivism, sexual recidivism plus sexual breaches, violent recidivism, any criminal recidivism (breaches excluded), and any criminal recidivism including breaches at 1, 2, 3, and 4 years.

ACUTE–2007 assesses seven acute, rapidly changing risk factors that correlate with sexual recidivism. In this scale, there are two factors. The first factor predicts sexual and violent re-offending and uses the following four risk factors: victim access, hostility, sexual preoccupation, and rejection of supervision. The second factor predicts general criminal recidivism using the aforementioned four factors plus emotional collapse, collapse of social supports, and substance abuse for a total of seven items. Each of these seven items is scored on a 4-point scale (0 = *no problem evident,* 1 = *some problem evident,* 2 = *significant problem evident,* and IN = *intervene now*) for a total of 14 possible points. An "Intervene Now" score calls for immediate intervention to prevent imminent re-offense or supervision catastrophes such as suicide. Once ACUTE–2007 has been scored, this outcome is combined with the offender's STATIC–99/STABLE–2007 score to estimate an overall risk priority. The offender is nominally classified as a low, moderate, or high risk for sexual and violent recidivism and as a low, moderate, or high risk for general criminal recidivism. Appropriate, empirically based risk ratios can then be applied to determine intervention priority.

The STABLE–2007 and the ACUTE–2007 instruments are easier to score than their predecessors, and combinations of the STATIC–99 and STABLE–2007 instruments produced receiver operating characteristic (ROC) curve values for sexual re-offense commonly in the 0.76 range. When used by "conscientious" officers, the STATIC–99/STABLE–2007 combined scores produced an ROC for sexual re-offense of 0.84 and 0.80 for violent recidivism. STABLE–2007 and ACUTE–2007 assessments were found to add predictive power above and beyond that available to assessments of static risk alone.

This study provides further evidence that trained community supervision officers can reliably score valid

and useful sex offender risk assessments. Results of this nature, even taking into account the need for replication and cross-validation, suggest significant policy and practice implications for the community supervision of sexual offenders. The STABLE–2007 and the ACUTE–2007 instruments have demonstrated predictive validity beyond that of the SONAR and the STABLE–2000/ACUTE–2000 packages. STABLE–2007 and ACUTE 2007 are available free of charge from the authors. The authors no longer support or recommend the use of SONAR, STABLE–2000, or ACUTE–2000 but recommend STABLE–2007 and ACUTE–2007 for assessing dynamic changes in risk for sexual offenders.

Stalking

While the legal definition of stalking varies across jurisdictions, behaviorally, it is generally considered to comprise any of a wide range of repeated acts that either threaten the victim, are intended to cause fear or harm, cause distress, or are otherwise unwanted by the victim. Before the proscription of stalking into criminal law, instances of stalking were sometimes addressed by other criminal laws (such as threats) or by the mental health system. Most of the initial research into stalking was conducted with stalkers who had come into contact with the mental health system. As stalking was criminalized, research extended to include the experiences and feelings of stalking victims as well as the examination of a broader range of stalkers. Additional research has included the manner in which the community perceives stalking behaviors, the factors influencing the occurrence of stalking and stalking violence, and effective strategies for treating stalkers.

Stalking as a Criminal Act

Although stalking may appear to be a new phenomenon, stalking behaviors have existed in some form for hundreds of years. It is only in the last 17 years the behaviors that constitute stalking have been recognized as criminal. Before its criminalization, instances of stalking brought to official attention were often dealt with by mental health professionals. In 1990, the first stalking legislation was instituted in California. A number of cases in which celebrities were stalked, and in some cases killed, by obsessed fans are surmised to have provoked the first law in California. However, stalking came to be recognized as occurring in a range of circumstances, including intimate relationships. Subsequently, all other American states introduced stalking laws (or laws proscribing harassment). Stalking laws have also been instituted in other countries such as England and Australia as well as in many Western European countries. Nevertheless, some stalkers are ultimately managed within the mental health system.

The Mental Health System and Stalking

Before stalking was recognized as criminal, the official response to those who committed stalking was to address their behavior within the mental health system. Some of the first studies of stalking examined stalkers who came into contact with this system. Such research has produced a number of different classifications or typologies of stalkers aimed at guiding approaches for treating the stalker. An example of a classification system used to categorize stalkers and their behaviors is that devised by Paul Mullen and colleagues. Stalkers are classified as rejected (the stalker engages in actions against the victim at the end of a relationship), intimacy seeking (the stalker tries to establish a romantic relationship with the victim), socially incompetent suitors (the stalker tries to establish a connection with the victim but their lack of social skills ultimately leads to their rejection), resentful (the stalker feels the victim has wronged them and wants the victim to feel afraid), and predatory (the stalker revels in the power they have over the person and may sexually assault the victim).

Use of this system may permit predictions regarding the likely course of stalking and may lead to suggestions for treatment. However, most typologies are yet to be empirically supported across a sufficient number of studies; therefore, there is a need for ongoing research in this area.

Definitions of Stalking

When stalking was criminalized, legal definitions of the behaviors that constituted stalking had to be devised. Previously, legal remedies could be used only when the stalker had escalated to violence against the victim, which left many stalking victims without legal recourse. The behaviors and requirements encompassed in legal definitions of stalking vary across jurisdictions. The key elements of the California stalking legislation are that stalking behaviors are engaged in, that a threat is made to the victim, and that the stalker intends to pursue the victim. Other stalking laws only possess one or some of these elements. One common element to definitions of stalking though is that stalking is a course of conduct engaged in over a period of time. This course of conduct is one that is unwanted by the victim. Definitions vary in how often stalking behaviors must be engaged in and which behaviors must be displayed. Also, there are differences in whether the stalker needs to have intended to cause some type of harm to the victim and whether a reasonable person would experience fear or some other type of harm.

Clinical definitions of stalking (or *obsessional harassment,* as is it also known in this field) tend to focus on the repeated nature of the stalking behavior and the fact that it is unwanted and causes distress to the victim. The element of intent to cause fear or harm is generally absent in such definitions. Therefore, there is dissimilarity between some legal and clinical definitions of stalking. This has led to the development of various methods to reduce the problematic behaviors displayed by stalkers. The disparity has also led to research interest in areas such as profiles of stalkers and victims, community perceptions, risk factors, and effectiveness of treatment approaches.

Stalkers

The demographic profile of a stalker is very different from the typical offender profile. Stalkers are generally much older than the typical offender and score higher on intelligence measures than the average offender. Stalkers are usually known to the victim, with a large percentage being current or former partners of the victim. This is in contrast to the often popular perception that victims of stalking are more likely to be pursued by strangers. Stalkers are also overwhelmingly male, which was demonstrated in a survey by Patricia Tjaden and colleagues of 16,000 respondents in the United States, with around 5% of these respondents having been stalked. They reported that approximately 90% of victims in the sample had been stalked by a male.

Victims of Stalking

While men are more likely to be the perpetrators of stalking, women are more likely to be the victims. In the survey by Patricia Tjaden and colleagues, it was found that approximately 80% of the victims were female. This survey also noted that approximately 8% of women had at some stage been stalked, with 2% of men having being stalked during their lifetime. A significant proportion of stalking victims are young adults, with the majority under 30 years.

Other studies conducted with stalking victims have investigated the impact of stalking. These consequences have included psychiatric symptoms, as victims have been known to develop a number of different disorders, such as depression and anxiety, after being stalked. There may also be an impact on victims' social lives, as stalking victims may be less likely to leave home as they are fearful for their safety. Another impact of stalking may be economic, as the victim may have to take time off work to attend medical or psychiatric services or to attend court hearings. Because of injuries suffered during the stalking period, their functioning at work may also be impaired.

Community Perceptions of Stalking

In addition to research with victims, studies have been conducted into how the community perceives stalking. If the community perceives stalking in a manner different from the conception embodied in the legislation, then police resources may be misused, with stalking incidents reported that do not fit legislative requirements. Such a disparity might also lead to genuine victims not having recourse to legal action as they are not considered stalking victims according to legislation. Thus, research into community perceptions of stalking may prove useful for examining the potential effectiveness of legislation and for suggesting changes to stalking laws.

Some vignette research into community perceptions has found that strangers are more likely to be perceived as stalkers, whereas other research has discovered that ex-partners are more likely to be identified as stalkers. Research has demonstrated that community members are more likely to perceive a situation as stalking when the stalker intends to harm or invoke fear in the victim. Also, when stalkers relentlessly engage in behaviors against their victims, the situation is more likely to be construed as stalking. Unless a low level of repetitive behavior is engaged in, intent to harm the victim is not an important requirement for behaviors to be classified as stalking. Some research has also identified that women are more likely to label certain behaviors as stalking and be more frightened than men who judge the same behaviors. The research reveals that men and women may seek legal assistance under different circumstances.

Risk Factors for Stalking

In addition to research on the characteristics of stalkers and stalking victims, another important area of research has been the examination of factors that increase the likelihood that a person will engage in stalking. Stalking is more likely to occur if there has been a previous intimate relationship between the victim and the stalker. Certain psychological and social traits of the stalker can also increase the likelihood that the person will stalk, such as having a personality disorder or possessing few social contacts. Such contacts can have an impact on the cessation of stalking as these social contacts can convey disapproval of the stalker's actions to the stalker, which may influence his future decisions to stalk. It is important for researchers to continue to investigate the factors that influence stalkers to persist in pursuing their victims, as these influencing factors might be altered to reduce the prevalence of stalking.

Violence as an Outcome of Stalking

In some cases, stalkers may escalate to violence against their victims. This violence can have a great impact on the victim and can lead to permanent damage or even death. Some research indicates that stalkers who escalate to violent acts have previous criminal convictions, whereas other research has revealed that having a previous criminal history has no relationship with engaging in stalking behaviors. There are some risk factors, however, that appear to consistently indicate that violence may be a likely outcome. Threats appear to be a precursor to violence in some cases. Some mental illnesses may also lend a person to engaging in violent stalking behaviors, although a psychotic stalker is less likely to engage in violence than a nonpsychotic stalker. The prior relationship between the stalker and the victim can also have an impact on the risk of stalking violence. The presence of a previous intimate relationship is more likely to lead to violence being committed against the victim compared with when the victim is a stranger to the stalker. If the victim's partner had engaged in substance abuse, this could also likely lead to violence. There needs to be more research conducted in this area to determine what risk factors are the most predictive of a stalker becoming violent.

Treatment of Stalkers

Further research is also required to determine the effectiveness of different methods of mental health treatment for stalkers. It must be noted that there is no treatment regime specifically for stalking, as stalking can be related to a number of mental disorders but itself is not a disorder. Furthermore, not all stalking is related to mental health problems. Thus, it may be difficult to determine the most effective type of treatment or management for stalkers. Despite these issues, some treatment methods have been found to be effective, such as attempting to rectify the disorder underlying the stalking behaviors or concentrating on the behaviors themselves. The victim may also undertake actions, such as legal measures, to attempt to arrest the stalking behaviors.

Stanford Prison Experiment

The Stanford Prison Experiment (SPE) has become a classic in the social sciences for its dramatic demonstration of the power of situational processes over individual dispositions of its participants. It pitted a powerful set of situational variables, which together comprised what is worse in the psychological experience of imprisonment, against the will to resist by a group of normal, healthy young men playing roles of prisoners or guards.

The SPE was conducted in 1971 by a group of Stanford research psychologists, led by Professor Phillip Zimbardo, and two of Zimbardo's graduate students, Curtis Banks and Craig Haney. The experiment was designed to control for the individual personality variables that were often used at that time to explain behavior in prison and other institutional settings. That is, the researchers in the SPE neutralized the explanatory argument that pathological traits alone could account for extreme and abusive behavior by (a) selecting a group of participants who were psychologically healthy and who had scored in the normal range of the numerous personality variables that they measured and selected for, and (b) assigning participants to either the role of prisoner or guard on a completely random basis. The behavior that resulted when these otherwise healthy, normal participants were placed in the extreme environment of a simulated prison would have to be explained largely if not entirely on the basis of the characteristics of the social setting or situation in which they had been placed.

The setting itself was designed to be as similar to an actual prison as possible. Constructed in the basement of the Psychology Department at Stanford University, the "Stanford County Prison" had barred doors on the small rooms that served as cells, cots on which the prisoners slept, a hallway area that was converted to a prison "yard" where group activities were conducted, and a small closet that served as a short-term "solitary confinement" cell that could be used for disciplining unruly prisoners. The prisoners wore uniforms that were designed to de-emphasize their individuality and underscore their powerlessness. Guards, on the other hand, donned military-like garb, complete with reflecting sunglasses and nightsticks. These guards generated a set of rules and regulations that in many ways resembled those in operation in actual prisons, and prisoners were expected to comply with their orders. However, guards were instructed not to resort to physical force to gain prisoner compliance.

Despite the lack of any legal mandate for the "incarceration" of the prisoners and despite the fact that both groups were told that they had been randomly assigned to their roles (so that, e.g., guards knew that prisoners had done nothing to "deserve" their degraded prisoner status), the behavior that ensued was remarkably similar to behavior that takes place inside actual prisons and surprisingly extreme in intensity and effect. Thus, initial prisoner resistance and rebellion was met forcibly by guards, who quickly struggled to regain their power and then proceeded to escalate their mistreatment of prisoners throughout the study at the slightest sign of affront or disobedience. In some instances, the guards conspired to physically mistreat prisoners outside the presence of the experimenters and to leave prisoners in the solitary confinement cell beyond the 1-hour limit that the researchers had set.

Conversely, prisoners resisted the guards' orders at first but then succumbed to their superior power and control. Some prisoners had serious emotional breakdowns in the course of the study and had to be released; others became compliant and conforming, rarely if ever challenging the "authority" of the guards. Despite the fact that the researchers could not keep the prisoners in the study against their will (and they had been informed at the outset of the study of their legal right to leave), as the study proceeded, they "petitioned" the prison "administrators" for permission to be "paroled" or returned passively to their cells when their requests were denied. By the end of the study, they had disintegrated as a group. The guards, on the other hand, solidified and intensified their control. Although some of the guards were more extreme and inventive in the degradation they inflicted on the prisoners, and others were more passive and less involved, none of the guards intervened to restrain the behavior of their more abusive colleagues. Although the study was designed to last for two full weeks, the extreme nature of the behavior that occurred led the researchers to terminate it after only 6 days.

Controversial from the outset, and widely discussed and cited since it was conducted, the study has come to stand in psychology and related disciplines as a

demonstration of the power of situations—especially extreme institutional settings such as prisons—to shape and control the behavior of the persons placed inside them. Its results give lie to the notion that extreme social behavior can only—or even mostly—be explained by the extreme characteristics of persons who engage in it. The SPE counsels us to look instead to the characteristics of the settings or situations in which the behavior occurs. It also stands as a challenge to what might be termed the "presumption of institutional rationality"—that is, the tendency to assume that institutions operate on the basis of an inherent rationality that should be accepted rather than questioned. Instead, the SPE (itself the most "irrational" of prisons, in the sense that the guards had no legal authority over the prisoners, who in turn, had committed no crimes that warranted their punishment) suggests that a kind of "psycho-logic" may operate in these settings, which controls role-bound behavior, whether or not that behavior actually furthers legitimate goals.

A recent detailed chronology of the events that transpired in the SPE from initial city police arrests through final termination is provided in Zimbardo's book, *The Lucifer Effect: Understanding How Good People Turn Bad.* The story unfolds in the present tense, first-person narrative for 8 chapters, with subsequent chapters discussing the ethics of such research, presenting its various data sources, and then setting that study in a broader context of other social science research that also demonstrates the power of social situations to influence or dominate individual behavior (additional information is available at www.luciferEffect.com). All original data and forms have been stored at the archives of the History of American Psychology in Akron, Ohio.

Statement Validity Assessment (SVA)

Statement Validity Assessment (SVA) is a tool designed to determine the credibility of child witnesses' testimonies in trials for sexual offenses. SVA assessments are accepted as evidence in some North American courts and in criminal courts in several West European countries. The tool originated in Sweden and Germany and consists of four stages. Much of the SVA research is concerned with the ability of Criteria-Based Content Analysis (CBCA), one of the four SVA stages, to discriminate between truth tellers and liars. The Validity Checklist, another stage of the SVA procedure, has also attracted attention from researchers.

That a technique has been developed to verify whether a child has been sexually abused is not surprising. It is often difficult to determine the facts in an allegation of sexual abuse, since often there is no medical or physical evidence. Frequently, the alleged victim and the defendant give contradictory testimony, and often, there are no independent witnesses to give an objective version of events. This makes the perceived credibility of the defendant and alleged victim important. The alleged victim is in a disadvantageous position if he or she is a child, as adults have a tendency to mistrust statements made by children.

SVA consists of four stages: (1) a case-file analysis; (2) a semistructured interview; (3) a CBCA that systematically assesses the quality of a statement; and (4) an evaluation of the CBCA outcome via a set of questions (Validity Checklist).

Case-File Analysis

The SVA procedure starts with the analysis of the case file. A case file should include information about the child witness (e.g., his or her age, cognitive abilities, relationship to the accused person); the nature of the event in question, and previous statements of the child and other parties involved. The case-file analysis gives the SVA expert insight into what may have happened and the issues that are disputed. The SVA analysis focuses on these disputed elements in the subsequent three stages.

A Semistructured Interview

The second stage of SVA is a semistructured interview where the child provides his or her own account of the allegation. Conducting a proper interview is never an easy task, but interviewing young children is particularly difficult because their descriptions of past events are notably incomplete. Therefore, interviewers routinely want more information than is initially provided, and they have to ask further, specific questions to learn more about an event. The danger interviewers face is that their questioning may become suggestive—that is, that the question suggests to the child what the answer should be and subsequently leads the child to providing that answer. Special interview techniques based on psychological principles have been designed to obtain as much information as possible from interviewees in a free narrative style, without inappropriate prompts or suggestions.

Criteria-Based Content Analysis

The interviews with the child are audiotaped and transcribed, and the transcripts are used for the third part of SVA: the CBCA. In this third part, SVA evaluators look for the presence in the transcripts of 19 criteria. The hypothesis is that truthful statements contain more of these criteria than do fabricated statements. Examples of these CBCA criteria are *unstructured production* (whether the information is not provided in a chronological time sequence), *contextual embeddings* (references to time and space: "He approached me for the first time in the garden during the summer holidays"), *descriptions of interactions* (statements that interlink at least two actors with each other: "The moment my mother came into the room, he stopped smiling"), and *reproduction of speech* (speech in its original form: "And then he asked: 'Is that your coat?'"). These criteria are more likely to occur in truthful statements than in fabricated statements because it is thought to be cognitively too difficult for liars to fabricate them. Other criteria are more likely to occur in truthful statements than in fabricated statements for motivational reasons. Truthful persons will not be as concerned with making a credible impression on the interviewer as deceivers, because truth tellers often believe that their honesty will shine through. Therefore, liars will be keener to try to construct a report that they believe will make a credible impression on others and will leave out information that, in their view, will damage their image of being a sincere person. As a result, a *truthful* statement is more likely to contain information that is *inconsistent* with people's stereotypes of truthfulness. Examples of these so-called "contrary-to-truthfulness-stereotype" criteria are *spontaneous corrections* (corrections made without prompting from the interviewer: "He wore a black jacket, no sorry, it was blue") and *raising doubts about one's own testimony* (anticipated objections against the veracity of one's own testimony: "I know this all sounds really odd").

The Validity Checklist

A CBCA evaluation itself is not sufficient to draw conclusions about the truthfulness of a statement, because CBCA scores may be affected by factors other than the veracity of the statement. For example, older children produce statements that typically contain more CBCA criteria than younger children, and statements are unlikely to contain many CBCA criteria if the interviewer did not give the child enough opportunity to tell the whole story. The fourth and final phase of the SVA method is to examine whether any of these alternative explanations might have affected the presence of the CBCA criteria in the transcripts. For this purpose a checklist, the Validity Checklist, has been compiled, which consists of 11 issues that are thought to possibly affect CBCA scores. By systematically addressing each of the issues addressed in the Validity Checklist, the evaluator explores and considers alternative interpretations of the CBCA outcomes. Each affirmative response that the evaluator gives to an issue raises a question about the validity of the CBCA outcome.

One issue mentioned in the Validity Checklist is *inappropriateness of affect.* This refers to whether the affect displayed by the child when being interviewed (usually via nonverbal behavior) is inappropriate for

the child's alleged experiences. For example, sexual offenses are emotionally disturbing and likely to upset victims. One could, therefore, usually expect a clear display of emotions from a truthful victim when being interviewed. Absence of these emotions may indicate that the story has been fabricated.

A second issue mentioned in the Validity Checklist is *appropriateness of language and knowledge.* This issue refers to whether the child's use of language and display of knowledge was beyond the normal capacity of a person of his or her age and beyond the scope of what the child may have learned from the incident. When this occurs, it may indicate the influence of other people in preparing the statement. For example, to obtain custody, a woman may encourage her child to falsely accuse her ex-husband of having had an abusive relationship with the child. In an attempt to make a convincing case, the woman may have prepared the statement together with the child and may have coached the child in what to say.

A third issue on the Validity Checklist is examining whether the child demonstrates any *susceptibility to suggestion* during the interview. Statements of suggestible children could be problematic to interpret because suggestible children may be inclined to provide information that confirms the interviewer's expectations but is, in fact, inaccurate.

Research and Evaluation

Despite the fact that SVA assessments are used as evidence in court in several countries, it is unclear how accurate these assessments are because no reliable data regarding the accuracy of SVA assessments in real-life cases are currently available. To examine the accuracy of SVA assessments in such cases, it is necessary to know what truly happened in the disputed event. Obtaining this so-called ground truth is difficult because it can only be determined via case facts, such as medical evidence or other evidence, which indisputably links, or does not link, the alleged perpetrator to the crime. Such case facts are often not present in sexual abuse cases.

Research has been carried out in the form of laboratory studies, but it has mainly been focused on the third phase of SVA: the accuracy of CBCA assessments. In those studies, either children, but more often undergraduate students, told the truth or lied for the sake of the experiment. Such studies showed similar results for adults and children. In alignment with the CBCA assumption, many CBCA criteria were more often present in truthful statements than in fabricated reports. Overall, 73% of the truths and 72% of the lies were correctly classified by using CBCA assessments. Whether this reflects the accuracy of CBCA assessments in real-life criminal investigations is unknown. Students or children who tell lies and truths in an experiment are different from children who tell truths and lies in criminal investigations, and the accuracy scores therefore do not necessarily reflect the accuracy scores in criminal investigations.

There are reasons to believe that applying the Validity Checklist is sometimes problematic. It is possible to question the justification of some of the issues listed on the Validity Checklist, for example, whether the child displayed an absence of affect or inappropriate affect during the interview. This issue implies that the notion of appropriate affect displayed by victims of sexual abuse exists, whereas it does not. That is, in interviews, some sexually abused victims express distress that is clearly visible to outsiders, whereas others appear numbed and cues of distress are not clearly visible. The communication styles represent a personality factor and are not related to deceit.

Some other issues, such as susceptibility to suggestion, are difficult to measure. To examine a child's susceptibility to suggestion, the interviewer is recommended to ask the witness a few leading questions at the end of the interview. Interviewers should only ask questions about irrelevant peripheral information, because asking questions about central information could damage the quality of the statement. Being allowed only to ask questions about peripheral information is problematic, as it may say little about the witness's suggestibility regarding core issues of his or her statement. Children show more resistance to suggestibility for central parts than for peripheral parts of an event.

It is difficult, if not impossible, to determine the exact impact that many issues have on CBCA scores. For example, in one study, SVA raters were instructed to take the age of the child into account when calculating CBCA scores. Nevertheless, several criteria positively correlated with age. In other words, even after being instructed to correct the CBCA scores for age, the results still showed age-related effects, with older children obtaining higher CBCA scores than younger children.

Given these difficulties in measuring the issues and in examining the exact impact of these issues on CBCA scores, it is clear that the Validity Checklist procedure is more subjective and less formalized than the CBCA

procedure. It is, therefore, not surprising that if two experts disagree about the truthfulness of a statement in a German criminal case, they are likely to disagree about the likely impact of Validity Checklist issues on that statement. One study revealed that Swedish experts sometimes use the Validity Checklist incorrectly, and this could be due to difficulties with applying it. First, although SVA experts sometimes highlight the influence of Validity Checklist issues on children's statements in general, they do not always discuss how these issues might influence the statement of the particular child they are asked to assess. Second, although experts sometimes indicate possible external influence on statements, they are inclined to rely on the CBCA outcome and tend to judge high-quality statements as truthful and low-quality statements as fabricated.

In sum, although SVA assessments are used as evidence in (criminal) courts to evaluate the veracity of child witnesses' testimonies in trials for sexual offenses, the accuracy of these assessments is unknown. However, research has shown that CBCA-trained evaluators make mistakes in classifying truth tellers and liars and that the use of the Validity Checklist is problematic for a variety of reasons.

STATIC–99 and STATIC–2002 Instruments

The STATIC–99 and the STATIC–2002 are actuarial instruments that predict sex offender recidivism. They were designed to be widely applicable risk scales for the prediction of sexual recidivism that could be scored using commonly available file information from forensic settings such as prisons and forensic hospitals. Actuarial instruments for sex offender re-offense categorize sexual offenders into distinct risk levels such as low, moderate, and high risk to re-offend. Identifying the level of risk for sexual offenders improves the management of sexual offenders in the criminal justice system by allowing for appropriate level of supervision and treatment depending on risk level. Lower-risk sexual offenders may be placed on probation and participate in outpatient short-term treatment programs. A high degree of control supervision and intensive treatment can be allocated to sexual offenders identified as being higher risk to sexually re-offend. In more extreme cases, actuarial instruments can assist the evaluator in making decisions for the civil commitment of sexual offenders deemed to have a mental disorder that causes them to be too dangerous for release from custody and in need of inpatient treatment and custody.

The STATIC–99

The STATIC–99 was developed by R. Karl Hanson and David Thornton in 1999 to measure the prediction of violent and sexual recidivism. It is designed to be used for adult males who have already been charged with or convicted of at least one sexual offense against a child or a nonconsenting adult. The instrument is not appropriate for females or juvenile sexual offenders. The STATIC–99 is a combination of two existing actuarial scales for sexual recidivism: the Rapid Risk Assessment for Sex Offender Recidivism (RRASOR) and the Structured Anchored Clinical Judgment (SAC–J–MIN). As the name implies the scale contains only static risk factors, or historical risk factors, that have been found in research to predict sexual re-offense. The STATIC–99 was developed on three Canadian samples of sexual offenders from mental health and correctional facilities. Institut Philippe Pinel (n = 344) in Montreal provided long-term (1–3 years) treatment for sex offenders referred from both the mental health and correctional systems. Millbrook Correctional

Centre (n = 191) is a maximum security provincial correctional facility located in Ontario, Canada. The Oak Ridge Division of the Penetanguishene Mental Health Centre (n = 142) in Ontario is a maximum security mental health center. The STATIC–99 was subsequently cross-validated on 563 sex offenders released from Her Majesty's Prison Service (England and Wales) in 1979 and followed for 16 years.

The predictive validity of the instrument was measured by the receiver operating characteristic (ROC) curve. The STATIC–99 showed moderate predictive accuracy for both sexual recidivism (r = 0.33; ROC area = 0.71) and violent recidivism (r = 0.32; ROC area = 0.69).

The STATIC–99 includes 10 items that are scored as a 0 if not present and a 1 if present, except for the item prior sex offenses, which is scored 0 to 3. The items on the STATIC–99 include young age, single (ever lived with a lover for at least 2 years), index nonsexual violence (conviction), prior nonsexual violence (conviction), prior sex offenses, prior sentencing dates, any convictions for noncontact sex offenses, unrelated victims, stranger victims, and male victims. The score on the STATIC–99 can range from 0 to 12 and risk classifications include low, medium-low, medium-high, and high risk. Each risk level is associated with a probability of sexual re-offense for the study sample for 5, 10, and 15 years. Since the development of the STATIC–99, it has been repeatedly cross-validated in multiple jurisdictions and countries.

The STATIC–2002

In 2002, R. Karl Hanson and David Thornton revised the STATIC–99 in an effort to make the instrument simpler, more clinically applicable, and easier to score. The scale construction was designed to maximize the prediction of sexual recidivism. The selection of variables for the STATIC–2002 was guided by established research on factors that predict sexual recidivism as well as other empirically developed sex offender risk scales. The authors also included a number of exploratory variables that were supported by the constructs they were attempting to assess. Twenty-two individual variables with a simple bivariate relationship to sexual recidivism were organized into five content areas, including age at release, persistence of sex offending, deviant sexual interests, range of available victims, and general criminality. Multivariate analyses were used to determine whether the subscale added incrementally beyond the subscales already considered. Using Cox regression, each subscale was statistically weighted for its contribution to sexual recidivism.

The resulting scale was developed on a more diverse group of samples than the STATIC–99 and included two of the three developmental samples of the STATIC–99—Institut Philippe Pinel (n = 363) and Millbrook Correctional Centre (n = 186)—as well as three Canadian Federal Samples (n = 1229)—the California Sex Offender Treatment and Evaluation Project sample (n = 1137), the Special Sex Offender Sentencing Alternative (SSOSA) sample from Washington (n = 587), and the Manitoba Probation sample (n = 202). The STATIC–99/STATIC–2002 (ROC area = .71) showed levels of predictive accuracy for sexual recidivism similar to the STATIC–99 (ROC area = .69) for the prediction of sexual recidivism. The potential advantages of the STATIC–2002 over the STATIC–99 include improved prediction of violent recidivism over the STATIC–99, less variability than the STATIC–99 across settings, and more meaningful content areas when applied to clinical cases. Replication studies need to be conducted on large samples before it is possible to associate specific risk levels to specific ranges of scores as provided by the STATIC–99. The STATIC–2002 is a new instrument that needs to be replicated with independent data sets before it is appropriate for wide clinical use.

The items in the STATIC–2002 include the following: age at release; the persistence of sexual offending cluster with subsections including (a) prior sentencing occasions for sexual offenses, (b) arrests for sexual offenses as both an adult and a juvenile, and (c) rate of sexual offenses; the deviant sexual interests cluster with subsections including (a) any convictions for noncontact sexual offenses, (b) any male victims, and (c) two or more victims below the age of 12 with one victim unrelated; the relationship to victims of sexual offenses cluster including subsections (a) any unrelated victims and (b) any stranger victims; the general criminality cluster including subsections (a) any arrest/sentencing occasions, (b) any breach of conditional release, (c) years free prior to index offense, and (d) any prior conviction for nonsexual violence.

Statistical Information, Impact on Juries

Statistical information is increasingly likely to be presented in court. It may appear in civil cases (e.g., percentages of men and women employees in a gender discrimination case) or criminal cases (e.g., the defendant's blood type matches that of a sample found at the crime scene and that blood type is found in only 20% of the population). Can jurors understand that information on their own, or must they rely on experts to explain its meaning? Even if jurors correctly understand statistical evidence, how do they combine that evidence with other, nonquantitative evidence?

In contrast to other areas of juror understanding (e.g., juror beliefs about factors affecting the accuracy of eyewitness identification), there is relatively little research directly answering these questions. Those studies can be broken into two broad categories. The first focuses primarily on understanding of the statistical evidence. The second asks how statistical evidence is combined with other nonstatistical evidence. Considered together, jurors have some difficulty understanding even a single piece of statistical evidence. That difficulty increases when faced with two pieces of statistical evidence. Jurors also tend to underuse statistical evidence, when compared with a Bayesian norm, even when provided with instructions on how to use such evidence. That underuse, however, conceals considerable variation.

Juror Understanding of Statistical Evidence

"Naked statistics" (sometimes referred to as *base rates*) are data that are true, regardless of what happened in a particular case. Mock jurors are not persuaded by naked statistics compared with mathematically equivalent evidence that is contingent on some ultimate fact (i.e., a fact essential to resolution of the case). For example, in the Blue Bus problem, a bus runs over a color-blind woman's dog. The defendant, Company A, owns 80% of the buses in the area, and all of Company A's buses are blue. Company B owns 20% of the buses, and its buses are gray. The color-blind woman cannot tell a blue bus from a gray bus, so she does not know which company's bus ran over her dog. She sues Company A on the theory that, because Company A owns 80% of the buses in the area, there is an 80% chance that a Company A bus killed her dog. In experiments, jurors in one condition hear that the defendant owns 80% of the buses in the area, while those in another condition hear an 80%-accurate weigh-station attendant's identification of the defendant bus company. Both sets of jurors believe it equally probable that the defendant's blue bus, rather than Company B's gray bus, killed the dog. But only jurors who heard the attendant's testimony are willing to find against the bus company. Jurors who simply heard the naked statistics (Company A owns 80% of the buses) do not find Company A responsible. Similarly, although learning that the defendant is responsible for 80% of the accidents in the county leads to high probability estimates that the defendant's bus killed the dog, jurors are unwilling to find the defendant responsible.

Most research has examined "nonnaked" statistical information—information in which one's belief about the ultimate fact (in the example above, whether or not a blue bus hit the dog) is linked to one's belief about the evidence (the weigh-station attendant's accuracy). Some research finds that the manner in which statistical information is presented may affect mock jurors' use of the information. For example, incidence rate information presented in the form of a conditional probability (there is only a 2% probability that the defendant's hair would match the perpetrator's if the defendant were innocent) may encourage some jurors to commit the prosecutor's fallacy. These jurors believe that there is a 98% chance that the defendant is guilty. If the same information is presented as a percentage and number (a 2% match in a city of 1,000,000 people, meaning 20,000 people share that characteristic), some others may commit the defense attorney's fallacy. They believe the evidence shows only a 1 in 20,000 chance that the defendant is the culprit. These errors may be more likely when an expert, rather than an attorney, offers the fallacious argument. An attorney who makes such an argument in the face of expert testimony (e.g., when the expert explains

Bayes's theorem) runs the risk of backlash; the defense attorney's fallacy combined with expert Bayesian instruction may increase guilty verdicts.

Even nonfallacious presentations of statistical evidence pose challenges for jurors, particularly when they are evaluating low-probability events. Compare DNA incidence rates presented as 0.1 out of 10,000, 1 out of 100,000, or 2 out of 200,000. Mathematically, these rates are identical, but psychologically, they differ; jurors are more likely to find for the defendant in the latter two cases. Why? The first, fractional incidence rate contains no cues that people other than the defendant might match the DNA. Each of the other rates contains at least one exemplar within it, which encourages jurors to think about other people who might match. This effect may rest in part on the size of a broader reference group; it is easier to generate exemplars with an incidence rate of 1 in 100,000 when considering a city of 500,000 people than when considering a town of 500.

Jurors' task becomes more difficult when they face both a random match probability (RMP) (e.g., there is a 1 in 1 million chance that the defendant's DNA sample would match that of the perpetrator if the defendant is innocent) and a laboratory error rate (LE) (e.g., the laboratory makes a mistake in 2 of every 100 cases). The probability that a match occurred due either to chance or to lab error is roughly 2 in 100. Yet jurors who hear the separate RMP and LE (as recommended by the National Research Council) convict the defendant as often as those who hear only the much more incriminating RMP.

Why do jurors fail in combining an RMP and an LE? Traditional explanations point to various logical or mathematical errors. Another explanation suggests that jurors' interpretation of statistical evidence necessarily reflects their expectancies about such data. Consider jurors who receive extremely small RMP estimates (1 in a billion) and comparatively large LE estimates (2 in 100), compared with those who receive comparatively large RMP estimates (2 in 100) and extremely small LE estimates (1 in a billion). Logical (e.g., we are more convinced by more vivid evidence, like 1 in a billion) or mathematical (e.g., we average probabilities) explanations for juror errors make identical predictions in the two cases. But instead, mock jurors are more likely to convict in the large RMP paired with small LE condition. Similarly, they are more likely to convict when presented with extremely small LE estimates and no RMP estimate than when presented with only an extremely small RMP estimate and no LE estimate. This difference may reflect jurors' preexisting expectancies that the likelihood of a random match is extremely small and that of laboratory error is relatively large.

Some forms of statistical evidence (e.g., bullet lead analysis) illustrate that jurors must consider not just the reliability of statistical evidence but also its diagnosticity (usefulness). The value of a forensic match (e.g., the defendant's DNA profile is the same as that of blood found at the crime scene) depends on reliability of the evidence (did the laboratory correctly perform the test?) and also its diagnosticity (could the match be a coincidence?). One study gave the same information about hit rate and false-positive rate to all jurors. It varied a third statistical piece of information: the diagnostic value of the evidence. Some jurors learned that all sample bullets taken from the defendant matched the composition of the murder bullet, while no bullets taken from a community sample matched (strong diagnostic evidence). Others learned that the matching rate for the defendant's bullets was the same as that for bullets taken from a community sample (worthless diagnostic evidence). Jurors who received the strong diagnostic evidence were more likely to believe the defendant guilty. However, this effect held only for mock jurors who were relatively confident in their ability to draw conclusions from numerical data. Jurors who were less confident did not differ across conditions. Furthermore, jurors who heard the worthless diagnostic evidence tended to give it some weight before they deliberated; deliberation eliminated the effect.

How Jurors Combine Statistical Evidence With Nonstatistical Evidence

How do jurors combine numerous pieces of evidence (not necessarily statistical) to make decisions? Both mathematical (e.g., probability theory) and explanation-based (e.g., story model) approaches have been proposed. Research specifically examining the use of statistical evidence has generally followed a mathematical approach and has compared jurors' probabilities (typically the probability that the defendant committed the crime) with probabilities calculated using Bayes's theorem.

Bayes's theorem prescribes how a decision maker should combine statistical evidence with prior evidence. Prior odds (the defendant's odds of guilt, based on all previously presented evidence) are multiplied by the likelihood ratio (the probability that the new

evidence would match the defendant if he or she is guilty, divided by the probability that the new evidence would match an innocent person). The product is the posterior odds. For example, after opening statements and eyewitness testimony, a juror might believe that there is a 25% chance that the defendant is guilty. The prior odds are 25:(100–25) = .33:1. If the defendant and the perpetrator share a blood type found in only 5% of the population, the likelihood ratio is 1:.05 = 20. The posterior odds, then, are .33:1 × 20 = 6.67:1. The probability of guilt is 6.67/(6.67 + 1) or .87. In short, for this juror, Bayes's theorem states that the probability of guilt should increase from .25 to .87.

Only a handful of studies have compared jurors' decisions with Bayesian norms, and the comparisons sometimes are difficult to make. Some studies have not asked for a prior probability, while others have requested beliefs that the evidence matched (instead of beliefs about guilt). Most have assumed that jurors accepted the statistical evidence at face value. Given these caveats, in general, jurors underuse statistical evidence, compared with a Bayesian norm. This general finding, however, masks underlying complexity. In many of these studies, the prior evidence, the statistical evidence, or both are relatively strong. In such cases, it is difficult to exceed Bayesian posterior probabilities (which are often .90 or greater). Also, there tends to be great variability in how jurors use the statistical evidence. That is, two jurors with identical prior probabilities may hear the same statistical evidence and arrive at very different posterior probabilities. These disparities may rest in part on differing expectancies about LEs (which typically have not been presented) or about other factors (e.g., potential investigator misconduct) affecting the value of the statistical evidence. But studies (reviewed above) of how jurors respond to statistical information by itself provide ample reason to suspect wide variation in jurors' understanding. For example, jurors who claim to be comfortable with mathematics are more likely to be affected by statistical information than those who express discomfort. To further complicate matters, at least one study has found that later, nonprobabilistic evidence leads to a reevaluation of the quantitative evidence presented earlier.

Does instruction help jurors combine the statistical evidence with nonstatistical evidence? Studies have provided simple instructions. Typically, they have included a statistician's testimony about how Bayes's theorem works. The expert displays a table or a graph showing some sample prior probabilities and, given the statistical evidence, corresponding posterior probabilities. These relatively unsophisticated means of instruction, generally, have not affected jurors' use of the evidence; jurors who receive the instruction come no closer to Bayesian norms than those who do not.

"Stealing Thunder"

In the context of the courtroom, "stealing thunder" refers to revealing damaging information first so as to diffuse its impact. If damaging evidence is going to be brought out by one's adversary, an attorney may choose to reveal this information first to the judge and/or jury, thereby stealing the adversary's thunder. This entry describes research on the effectiveness of stealing thunder and also explores why stealing thunder works.

Trial lawyers have concerned themselves with several questions related to stealing thunder, and the answers are usually a matter of conjecture based on learned opinion and experience.

First, do attorneys use this tactic? The answer, based on interviews, informal surveys, trial advocacy books, and observations of courtroom trials, is that they do. In fact, stealing thunder appears to be used unquestioningly in criminal and civil trials, by defense, prosecution, and plaintiff's attorneys.

A second question might be, "Why do attorneys use it?" Again, based more on trial advocacy books and interviews than actual research (of which there appears to be none by trial lawyers themselves), the answer appears to be that it works for two reasons: (1) to give the appearance of honesty and being "up front" with the triers of fact and (2) to allow the attorney who steals thunder to frame the evidence in such a manner that it diminishes its importance. In other words, attorneys can put their own spin on the potentially damaging information.

A third question that attorneys may ask is, "What can be done to counteract the stealing thunder tactic?" Little or no information appears on this topic when reading trial advocacy books.

Note that none of the questions asks whether stealing thunder works. The empirical research started with this particular question.

Research Evidence

Effectiveness

Research has demonstrated that stealing thunder is an effective way to minimize or eliminate the impact of incriminating information in many legal contexts. Most legal experts are already aware of its benefits, even if they are not aware of the reasons why it works, and use it regularly in court.

In mock trial studies, researchers have found that attorneys can benefit by stealing thunder. The benefit is that stealing thunder diminishes the impact (usually measured by percentage of guilty verdicts or probability of guilt ratings) when compared with a "thunder" condition in which the attorney's adversary brings out the information as evidence. Sometimes, the tactic works so well that it brings verdicts to the same level as that with no thunder at all, but effectiveness is usually simply defined in terms of observing less damage than the comparable thunder condition.

Stealing thunder has been found to be successful with U.S. populations for criminal and civil trials and in Australia with criminal trials, suggesting that stealing thunder enjoys generality across trial type and across at least two (albeit Western) cultures. The timing of stealing thunder has not been shown to be pivotal; that is, it can occur at the beginning of the trial or later on, as long as it precedes the adversary's revelation. Also, the adversary does not need to reveal the damaging information at all for stealing thunder to work. There have been no differences between stealing thunder with and without the opposition's discussion of it. Finally, the "thunder" can range from something rather minor to something seemingly integral and damning. Thus far, there has been no research setting an upper limit on how damaging the thunder can be for it to be successfully stolen. In a mock court case involving homicide resulting from reckless driving, stealing thunder was effective at reducing the damaging information even when the defendant admitted to drinking alcohol and veering into the oncoming traffic lane.

It should also be noted that stealing thunder works in other nonlegal domains too, such as in politics (with mock voters and journalists) and interpersonal impression formation.

Counteracting the Stealing Thunder Tactic

So far, the only successful attempt to counteract the stealing thunder tactic is to, post hoc, reveal the tactic's use on the jury. If mock jurors were told during closing arguments that the other attorney manipulated their opinions through the use of the stealing thunder tactic, stealing the thunder no longer dissuaded them from its damaging implications.

Why Does Stealing Thunder Work?

Recent research suggests that there are several paths by which stealing thunder operates. First, in line with trial attorney intuition, research supports that the thunder stealer enjoys heightened impressions of honesty and credibility. The reasoning would go like this: If the attorney is willing to admit such damaging information without being forced into it, then surely the attorney can be trusted to present an objective and honest case.

Are attorneys also correct in assuming that stealing thunder works because it allows the revealer to put his or her own spin on the information, lessening its importance? To this question, the answer from available research is no; self-favorably framing the information is not necessary for it to be an effective tactic. It may help, but the available evidence is not even supportive of this notion. It appears that simply stating the incriminating information bluntly, without any spin or admonishment, is sufficient for the tactic to do its work on (mock) jurors. What apparently happens is that the mock jurors, without encouragement by the revealing attorney, put a diminishing spin on the information themselves when

the attorney does not. Here, the reasoning goes like this: What I just heard surprises me because it appears to hurt the attorney's case. But this doesn't make sense, so it must not really be all that bad after all. Thus, the research suggests that mock jurors work on the meaning of the "thunderous evidence," so that it is not so thunderous.

Thus, two very different processes appear to be involved, both of which assist in making stealing thunder an effective strategy. One is the relatively heuristic form of processing that involves simply the impression of truthfulness that then casts a positive glow on the attorney, the client, and the attorney's case. The other process is a rather effortful and creative process of twisting the negative information, such that it takes on a meaning that renders it harmless. This process, presumably, takes effort and thought.

Story Model for Juror Decision Making

To better explain how jurors make decisions in trial, psychologists have proposed a variety of decision-making models. Some research has examined the decision-making process at the jury level, but the majority of research has examined juror decision-making processes at the individual level. These models are typically grouped into two categories: explanation-based models and mathematical models. The story model is the most popular explanation-based model and was developed by Nancy Pennington and Reid Hastie. The story model rests on the assumption that jurors organize evidence they hear during trial in a narrative, storylike format. According to the story model, the process of decision making takes place in three steps: story construction, learning verdict alternatives, and rendering a verdict. The story model not only describes the process the juror undergoes when making a decision in a trial but claims that the story constructed by the juror ultimately determines the verdict chosen by the juror.

Story Construction

In a typical trial, the evidence is presented to jurors in a disconnected format over several days. Not only are witnesses often not presented in a logical, temporally relevant order, but the actual content of the witnesses' testimonies is also disconnected, in that witnesses are providing information in reaction to attorney questions rather than narrating the sequence of events. According to the story model, jurors play an *active* role during the trial by gathering the evidentiary information and organizing it into a comprehensive narrative with a causal structure, describing the sequence of events under question. That is, they actively place the evidence gathered at the trial into a "story" to account for what actually occurred. In constructing the story, they use three things: the evidence presented at trial (e.g., the information gained from witnesses), their personal knowledge of similar events (e.g., knowledge gained from personal experiences, media portrayals, or secondhand accounts of a particular crime), and their expectations for what makes a complete story (e.g., knowing that actions are usually preceded by intentions or goals).

In addition to describing how the jurors construct their stories, the story model describes the structure of those stories. Specifically, stories are made up of units called episodes. An episode is made up of a series of events that are paired with intentions or motivations to result in an action. Events, intentions, and motivations can be taken either from trial or from a juror's personal

knowledge. For example, an episode may consist of initiating events that led the defendant to a certain mental state, which then led the defendant to create goals or to have certain motivations, which then resulted in the defendant acting in a particular way. Jurors may get some of the information to complete the episode from trial evidence and may have to infer some of the episode elements based on their knowledge of the world. Episodes are hierarchically organized, in that each component of any given episode may be broken down into its own individual episode. The highest level episodes are the most important in explaining the actions that occurred; thus, the story model accounts for the weight jurors assign to different pieces of evidence.

One of the greatest strengths of the story model is that it accounts for jurors' unique experiences and indicates when they add those unique experiences and pieces of knowledge into the decision-making process. Witnesses do not often have the opportunity to explain why particular events happened or how they personally reacted to a particular sequence of events. So, jurors fill in those blanks with inferences based on their own personal knowledge of similar events. In addition, jurors' expectations about what makes a complete story are important to help them determine when important pieces of information are missing or when an inference about human behavior or how someone might act in a particular situation needs to be made. Jurors then can make this inference based on their personal knowledge. The story model accounts for differences in stories between jurors by accounting for the different world experiences and expectations jurors bring to the story construction process.

Certainty Principles

Three certainty principles govern whether a juror will find a particular story acceptable, and following acceptability, how much confidence a juror will have in a particular story. The first two—coverage and coherence—contribute to whether a story will be accepted and, if accepted, how much confidence the juror will have in the story. The third principle, uniqueness, contributes solely to the juror's confidence in the story.

Coverage refers to the amount of evidence accounted for by a particular story. The more coverage a story has, the more likely the juror is to deem the story acceptable and, if accepted, the more confidence the juror will have in that story. Conversely, the less evidence the story accounts for, the less likely it is to be accepted by jurors. If accepted, jurors are likely to have less confidence in the story compared with if the story had a high level of coverage. If a story has low coverage and, therefore, the juror has a low amount of confidence in the story, the juror would also have a low level of confidence in the final decision based on that story.

The second principle is coherence. A story's coherence is determined by a combination of three variables: consistency, plausibility, and completeness. To be consistent, a story must contain no internal contradictions or contradictions with pieces of evidence the juror believes are true. To be plausible, the story constructed must be similar to the juror's knowledge of what typically happens in these situations. That is, a story must not contradict the juror's knowledge about the world in general. Last, to be complete, the story must contain all the parts of what a juror believes makes up a story. The more consistent, plausible, and complete the story, the higher the coherence of the story. If a story is deemed coherent, the juror is more likely to think that the story is an acceptable account of the events in question and the more likely the juror is to be confident in the story.

The story model posits that jurors can construct more than one story, but one story usually emerges as the best explanation of events. However, what happens when jurors create more than one story and each of the stories is high in both coverage and coherence? According to the story model, this compromises the last certainty principle, the uniqueness of the story. If jurors construct more than one acceptable story, they are less likely to believe either story, and the confidence in both stories goes down.

Learning Verdict Options

In the second stage of the story model, jurors learn which verdict options are available to them. Generally, the different verdict options along with the definition of what constitutes each verdict option are given to the jurors in the judicial instructions at the end of the trial. The combination of this one-trial learning task with the difficulty of legal language makes this task difficult for jurors. In fact, research has demonstrated that jurors generally do not comprehend the majority of judicial instructions presented to them. In addition, jurors also have preconceived notions of what constitutes various crimes. Those preconceived notions, accurate or inaccurate, may interfere with jurors' understandings of the verdict options in the case.

Rendering a Verdict

In this last stage of the story model, jurors map their accepted story onto each of the verdict categories to determine which verdict category best matches the accepted story. This mapping sequence is intentional on the part of jurors and is difficult because they are mapping their accepted story onto unfamiliar, newly learned concepts. However, jurors are somewhat aided in this process by the structure of the verdict options. Typically, verdict options consist of elements that closely mimic the episodic structure that jurors used when creating the story. For example, the verdict definition of first-degree murder includes an element of identification (identifying the person who committed the crime), mental state (that person intentionally killed the victim), circumstances (the victim gave no provocation and the murder was premeditated), and actions (the killing was intentional and unlawful). These correspond to the elements that make up an episode in a story.

Once the jurors have chosen which verdict category best matches the story, jurors apply the judge's procedural instructions to make a decision in the case. For example, in a criminal case, if the best-fit verdict option exceeds the jurors' threshold for reasonable doubt on each of the elements of that verdict option, then the juror is likely to choose that verdict. If not, the juror does not choose that verdict option. If no match of verdict option and story exceeds this threshold, then the juror defaults to a verdict of not guilty. In addition, the goodness of fit, or the jurors' confidence in a verdict category-story match, will affect whether the juror is likely to choose that verdict. If the goodness of fit is low, the juror is less likely to be confident in that verdict than if the goodness of fit is high.

Research Investigating the Story Model

The initial study in the development of the story model was designed to provide a picture of how jurors processed evidence and established that jurors created narrative structures to explain and account for evidence. Further research demonstrated that the actual creation of the narrative was a spontaneous act of the juror and that the story is actually a mediator in the verdict decision. That is, jurors heard the evidence, created a story, and then the story caused the jurors to choose a particular verdict. Last, the researchers also conducted a study demonstrating that the story model was a more complete and accurate explanation of juror decisions compared with more traditional models of decision making. Other researchers have also applied the story model of juror decision making to successfully explain jurors' decisions in rape trials, civil cases, and sexual harassment cases.

In sum, the story model of juror decision making is an explanatory model of decision making that asserts that jurors actively create a narrative (in the form of multiple episodes) to organize trial evidence. In creating the story, jurors use evidence presented at trial and their own knowledge of both real-world events and the elements that make up a story. To determine whether a story is acceptable, jurors use the certainty principles of coverage and coherence. Coverage and coherence, combined with the story's uniqueness, also contribute to the juror's subsequent confidence in a story. The second stage of the story model is the stage in which jurors learn the verdict options available to them, and this happens during judicial instructions at the end the trial. Jurors' preconceived notions about certain crimes may also affect the way in which they perceive the verdict categories. In the last stage, jurors map their chosen stories onto the various verdict categories and apply the standard of proof given to them by the judge. If the match exceeds the standard of proof, then the juror chooses that verdict. If not, the juror defaults to a not-guilty verdict. Last, research has generally demonstrated support for the story model of juror decision making in a variety of cases.

Stress and Eyewitness Memory

Stress exerts complex effects on eyewitness memory. On the whole, it has a negative effect, but this can be quite variable depending on the level of stress and the aspect of the witnessed event that one is trying to remember. Stress operates similarly in affecting person recognition (i.e., lineup performance) and recall of event details.

The effects of stress on eyewitness memory and identification are of interest because of the fact that persons witnessing a crime, especially a violent crime, commonly (though not always) experience stress. "Stress" is itself a rather vague term that has been interpreted differently by various commentators, but generally, it can be taken to denote a negative emotional state associated with both physiological changes and a subjective set of cognitions. The physiological experience of stress is associated with increased arousal, marked by increases in heart rate, blood pressure, and muscle tone. The subjective experience typically includes some perception of threat and feelings of anxiety.

People often assume that a high level of emotion, positive or negative, will facilitate memory; however, it is also possible that intense emotion, especially the high level of stress associated with witnessing a crime, would lead to decrements in memory for details of the crime itself and for the ability to recognize the persons involved. Early studies investigating the effects of stress on memory yielded inconsistent findings. Some researchers found that accuracy suffered when witnesses were under stress, others found that it was unaffected, and a minority of researchers reported improvements in accuracy. This ambiguity can be explained, in part, by variations in the degree of stress. The Yerkes-Dodson law proposes that the relationship between arousal and performance can be plotted as an inverted U, where with moderate increases in arousal, performance is improved but with too much arousal performance declines. This theory was subscribed to by many researchers, and initially, it was thought to provide an explanation for the seemingly contradictory pattern of research findings. The studies that found improvements may have elicited an optimal level of stress or arousal, whereas those studies that had found decrements had exceeded that optimal level of stress. However, this explanation proved inadequate as the body of research grew because of the difficulty in comparing degrees of stress and also because of findings indicating that stress is not a unidimensional construct, as proposed by the Yerkes-Dodson law, but instead has multiple components (e.g., physiological, affective, cognitive, behavioral, etc.).

An alternative explanation is that with higher levels of emotional stress, the observer's attention becomes narrower and more focused. As a result, memory for central and closely attended-to details improves, while memory for more peripheral details declines. This distinction between central and peripheral details also helps explain some of the inconsistent findings, where stress sometimes helps but at other times impairs memory.

Research reviews and meta-analyses of the topic reveal that, taken as a whole, stress has more of a negative than a positive impact on eyewitness memory in terms of both identification of the perpetrator and recall of event details. Eyewitnesses in high-stress situations are less likely to be able to correctly identify a perpetrator from a lineup, and recall of details associated with the witnessed crime is less likely to be accurate. The type of lineup administered and the type of recall appear to moderate the effect of stress on accuracy. High-stress situations disproportionately affect eyewitness identification accuracy, such that the likelihood of an accurate identification is reduced when the target person (i.e., perpetrator) is present in the lineup, but the effect on target-absent lineups is negligible. In other words, when the target person is present in the lineup, witnesses are more likely to select someone other than the target (i.e., a foil—namely, an innocent person in a police lineup) or incorrectly report that the target is not present in the lineup, thus rejecting the lineup. In contrast, when the target is absent, the likelihood that a witness will correctly reject the lineup is virtually unaffected.

In eyewitness studies, witnesses are typically asked to report information in one of two ways: narrative or interrogative. With narrative or free recall, witnesses are asked to report what they recall and can choose what information to report. The interrogative type of recall requires a witness to answer specific questions about various details of the witnessed event. High-stress situations produce a greater decline in accuracy for interrogative recall than for narrative recall. One possible explanation for this difference is that with narrative recall, witnesses are free to choose what information to report and may opt not to report details of which they are not certain.

These findings extend partly to children as well. Child eyewitnesses perform worse when under stress, but it is unclear whether stress has a disproportionately negative effect on children. Stress effects can also be complicated by the presence of a particularly arousing, eye-catching aspect of the event, such as gore or a weapon. Research on stress and memory also suffers from methodological complications. There are limits to the amount of stress that one can ethically induce in an experimental situation, and even with highly arousing materials, research participants are usually not personally threatened by the witnessed event; that is, they are bystanders rather than victims or potential victims, which is likely to influence not only their stress level but also their behavior, degree of attention, and so forth. Some innovative research designs have attempted to overcome this limitation by studying victims/witnesses of real crimes or individuals undergoing stressful medical procedures.

In conclusion, it is hard to generalize about the effects of stress on eyewitness memory. The findings are somewhat mixed, and the explanation for stress effects on memory is far from clear, making generalization difficult. More research is necessary to resolve this uncertainty. However, it is clear that, overall, high levels of stress harm eyewitness memory in more ways than they help it.

Structured Assessment of Violence Risk in Youth (SAVRY)

The Structured Assessment of Violence Risk in Youth (SAVRY), developed by Randy Borum, Patrick Bartel, and Adelle Forth, is a risk assessment instrument designed to structure appraisals of violence risk and risk management plans for adolescents. Such assessments are routinely required by juvenile and criminal courts and at nearly every juncture of the juvenile justice system. In the SAVRY, one's risk for serious violence is viewed as the result of dynamic and reciprocal interplay between factors that increase and factors that decrease the likelihood of violence in the developing juvenile over time. Its central objective is to facilitate assessments that are systematic, empirically grounded, developmentally informed, treatment oriented, flexible, and practical.

The SAVRY is based on the "structured professional judgment" (SPJ) risk assessment framework, and is designed for use with adolescents between the approximate ages of 12 and 18 who have been detained or referred for an assessment of violence risk. Evaluators systematically assess predetermined risk factors that are empirically associated with violence, consider the applicability of each risk factor to a particular examinee, and classify each factor's severity. The ultimate determination of an examinee's overall level of violence risk is based on the examiner's professional judgment as informed by a systematic appraisal of relevant factors. In this way, the SPJ model draws on the strengths of both the clinical and actuarial (formula-driven) approaches to decision making and attempts to minimize their respective drawbacks.

The SAVRY protocol is composed of 6 items defining protective factors and 24 items defining risk factors. Items are coded on the basis of reliable, available information. Information should be obtained from multiple sources, including an interview with the youth and a review of records (e.g., police or probation reports and mental health and social service records). Risk items are divided into three categories: historical, individual, and social/contextual, and each is coded for severity according to a three-level coding structure (high, moderate, or low). Protective factors are coded as present or

absent. The coding form also includes a section for listing "additional risk factors" and "additional protective factors" because the SAVRY is not exhaustive in identifying all potential risk and protective factors for any given individual. If these additional factors are present, they should be documented and weighed in final decisions of risk.

Though the SAVRY is sufficiently flexible to accommodate varying styles of risk communication, the coding form prompts evaluators to make a final *summary risk rating* of low, moderate, or high. The ultimate risk rating is not based on cutting scores (SAVRY items are not assigned numeric values) or a specific formula. Evaluators exercise their professional judgment to determine the nature and degree of the juvenile's risk for violence after carefully weighing the relevant risk and protective factors.

Psychometric Properties

One of the primary indices used in SAVRY research (not in practice) is the "SAVRY Risk Total." This is calculated by transposing item ratings of *low, moderate,* and *high* to numerical values of 0, 1, and 2, respectively, and summing the values. The summary risk rating is similarly transposed for statistical analysis.

Reliability and Internal Consistency. The internal consistency (alpha coefficient) of the SAVRY Risk Total has been shown to fall in the range of .82 to .84. Interrater reliability for the SAVRY Risk Total has ranged between .74 and .97, with an unweighted average of .84. Interrater reliability coefficients for the Summary Risk Rating have ranged between .72 and .85, with an unweighted average of .78.

Validity. The concurrent validity of the SAVRY has been examined in relation to the Youth Level of Service/Case Management Inventory (YLS/CMI) and the Hare Psychopathy Checklist: Youth Version (PCL:YV). In the initial validation study, the SAVRY Risk Total correlated significantly with both instruments among offenders and in community samples (e.g., .89 with YLS/CMI and .78 with PCL:YV among offenders). The SAVRY protective domain was negatively correlated with both the other measures. Across five studies, correlations between the SAVRY Risk Total and the PCL:YV Total Score have ranged from .48 to .74, with an unweighted average of .67. Although the correlations are significant, indicating that the SAVRY shares variance with other measures, it also possesses independent predictive power.

With regard to criterion validity, studies have found significant correlations between SAVRY scores and various measures of violence in juvenile justice and high-risk community-dwelling populations. In the initial validation sample, SAVRY Total Risk scores were all significantly related to behavioral measures of institutional aggressive behavior (.40) and aggressive conduct disorder symptoms (.52). The SAVRY has also demonstrated incremental (criterion) validity (or predictive power) beyond the YLSI and the PCL:YV. Results of hierarchical regression analyses showed that adding the SAVRY improved the power of the YLSI and the PCL:YV in predicting both institutional aggressive behavior and serious aggressive conduct disorder symptoms. The SAVRY also accounted for a large proportion of the explained variance in each type of violence.

Using receiver operating characteristic (ROC) analysis, which measures predictive accuracy in terms of relative improvement over chance, we found that areas under the curve (AUCs) for the total score average about .74 to .80 across studies. Interestingly, the examiner judgments (summary risk rating), not made on the basis of any cutting score, consistently perform as well as, and often better than, the linear combination of the scores themselves. For example, using ROC analysis, an unpublished master's thesis at Simon Fraser University reported an AUC of .70 for the SAVRY total score, but the AUC for the SAVRY Summary Risk Rating was .89. This finding has been evident in research on other SPJ tools as well and provides some of the first empirical evidence that clinical judgments—properly structured and based on sound assessments—can achieve levels of accuracy that rival that of any other known predictors, while maintaining latitude for case-specific analysis.

Additional research is needed and is under way to clarify the SAVRY's applicability in different countries, across genders, and with various ethnic groups.

Structured Interview of Reported Symptoms (SIRS)

The Structured Interview of Reported Symptoms (SIRS) is a fully structured interview that is designed to assess feigned mental disorders and related response styles. Each of its eight primary scales was constructed to evaluate well-established detection strategies for differentiating between malingered and genuine psychopathology. These primary scales consist of Rare Symptoms (RS), Symptom Combinations (SC), Improbable and Absurd Symptoms (IA), Blatant Symptoms (BL), Subtle Symptoms (SU), Selectivity of Symptoms (SEL), Severity of Symptoms (SEV), and Reported Versus Observed Symptoms (RO).

Description and Development

The initial development of the SIRS was based on an exhaustive review of potential detection strategies for feigned mental disorders. SIRS scales were developed based on the likely effectiveness of the underlying detection strategy and the adaptability of each strategy to interview-based assessments. Final item selection was based on independent judgments by eight experts in malingering and was subsequently refined to improve scale homogeneity. The SIRS is composed of 173 items that are organized by eight primary and five supplementary scales.

The original validation of the SIRS combined samples from multiple studies to form four groups: 100 inpatients and outpatients, 97 controls from community, correctional, and college settings, 170 simulators including coached and uncoached participants, and 36 likely malingerers from forensic settings. Subsequent validation research has included clinical and correctional samples with an additional 255 participants.

Reliability

Internal consistencies (alpha coefficients) for SIRS primary scales were excellent: They ranged from .77 to .92, with a mean alpha of .86. The reliability of individual scores was examined via standard errors of measurement (SEM). The SEMs were low for both clinical and control samples, indicating high reliability for individual scores. A central issue for the SIRS was its interrater reliability. These estimates were impressive, ranging from .89 to 1.00. The median reliability was .99, which represents almost perfect agreement.

Validity

SIRS validation relied on a combination of simulation designs and known-group comparisons. The simulation design capitalizes on internal validity in its use of analog research with clinical comparison samples. In contrast, known-group comparisons provide unmatched external validity in their use of individuals from actual clinical-forensic settings who were independently evaluated as malingering by established experts. For the assessment of malingering, convergent results from simulation and known-group studies provided the strongest evidence of SIRS validity.

A major focal point of the SIRS is its discriminant validity. The critical issue is whether each of the primary scales systematically differentiates between genuine and feigned psychopathology. Combining across studies, effect sizes can be computed for the critical distinctions (a) simulators versus clinical honest and (b) suspected malingerers versus clinical honest. For simulators, Cohen's *d*'s were very large: They ranged from 1.40 (SU) to 2.31 (RS) with an average *d* of 1.74. Cohen's *d*'s were also very large for suspected malingerers but showed less variability: 1.20 (IA) to 1.98 (SEL). The average effect size for malingerers was identical to that of simulators ($d = 1.74$). These combined data provide very strong evidence of discriminant validity.

Convergent validity was evaluated by comparing the SIRS with other measures of feigned mental disorders. The SIRS evidenced robust correlations with MMPI–2 validity scales. For example, the SIRS primary scales are strongly correlated with Scale F (*r*'s from .71 to .80). As also expected, they are negatively correlated with Scale K ($Mr = -.35$), a measure of defensiveness.

Construct validity was examined via discriminant analysis and factor analysis. A two-stage, stepwise discriminant analysis with a canonical correlation of

.79 demonstrated the usefulness of SIRS primary scales for the accurate differentiation of feigned from clinical honest profiles. A high level of accuracy was maintained across calibration and cross-validation samples. Recently, a confirmatory factor analysis yielded strong support for a two-factor model of the SIRS (i.e., spurious presentations and plausible presentations) that was theoretically relevant to the assessment of malingering.

Forensic Applications

The SIRS is widely accepted as one of the best-validated measures of feigned mental disorders in clinical and forensic settings. Its classification of malingering in forensic settings is highly accurate. These classifications are based on either (a) three or more primary scales in the probable feigning range or (b) one or more primary scales in the definite feigning range. The probable feigning range was established so that it would include most feigners (typically >75%) but very few genuine patients (<10%). By using the established criterion (>3 scales in the probable feigning range), very few genuine patients were misclassified as feigners (i.e., 2.1% at 3 scales; 0.0% at >4 scales). Scales in the definite feigning range are set very high to minimize false positives.

Research by other investigators generally confirms the accuracy of the SIRS and its low false-positive rates. Ongoing research suggests that the SIRS provides useful data for civil-forensic applications such as disability evaluations. As a caution, the initial data indicate that its cut scores may not be useful for a subset of inpatients with dissociative disorders and multiple traumas beginning before adulthood.

Future Directions

Research is currently under way for validating a Spanish-language SIRS. The SIRS was independently translated by three bilingual psychologists. The composite translation was back-translated by an independent bilingual psychologist; minor discrepancies were found for only 11.0% of the SIRS items. A revised Spanish SIRS was subjected to further translations and reviews. With the Spanish SIRS established, the comparability of the Spanish and English SIRS is currently being tested with bilingual Hispanic patients.

Substance Abuse and Intimate Partner Violence

Research indicates that substance abuse is a risk marker for intimate partner violence (IPV). This entry reviews the evidence for this association, possible explanations for it, and implications for theory and practice for professionals who work in this area.

Substance Abuse as a Risk Marker for IPV

Studies using a variety of passive-observational research designs have established that substance abuse is a risk indicator for IPV. For example, population-based studies as well as studies of clinic- or court-referred groups, have examined rates of substance abuse in people with and without a history of IPV victimization, IPV perpetration, or IPV recidivism (i.e., repeated IPV following an initial incident). According to narrative and meta-analytic reviews of these studies, the association between substance abuse and IPV is moderate or even moderate-to-large in magnitude. About 20% to 50% of all incidents of IPV occur when one or both partners have consumed and are under the influence of alcohol or illegal drugs. Substance abuse increases the odds of IPV perpetration or victimization by a factor of about 2 to 4. The association tends to be strongest when (a) the substances of abuse are alcohol, cocaine (in various forms), or heroin; (b) substance abuse is defined in terms of problematic patterns of use, rather than frequency of use or amount consumed; (c) IPV is defined

in terms of moderate or severe violence, rather than minor violence; and (d) substance abuse and IPV are defined in terms of a broad time frame (e.g., lifetime) rather than a narrow time frame (e.g., past year). The association does not appear to be influenced by the legal status of the intimate relationship (married vs. cohabiting vs. dating), the sexual orientation of the intimate partners (heterosexual vs. same sex), or the gender of the perpetrator and victim.

Explanations for the Association Between Substance Abuse and IPV

There are several possible explanations for the observed association between substance abuse and IPV. First, the association may be false—the result of perpetrators attempting to avoid moral and legal culpability by claiming that they were intoxicated at the time they committed IPV. But the substance abuse/IPV association is observed even in studies that relied solely on victims to provide information and even in studies where substance abuse was measured months or even years prior to the first occurrence of IPV.

Second, the association may be artifactual—the result of some third factor that is causally related to both substance abuse and IPV. Potential third factors could include mental disorder in the perpetrator (e.g., antisocial personality disorder or psychopathy) or severe conflict in the victim-perpetrator relationship (e.g., recent separation or divorce). But studies that attempted to control for potential third factors have found that they accounted for only a small part of the association.

Third, IPV may be a cause of (i.e., have a causal influence on) substance abuse. Longitudinal research supports this view, at least in part. People who experience IPV increase their use of alcohol or illegal drugs, which in turn leads to increased risk for (repeated) IPV.

Fourth, substance abuse may be a cause of IPV. The same longitudinal research that found that IPV increases substance abuse has also found that substance abuse increases risk for IPV, even when the substance abuse came months or years before the IPV. For example, substance abuse as a young adolescent predicts IPV as a young adult, and premarital substance abuse predicts IPV after marriage. In addition, treatment outcome research has found that reductions in substance abuse are associated with subsequent reductions in risk for IPV.

In summary, the association between substance abuse and IPV appears to be bidirectional in nature: Substance abuse is both a cause and a consequence of IPV. With respect to substance abuse as a cause of IPV, theory and research suggest that several direct or proximal and indirect or distal causal mechanisms may exist. Putative direct mechanisms focus on the psychopharmacological or psychological effects of substance abuse. Intoxication and withdrawal may impair cognitive functions, leading to reduced inhibitions against violence (e.g., underestimation of negative consequences, overestimation of positive consequences, failure to consider alternatives to violence) or misperception of social cues (e.g., misattribution of hostile intent in others). Putative indirect mechanisms focus on the destabilizing effects of substance abuse on social adjustment. For example, the short- and long-term consequences of substance abuse—such as problems with employment, finances, health, and family arguments about drinking patterns or the consequence of drinking on employment, finances, and relationships with family or friends—cause conflict between partners in intimate relationships, which in turn increases the risk that IPV will occur. Similarly, the consequence of substance abuse may impair one partner's ability to cope with conflictual or aggressive behavior by the other partner (through the use of strategies such as de-escalation, deterrence, or escape), thus increasing vulnerability to victimization and, ultimately, the risk that IPV will occur.

Implications for Research and Practice

It is clear that substance abuse is neither a necessary nor a sufficient causal factor for IPV but rather one of many contributory causal factors. Currently, researchers are trying to further understand the various causal mechanisms that may exist and how substance abuse interacts with other causal risk factors to cause IPV.

Professionals who work in the field of IPV need to be aware that substance abuse increases risk for IPV, and treating substance abuse mitigates risk. For these reasons, substance abuse is included as a risk factor in several IPV risk assessment procedures, including the Danger Assessment Instrument (DA) and the Spousal Assault Risk Assessment (SARA) Guide, and many intervention programs for perpetrators and victims of IPV focus in part on decreasing substance abuse. The challenge for professionals is to determine what role substance abuse plays (i.e., which causal mechanisms are relevant) in a given case and then deliver appropriate services.

Substance Abuse Treatment

A number of different methods are used to treat substance abuse. The most common method often used by treatment facilities is 12-step counseling, although little is known about its effectiveness. Treatment modalities include inpatient, day treatment, and outpatient care, usually followed by aftercare. Twelve Step Facilitation Therapy has been scientifically validated but is rarely adopted for use in 12-step treatment facilities. Motivational interviewing has been determined to be an effective means to motivate clients to seek therapy and change substance use and can be particularly effective with unmotivated clients. Numerous cognitive-behavioral therapies have been effective as interventions in substance use disorders. Relapse prevention therapy is the most widely used cognitive-behavioral approach. Twelve-step counseling, cognitive-behavioral therapy, therapeutic communities, and even *Vipassana* meditation have been used in jails and prisons to intervene in substance use disorders and recidivism.

Substance Abuse Treatment and the Criminal Justice System

Evidence exists that quality substance abuse treatment can lead to lower recidivism and relapse rates among substance users in the criminal justice system. In addition, court-ordered treatment has been found to be extremely cost-effective when compared with incarceration as an alternative. Many jurisdictions now have drug courts that generally offer treatment as an alternative to imprisonment, but the type of treatment available to participants varies widely across the country. Traffic courts often include mandated treatment courses for DUI offenders, but the evidence that these programs change drinking and driving behavior is inconsistent, perhaps because the content of these courses vary widely across jurisdictions. Treatment outcomes are often used by mental health courts, probation officers, and parole boards as evidence to determine the success of rehabilitation efforts.

Typical Care at Treatment Facilities

The prevailing model of treatment in the United States uses 12-step counseling (often referred to as the Minnesota Model). Although many of these programs have abstinence as a requirement for entry into the facility and as a goal for treatment, researchers find that many clients do not remain abstinent but will reduce their substance use. Although most treatment centers use a similar model, the quality and content of the 12-step counseling across treatment facilities is not consistent. In addition, the 12-step counseling provided by many treatment centers has not been tested under controlled conditions to determine if it is in fact effective.

Addiction counselors are certified by state boards. The process often requires documentation of counselor education in Minnesota Model principles and an examination of counseling skills by peers. Although some addiction counselors have undergraduate and graduate degrees, many states do not require these credentials for a counselor to be certified. Addiction counselors often have personal experiences in 12-step recovery.

Treatment Modalities

Treatment modalities vary. Treatment can be conducted in inpatient or outpatient settings. In the past, most treatment was provided in 28-day inpatient stays, until research showed that outpatient care is just as effective as inpatient care for most clients. Since those findings, the insurance industry has pushed the treatment toward a predominantly outpatient model. People with substance use disorders and co-occurring severe mental disorders (such a debilitating depression or psychoses) may benefit more from the structured environment of an inpatient stay. Day treatment also is available in some communities to provide structured treatment and care during business hours (clients return home during the evening). Many treatment facilities provide medical care, family programs, and sometimes nutrition and fitness programs. Counseling format varies between

individual sessions with a primary counselor to group sessions with peers and counselors. In addition to inpatient and outpatient services, treatment centers generally provide aftercare to provide ongoing support to clients who have completed treatment.

Support Groups

Treatment providers generally encourage support group participation as an adjunct to therapy. Support groups vary in terms of philosophies. Twelve-step groups operate under the assumption that substance use disorders are chronic incurable diseases that require a lifetime of working the 12 steps to facilitate abstinence. Other groups such as Rational Recovery understand substance use disorders as a problem of disordered thinking and behavior that can be changed permanently with aid of the group and the Rational Recovery Program (based on the work of Albert Ellis). Moderation Management is an example of a support group that works with individuals who do not necessarily have abstinence as a goal but, instead, want to reduce substance use. Each program seems to be successful for participants when program philosophies closely match the values and worldview of the participants.

Evidence-Based Treatment

Researchers have developed and tested a great variety of therapies that have proved effective as interventions in substance use disorders. To provide quality and consistent care for psychological disorders, including substance use, the therapy used has to have two characteristics. The first is demonstration that the treatment has worked better than nothing at all by comparing outcomes in a particular therapy with a no-therapy or care-as-usual control group. The second important characteristic is conducting therapy using a manual. Manualized therapy promotes adherence to the scientifically validated treatment protocol to prevent drift. The following sections review therapies that have been tested under controlled conditions or have manuals or guidelines available for use by physicians/therapists to provide best practices to clients.

Biopsychosocial Model

Research supports a biopsychosocial model for addictive behaviors. Successful models of treatment incorporate biological (physiological), psychological, and social (environmental) interventions to modify biopsychosocial processes associated with substance misuse. For example, physiological (biological) treatment methods typically involve pharmacological means. There is evidence that certain medications may be helpful to promote treatment success among clients with alcohol use disorders. Disulfiram (Antabuse) has been used as a disincentive to alcohol use among people at high risk for relapse but with mixed results. Disulfiram blocks metabolism of alcohol and causes clients to become violently ill when they drink, which sometimes persuades clients to remain abstinent when they are tempted to drink. However, clients have been known to drink when on disulfiram, and client compliance for taking the medication is a problem. Naltrexone and acamprosate have been shown in some studies to help reduce cravings and improve treatment outcomes. Methadone has been used as a safe substitute for heroin. For clients with co-occurring mental disorders, such as depression, bipolar disorders, and schizophrenia, psychiatric medications can help reduce substance use. Many clients believe that substance use helps with psychiatric symptoms. When prescribed medications function to control psychiatric symptoms, it may reduce the desire to self-medicate with illicit substances.

Psychological Therapies

Several types of psychological therapies have been found to be efficacious for the treatment of substance use disorders. Twelve Step Facilitation Therapy has been found to be efficacious in treating substance use disorders. This is a 12-session therapy that includes a manual to promote consistency in the delivery of the treatment. The therapy incorporates principles from 12-step programs (such as Alcoholics Anonymous and Narcotics Anonymous). Although Twelve Step Facilitation Therapy has been found to be an effective treatment under controlled conditions, many treatment centers across the country do not use this therapy, even though the manual is readily available from the National Institute of Alcohol Abuse and Alcoholism. Use of this therapy manual would likely increase quality and consistency of care in treatment centers dedicated to the 12-step model.

Cognitive-behavioral therapy, which involves the use of scientifically developed and tested cognitive and behavioral modification methods to change behavior, has been found to be an effective means to intervene in substance use disorders. Many psychologists use

cognitive-behavioral therapy in individual psychotherapy with clients who have substance use disorders. As its name would suggest, cognitive-behavioral therapy includes change strategies described subsequently that target cognitions and behavior chains associated with substance use patterns in clients.

Cognitive change strategies challenge and modify beliefs about substance use behavior. For example, beliefs about substance use influence motivation to change behavior, which in turn predicts whether a client will take steps to change behavior. Client motivation levels vary widely in treatment; so assuming that a client is ready to change is unreasonable. In addition, client motivation changes over time so that one minute he or she can appear committed and then uncommitted the next. Ambivalence about change is normal, especially early in therapy, and reflects the reality that clients are weighing beliefs about the pros of substance use against the cons. The Transtheoretical Stages of Change Model, a widely used model to understand addictive behavior change, indicates that commitment to change will occur when clients resolve their ambivalence in favor of resolve to take action.

Motivational interviewing and motivational enhancement therapy have been found to be very helpful to enhance motivation to change among clients. Motivational interviewing is a scientifically validated therapy that uses strategic methods to help clients to explore and resolve their ambivalence about continued substance use and that enhances motivation to change. Research has found that use of motivational interviewing can be very effective to encourage reductions in substance use and can be used effectively in conjunction with other therapies. Motivational enhancement therapy is a scientifically tested therapy conducted over four sessions and includes the use of motivational interviewing along with other change strategies. Motivational interviewing seems to be especially effective with clients uncommitted to therapy.

Other beliefs associated with substance use include expectancies and self-efficacy. Expectancies are beliefs that people have about the expected outcomes of substance use, and they have been found to be a good predictor of substance use pre- and posttreatment. The research suggests that interventions that increase negative expectancies and decrease positive expectancies may be helpful to improve treatment outcomes. Therapists use various cognitive strategies to accomplish this goal. Self-efficacy, or confidence and competence in being able to negotiate particular situations without substance use, is another consistent predictor of treatment outcome. Therapists teach, rehearse, and reinforce new skills to cope effectively with high-risk situations to establish competence and to develop confidence in appropriately using the skills to enhance self-efficacy so as to avoid substance use in those situations.

Several behavior modification strategies have been found to be effective to foster change. Aversion therapy pairs substance use with aversive agents to discourage the use of the substance. Typical methods are pairing the smell or taste of the substance with electric shock or an emetic agent to condition avoidance of substance use. Studies have found that aversion therapy can result in successful outcomes initially, but those posttreatment gains may be lost over the long term without concurrent use of relapse prevention (see below). Contingency management strategies have been used successfully to encourage positive outcomes in treatment. Contingency management modifies client behavior by providing incentives to successfully engage and complete targeted tasks in therapy. Incentives have been used to increase attendance and participation in sessions as well as promote reduction targets or cessation of substance use. However, contingency management is not widely used, perhaps because of the costs involved with incentive-based care.

Coping skills therapy has been supported by science as well. New skills are taught to aid clients to cope effectively and solve problems without the use of substances. Therapists may also teach anger management, daily life management, assertiveness training, and relaxation methods (including meditation) to increase the repertoire of skills available to clients. Relapse prevention methods developed in the cognitive-behavioral model have been shown to be highly successful to reduce the severity and duration of relapse events when they occur. Relapse prevention teaches clients that relapse is normative rather than a failure and can be used to identify and correct problems in posttreatment behavior. Relapse prevention also teaches substance refusal skills, develops and rehearses plans to cope with relapses, and uses cognitive and behavioral modifications previously mentioned in this section. In addition to one-on-one methods with clients, cognitive-behavioral interventions that target couples, family relationships, schools, and other peer groups have been associated with changes in substance use.

Substance Use Disorders

Substance use disorders are defined as the use of a substance that results in persistent and sometimes pervasive aversive consequences. Substance use disorders have profound economic and public health impacts in the United States. Researchers have identified important biological, psychological, and social factors that predict the development and resolution of substance use disorders. Biological processes related to substance use include physiological reactivity, changes, and adaptations. Psychological processes associated with substance use include conditioning, observational learning, beliefs about substance use, and emotions that cue substance use. Social relationships and environmental stressors also have been found to influence the course of substance use. Diagnostic criteria have been established to define severity and to specify the course of the disorder. Substance use disorders are thought by some to be chronic and progressive, but research on the natural course of these disorders disputes those beliefs.

Impact of Substance Use Disorders

The total costs of abuse of alcohol and abuse of other drugs including tobacco to the American economy has been estimated by the federal government to be more than $400 billion annually. The two most common substances of abuse are tobacco and alcohol. Conservative estimates indicate that about 20% of the population in the United States abuses tobacco, and between 8% and 13% of the population abuses alcohol. Men are more likely to abuse substances than women. Treatment often results in positive outcomes.

Substance abuse has been associated with the five leading causes of death in the United States in 2004: heart disease, cancers, strokes, chronic lower respiratory illnesses, and unintentional injuries. Some ethnic minority groups may be at high risk for substance use problems. For example, liver diseases often associated with alcohol abuse were the sixth leading cause of death for Hispanics and Native Americans. In contrast, liver diseases are not in the 10 leading causes of death for either Whites or Blacks. However, it is also worth noting that there is often wide variation in substance use within demographic groups. Interestingly, Native Americans also have the highest abstention rate from alcohol when compared with any other ethnic group.

In the United States, the recent trend is greater abuse of prescription medications and methamphetamines. Abuse of substances not traditionally classified as psychoactive, such as steroids and erectile dysfunction medications, has been commonly seen over the recent years. Although these substances often are not listed among traditional drugs of abuse, they can become problematic for users.

Substance abuse is strongly associated with legal consequences. In addition to violation of controlled substance statutes, substance abuse has been associated with domestic violence and other violent crimes such as suicide, property damage, vehicular offenses, and sexual perpetration. In the United States, crime-related costs of substance abuse have been projected to be around $100 billion annually, and conservative estimates have indicated that at least 1 million people have substance abuse problems. Substance abuse is also a major contributing factor to traffic and workplace accidents. Extreme substance-related toxicity can contribute to psychotic symptoms, although sometimes those symptoms preceded the substance use and were masked.

Biopsychosocial Model

Researchers use a biopsychosocial model to understand addictive processes. Biological processes that have been identified include physiological reactivity to the

ingestion of substances, physiological changes due to acute or chronic use of substances, and physiological adaptations to the level of exposure to the substances. Physiological reactivity occurs in response to the substance and results in metabolic changes in the body. Substances activate the pleasure-reward system in the brain, which often results in euphoria. Acute or chronic substance abuse can cause neurotoxicity and damage to vital organs. Commonly experienced cognitive impairments include difficulties with short-term and working memory; problems with executive cognitive functions related to decision making, problem solving, impulse control, and abstraction; and, in some cases, difficulties with balance and motor functions. Existing evidence suggests that some physiological changes are reversible, including cognitive impairment, after a period of abstinence.

Psychological processes include behavioral, cognitive, and emotional responses to substance use. Behavioral processes operate according to learning principles. Classical conditioning in substance abuse occurs when particular stimuli are paired or associated with substance use. In substance abuse research, these stimuli are often referred to as *cues* or *triggers.* Substance use may occur at an automatic level when cues trigger substance use so quickly that the individual may be momentarily unaware of actions. Common triggers or cues include places, situations, things, physical senses (sensations, sights, sounds, smells, and tastes), emotions, or events that become paired with substance use and may trigger cravings or desires to use.

Operant conditioning operates when substance use is reinforced or punished. Positive reinforcement is conceptualized as a consequence following a behavior that is rewarding or pleasurable and makes it likely that the behavior will be repeated. Substance use can have rewarding properties that positively reinforce the behaviors related to substance use. In addition, substance use can be negatively reinforced. Negative reinforcement occurs when an aversive consequence is lifted or withdrawn, which in effect reduces an aversive experience. Because the aversive consequence is withdrawn or reduced, it makes it more likely that the behavior will be repeated. An example of this process is when someone uses substances because it has reduced pain or discomfort previously (negatively reinforced) as opposed to using substances because it has caused euphoria in the past (positive reinforcement). An excellent and common example of substance use being negatively reinforced among users is when they described using substances to "self-medicate" symptoms. The behavior described as self-medication alludes to a history where the substance use may have caused aversive symptoms to subside. Research has demonstrated that punishment can effectively stop or reduce substance use over the short term but that for long-term changes to occur punishment must be followed by learning new behavior and having that reinforced.

Substance abuse is difficult to change because it is reinforced on a variable schedule. Since substances are sometimes reinforcing and sometimes not, the user cannot predict when substance use will be reinforcing and continues using substances in the hope that the next event will be reinforcing. Variable reinforcement is one process that contributes to the transition from recreational use to substance abuse.

Observational learning also is a powerful predictor of substance use. Youths and young adults are very much influenced by observing and then modeling the behaviors of significant others in their lives. Before adolescence, youths tend to model the substance use behavior of their parents. Researchers have noted that substance abuse tends to be intergenerational in family systems. The assumption for many years was that this intergeneration "transmission" of substance abuse must be genetic. However, recent research has identified that at least part of the intergenerational phenomenon in family systems appears to be learned behavior, principally from observing and modeling parents who misuse substances. As youths move into the teen years and early adulthood, peer groups tend to influence substance use more than parents. In addition, researchers have found that adolescents and young adults tend to overestimate the substance use of peers and at the same time underestimate their own substance use.

Cognitive factors related to addictive processes include expectancies about substance use, motivation to change, and self-efficacy. Expectancies are beliefs about the expected effects of substance use. Expectancies can develop through personal experience or observational learning. As an example of the latter, to sell their products advertisers of alcohol beverages often advertise that alcohol makes people sexy or socially attractive, beliefs that are assumed by youths who observe the advertisements. Positive expectancies refer to beliefs that substance use will provide a desirable outcome, whereas negative expectancies refer to beliefs that substance use will lead to an undesirable outcome. Positive expectancies have been found to predict continued and sometimes increased substance use, whereas negative expectancies have been linked to reductions.

Motivation to change determines whether a user will consider and ultimately change substance use.

Decisions to change often follow a process known as the decisional balance, where a user considers the pros and cons for change. Ambivalence is quite normal for someone contemplating change. If a user decides that the pros for change outweigh the cons, then she or he likely will be more committed to changing behavior and seeking help. Self-efficacy also has been found to predict substance abuse. *Self-efficacy* is a term from social learning theory that describes, in the case of substance abuse, whether a person has competence and confidence to negotiate a specific situation without use of substances. Lower self-efficacy in a situation predicts poorer substance use outcomes in that situation.

Cognitive impairment is of concern when a user has engaged in extreme or chronic substance abuse. Perceptual problems result from acute intoxication. One phenomenon, substance use myopia, refers to how cognitive processes become impaired as intoxication increases, literally narrowing a person's ability to see or accurately perceive events occurring around him or her. During substance use myopia, clients are vulnerable to impulsive, disinhibited, and risky behavior because perception of risk is impaired. As an example, substance-induced myopia leads to poor judgment, such as believing that it is safe to drive under the influence of substances.

Emotions and moods also have been associated with substance abuse. Many users report links between emotional events and substance use behavior, and relapses have been linked to extreme emotions (positive or negative). Users often use substances to manage emotions and moods but also report that substance use contributes to loss of emotional control. Research has established that chronic substance use may disrupt emotional expression and contribute to substance induced dysphoria.

Social and environmental factors linked to addictive processes may include relationship stressors and environmental stressors such as unemployment and poverty. Some researchers believe that a major function of substance misuse is in tension reduction. Changes in relationship interactions and environmental conditions have been linked to changes in substance use. Youths are especially vulnerable to changes in the environment and substance abuse in that age group can be influenced heavily (both positively and negatively) by such changes.

Diagnosis of Substance Use Disorders

Misuse of substances can be diagnosed by means of structured clinical interviews that assess for criteria specified by the American Psychiatric Association in the *Diagnostic and Statistical Manual of Mental Disorders,* fourth edition (*DSM-IV*). The most commonly used interviews are the Structured Clinical Interview for *DSM-IV* (SCID) and the Diagnostic Interview Schedule (DIS). Substance misuse is classified as either substance abuse or dependence for a single substance or for multiple substances. *DSM-IV* diagnostic categories also include "specifiers" that denote abuse with or without physiological dependence and "course specifiers" that define the course of the disorder, including early full remission, early partial remission, sustained full remission, sustained partial remission, on agonist therapy (such as methadone), or in a controlled environment (where access is restricted).

DSM-IV diagnoses conceptualize substance abuse as a chronic condition subject to periods of remission. However, researchers have found evidence that a subgroup of people diagnosed with alcohol dependence, for example, show evidence of controlled moderate drinking without problems later in life. In addition, other research shows that the course of substance abuse does not necessarily worsen with time nor do users need to hit the bottom to want help. Substance use diagnoses for adolescents have been found to be very unstable. Many adolescents meeting *DSM-IV* criteria for substance abuse or dependence experience a "maturing out" process as they age and go on to adult lives free of substance-related problems. Therefore, substance use diagnoses for adolescents should be interpreted with caution.

Suicide Assessment and Prevention in Prisons

Prisoner suicide assessment and prevention is an area of active research and clinical involvement. Indeed, it is an important component of the forensic psychologist's clinical responsibilities due to the disproportionately high incidence of prison suicide as compared with the general population. This high incidence is a consistent phenomenon across countries. In some countries, this translates into suicide being a major cause of death among prisoners. To address the topic of suicide assessment and prevention, first the research challenges in conducting prisoner suicide research and the relevant theory in conceptualizing the process of prisoner suicidality are briefly summarized. A review of relevant risk factors as evidenced by research are categorized into several domains and described. These domains include demographic factors, historical factors, criminality factors, and clinical factors. Following a review of risk factors, suicide prevention within the prison setting is summarized.

Research and Theory

In an effort to better understand and assess (i.e., predict) prisoner suicide, a large body of research has investigated the risk factors related to prisoner suicide. However, there are some intrinsic challenges in the prediction of suicide generally, and there are some methodological weaknesses in prisoner suicide research specifically. The major challenge in predicting suicide is that it is a relatively rare event (i.e., has a low base rate). Statistically, it is more difficult to predict a rare event than a frequent event. This creates significant challenges for researchers in designing good-quality predictive studies. For example, because suicide is a relatively infrequent event, a researcher would need to have a very large number of subjects at the beginning of a study for there to be a sufficient sample size of eventual suicides for analyses. For individual clinicians, this difficulty in predicting rare events creates the higher risk of false positives (i.e., predicting suicide where none occurs). False negatives (a suicide occurs when it was predicted that no suicide would occur) literally have life and death implications and represent what most clinicians and staff members want to avoid.

Some particular methodological weaknesses in prisoner suicide research include samples consisting of mixed populations of prisoners (e.g., remanded and sentenced prisoners), lack of control or comparison groups of nonsuicide or nonattempter prisoners, and reliance on descriptive studies, which generates difficulties in establishing a causal relationship between risk factors and outcome. Of note is that, in recent years, researchers have made efforts to address these methodological problems. There have been efforts to design more comparative studies, to use more sophisticated statistical analyses (e.g., logistic regression), and to even undertake matched control studies. This is a welcome shift in the research approach to prisoner suicide. Indeed, given the plethora of descriptive studies generated over the last 25 to 30 years, there are limitations in the value added by purely descriptive studies of prisoner suicide at this time. Designing more methodologically sound studies will more meaningfully build on current knowledge.

Overall, despite the challenges presented by researching prisoner suicidality, identifying relevant risk factors has facilitated the development of suicide assessment protocols and scales. Prior to reviewing relevant risk factors, it is important to note that, as useful as individual risk factors are, there has been a major contribution by researchers who have offered valuable conceptualizations of the suicidal process as one that occurs over time and is affected by multiple factors. In particular, Marti Heikkinen and colleagues have provided one of the most well-developed models. Their process model of suicide consists of risk factors, precipitating factors, vulnerability factors, and protective factors that contribute to the process of suicidality. In this model, the suicidal process is viewed as dynamic and affected by several categories of risk factors (i.e., biological, psychological, social, cultural). At the same time, the individual's vulnerability and protective factors affect risk. For instance, a prisoner who has difficulty in coping with various areas of his life will likely experience greater risk. A prisoner with a strong social support system would likely experience some protection against risk. Finally, the model includes precipitating factors such as stressors and external events that contribute to triggering suicidality (e.g., loss of support, negative decision regarding release).

Risk Factors

Research on prisoner suicidality reveals several domains of risk factors that are relevant to suicide assessment. These general domains include demographic factors, historical factors, criminality factors, and clinical factors.

Demographic Factors

During the last couple of decades, predominantly descriptive research has linked prisoner's age with suicidal risk. Generally, the research has suggested that younger age groups (e.g., approximately under the age of 30 years) are overrepresented in suicide completer samples. However, a couple of recent and more methodologically sound research studies have challenged this conclusion, suggesting that either no relationship exists or that older age (i.e., 40 years and above) is predictive of prisoner suicide. More research will be required to clarify predictive relationships between age and prisoner suicide. A relatively new result provided by one of these recent studies was identifying homelessness as a predictive factor. It is worth mentioning that many descriptive studies have examined marital status as a correlate of prisoner suicide. These results have been equivocal and not uniformly supported by the recent better-quality research.

Historical Factors

The research has been fairly convincing that both the presence of a psychiatric history (typically broadly defined in prisoner suicide research) and a history of substance abuse are connected to an increased risk of prisoner suicidality. Recent research using the matched control methodology and/or logistic regression analyses has supported these predictive relationships. Some research suggests that recent psychiatric contact or intervention may possess additional predictive power. Results from the larger body of suicide research have revealed the increased risk generated by a family history of suicide. In particular, a genetic component has been attributed as partly responsible for the relationship. Individuals with first-degree relatives (i.e., parents, siblings) who committed suicide are at greater risk for committing suicide. This risk becomes more elevated if the relative suffered from a mood disorder (i.e., depression, bipolar disorder). Given this research, it is important to consider this factor in assessing prisoner suicidality.

Criminality Factors

Several criminality factors are linked with greater risk of prisoner suicidality. These include sentence length, time served in sentence, security level, criminal history, and institutional adjustment. In terms of a prisoner's sentence length, generally prisoners with lengthier sentences are disproportionately represented among prisoner suicides. In particular, those prisoners with life or indefinite sentences may be at higher risk. The amount of time served in one's sentence is also linked to prisoner suicide but not as definitively as sentence length. Generally, prisoners who commit suicide do so earlier in their sentences (within approximately the first 2 years of being sentenced). A prisoner's security level appears to be relevant to suicidal risk. A limited amount of recent research, some of which has used logistic regression, has revealed an overrepresentation of higher security prisoners (i.e., maximum security level) among suicide completers and attempters. Recent more methodologically sound research has indicated that several characteristics of prisoner criminal history are linked with suicidal risk. In one study, suicide attempters were more likely to have current convictions for homicide, break and enter, or robbery. Consistent with that result were two studies that found having a current violent offense was more predictive of suicide completers. In addition, prisoners with a history of prior criminal involvement (variously defined as prior offense[s], prior incarceration) were more likely to attempt or commit suicide. One study found that suicide completers and attempts were more likely to have had breach of trust offenses (i.e., escapes, violations of parole or probation). Finally, limited recent research using comparison groups and logistic regression found that both suicide completers and attempters had demonstrated negative institutional adjustment (e.g., institutional violence, contraband violations, substance abuse incidents, escape, requests for protective custody). Prisoners with a history of contraband-related incidents were three times more likely to attempt suicide. Those with a disciplinary history were 19 times more likely to engage in a suicide attempt. Both suicide completers and attempters participated in correctional programs less than nonattempters.

Clinical Factors

In addition to assessing the risk factors characteristic of suicidal prisoners, there is a fundamental role for the assessment of relevant generic clinical factors as part of the suicide assessment. In other words, a good assessment of prisoner suicidality is predicated on conducting a competent clinical assessment. In fact, there are several salient clinical factors that require particular attention. Clinical domains and factors important to the

suicide assessment are described. The work of John and Rita Sommers-Flanagan has been used to lend some structure to the description of clinical factors. In addition, where relevant, prisoner suicide research related to that factor is summarized. The overarching clinical factors include the presenting problem, depression, suicidal ideation suicidal intent, suicidal plan, self-control, vulnerability, and coping.

Presenting Problem

Similar to a suicide assessment with a nonforensic client, the initial goal is to attempt to establish rapport and determine the nature of the presenting problem. Determining the prisoner's level of distress and coping efforts will provide some indication of how to pace the remainder of the assessment. Identifying the precipitating factors and current stressor(s) provides some contextual and situational information.

Depression

There is a strong relationship between depression and suicidality as well as between depression and hopelessness. If a user combines alcohol and depression, then risk will further elevate. Therefore, it is important to determine the presence of depressive symptomatology. The diagnostic criteria and symptomatology of depression are not detailed here. Rather, relevant domains of functioning are reviewed as a means of suggesting some structure for the assessment process. These include emotional, physical, cognitive, behavioral, and social domains.

The *emotional domain* primarily refers to determining the presence of depressed mood and related factors such as frequency, intensity, and duration. Of particular concern is the presence of hopelessness. Research has established hopelessness as a strong predictive factor of suicide generally. Available research investigating this factor in prison populations has confirmed the predictive relevance of hopelessness. An additional emotional factor that warrants attention is the occurrence of a sudden and unexplained change in the individual's mood and/or functioning. This is a salient clinical sign that has traditionally been interpreted as an indication of increased risk. Experts in suicide assessment suggest that the improvement may result from the individual making a decision about ending his or her emotional pain or result from an alleviation of mental illness. The suggested dynamic is that either of these occurrences reduces ambivalence, brightens moods, and frees up energy to act (and possibly carry out a plan for suicide).

The *physical domain* refers to determining the presence of physical symptomatology indicative of depression. Relevant factors include appetite, weight, sleep, energy level, concentration, psychomotor functioning, and self-care.

The *cognitive domain* involves assessing whether cognitive functioning is intact. For example, there may be the presence of thought distortions, disorganized thought, impaired judgment, or event psychotic symptoms. Research has also pointed to the relationship between depression and the presence of negative thinking about oneself, the world, and the future (referred to as the cognitive triad).

The *behavioral domain* refers to behavioral symptoms of depression that can be observed. These may include decreased pleasure in one's usual activities, decreased physical activity, restlessness, poor concentration, and poor problem solving. Changes in self-care and other negative behavior may be present.

The *social domain* refers to interpersonal and social functioning. Some examples can include social withdrawal, rejecting support, interpersonal conflict, and decline in social skills.

Suicide Ideation and Suicidal Intent

Suicidal ideation and suicidal intent are related to increased risk for suicide. Ideation does not necessarily result in high risk. Expressing suicidal intent generally presents a greater risk than ideation. Inquiring directly about ideation and intent is important. Questions regarding frequency, duration, and intensity can provide additional information. In addition, collateral information and/or behavioral observations can be useful. If the prisoner commits or contracts, it is suggested that the commitment be made for both self-harm and suicide rather than assuming the commitment for one act will generalize to the other.

Suicide Plan

Having a suicide plan can present a serious level of risk. Determining the details is crucial. Relevant domains of functioning to assess include prior suicide attempts, specificity, lethality, availability, and proximity.

A history of prior suicide attempts increases the risk for suicide. A suicide attempt within the past year elevates risk even further. Obtaining details about the prior

attempts can help identify any patterns or past precipitants that may be relevant to the current situation.

Specificity of the suicide plan needs to be determined. Generally, the more detailed (i.e., high specificity) a plan, the greater the risk of suicide.

Lethality of a suicide plan is defined as the amount of time that passes between initiating the suicidal act and dying. High lethality is a plan that results in a quick death (e.g., hanging) and translates into high risk. In addition to the lethality presented by a specific method, there is also an impact resulting from how the method will be used. Research on prison suicide has revealed that hanging, a very lethal method, is the primary method of committing suicide.

Self-Control

By examining a prisoner's behavioral history (e.g., history of impulse control difficulties) and obtaining information about previous suicide attempts, the prisoner's degree of self-control can be assessed. Another factor affecting self-control is the use of alcohol or substances.

Coping and Vulnerability

A prisoner's poor ability to cope is a risk factor of suicide. Research has identified a component of the prison population that is particularly vulnerable and poor copers. These individuals tend to have difficulty coping across time and situations.

Psychosocial isolation (e.g., emotional and social support) increases the likelihood of suicide. The prisoner's access to emotional and social support resources should be assessed.

Physical isolation of suicidal prisoners can have a detrimental effect. Research addressing this issue had revealed that placing suicidal prisoners in some form of isolation (e.g., constant observation) is quite detrimental and can actually contribute to increased suicidal risk.

Suicide Prevention

Suicide prevention is typically conceptualized as an institutional or organizational approach to preventing prisoner suicides. Among the preventive strategies, there can be policies and procedures that specify the management of identified suicidal prisoners (e.g., type, frequency, and/or location of observations; mental health referrals). More broadly, there can be policies, procedures, and programs designed to improve identification of suicidal prisoners. Screening for suicidal risk at intake can be a valuable preventive strategy. During the last decade, there has been an appreciable amount of research directed toward developing effective screening instruments. Some scales are designed to be administered by nonclinical frontline staff at intake (e.g., correctional staff), while other scales require mental health training to administer. Some screening instruments have been designed for specific settings (e.g., remand centers vs. prisons), while other scales have been designed for use across a variety of settings. Implementing a screening instrument can be influenced by human resource and cost factors. A brief scale that requires no mental health training to administer is typically less resource intensive than a scale that may require clinically trained staff (e.g., nurse) to administer. However, the administrative costs must be weighed against the effectiveness of the scale to accurately identify prisoners as potential suicide risks.

An important component of suicide prevention programs includes training programs for prison staff. These programs can vary in scope. Some training programs target improved knowledge about the indicators of suicidality, while others target skill building in detection and basic intervention. Indeed, some institutions or jurisdictions have developed programs that provide training to prisoners in an effort to improve knowledge and/or provide skills that facilitate detection and peer support. Yet another suicide prevention strategy can involve changes to the physical environment that essentially decrease opportunity for a suicidal prisoner. For example, changes in cell location (e.g., observation cell) may improve visibility of a suicidal prisoner. Improvements to the physical structure of a cell may include installing tamper-proof fixtures and eliminating structures that provide opportunities to implement a suicide plan (e.g., a noose attached to a pipe).

Overall, research supports the conclusion that suicide prevention programs can reduce the incidence of prisoner suicides. Wider implementation of suicide prevention policies, procedures, and programs is necessary to further advance prevention efforts. Indeed, more comprehensive suicide prevention programs would also be beneficial.

Suicide Assessment Manual for Inmates (SAMI)

The Suicide Assessment Manual for Inmates (SAMI) is a new instrument designed to assess risk for suicide attempts among individuals admitted to a pretrial remand center or jail. The SAMI is a 20-item clinical checklist of risk factors derived from the suicide research literature. Initial research on the SAMI has focused on its factor structure and predictive validity.

Suicide is the leading cause of death of inmates in jail facilities. Research on suicide prevalence rates indicates that the rate of suicide in an incarcerated population is higher than that in the general population, with some estimates indicating the prevalence to be as much as nine times higher in incarcerated populations. In addition, the prevalence of suicide may be higher in a population of remanded (pretrial) offenders than in a population of sentenced offenders. Suicide is a low base rate behavior; therefore, it is difficult to predict which individuals will attempt to commit suicide. It is, however, important to be able to identify those inmates who are at an increased risk for suicide on admission to a correctional facility so that they may be classified and housed accordingly.

Structured clinical guidelines are useful in attempting to determine which individuals are at an increased risk for suicide. The SAMI was developed to provide a framework of important variables that should be assessed for each individual admitted to a pretrial remand center or jail to determine that individual's risk for suicide within the next 24 hours. The SAMI is a clinical checklist of risk factors for institutional suicide attempts. It consists of 20 items that were identified by a review of the literature on suicide in general as well as suicide in jails and prisons. The purpose of the SAMI is to guide evaluators through important information and variables that should be assessed to determine an inmate's risk for institutional suicide. The SAMI was developed for use as a way to structure professional judgment in the assessment of institutional suicide risk.

Each of the 20 items contained in the SAMI can be rated on a 3-point scale, with a score of 0 being associated with low risk, a score of 1 being associated with moderate risk, and a score of 2 being associated with high risk with respect to the particular item. It is important to note, however, that like many instruments developed to structure professional judgment, the item scores on the SAMI are not to be added but, rather, are to be considered within the full context of the individual, the institution, and the circumstances. Both the self-report of the inmate as well as the observations and professional judgment of the evaluator are to be considered for each item.

Extensive and thorough literature reviews have identified numerous variables that are associated with risk for suicide in general as well as in jails and prisons, including age; sex; marital status; history of drug or alcohol abuse; psychiatric history; history of suicide attempts; history of institutional suicide attempts; family history of suicide; arrest history; history of impulsive behavior; high-profile crime or position of respect within the community; current intoxication; concern about major life problems; feelings of hopelessness or excessive guilt; presence of psychotic symptoms or thought disorder; symptoms of depression,

stress, and coping; social support; recent significant loss; suicidal ideation; suicidal intent; and suicide plan. The SAMI includes an assessment of each of these variables, with the exception of age and sex given the low variability on these factors since the vast majority of jail inmates are males in their 20s and 30s.

The SAMI is a new instrument, and research examining its reliability and validity is limited. Results of a preliminary study in which the SAMI was administered to 138 pretrial defendants indicate acceptable levels of interrater reliability. In addition, this research indicates that scores on the SAMI items are related to institutional category of risk for suicide (low, medium, high), need for mental health services, and need for monitoring within the pretrial facility. Factor analysis of the SAMI items identifies six factors: affective disturbance, suicide history, current cognitive state, current situational variables, impulsivity, and support and coping. The first three factors (affective disturbance, suicide history, and current cognitive state) are strongly associated with institutional category of risk for suicide, need for mental health services, and need for monitoring within the institution. The sixth factor, support and coping, is also strongly associated with need for mental health services. Regression analyses with the SAMI have indicated that Factors 1 and 2 (affective disturbance and suicide history) are predictive of referral to mental health services within the institution, whereas Factors 2 and 3 (suicide history and current cognitive state) are predictive of category of institutional suicide risk. Further research investigating the predictive utility of the SAMI is currently underway.

Suicide by Cop

Suicide by cop (SbC) is a phenomenon confronted by police officers in which suicidal individuals behave in such a way as to force officers to use lethal force against them. Research findings have found common characteristics and behaviors among SbC subjects. The phenomenon is recognized sufficiently that there are a number of court decisions that are relevant to incidents that are defined as SbC. Finally, police officers often suffer psychologically after their involvement in SbC incidents. Their suffering must be addressed if they are not to have long-term effects.

Suicide requires an active decision to kill oneself. Such action may conflict with religious ideology, or the subject may fear societal stigma. Suicidal individuals also may fear pain and believe that the police officers' training in lethal force will ensure their instant death. Some of these individuals have a desire to die in a high-profile "blaze of glory." Often, the decision of individuals to induce the police to use lethal force against them is impulsive. Emotionally distraught and under the influence of alcohol, many individuals form a cloudy decision to die only when the police arrive in response to a precipitating event such as a domestic dispute. Due to some of these conditions, suicidal subjects may become SbC subjects, inducing officers to kill them.

As with other suicidal behavior, the subject frequently is ambivalent about death. If the police can delay a confrontation, SbC subjects often are open to negotiation, especially if they become sober. Unfortunately, as found by studies conducted by the author, SbC subjects often place officers in situations in which they cannot get themselves or the victims in a safe place, so must shoot the SbC subjects. Also similar to other forms of suicide attempts, the behavior that often accompanies an SbC incident is an endeavor to cope with stressful life events by self-destructive behaviors.

SbC subjects primarily are male, White, and more than 25 years old. They often have a mental illness history, including mood and personality disorders. Alcohol is used in a majority of the recorded SbC incidents, with a number of the individuals having a history of alcohol abuse. Subjects under the influence of alcohol overcome their inhibitions and are more impulsive and lethal. Often, anger and aggression are indicated by a number of past assault or domestic violence complaints, homicidal pre-incident conversations, and negotiation conversations that include injury to others.

Precipitating events to the SbC incidents often include the termination of a relationship and/or other family problems. SbC subjects have been known to attempt to use the incident as a means to coerce a significant other to remain in a relationship or for revenge against a significant other. Unlike other suicide victims,

SbC subjects usually have significant others in their lives, although these others are often part of the problem. Outstanding criminal warrants on the SbC subject also are prevalent. They may state that they would rather die than return to prison.

Although early research in SbC focused on preparation by SbC subjects, more recent research done by the author has found that about half of the SbC incidents are impulsive rather than planned. About half of the SbC subjects, who she studied, had made some sort of statement or had a change in behavior that could be interpreted as presuicidal. These behaviors included writing and leaving a note, telling a therapist or significant other of what they were considering, and giving away possessions. Prior suicide attempts overall were not very prevalent; however, those who had attempted suicide in the past were more likely to be successful in their attempts in inducing police officers to shoot them.

The courts have not decided predominantly in favor or against police officers in all SbC cases; however, the courts have agreed that only the facts known by the officers at the time of the incident are relevant to the case. Intentions or motives of the SbC subjects discovered later are not directly related. The degree of danger that the officer or another person is in is judged at what is known by the officer at the time of the incident. Officers are granted qualified immunity unless they violate established law. The plaintiff has the burden to prove that the officers committed a constitutional violation.

Although the courts should consider only what the officer would have known at the time of the incident, it is useful to conduct a psychological autopsy to investigate what the individual's state of mind was at the time of the SbC incident. Such information will give officers a better understanding of the subject's motivation, plan, and pathology. It can help also in officers' psychological debriefings. Information for a psychological autopsy often is obtained from the subject's friends, family, and co-workers, as well as from any notes left by the subject, recent high-risk behavior, the giving away of personal property, and actions or statements that suggest preoccupation with death and/or suicide.

Officers who are involved in the SbC incident, especially the officer(s) who actually shoot the subject, are quite likely to suffer psychological traumatic stress disorder. Often, the subject does not actually have a loaded or real gun, although it appears real at the time of the incident. The officer may feel manipulated by the subject and is unprepared for the emotional and physiological reactions that follow the shooting. The officer also is often not given the opportunity to verbalize or emotionally ventilate his or her emotions. It is critical that police agencies require officers to see a therapist if they are involved in shootings or other violent incidents.

Supermax Prisons

Super-maximum secure or "supermax" prisons are used to hold those prisoners whom prison authorities regard as the most problematic in the prison system. These facilities merge the 19th-century practice of long-term solitary confinement with 21st-century technology in ways that subject prisoners to unparalleled levels of isolation, surveillance, and control, usually for long duration, with the potential to inflict significant amounts of psychological harm. Despite a range of academic studies documenting the serious and potentially long-lasting psychological harm it may inflict, and several judicial opinions criticizing the risks it entails and significantly limiting its use, the supermax prison form persists. This entry describes the conditions in which prisoners in supermax confinement are held, characteristics of the supermax population, effects on prisoners of supermax confinement, and the current legal status of supermax prisons.

Although different prison systems employ different terminology to refer to supermax-like conditions (e.g., "control unit," "special management unit," "security housing unit," or "close management"), these units have enough distinctive features in common to be analyzed as

a separate penal form. Their use has continued to increase over the past several decades, and there are now tens of thousands of prisoners in supermax-type confinement throughout the United States.

Conditions of Supermax Confinement

Conditions in supermax confinement are marked by the totality of the isolation, the intended duration of the confinement, the reasons for which it is imposed, and the technological sophistication with which it is achieved. Supermax facilities house prisoners in virtual isolation and subject them to almost complete idleness for extremely long periods of time. These prisoners rarely leave their cells and are typically given at most 1 hour a day of out-of-cell time. They eat all their meals alone in the cells, and typically, no group or social activity of any kind is permitted. In most of these units, prisoners are escorted outside their cells or beyond their housing units only after they first have been placed in restraints—chained while still inside their cells (through a food port or tray slot on the cell door)—and sometimes tethered to a leash that is held by an escort officer.

Prisoners in supermax confinement are rarely if ever in the presence of another person (including physicians and psychotherapists) without being in some form of physical restraints (e.g., ankle chains, belly or waist chains, handcuffs). They also often incur severe restrictions on the nature and amounts of personal property they may possess and have limited access to the prison library, legal materials, and canteen. Their brief periods of outdoor exercise or "yard time" typically take place in caged-in or cement-walled areas that are so constraining they are often referred to as "dog runs." In some units, prisoners get no more than a glimpse of overhead sky or whatever terrain can be seen through the tight security screens that surround their exercise pens.

Supermax prisoners often are monitored by camera and converse with staff through intercoms rather than through more direct and routine interactions. In newer facilities, computerized locking and tracking systems allow most of their movement to be regulated with a minimum of human contact (or none at all). Some supermax units conduct visits through videoconferencing equipment rather than in person, which means that prisoners are denied immediate face-to-face interaction (let alone physical contact), even with loved ones who may have traveled great distances to see them. In addition to "video visits," some facilities employ "telemedicine" and "telepsychiatry" procedures in which prisoners' medical and psychological needs are addressed by staff members who "examine" and "interact" with them over television screens from locations many miles away.

As noted, supermax prisons routinely keep prisoners in this near-total isolation and restraint for extremely long periods of time. Unlike punitive segregation in which prisoners typically are isolated for relatively brief periods of time for specific disciplinary infractions, supermax prisoners may be kept under these conditions for years on end. In addition, many correctional systems impose supermax confinement as part of a long-term strategy of correctional management and control rather than as an immediate sanction for discrete rule violations.

Population of Supermax Prisons

Supermax prisons are usually justified by reference to the alleged dangerousness of the prisoners who are housed there—the "worst of the worst," as correctional administrators often characterize them. Thus, the increased use of this distinctive prison form is linked to the contention that an especially dangerous or "new breed" of disruptive prisoner now inhabits the modern maximum security prison. In fact, there is little or no empirical support for these contentions. Instead, many prisoners appear to be placed in supermax less for *what* they have done than *who* they are judged to be (e.g., "dangerous," "a threat," or, especially, a member of a "disruptive" group).

In many states, a large group (sometimes the majority) of supermax prisoners has been given "indeterminate" terms, usually on the basis of having been officially labeled by prison officials as gang members. An indeterminate supermax term often means that these prisoners will serve their entire prison sentences in isolation unless they "debrief" by providing incriminating information about other alleged gang members. These practices have resulted in a significant overrepresentation of racial and ethnic minorities in supermax prisons and what analysts have described as an "overclassification" of the prisoners who end up in these units.

In addition, the percentage of mentally ill prisoners in supermax appears to be much higher than in the general prison population. Thus, researchers estimate that approximately 30% of supermax prisoners suffer from "severe mental disorders." This overrepresentation of the

mentally ill likely results from the fact that some mentally disturbed prisoners engage in disruptive behavior that prison officials punish rather than treat. It also may indicate that supermax conditions themselves are severe enough to exacerbate and perhaps even create psychological disturbances in persons subjected to them.

Effects of Supermax Confinement

Numerous empirical studies have documented the harmful psychological consequences of living in supermax facilities. The evidence is substantial and comes from personal accounts, descriptive studies, and systematic research on solitary and supermax-type confinement conducted over a period of many decades by researchers from several different continents with diverse backgrounds and a wide range of professional expertise.

Direct studies of prison isolation have documented an extremely broad range of harmful psychological reactions, including potentially damaging symptoms and problematic behaviors such as negative attitudes and affect; insomnia, anxiety, withdrawal, hypersensitivity, ruminations, cognitive dysfunction, hallucinations, loss of control, irritability, aggression; and rage, paranoia, feelings of hopelessness, lethargy, depression, a sense of impending emotional breakdown, self-mutilation, and suicidal ideation and behavior. Self-mutilation and suicide are also more prevalent in isolated prison housing—the hallmark of supermax confinement, as are deteriorating mental and physical health (beyond self-injury); other-directed violence, such as stabbings, attacks on staff, and property destruction; and collective violence. In fact, many of the negative effects of solitary confinement are analogous to the acute reactions suffered by torture and trauma victims, including posttraumatic stress disorder.

Some researchers have estimated the prevalence rates of these adverse symptoms among prisoners who are confined in supermax-type conditions. One study found that three-fourths or more of a representative sample of supermax prisoners reported suffering from ruminations or intrusive thoughts; an oversensitivity to external stimuli; irrational anger and irritability; confused thought processes; difficulties with attention and often with memory; and a tendency to withdraw socially, to become introspective, and to avoid social contact. An only slightly lower percentage of prisoners in the same study reported a constellation of symptoms that appeared to be related to developing mood or emotional disorders—concerns over emotional flatness or losing the ability to feel, swings in emotional responding, and feelings of depression or sadness that did not go away. Finally, sizable minorities of supermax prisoners reported symptoms that are typically only associated with more extreme forms of psychopathology—hallucinations, perceptual distortions, and thoughts of suicide.

In addition to these specific symptoms, many supermax prisoners undergo other kinds of significant and potentially damaging transformations during their isolated confinement. Because they are so tightly and completely controlled, they may lose the ability to initiate or to control their own behavior or to organize their personal lives. Because individual identity is socially constructed and maintained, the virtually complete loss of genuine forms of social contact and the absence of any routine and recurring opportunities to ground thoughts and feelings in a recognizable human context leads to an undermining of the sense of self. For other prisoners, total social isolation leads, paradoxically, to social withdrawal. That is, some prisoners recede even more deeply into themselves than the sheer physical isolation of supermax requires.

Legal Regulation

Because supermax prisons are of relatively recent origin, their constitutionality—the question of whether the conditions of confinement in this new prison form represent "cruel and unusual punishment"—has been tested in only a few important legal cases. The first of these cases, *Madrid v. Gomez* (1995), addressed conditions of confinement in California's Pelican Bay Security Housing Unit. Although the judge found that overall conditions in the supermax units were harsher than they needed to be, he concluded that he lacked any constitutional basis to close the prison or even to require significant modifications in many of its general conditions. Instead, he barred certain categories of prisoners from being sent there because of the tendency of the facility to literally make them mentally ill or to significantly exacerbate preexisting mental illness. However, he also emphasized that the record before him had pertained to prisoners who had been in supermax for no more than a few years and that longer-term exposure might lead to a different result. The constitutionality of supermax confinement has been tested in federal courts in several other states (notably in Texas and Wisconsin), with largely similar results—a strongly worded condemnation of the

harshness of the conditions, exclusionary orders that exempted certain categories of prisoners from such confinement, but a concession that there was no legal basis to order that the supermax prisons be closed.

The legal threshold for finding conditions of confinement unconstitutional has been set especially high in the United States over the past several decades. Supermax prisons per se continue to come very close to this threshold and, in the case of mentally ill prisoners, were found to have crossed it. As the empirical record about the psychological effects of this kind of confinement continues to be augmented, and the consequences of long-term confinement in these units becomes clearer, other courts may reach different and perhaps even more sweeping conclusions about the legality of supermax.

T

Tender Years Doctrine

The tender years doctrine, or the practice of awarding infants and young children to mothers in custody disputes, was employed in most state courts from the late 19th century until the 1960s. The tender years doctrine is based on the idea that mothers have superior, "natural" nurturing abilities and a biological connection to their infants. In the 1970s, most states abolished the tender years doctrine and replaced it with a gender-neutral "best interests of the child" standard. However, some current research claims that a maternal preference, especially in custody disputes over infants, continues to exist in practice in lower-level courts.

History of Child Custody Law

Historically, fluctuations in child custody law have reflected societal changes in beliefs about parenthood. Until the mid- to late 1800s, fathers had sole rights to custody, reflecting the notion that women and children were considered the property of the male head of the household. The father's absolute claim to custody also reflected the view of children at the time: In the primarily agrarian economy of the early 19th century, children were seen as economic assets. This agrarian economy shifted to an industrial one in the mid- to late 19th century, which made children less economically valuable and also necessitated the separation of home and work. With the emergence of separate spheres, men worked outside of the home, and women had responsibility for the home. At this time, the law shifted to a "tender years" doctrine. The tender years doctrine emphasized mothers' biological superiority as a parent and gave a legal preference to mothers in custody matters.

In the past few decades, most states have replaced the tender years doctrine with a best interests of the child doctrine, under which both mothers and fathers are considered equally. This shift in custody law reflected more widespread changes to gender-neutral legal language. For example, in *Watts v. Watts* (1973), a New York family court stated that "application of the 'tender years presumption' would deprive [the father] of his right to equal protection of the law under the Fourteenth Amendment to the United States Constitution." Adopting the "best interests" standard also coincided with increasing public acceptance of the notion that fathers are able to care for children as well as mothers. In 1986, in *Pusey v. Pusey*, a Utah appeals court held that a maternal preference "lacks validity because it is unnecessary and perpetuates outdated stereotypes."

At the same time, psychological research was used in legal proceedings to bolster the idea that mothers or fathers could be good caregivers to young children. Research on father-child interactions supported this idea, as did studies claiming that preserving the child's relationship to its "psychological parent"—the adult most responsible for and connected to the child—was paramount. This psychological research was used to discredit the tender years doctrine and to endorse the best interests of the child policy.

Current Research on the Tender Years Doctrine

Despite the shift to a more gender-neutral custody standard, the consideration of tender years is not a relic

of the past. As recently as 1989, a Florida appeals court, in *DeCamp v. Hein*, applied a maternal preference in the case of a child of tender years. And until 1997, the Tennessee child custody statute allowed judges to consider the sex of the parents in the case of a child of tender years. Thus, some scholars argue that judges in the lower courts have not "caught up" with this change in the law. Even if the tender years doctrine is not endorsed in statutory or case law, trial court judges may subscribe to it.

A recent study examined both judges' views of the tender years doctrine and whether their views were consistent with contested custody rulings. In face-to-face interviews, judges were asked directly about the tender years doctrine and also asked to assess a hypothetical custody case involving an infant. Despite the current gender-neutral custody policy, over half the judges interviewed expressed some support for the tender years doctrine. These views of the tender years doctrine were explained, in large part, by the gender of the judges and, relatedly, by their gender role attitudes; female judges reported more egalitarian views and were less likely to support the tender years doctrine than male judges. When comparing judges' views of the tender years doctrine with their decisions in custody disputes, judges' accounts were generally consistent with their rulings in contested custody disputes. Judges who endorsed the tender years doctrine were more likely to award custody of infants and young children to mothers than judges who did not endorse the tender years doctrine.

This research suggests that although state appellate courts and legislatures have abolished the tender years doctrine, practice in lower courts may continue to perpetuate some vestiges of the tender years doctrine. So despite greater legal and cultural acceptance of the idea that fathers and mothers are equally qualified to raise children, there are complex processes at work in the legal system that may perpetuate traditional notions of motherhood and fatherhood.

Termination of Parental Rights

When families fail to care for and protect children, states have the authority, when granted legal jurisdiction by the court, to initiate family services and to provide substitute care for the children. The prevailing legal standard for the care and protection of children is the *best interest* standard. The state is expected to act in the best interest of the child. Termination of parental rights is a legal action initiated in state family or juvenile court by the state's child protective services department. It typically follows a series of care and protection hearings and interventions designed to protect children within the confines of child welfare laws and regulations promoting child safety, family life, and parental rights. Cases of severe maltreatment, defined by statute, may move immediately to termination of parental rights without the provision of family services. Less serious care and protection cases are resolved without a termination hearing. When the conditions for family reunification remain unsuitable, a termination hearing is initiated according to state statutes, child protective service regulations, and codified timelines. The content of termination statutes varies across state jurisdictions (in some instances, federal statutes apply). Common thresholds for state jurisdiction and subsequent termination of parental rights include serious harm or the threat of serious harm to a child due to a caregiver's physical abuse, sexual abuse, or physical and emotional neglect of the child. Some statutes contain other criteria, such as the amount of time the child has been in substitute placement and the child's attachment to substitute caregivers after a defined period of time in their custody.

Termination of parental rights is a legal action and a subsection of child and family law and psychology. In termination proceedings, the attorney's role depends on whom the attorney represents. The child protective services agency's attorney, employed by the state, represents the interests of the state in the care and protection of children. When facing a termination hearing, parents in states allowing indigent funding are

provided with attorneys. In other states, parents must hire attorneys privately. Usually, each caregiver has his or her own attorney. Children may be provided their own attorneys to represent their expressed interests and guardians *ad litem* to represent their best interests as determined by substituted judgment. The role of the psychologist, as a forensic evaluator or consultant, depends on the referral source and the referral question(s). The psychologist is retained by the court, the state, or one of the attorneys for the parent(s) or child. Evaluations are requested for five main reasons: (1) to assess the caregiver's need for interventions after the state assumes jurisdiction; (2) to evaluate the risk of harm, if any, the caregiver poses to the child; (3) to assess the child's level of functioning and intervention needs; (4) to assess the caregiver's amenability to interventions; and (5) to determine the caregiver's participation and progress in recommended interventions. Referral questions may be comprehensive, involving the evaluation of multiple family members; or they may be limited to a specific feature of the case.

A properly qualified forensic psychologist has knowledge of jurisdictional legal and regulatory care and protection standards. The acceptance of a referral takes place within the legal context. The referral question is framed in a manner that respects parents' rights, the rights of children, the socioeconomic and cultural dynamics of the case, and the role and purview of the judicial finder of fact. Psychologists consult ethical standards and guidelines for practice, and they have a strong foundation in theories and research relevant to child maltreatment, parenting, child development, parental risk of harm through violence and neglect, parental mental illness and substance abuse, parental intellectual functioning, and parental poverty. They use the forensic assessment report and court testimony as communication mechanisms addressed to all parties relevant to the case.

Legal and Regulatory Standards

Societal responses to child maltreatment take many shapes, with the legal system representing the most formal mechanism of response. The nature and breadth of state jurisdiction in child care and protection matters are found in legal definitions of child maltreatment and in legal and regulatory procedures for identifying, investigating, intervening in, and making judicial decisions about family reunification or separation. Broad constitutional rights serve as the legal basis for family privacy, parental rights, and children's rights. Federal regulations influence developments and changes in state statutes, with the most recent guidance found in the Adoption and Safe Families Act of 1997. Child-abuse-reporting requirements and statutes influence the frequency and nature of cases entering the child protective services system. Procedural laws and regulations govern the sequence of hearings and the structure and process of service provision as cases move through the system. The confluence of these sources of laws and procedures provides a framework for the relative judicial weight given to state jurisdiction, family privacy, parental rights, and children's interests in their protection from harm or the threat of harm. From a legal perspective, children are neither fully independent nor fully dependent legal actors in actions taken by the state over the competence of their caregivers.

A typical case in which a termination hearing is eventuated moves through the following phases: an anonymous report of maltreatment by a mandated or a nonmandated reporter; an initial screening of the complaint by the local or regional child protective services agency representatives; an investigation of the allegations in the complaint; an emergency evidentiary hearing and removal of the children from the custody of the caregivers; an evidentiary hearing over whether the emergency removal will stand or will be overturned; placement of the children in substitute care; provision of relevant services to the caregivers and the children; periodic reviews and hearings relevant to the continued need for state intervention and service provision; and a final evidentiary hearing that leads to an outcome of a reunification plan, permanent substitute care, or termination of parental rights. Only the most serious and protracted cases reach termination. If their rights are terminated, parents occasionally are allowed posttermination contact with their children under carefully specified and limited circumstances. More commonly, ties are severed, and posttermination contact is disallowed.

Forensic Assessment in Context

Referrals for forensic assessment in the context of care and protection matters are made to assist the court in gathering data relevant to the case. Referrals may originate directly from the court by prior agreement of all involved parties, through an ex parte motion by the attorney for one parent or a joint motion by the attorneys for both parents, from a representative or an attorney for the child protective services agency, through

a regional child protection agency's contracted relationship with specific consultants/evaluators, or through an ex parte motion by the attorney for the child. Ex parte motions are those that occur in front of the judge without the knowledge of the other parties to the case. They preserve attorney–client privilege until the report is introduced into evidence. Motions may or may not be requested in this private fashion. The use of exparte motions gives the attorney the option of quashing results unfavorable to the client's case. The disadvantage is the difficulty of retaining attorney–client confidentiality and protecting the evaluation results under the attorney work product rule because of the eventual need for the evaluator to contact multiple parties to conduct a thorough evaluation that would typify most referral questions in care and protection matters.

Referral questions cover a range of topics. The evaluator might be asked to assess the child's psychological well-being in the aftermath of maltreatment or threats of maltreatment, to determine what services should be offered to the child and/or the caregiver to promote child well-being and safety, the amenability of the caregiver to interventions designed to reduce the risk of harm to the child, the psychological impact on the child of a return to the custody of the caregiver, the psychological impact on the child of permanent substitute care or parental rights termination, and the child's attachment to substitute caregivers.

Ethical Standards and Guidelines for Practice

Psychologists and other mental health professionals seek the relevant education, professional training, postdoctoral training, and continuing education. They turn to ethical standards and principles to guide their practice. Professional organizations develop guidelines for practice. Guidelines have been written specifically for the subspecialty of forensic assessment and consultation in care and protection matters. Guidelines relevant to cultural competence are particularly important because of the broad diversity of families that come to the attention of the care and protection system. Advocacy organizations for child welfare sometimes develop their own suggested practice guidelines.

Child Maltreatment

Legal definitions of child maltreatment are drawn from statutes, child protective service regulations, and case law. Social science definitions and nosologies of child maltreatment may not be fully consistent with the legal standards because of differing classification schemes and thresholds for maltreatment. Research on the etiology and impact of child maltreatment is complicated by differences in the definitions of maltreatment, differing standards for quantifying the scope and impact of maltreatment, and differing classification and diagnostic schemes. Theories of child maltreatment are drawn from sociobiology, the emerging field of genetics and human behavior, the psychology of human attachment, and the psychology of the inner life of the individual. Such theories may also take into account violence in the individual and society, parental attribution style, parental intellectual and social support resources, the impact of mental illness and substance abuse on parenting, intergenerational transmission or desistance of child maltreatment (i.e., whether parents who were victimized by child abuse become abusers or set about making sure they do not become abusers), social isolation, youthful parenting, and macrosocial issues such as neighborhood quality or the stress of parental impoverishment. Scholars are careful to point out that parents may parent competently even when they face multiple challenges. Parental factors such as mental illness, parental substance abuse, or intellectual limitations must be linked directly to the maltreatment to be considered legally relevant. Parental violence and neglect involve multiple complex factors that result in child maltreatment by some but not all parents. Research usefully illustrates the features that are common in cases of child maltreatment, but none of the features or combinations of features is isomorphic with maltreatment per se. Although much is known about the factors that predict child maltreatment, the relative weight of individual factors is less clear. Cumulative risk and chronicity of risk are not well researched, in part because of the inherent ethical and methodological challenges of conducting relevant empirical research in applied settings.

Parenting and Child Development

Theories of parenting and child development provide a framework for considering multiple styles of parenting, multiple forms of family structure, and child development trajectories. Theory serves as an organizing framework for understanding the inner life of individuals, family dynamics, the social biological

context, and the cultural context of cases. It facilitates the use of logic and reasoning in the integration of evaluation data. Research provides a basis for understanding family relationships, understanding the family system from the child's perspective, recommending relevant interventions, understanding and interpreting parental risk of harm, and placing parameters around interpretations and recommendations based on limitations in the state of the science. A forensic assessment report with legal utility has probative value based on the science of psychology as it is applied to and interpreted within specific legal standards.

Forensic Assessment in Care and Protection Matters

Evaluation methodology and forensic assessment reports in care and protection matters vary with the breadth and comprehensiveness of the referral questions(s). A typical evaluation involves an interview with the caregiver(s), an interview with the child, caregiver-child observations, collateral information, relevant records, and psychological assessment and/or risk assessment measures when indicated. Multimodal assessment is the most optimal approach. Focus is placed on hypothesized factors that potentiated family distress and child maltreatment, the viability and treatment utility of the service plan, whether conditions have changed or have been adequately addressed, and whether positive changes might be stable over time. Evaluation methodology might alternatively focus on the child's attachment to substitute caregivers and the child's readiness for adoption. Depending on the referral question, the interpretation section of a report might address the parent's level of functioning; the strength and quality of the parent-child relationship; child maltreatment risk and the mediators of risk; parental amenability to treatment; accommodations that might contribute to parental amenability to treatment; the expected intervention outcome for a parent or a child; specific changes (or lack thereof) in a parental condition, such as mental illness or substance abuse; support services that would allow a parent with intellectual limitations to parent adequately; the description of a particular child's special needs and their bearing on the child's parenting needs; and the matter of whether a positive intervention outcome might be expected within statutory time limits. Meaningful reports and testimony answer the referral question(s) with scientific integrity, within the parameters of the legal standards and context, in a tone respectful of all parties to the case and the judiciary, and with appropriate caveats.

Terrorism

Terrorism, like many other horrific types of violence, has begged in the minds of many for a psychological explanation. The research and systematic analysis that has been done on the topic, however, show that neither mental illness nor a simple "lack of conscience" are significant primary causes of terrorism. There is no known "terrorist personality." The pathways and influences that lead certain individuals to become terrorists are quite diverse. Psychological research and systematic analysis, however, can help illuminate the processes by which people and groups come to adopt extremist ideologies and subsequently use those ideas to justify violent actions.

Since the attacks on the United States on September 11, 2001, leaders in the U.S. intelligence, diplomatic, and law enforcement communities have concurred that terrorism currently poses the most serious threat

to American national security. Understanding the causes, motivations, and determinants of terrorist behavior poses an enormous challenge in countering that threat, leading to a heightened interest in the "psychology of terrorism." This entry focuses on the psychological dimensions of terrorist behavior, deemphasizes the analysis of sociologically based explanations (sometimes referred to as *root causes*) or macrolevel economic and political theories, and does not address the psychological effects of terrorism.

After decades of social science research, no single theory of aggression has gained ascendance as an explanatory model for all types of violence. Terrorism is a distinct form of violence, although the basic question of how best to define terrorism has itself been a vexing problem. For heuristic purposes, though, most agree that terrorism would include acts of violence (as opposed to threats or more general coercion) intentionally perpetrated on civilian noncombatants with the goal of furthering some ideological, religious, or political objective.

Issues of intent, tactics, motive, ideology, and legitimacy of targets all add complexity and plurality to the construction of terrorism as a form of violence and challenge the emergence of a unifying explanatory theory. Commenting on the search for a master explanation of terrorism generally, Walter Laqueur has insightfully observed that there exist "many terrorisms" and that the factors that cause, sustain, or weaken them may vary greatly for different groups in different contexts at different points in time. From a psychological perspective, the psychiatrist Jerrold Post believes that there is not one terrorist psychology, but multiple terrorist psychologies.

Psychological theory and research on terrorism has evolved considerably since the 1960s. The earliest line of work was drawn principally from psychoanalytic theory and tended to focus on narcissism and hostility toward parents as explanatory variables. More recent explanations have moved away from this approach. A summary of the more contemporary body of professional literature on the psychology of terrorism is outlined below and framed around a series of functional questions.

How and why do people enter, remain in, and leave terrorist organizations? Research on terrorists and violent extremists who adhere to a broad range of ideologies shows that the pathways to, and motives for, terrorism are quite varied and diverse. Among the key psychological factors in understanding whether, how, and which individuals in a given environment enter the process of becoming a terrorist are motive and vulnerability. By definition, *motive* is an emotion, desire, physiological need, or similar impulse that acts as an incitement to action, and *vulnerability* refers to susceptibility or liability to succumb, as to persuasion or temptation. Regarding motive, researchers have begun to distinguish between the reasons for joining, remaining in, and leaving terrorist organizations, finding that motivations may be different at each stage and not even necessarily related to each other. Regarding vulnerability, there do appear to be some common vulnerabilities and perceptions among those who turn to terrorism—perceived injustice, need for identity, and need for belonging, though certainly there are persons who share these perceptions but do not become terrorists.

In 2006, at Pennsylvania State University, an Advanced Research Workshop was convened of professionals who study the psychology of terrorism. The common "risk factors" for terrorism identified by the participants of the workshop included the following:

- Perceptions of isolation or alienation from general society
- Perceptions of individual or group humiliation, injustice, shame, or dishonor
- Social isolation
- Need for identity and desire to belong
- Sense of disillusionment with the available alternatives
- Ideology that legitimizes terrorism
- Role models and heroes
- Sense of being or identifying with victims

Promising areas of inquiry have focused on common stages and processes in adopting extremist ideologies rather than on the content of the motive or justification per se. Three contemporary theories describing the adoption of extremist ideologies include Randy Borum's generic four-stage *terrorist mindset* model, which attempts to explain how grievances and vulnerabilities are transformed into hatred of a target group and how hatred is transformed—for some—into a justification or impetus for violence. Also recently introduced is Ali Moghaddam's *staircase to terrorism* model, in which he describes a convergent (i.e., fewer people proceed to each successive stage), five-step progression that transforms the personal experience of adversity into violent terrorist action. Using a more socially based framework in a study of people affiliating with Al-Muhajiroun in the

United Kingdom, Quintan Wiktorowicz outlines a four-part, developmental process based on social movement theory. Although each model was developed independently, and almost contemporaneously, the consistency of the major themes across the three models is quite striking.

To what extent is psychopathology relevant for understanding or preventing terrorism? Research on the psychology of terrorism has been nearly unanimous in its conclusion that mental illness and abnormality are typically not critical factors in explaining terrorist behavior. Studies have found that the prevalence of mental illness among samples of incarcerated terrorists is as low as or lower than in the general population. Moreover, although terrorists often commit heinous acts, they would rarely be considered classic psychopaths. Terrorists typically have some connection to principles or ideology as well as to other people (including other terrorists) who share them. Psychopaths, however, do not form such connections, nor would they be likely to sacrifice themselves (including dying) for a cause.

To what extent is individual personality relevant for understanding or preventing terrorism? There is no terrorist personality "type," nor is there any accurate profile—psychologically or otherwise—of the terrorist. Moreover, personality traits alone tend not to be very good predictors of behavior. Becoming a terrorist is probably best regarded as a process rather than as a single decision. That process is affected not only by the individual psychological characteristics, but also by situational factors, recent experiences, associations with others, and the ambient political environment and influence of people's constituencies. The quest to understand terrorism principally by studying the personality traits of terrorists is likely to be an unproductive area for further investigation and inquiry.

To what extent are an individual's life experiences relevant for understanding or preventing terrorism? Certain life experiences tend to be commonly found among terrorists. Histories of childhood abuse and trauma appear to be widespread. In addition, themes of perceived injustice and humiliation often are prominent in terrorist biographies and personal histories. None of these contribute much to a causal explanation of terrorism but may be seen as markers of vulnerability, possible sources of motivation, or mechanisms for acquiring or hardening one's militant ideology.

What is the role of ideology in terrorist behavior? Ideology is often defined as a common and broadly agreed on set of rules to which an individual subscribes, which help regulate and determine behavior. Ideologies that support terrorism, while quite diverse, appear to have three common structural characteristics: They provide a set of beliefs that guide and justify a series of behavioral mandates; those beliefs are inviolable and must be neither questionable nor questioned; and the behaviors are goal directed and seen as serving some cause or meaningful objective. Culture is a critical factor in the development of ideology, but its impact on terrorist ideologies specifically has not been extensively studied. Ideology guides and controls behavior, perhaps by providing a set of behavioral contingencies that link immediate behavior and actions to long-term positive outcomes and rewards, or it may best be viewed as a form of rule-following behavior.

What distinguishes extremists who act violently from those who do not? Not all extremist ideologies facilitate violence, nor are all extremists violent. One potentially useful distinction to consider is the direction of activity—that is, whether the focus is more on promotion of a cause or destruction of those who oppose it. Even within destruction-oriented extremism, it usually takes more than ideology to compel violent action. Psychological and social influences must erode the powerful, naturally occurring barriers that inhibit widespread human killing. The two main avenues of assault on those barriers are outside-in (i.e., effects of the group or social environment) and inside-out (i.e., making an internal cognitive adjustment about how to perceive the environment or situation).

What are the vulnerabilities of terrorist groups? Terrorist groups, like all social collectives, have certain vulnerabilities in their existence. Some come from within the organization, and some operate from outside. Internal vulnerabilities include internal mistrust, boredom/inactivity, competition for power, and major disagreements. Some of the more common external vulnerabilities include external support, constituencies, and intergroup conflict.

How do terrorist organizations form, function, and fail? Surprisingly little research or analysis has been conducted on the stages and cycles of terrorist groups' organizational development and functioning. In particular, there has been little systematic inquiry on the process of terrorist recruitment, despite the fact that

thwarting tomorrow's terrorists is at least as critical as understanding extremists of the past and the present. There are three tentative conclusions on extremist recruitment: (1) terrorists focus their recruitment where sentiments about perceived deprivation are deepest and most pervasive, (2) social networks and interpersonal relationships provide critical connections for recruitment into terrorist organizations, and (3) effective terrorist recruiters either identify in or impart on the prospect a sense of urgency and imminence in "closing the deal." Though some anecdotal reports exist on how some specific individuals came to join a terrorist group, there has been little serious scientific or systematic study of recruitment and radicalization processes.

From extremist group research based on organizational behavior principles, it does seem clear that the group must be able to maintain both cohesion and loyalty. Effective leaders of terrorist organizations must be able to maintain a collective belief system, establish and maintain organizational routines, control the flow of communication, manipulate incentives (and purposive goals) for followers, deflect conflict to external targets, and keep the action going.

The State of Research

Social science researchers in the field of terrorism studies are nearly unanimous in their conclusion that its research largely lacks substance and rigor. Several fundamental problems remain unresolved: There still is no agreed-on definition of terrorism, most of the existing research is not empirical or based on any data, and the existing research is largely inapplicable to operational considerations. Future endeavors designed to inform counterterrorism operations should be operationally informed, maintain a behavior-based focus, and derive interpretations from analyses of incident-related behaviors.

In addition, to further the basic social science of terrorist behavior, NATO's Advanced Research Workshop posed the following as "high-priority" research objectives for the future:

- A more rigorous, specific understanding of social and political movements that are not involved in violence, in order to understand what leads some organizations toward violence
- More primary research—better access to and more interviews with activists and terrorists
- Better triangulation of data obtained from these sources

Furthering psychological and other behavioral science research on terrorism will, it is hoped, enhance international security and prevent acts of violence toward innocent civilians.

Testamentary Capacity

Under Anglo-American law, the *right of testation* refers to the freedom to choose how one's property and other possessions will be disposed of following one's death. For a will to be valid, the testator (the person making the will) must have testamentary capacity (TC) at the time that the will is executed. TC is thus a legal construct that represents the level of mental capacity necessary to execute a valid will. If TC is absent, then the will is void and fails. For reasons of public policy, courts have traditionally applied a low legal threshold for finding TC.

Conceptually, TC falls within the broader concept of *financial capacity*, but for reasons of history and tradition, TC continues to receive distinct attention within the legal system. Each state jurisdiction, through its statutes and case law, sets forth the legal elements or criteria for TC. The absence of one or more of these elements of TC can serve as grounds for a court to invalidate a will. A will can also fail if the testator has an *insane delusion* that specifically and materially affects the testator's creation or amendment of a will. Finally, a will is often challenged on the conceptually separate

ground that it was the product of *undue influence* on the testator exerted by a family member or a third party.

As TC represents a legal construct closely associated with the testator's mental status, clinicians are often asked to evaluate TC and offer clinical testimony in legal proceedings. Such evaluations are sometimes conducted contemporaneously with a will's execution but more often occur retrospectively following the incapacity or death of a testator and probating of the will. In recent years, there has been an increase in will contests in the probate courts, with associated claims of impaired TC and also undue influence.

There is currently relatively little literature on TC. Several papers addressing the general clinical guidelines for assessing TC and undue influence exist. However, there is a great need for conceptual and empirical work in this area.

Legal Elements of TC

Although the requirements for TC vary across states, four criteria must generally be met. A testator must have (a) knowledge of what a will is, (b) knowledge of the class of individuals that represents the testator's potential heirs ("natural objects of one's bounty"), (c) knowledge of the nature and extent of his or her assets, and (d) a general plan of distribution of assets to his or her heirs.

The absence of one or more of these elements can serve as grounds for a court to invalidate a will due to lack of TC. However, the way in which courts weigh the legal elements of TC in determining the validity of a will varies across states. Some states require that the testator meet only one of the criteria for a will to be valid. Other states require that the testator not only must understand a will and demonstrate memory of all property and potential heirs but also must hold this information in mind while developing a plan for disposition of assets. Accordingly, the reader is strongly encouraged to review the relevant law on TC specific to his or her state jurisdiction.

Insane Delusion and TC

Even when the legal elements of TC are present, a will can fail due to an insane delusion. Specifically, some states require that the testator be free of delusions and hallucinations that result in the testator devising property in a way that he or she would not have done in the absence of the delusions and hallucinations. A psychiatric disorder with delusions and other symptomatology is not by itself sufficient to invalidate the will. It must be shown that the delusion specifically and materially affected the testator's creation or amendment of a will. In other words, the will must be the direct product of the insane delusion.

Undue Influence

A will can also fail on the separate ground that it was the product of undue influence. Although undue influence is conceptually distinct from TC, these two legal issues very often co-occur and intertwine when wills are contested. Under the law, undue influence exists in those situations where the will is the product of manipulation, persuasion, or coercion exerted by the "influencer" (e.g., family member, friend, neighbor, caregiver) and is not truly the volitional act of the testator. It commonly occurs in relationships where the testator has a special trust in or reliance on the influencer and where dependency has been increased through the influencer's use of isolation and manipulation. In some instances, the testator may be subjected to explicit threats and intimidation by the influencer. Conceptually, undue influence assumes some preserved level of TC in the testator, which, however, is supplanted by the wishes and actions of the influencer. For this reason, undue influence should be considered conceptually distinct from TC, albeit closely linked to it. Clinicians need to understand both TC and undue influence when conducting evaluations in this area.

Attorney Observations of TC

Typically, issues of TC may first arise in the context of a testator's interactions with his or her attorney. During the course of the client interview, an attorney may observe signs of diminished TC, such as an inability to recall the names of family members or to appreciate the full value of different assets. Variability in a client's state of mind and a lack of consistency between the client's current choices and his or her long-term values and previously stated wishes can also raise red flags. From a professional standpoint, attorneys must be sensitive to indicators of diminished TC in their clients and, where necessary, take steps to protect their client's best interests. In many instances, this may involve seeking consultation from a clinician.

Clinical consultation regarding TC can substantially inform the way in which attorneys and judges understand and determine the legal issues of TC. The role of clinicians in cases of TC includes informal

consulting with attorneys about clients with questionable capacity, contemporaneous clinical evaluations of TC prior to will execution, and retrospective evaluations of TC in cases involving a now-deceased or incompetent testator.

Consultation Regarding TC

An attorney may choose to consult with a clinician prior to, or instead of, seeking a formal clinical assessment. In this situation, the clinician provides an informal opinion regarding TC based solely on client observation and the information provided by the attorney. The clinician may also identify concerns or issues that the attorney may have overlooked, as well as suggest strategies for enhancing TC. Clinical consultation may assuage an attorney's concern regarding a client's TC or justify pursuing a formal clinical evaluation of TC.

Contemporaneous Clinical Evaluation of TC

In certain circumstances, the testator, a family member, or his or her attorney may request that a clinician assess the testator's TC prior to will execution. Two scenarios are common in such a referral. The attorney may have concerns about TC and desire clinical expertise and input on the issue before proceeding further. Alternatively, in cases of ongoing or anticipated family conflict, the attorney may seek to preempt a future will contest by having an assessment of TC conducted as part of the will execution.

Contemporaneous evaluations of TC are multifaceted and involve (a) collecting relevant data regarding the testator's assets, potential heirs, and general cognitive and everyday functioning from collateral sources (i.e., a spouse, other family members, and friends); (b) conducting a comprehensive mental status examination of the testator to identify cognitive and psychiatric impairments that may interfere with TC; and (c) completing a thorough clinical interview of the testator to assess TC according to the above legal criteria. Spar and Garb have proposed a valuable semistructured interview approach that clinicians can use to assess TC. Because the validity of a will is dependent on the testator's TC at the specific time that the will is executed, clinicians should conduct evaluations of TC as close to the time of will execution as possible.

Retrospective Evaluation of TC

Although contemporaneous assessment of TC is highly desirable, retrospective evaluations probably represent the majority of these forensic assessments. Retrospective evaluations arise after the death or incompetency of a testator, when potential heirs or other parties contest a will on the grounds that the testator lacked TC at the time the will was executed. Retrospective evaluations of TC are based on a thorough record review and information obtained from the testator's family, friends, business associates, and other involved professionals (often through deposition testimony). Primary attention is given to gathering evidence of mental status and neurobehavioral and everyday functional skills as close as possible to the date the will was executed. Relevant personal records include the testator's business records, checkbook and other financial documents, and personal documents (e.g., letters, diaries, family films, or videos). Medical records can yield particularly useful information, including mental status, behavioral observations, diagnosis, level of impairment, dementia stage (if applicable), and psychological test results. Clinicians may also find it beneficial to interview the testator's surviving family, friends, business associates, and other involved professionals regarding the testator's cognitive and functional abilities at the time the will was executed.

Ultimately, the clinician must assemble all of this information and retrospectively determine whether or not the testator clinically had TC at the prior relevant legal time point(s). In some cases, it may not be possible to render such a judgment if there is insufficient evidence of the testator's cognitive, emotional, and functional abilities contemporaneous with the prior will execution.

With respect to both contemporaneous and retrospective forensic evaluations of TC, it is important to emphasize that the clinician's opinions regarding TC represent clinical judgments that the court may consider and weigh in arriving at a dispositive legal judgment of TC.

Research on TC

TC as a civil competency represents a key knowledge gap in forensic science. There is relatively little published research on TC. Several good articles exist that provide general clinical guidelines and tips for assessment of TC and undue influence. However, there has

been an absence of conceptual and empirical research in this area. Specifically, there is a need for cognitive and neuropsychological models of TC, assessment instrument development, and empirical clinical studies.

Test of Memory Malingering (TOMM)

The issue of malingering is becoming increasingly important in the field of forensic psychology, particularly in cases involving traumatic brain injury, where alleged memory impairment is often used to seek personal compensation or as a defense against prosecution for various types of crimes. The Test of Memory Malingering (TOMM) was developed by the author to provide an objective, criterion-based test that is able to discriminate between individuals with bona fide memory impairment and those with feigned symptoms of impaired memory. The acronym *TOMM* was selected to emphasize that the test was developed with a definite, preconceived notion—to determine whether or not an individual is feigning or malingering a *memory* impairment. Thus, the TOMM should not be viewed as a malingering test per se.

The TOMM consists of two learning trials and a retention trial. The learning trials consist of a learning phase and a test phase. The study portion of each learning trial contains 50 line-drawn pictures (targets), each presented for 3 seconds with a 1-second interval between pictures. The same 50 pictures are used on each learning trial. However, they are presented in a different order on the second trial. During the test phase, each target is paired with a new line drawing (distractor). The position of the target is counterbalanced for the top and bottom positions. The person is required to select the correct picture (i.e., target) from each panel. For each answer, the examiner provides feedback about the correctness of the response. A delayed retention trial, consisting only of the test phase, is administered approximately 15 to 20 minutes after completion of the two learning trials. The TOMM is available in a computerized as well as a paper-and-pencil format.

Development and Validation

The TOMM was initially validated with 475 community-dwelling adults ranging in age from 17 to 84 years and 187 neuropsychological assessments from patients classified as follows: no cognitive impairment ($n = 13$), cognitive impairment ($n = 42$), aphasia ($n = 21$), traumatic brain injury (TBI) ($n = 45$), depression ($n = 26$), and dementia ($n = 40$). Inspection of the distribution of correct responses for the cognitively intact participants and the clinical patients showed that most nondemented individuals achieved a perfect score on Trial 2 and the retention trial. Moreover, rarely did a nondemented patient obtain a score lower than 45. In view of these results, the criterion score of 45 on Trial 2 or on the retention trial was selected. That is, any score lower than 45 should raise concern that an individual is not putting forth the maximum effort and is likely malingering. The criterion score correctly classified 100% of the community-dwelling participants and 95% of the nondemented clinical patients (cognitively impaired = 90%; aphasia = 95%; TBI = 98%; depressed = 100%; and dementia = 73%). Thus, the only clinical sample with a relatively

low sensitivity score was the dementia group. Even these individuals still obtained a score of greater than 92% on Trial 2. The finding that the scores on the TOMM were less than 95% for the dementia group is not particularly negative since it is unlikely that feigning memory impairment is a major issue when dementia patients undergo neuropsychological assessment.

It should be noted that "below-chance" performance (<18 correct at the 95% confidence level) also can be used as a statistical decision rule. However, experience has shown that malingerers or individuals simulating malingerers do not ordinarily obtain below-chance scores on the TOMM on any trial. Of course, if they do, the decision rule can be applied.

Five experiments using different types of participants and different types of experimental designs provide evidence that the TOMM readily differentiated between malingering and nonmalingering individuals and show that the TOMM is a useful psychometric test for detecting exaggerated or deliberately faked memory impairment. In this context, it should be noted that the TOMM meets all the guidelines established in *Daubert v. Merrell Dow Pharmaceuticals* (1993) to define the generally accepted standards for judges to use in determining the scientific admissibility of evidence, particularly when presented by expert witnesses.

Interpreting the TOMM

Interpretation of the TOMM should never be made solely on the basis of the TOMM score that a patient achieves. It depends on many factors, starting with the basic conceptual issues on how *malingering* is defined. The TOMM does not measure a general trait called "malingering." In forensic assessments, the TOMM is not an appropriate test to evaluate whether or not a person is faking a psychiatric disorder any more than it would be appropriate to use it to determine if a person is faking a back injury. Moreover, the interpretation of the TOMM should not be used to identify a "malingerer" but rather to indicate that a person is putting forth less than the maximum effort. Although individuals malinger, malingering cannot be legitimately viewed as a personality trait. Malingering in one situation does not necessarily mean that the person will always malinger or, in fact, will ever malinger again. In many, if not most, instances, individuals with TBI who malinger are "good" people caught in "bad" situations. It must also be remembered that malingering is not an all-or-none phenomenon but that it exists in different degrees, ranging from minor exaggeration of existing symptoms to flagrant faking of nonexistent symptoms.

Therapeutic Communities for Treatment of Substance Abuse

Therapeutic communities use interpersonal interactions within a structured community milieu to treat substance abuse. They have shown promising outcomes, especially among people with substance use disorders who require a highly structured environment to succeed. Therapeutic communities are used frequently in correctional institutions to treat inmates with severe substance use disorders and who exhibit antisocial behavior. Positive outcomes have been found for many participants, such as reduced substance use and recidivism after release from incarceration. Since therapeutic communities focus on communal processes to facilitate change, this treatment may not be an effective means to individualize care. In addition, the communities may not be helpful for autonomous, high-functioning individuals or people with severe co-occurring psychiatric

disorders. However, these communities have functioned well in correctional settings and seem to be well designed to serve the needs of inmates with severe substance use disorders who are motivated to change their behavior.

Substance Abuse Treatment Within Therapeutic Communities

Therapeutic communities are commonly used in correctional institutions to treat substance use disorders and other life problems. Therapeutic communities operate under the assumption that substance use is a consequence of a dysfunctional lifestyle that requires a holistic treatment solution to facilitate change. Holistic healing occurs within a highly structured peer milieu that seeks righteous living without substance use. In therapeutic communities, the interpersonal interactions within the context of communal living are considered to be the mechanism for treating substance use. The community models appropriate behavior for individual members, serves to correct the behaviors of individuals when they are inappropriate, and shapes changes in individuals. The historical roots of therapeutic communities for substance abuse can be traced to the Synanon community.

Therapeutic communities often include group work and may provide opportunities to participate in 12-step support groups. However, therapeutic communities differ from traditional treatment in that they view engaging in everyday life activities within the context of the community as a critical part of the healing process. For example, treatment involves engaging in work activities that benefit the community. In correctional institutions, staff and senior community members assume mentorship roles for the junior members of the community. They often function as closed communities, operating as independently of their surroundings as possible, and frequently require junior members of the group to limit exposure to events outside the community until they reach a certain level of maturity in the program.

Emphasis is placed on the importance of social relationships and reciprocal social support among participants and staff in the therapeutic community which can contribute to persistence in treatment engagement and better treatment results. Encouraging friends and family to participate in treatment also has been used to enhance social support with positive results among therapeutic community participants. Following treatment, participants often report improved relations with friends and family.

Research on Therapeutic Communities

Data concerning the efficacy of therapeutic communities are somewhat sparse, and interpretation of results is complicated by the lack of a standardized model, which makes comparisons across sites difficult. Therapeutic communities can work well for people who have severe substance use problems and would benefit greatly from treatment in a highly structured environment. Researchers examining the efficacy of therapeutic communities in the United States and Europe have found evidence that inmates, homeless people, adolescents, older adults, and certain ethnic minority groups may benefit from participation. Positive outcomes have included lower levels of distress, drug and alcohol use, and criminal involvement among participants. In addition, there is evidence that participation may enhance self-esteem, promote the taking of prescribed medications as directed, lead to gainful employment, and increase social and coping skills. Relapse prevention strategies and aftercare have been used to improve the efficacy of therapeutic communities' intervention in substance use disorders.

Evidence suggests a positive relationship between the length of association with therapeutic communities and successful outcomes after treatment. Motivation to participate in therapy and change current behavior patterns commonly is related to better treatment retention and less drug use after treatment. Participants in therapeutic communities often report greater motivation to change and higher satisfaction with treatment than people in other types of substance abuse treatment. However, these results may be confounded with self-selection biases since members choose to join these communities and participation requires a high degree of commitment.

Differential treatment outcomes associated with gender have been found. Because of these differences, some researchers have suggested that it may be helpful to use gender-specific treatment strategies. Women commonly enter therapeutic communities with lower levels of social functioning than men. They may exhibit evidence of greater psychological distress, often including suicidality and trauma histories, which need to be addressed in treatment. After participation in therapeutic communities, many women experience less victimization by

their partners and are less likely to engage in risky sexual behaviors, including trading sex for money.

Participants who are higher functioning and do not require highly structured care may not benefit from therapeutic communities. In addition, research suggests that people with severe mental health disorders may not have positive outcomes in therapeutic communities. Participants with greater psychological distress and more mental health symptoms when they enter the therapeutic communities seem to be more likely to drop out. Participants in need of limited social and environmental stimulation may find it difficult to tolerate the intense social interactions encouraged in this treatment model. Tailoring treatment to the needs of individuals with greater mental health symptoms would likely increase the chance of a successful outcome. One of the criticisms of the therapeutic community model in general has been that it does not account for individual differences or needs in treatment. However, the therapeutic community model meets the needs of inmates with severe substance use disorders in correctional settings such as jails, prisons, and halfway houses by providing a highly structured and safe community dedicated to staying substance free.

Therapeutic Jurisprudence

Therapeutic jurisprudence (TJ) is an interdisciplinary approach to the study and practice of law and the role of legal actors. It aims to focus on the often underappreciated aspect of the law and legal actors' role in producing therapeutic or antitherapeutic consequences. It is a normative framework that advocates the use of the social sciences to inform the processes and outcomes of legal interactions and procedures. It does not suggest that therapeutic concerns should override other important elements of the legal system (such as due process or justice concerns), but it does suggest that the therapeutic consequences of the law and legal actors be considered and systematically studied. TJ has become a highly influential framework for thinking about the law and the way legal actors interact with their clients.

The influence of TJ has recently begun to move from the conceptual to the empirical. Social science researchers are now beginning to empirically test the conceptual assumptions of the therapeutic framework. This is ushering in a new and exciting wave of TJ scholarship, for now, the TJ scholars are using not only the insights of the social sciences to develop law and legal processes but also the methods of the social sciences to test those insights. The near future of TJ scholarship promises to be an exciting and fruitful one for the development of law and legal processes.

This entry examines this newly emergent and important aspect of the intersections between law and psychology (and the wider social sciences). It provides an overview of the concept, a brief history of its development, a review of the practical implications of the framework, and an overview of its international appeal.

Therapeutic Jurisprudence: An Overview

TJ is, at its most basic, a therapeutic perspective of the legal system. It aims to use the knowledge and expertise of the social sciences–including psychology, criminology, social work, and others—to study the therapeutic and antitherapeutic aspects of the law and the wider legal system. TJ suggests that, whether one likes or acknowledges it or not, the law and the way legal actors interact with people have therapeutic consequences; thus, when the opportunity arises, legal actors should attempt to maximize the therapeutic potential (or at least minimize the antitherapeutic potential) of the legal interaction, providing that legal safeguards such as due process and justice considerations are not compromised.

TJ is not a paternalistic framework and does not call for increased state intervention or coercion. Therapeutic jurisprudence simply suggests that the therapeutic potential of the law and legal actors be recognized, systematically studied, and, when appropriate, acted on.

It suggests that all things being equal, the law should be constructed in such a way as to enhance the therapeutic potential of the law and legal actors.

TJ does not suggest that therapeutic ends should trump other considerations of the law. The law often serves other purposes that are equally valuable or more valuable than therapeutic ones. The TJ framework suggests that to achieve truly effective and humane law reform, policymakers should strive for a solution where these values converge. However, where these values conflict, TJ does not itself resolve the conflict, but it does sharpen and enrich the discussion.

The Development of Therapeutic Jurisprudence

Initial Origins: The Law and Mental Health

TJ began in the area of mental health law. It aimed to systematically study the previously neglected aspect of the law's therapeutic or antitherapeutic effects in relation to mental health law, in order to minimize the antitherapeutic effects and highlight the need for further analysis on therapeutic grounds. The first exploration of the framework occurred in 1987, when David Wexler delivered a paper to the National Institute of Mental Health in the United States. The impetus for the development of TJ was a reaction to the antipsychiatry perspective that had developed in the late 1970s and through the 1980s in mental health law. TJ suggested that psychiatry, and indeed the wider disciplines of the social sciences, had valuable insights to offer to the field of law and mental health and that the law and the legal profession should attempt to use those insights where appropriate.

The Spread Across the Discipline of Law

Through the early part of the 1990s, David Wexler, Bruce Winick, and a growing group of legal scholars in the mental health field sought to investigate the scope of TJ and its application to not only mental health law but other areas of the law as well. The interdisciplinary scope and easy applicability of its mission statement—to enhance the therapeutic potential of the law and legal actors—made the framework appealing to a number of different areas of the legal system.

By 1996, TJ had expanded to include legal arenas such as correctional law, criminal law, family and juvenile law, sexual orientation law, disability law, health law, personal injury and tort law, law of evidence, labor arbitration law, contracts and commercial law, and the legal profession, as well as theoretical explorations and empirical examinations of the concept. The wide scope of the TJ framework quickly made it a valuable resource for the future development of legal areas and law reform. Toward the end of the millennium, the concept became thought of in conjunction with a number of other legal developments of the comprehensive law movement, including preventive law, collaborative law, and problem-solving courts. The convergence between these practical applications of the legal system and the principles of TJ has seen the concept move from a theoretical (and largely academic) enterprise into a collaborative form of scholarship with truly practical implications.

Practical Implications

The move from theory to practice has thoroughly enriched the scope and application of the TJ framework. This entry will now highlight some of these.

Problem-Solving Courts

In an important joint resolution in the United States, the Conference of Chief Justices and the Conference of State Court Administrators endorsed the continued use and expansion of problem-solving courts (such as drug treatment courts, mental health courts, and domestic violence courts) and made specific reference to the courts' use of the principles of TJ. Although TJ and problem-solving courts (which emerged in Miami in 1989 with the first Drug Treatment Court) developed around the same time, their development was independent of each other, and for almost a decade, they each continued to show significant development within the U.S. legal system. However, in the mid-1990s, Judges Peggy Hora and William Schma began collaborating with David Wexler and Bruce Winick, speaking at conferences, and writing about the applicability of the TJ framework to the problem-solving (specifically, drug treatment) court phenomenon. Since then, the two concepts have developed a symbiotic relationship, and most problem-solving courts acknowledge the influence of the principles of TJ in their day-to-day work.

General Criminal Jurisdiction

Recently, scholars and, perhaps more significantly, judges and court administrators have begun to apply

and implement the principles of TJ in courts of general jurisdiction. An excellent example is a manual produced by Canada's National Judicial Institute. The manual uses TJ principles to inform judges how they might use probation as a behavioral contract. Also, with the implementation of insights such as relapse prevention planning, scheduled periodic review hearings, and early termination of probation after successful probationary sentences, the insights of TJ have added to the tools of judges in Canadian criminal courtrooms. In England, TJ principles have guided the way judges act even when handing down a custodial sentence. There, instead of simply sending the offender to custody without an explanation of the purpose of or reason for the custodial sentence, a community court judge completes a "Statement of Reasons," which explains the rationale behind the incarceration, and sends a follow-up letter to further explain the need for the custodial sentence. In this case, the judicial officer takes care to condemn the act and not the person. Such practices use the psychological principles of procedural justice to inform their functions, and it is hoped that these practices increase the defendant's sense of fair treatment and potentially facilitate future compliance with the law.

Civil Law

Besides its focus on criminal law, TJ continues to grow in the area of its origin—mental health law, principally through the work of Bruce Winick, Michael Perlin, Kate Diesfeld, and Ian Freckelton. There have also been important developments in family law and child protection law. Scholars such as Daniel Shuman and Katherine Lippel have looked at topics such as compensation in tort law and procedural justice elements in workers' compensation.

Lawyering

TJ influences the processes of the courtroom and urges an expanded rehabilitative role for criminal lawyers. TJ also influences the way lawyers undertake their roles in their offices. The TJ perspective suggests that lawyers work with their clients to achieve outcomes that are good from a therapeutic standpoint as well as a legal one. It also encourages lawyers to explain the potential consequences of pursuing certain forms of action. For example, when combined with preventive law, TJ asks the lawyers not only to identify legal "soft spots" (potential legal problem areas) but also to identify *psycholegal* soft spots—areas where legal interventions may lead to antitherapeutic consequences regardless of the legal outcomes. TJ suggests that lawyers should discuss these potential soft spots with the client prior to any legal intervention to ensure that the client has a full understanding of the potential for therapeutic harm.

Legal Education

TJ has now established itself in the curricula of many law schools as well as a number of social science courses. The concept is also gaining prominence in clinical legal education.

International Appeal

The wide appeal of TJ has seen it spread from its birthplace in the United States to a number of countries, including Australia, Canada, New Zealand, England, Pakistan, Scotland, Puerto Rico, South Africa, India, Vanuatu, Spain, Israel, Italy, Sweden, and Argentina. Publications now appear in English, Spanish, French, Italian, Japanese, Swedish, Hebrew, and Urdu. Indeed, at the Third International Conference on Therapeutic Jurisprudence, held in Perth, Western Australia, about nine countries were represented.

The Future of Therapeutic Jurisprudence

The wide-ranging appeal and international growth of TJ have seen the concept move from the theoretical to the practical, with a growing number of justice systems around the world implementing the ideas and principles of the concept in new and exciting ways. The next chapter in the development of TJ will provide researchers, policymakers, and those involved in the justice system with an excellent platform to think about the way we see the law, legal actors, and the justice system in the future.

Training of Eyewitnesses

The ability to accurately recognize others is important to everyone, particularly because important social, personal, physical, and economic resources are uniquely associated with individual persons. The recognition training that most people experience comes with everyday social interaction, containing the incentives within their social environment. The ecology of personal recognition and the social-cognitive processes through which it develops have hardly been studied, and the social conditions under which some persons might become more accurate recognizers than others are largely unknown. Attempts to improve face recognition through short-term training focused on changing the attributes of faces that participants attend to or use in encoding facial information have largely proved ineffective.

There are social environments in which higher recognition performance levels would be very valuable. These are most commonly environments in which individuals to be recognized or identified have committed some crime and need to be apprehended. For example, persons at risk as victims due to their employment (bank tellers, convenience store clerks) might benefit from being capable of high recognition performance levels. Law enforcement, military, or intelligence personnel likewise would benefit from higher levels of recognition capability than the general public. For this reason, developing effective training in face recognition has real practical utility. Unfortunately, the available evidence is not encouraging: There is little evidence that persons of any occupational group are reliably better or worse at recognizing faces than others. Research conducted with law enforcement officers suggests that they are no better than other citizens in face recognition accuracy; however, officers have been shown to perform better at recalling the details of an event.

Research on face recognition training also has theoretical utility because of the need to better understand the basic cognitive and social psychological processes that form the basis for training. While face recognition processes have been shown to involve both featural and holistic components, few studies have been directed at using these aspects of face recognition to improve recognition. We know that elaborated or inferential processing of faces leads to higher levels of recognition performance, and it appears that such processing is the default mode. Instructing participants to attend narrowly to specific features causes their recognition performance to suffer. Some studies show that attempts to change or refine the facial information research participants extract at the point of encoding can lead to reduced recognition performance. This may result from attempting to substitute new memory strategies based on relatively short training experiences for encoding and recognition strategies that are based on a lifetime of practice. There is growing evidence that we develop selective processing of faces very early in life and that this processing is selective for our own "race" (or that which is experienced early).

A deficit in face recognition accuracy has been shown when people attempt to recognize faces of other "races." Known as the cross-race effect, studies have consistently shown the deficit in recognition across a variety of races, ethnicities, and nationalities. A few studies have attempted to train individuals in order to improve their ability to make accurate cross-race identifications; however, the studies have shown limited success, demonstrating that training effects are at best temporary and inconsistent. The methods used to train in face recognition have varied immensely since the early 1970s. For instance, one of the first training studies administered electrical shock following an incorrect recognition judgment. After only 1 hour of training, the shock feedback improved recognition performance. Effects of training over longer intervals were not examined. Another study trained participants to focus on critical facial features that were believed to differ between White and Black faces. Once again, participants showed immediate improvement in their face recognition ability; however, these effects diminished after the passage of 1 week. More recent research has focused on "feature-critical training" using INDSCAL (INdividual Differences SCALing software) analyses of the physiognomic differences between certain races. Results suggested that such training improved cross-race face

recognition; however, once again there was no indication of the persistence of the improvement or whether the improvement could be generalized across faces within that race. It is unclear at this juncture whether or not systematic training can, or ever will, reduce or eliminate the cross-race effect.

Natural experience (or the lack thereof) appears to be the basis for the cross-race effect, and studies of the effects of changing environments over a period of years (e.g., residential school experience) support this, as do studies of the effects of high levels of interest in sports where many of the outstanding performers are of a "racial" group contrasting with the "racial" group membership of many fans. Fans investing large amounts of time in watching the sport and who have a high level of detailed knowledge about the players show a reduced level of the cross-race effect. It is thought that social incentives and penalties exist for successful recognition and recognition errors or omissions, respectively. As good an idea as this might be, manipulating incentives as a training technique has not been studied.

Given the general failure in training individuals to improve their recognition of faces, a current movement among researchers has involved developing computer-based recognition algorithms. A number of procedures have been developed to use information from facial images to match one instance of a person to another of the same individual, under different conditions. Great progress has been made in this line of research, and it has now been shown that face recognition algorithms can be superior to human face recognition even under previously troublesome conditions, such as differences in illumination and shadow between the two photos to be matched. In addition, fusing the use of computer-image-processing algorithms with human similarity judgments leads to near-perfect recognition. Nevertheless, the problem of extracting accurate identifications from human memory remains. While human judgments have led to improvements in computer-based face recognition, computer-based support systems using genetic algorithms have been shown to provide effective assistance in human recognition.

Overall, training the human cognitive system to achieve higher levels of face recognition performance is an important goal, with only modest advances having been achieved.

See Waiver to Criminal Court

Translated Testimony

As society becomes increasingly more diverse culturally and linguistically, translated testimony will become a more frequent component of the American justice system. Due to the complex nature of the translation process, errors and misunderstandings of interpreted testimony are nearly unavoidable and can affect jurors' perceptions of a trial. Misjudgments may occur due to the inadvertent influences of the court interpreter or jurors' biased perceptions of a defendant's translated testimony. Psychological theories related to individuals' social identity and the human propensity to categorize other people as members of one's in-group or out-group may provide a framework for understanding the potential biasing nature of translated testimony. The implications for law and policy provided by research pertaining to translated testimony are vital for the fair and impartial treatment of all people within the U.S. justice system.

From the perspective of courts in the United States, the official language of courtroom proceedings is

English. When a trial participant does not speak or understand English, court interpreters are used. The court interpreter's task is to completely, impartially, and accurately reiterate in English the utterances of a trial participant that originate in a speaker's native language. The interpreter also renders the utterances that originate in English into the native language so that the non-English-speaking witness or defendant can understand the proceedings as well.

The number of monolingual and minimally bilingual non-English-speaking individuals who come in contact with the U.S. criminal justice system is increasing. According to the 2005 Annual Report of the Director of the Administrator's Office of the United States Courts, the number of cases requiring the use of court interpreters increased by 1.5% in 2005, with the Spanish language involved in 94% of these cases. The 2000 U.S. Census indicated that the percentage of Spanish speakers living in the United States increased by 3.2% since 1990; additionally, 10% of the Spanish-speaking population was monolingual. This rise in the monolingual Spanish-speaking population has created a need for Spanish-English interpreters, in particular in the United States.

Perceptions of Translated Testimony

Linguistic minority speakers are at a disadvantage in the courtroom. Early research demonstrated that English-speaking individuals perceive unaccented English more favorably than either Black vernacular English or Mexican American accented English. Thus, if linguistic minority witnesses and defendants choose to communicate in English during the court proceedings, they may be perceived less favorably by the jury because of their accented or limited English. Providing translated testimony to counter the linguistic minority speaker's limited English does not remove this bias.

Furthermore, the court interpreter's translation of testimony can shape jurors' views of speakers in the courtroom due to linguistic alterations in the translation process. Interpreters tend to lengthen testimony by using uncontracted versions of words and altering fragmented speech into a more narrative form. For example, in Spanish-to-English translation, English interpreters often add hedges such as ". . . uh, . . . well, and . . . um" into the speaker's testimony. These added hedges may reflect the interpreter's own performance deficiencies in the translated language; however, such additions to testimony cause the jurors to perceive the witness, not the interpreter, less favorably.

Finally, linguistic minority defendants and witnesses are forced to rely on the interpreter to understand the courtroom proceedings. During translation, interpreters may inadvertently alter an attorney's intended meaning during questioning by weakening the force of leading questions or including additional words. For example, if an interpreter adds words such as "well" or "now" to the beginning of an attorney's question during cross-examination, the witness may view the attorney as confrontational. Such alterations in the structure of the questions can influence the witness's perception of the attorney and understanding of the questions, thus altering the resulting testimony.

Impact on Jurors' and Juries' Decisions

The fact that interpreted testimony per se may influence the outcome of criminal cases has been demonstrated as well. Empirically derived data reveal that jurors see criminal defendants who testify in a language other than English with the assistance of an English interpreter more negatively than defendants who testify in English. For example, data collected in Texas courts in the 1990s showed that criminal defendants who testified in Spanish with interpretation into English were at significantly greater risk of conviction than were similarly situated defendants who testified in English. That is, the negative perceptions of non-English speakers were converted into a predisposition to vote for conviction of the defendant. This occurred even when people who themselves were Spanish speakers served on the juries that convicted.

More recent experimental data collected in the same jurisdictions suggested that the language of a defendant's testimony continues to have an impact on jurors' judgments about the guilt of defendants but that now the direction of the outcome has changed. That is, jurors serving on cases where defendants testify in Spanish with English interpretation are less likely to be conviction prone, other things being equal, than jurors serving on cases with equivalently situated defendants who testify in English. However, this effect seems to be diminished when jurors deliberate, when the language of defendants' testimony does not appear to influence juries' decisions. An important

additional finding from this research is that the jurors' own language use influences both voting preference prior to deliberations and jury verdicts after deliberations. Spanish-English bilinguals seem to be more lenient in general than are monolingual English speakers.

Explanations of the Impact of Language

One theoretical explanation proposed for these results follows social identity theory. This theory postulates that individuals are motivated to maintain a positive social identity. In addition, it is presumed that humans have a universal and natural tendency to categorize other people as members of the categorizer's in-group or members of some other out-group. One can use a variety of strategies to maintain a positive self-image, but important strategies relate to the way we interact with and reward those we see as in-group or out-group members. One can, for example, increase one's own positive self-image by perceiving members of one's in-group more favorably than members of out-groups and by differentially rewarding those who are in-group members. In a legal context, leniency would be expected from those jurors who perceive themselves to be most similar to the defendant. Spanish-speaking jurors would be expected to perceive Spanish-speaking defendants as more similar to themselves than would English monolinguals and thus would be expected to act more favorably toward Spanish-speaking defendants. Similarly, English monolingual jurors should be more lenient, other things being equal, with English-speaking defendants and more punitive with Spanish speakers. The empirical data from the studies conducted to date do not support this logic, however. Rather, Spanish-speaking jurors are more lenient toward defendants in general, no matter what the defendants' language of testimony. In addition, regardless of their own language use, jurors treat Spanish-speaking defendants more leniently.

An alternative hypothesis is that jurors should be motivated to see themselves, and be seen by others, as different from those who are accused of crimes. Other things being equal, they should be predisposed to convict defendants to clarify the fact that they are different from that person.

By testifying in a language other than the mandatory language of the proceedings (i.e., English), a Spanish-speaking defendant also may be seen as an out-group member by *all* the jurors. To serve as a juror, an individual must be able to read and write the English language. Therefore, by testifying in Spanish, the defendant is demonstrating that he or she is distinctly different in this regard.

While out-group members may be treated more punitively than in-group members, this punitive treatment may not be manifest in the bilingual courtroom. Indeed, quite the opposite may occur. The commission of a crime is what society would define as deviant behavior. Violations of norms result in negative sanctions (e.g., convictions and imprisonment), but this also is contingent on the observers' (e.g., the jurors) recognition that the person who violated the norms was able to conform to the expectancies in the first place.

When they testify in Spanish, defendants may be perceived as foreigners in a system that they do not understand. Jurors may be sympathetic toward the Spanish-speaking defendants because they see them as individuals who do not understand the situation in which they find themselves. This speculation suggests a new line of inquiry to pursue empirically. That is, if a defendant is seen as a "stranger" to the system, jurors may heighten their standard for the burden of proof and require the prosecution to justify the conviction of an individual who does not completely understand the consequences of his or her actions.

Community attitudes also may explain the results of the research outcomes to date. Recall that the impact of jurors' language use has been shown to be greater than that of the defendant's language of testimony. It may be that jurors' views of the American judicial system are critical in providing a context for their decisions. So, for example, it may be that more people who serve as jurors today hold more negative attitudes regarding law enforcement and the courts than those who served as jurors in the past, producing a more lenient outcome for defendants.

Implications for the Law

Court interpretation plays a pivotal role in the provision of justice to linguistic minorities in the United States. Future empirical research concerning court interpreters and the impact of translated testimony on jurors will provide useful information for the legal system and allow for unbiased due process for all defendants.

It is vital that standards remain consistent concerning the availability of a translator in all cases involving

linguistic minorities. The establishment of state and federal training and certification procedures ensures that courts handle such cases in a consistent and impartial manner. Furthermore, programs allowing for contract interpreters and telephone interpreting in districts where no certified interpreters are available are important steps to facilitate due process for all defendants. In addition to training court interpreters consistently, training for legal professionals such as judges and attorneys may allow for a better understanding of the special challenges associated with such cases. This type of training will generate greater awareness of the rights of defendants and the responsibilities of federally certified interpreters.

The fact that jurors are prepared to treat defendants who testify in the official language of trials (English) differently from those who do not is disturbing. Regardless of the quality of the interpretation, the fact that interpretation is provided at all seems to be an influential factor in the outcome of cases. At a minimum, courts may need to provide additional instruction to jurors to set aside their beliefs about those who do not testify in English. If jurors are instructed that the language of testimony is not to be included in consideration of the meaning and importance of facts presented in evidence, they may be able to hold their predilections in abeyance, and equal treatment can be given to all defendants.

Treatment and Release of Insanity Acquittees

For more than one and a half centuries, from the first insanity defense commitment of John Hadfield in England in 1800 through the mid-1960s, insane defendants (those not guilty by reason of insanity, or NGRIs) were automatically and indefinitely committed to a secure psychiatric facility until the state determined that they could be released. Until the mid-1960s, most were never released regardless of their crime. Treatment for NGRIs then and today mirrors the standard psychiatric treatment of the time—ranging from simple confinement in pretreatment eras to increasingly more sophisticated interventions such as those available starting in the 1950s. Today, most people found that NGRIs in the United States and elsewhere have a major mental disorder such as schizophrenia or bipolar disorder, and their treatments are at least initially as inpatients in a public psychiatric hospital. Due to legal changes from the 1970s onward, states that take custody of this population must also provide them with medical and mental health care whether they are inside or outside the hospital.

The Role of the Physician

Mental illness has for centuries been considered a mitigating circumstance in criminal behavior. Beginning in England in 1760, physicians specializing in madness have testified before the court that an individual's criminal responsibility could be diminished due to mental state. While such testimony was not an insanity defense per se, the early role of the physician as a court expert established medicine's domain, which continues today in many criminal trials throughout the world. Few defendants are found not criminally responsible without psychiatric testimony, confirming the long-held view that mental disorder is a medical illness and that responsibility for treatment lies with the medical profession. Today, while psychologists and social workers are included in evaluation, treatment planning, and service delivery, it remains the physician's responsibility to decide whether a defendant is mentally ill, to prescribe medications—the treatment of choice, and to recommend the confinement or release of an insane defendant.

Treatment

Treatment for NGRIs is delivered primarily by the public mental system. The first public mental hospitals in the United States were built after the 1830s, and there was no distinction between patients committed by family and those brought in by law enforcement. *Insanity* was used interchangeably to refer to all patients who were believed to be unable to make decisions due to mental illness. As suspicions rose about the use of civil commitment for inappropriate motives, such as acquiring family wealth or obtaining a divorce, the laws were changed in the late 1800s to require hearings prior to civil commitment, at which time the patient could object. These concerns were not directed at the legally insane patients. The concern with unfair commitments was short-lived as many states began allowing unrestricted, streamlined emergency commitments, as is still the case today. It was not until the judicial activism of the U.S. federal bench starting in the 1950s that civil commitment laws began to change, but these early federal decisions did not extend to NGRIs. This population of patients was committed for life and was not covered by the new, stringent civil commitment laws. Treatment continued unscrutinized in hospitals, and insanity acquittees could expect to spend their lives confined to the state hospital.

Public Policy on the Rights of the Insane

This period of complete neglect of the legal and treatment interests of the insane extended until 1966, when the U.S. Supreme Court ruled that convicted and hospitalized defendants were to be held to civil commitment standards. This holding was extended to NGRIs on the grounds that they had been denied equal protection due to lack of review of their automatic, indefinite commitment to maximum-security hospitals. The next year, the Court held that sex offenders were entitled to a hearing before being transferred from prison to a hospital after serving their sentence. The following year, the D.C. Court of Appeals held that insanity defendants were to be given the same procedural protections as other patients. In case after case, federal courts decided in favor of both NGRIs and convicted defendants with mental illness, requiring states to prove why continued commitment was necessary. As these new commitment laws were written, most states had the burden of proving that persons found NGRIs were mentally ill, dangerous, and in need of hospitalization. If treatments were not being provided, the state failed to meet the burden. Hearings were now required to review the continued hospitalization of all patients.

Prosecutors opposed to an insanity defense in a particular case were put in the awkward position of first arguing at trial that the individual's mental disorder was not so severe as to require an insanity verdict and then following this with the argument that the mental disorder was so severe that the person acquitted should be involuntarily committed. Not surprisingly, many insane patients no longer met the criteria for commitment and were released. The lack of treatment and supervision they encountered is legend, and beginning in the late 1960s, states began releasing NGRIs who no longer met the criteria for commitment—mental illness and dangerousness. At the same time, the costs of inpatient mental health care continued to rise due in part to "right to treatment" cases. For myriad reasons, such as the lack of resources, the belief that treatment would be ineffective, and fear, there was considerable community resistance to treating this forensic population.

The relatively unsupervised release of insanity defendants who had, in many cases, been hospitalized for decades caused fear and concern among the general public. Complicating the issue, a number of states had notorious cases in which a former NGRI committed a particularly heinous crime, leading to a reconsideration of the release procedures of insanity defendants. States began to make the release procedures more stringent, placing more responsibility on the defendant. The landslide of legislative change accelerated with the 1983 insanity acquittal of John Hinckley for his attempted assassination of President Ronald Reagan (and serious injuries to other victims). Following this widely publicized case, most states tightened their insanity defense laws, shifting the burden of proof to the defendant; changing the test for insanity from the American Law Institute's guidelines back to the more restrictive M'Naghten test; adopting guilty but mentally ill statutes; abolishing the affirmative insanity defense; and creating new, less defendant-friendly release procedures. Whether such legal reforms created the intended outcomes has been the subject of extensive research. While Hinckley did not start the retrenchment movement, his acquittal completed it.

Public Sentiment and the Insanity Defense

Research conducted from the 1960s through the 1980s reveals that the public views NGRIs as more dangerous than ordinary inmates, consistent with other research on public views of persons with mental illness as being dangerous. Therefore, little public sentiment exists to attend to the rights of NGRIs. Even when faced with overwhelming expert testimony that a defendant's mental illness is so severe that he or she could not have known right from wrong, juries more often than not find a defendant guilty, perhaps hoping that they will receive treatment in prison. When asked following the trial why they rejected the insanity defense, jurors often state that although they do not dispute the evidence of psychosis, they are fearful that the individual will be released from the hospital.

As public opinion shifted away from reform favoring defendants' rights, the courts turned away from defendants as well. What followed from 1983 to the present could be summarized as a refinement of procedures and laws regarding the insanity defense, within a context where standard psychiatric treatment is constitutionally required for NGRIs. In 1983, the Supreme Court ruled that an insanity acquittal for any crime is a presumption of dangerousness for purposes of commitment. In 1992, the Court held that NGRIs must be released if they no longer meet commitment criteria. An exception is made for convicted sex offenders, who can be involuntarily committed to a psychiatric hospital following completion of their sentence until their "mental abnormality" is cured. The implication of the Court's ruling is that sex offenders can be treated by mental health professionals, even though there is lack of evidence for the efficacy of these treatments.

Treatment and Release of Insanity Acquittees

One effect of the documented reduction of insanity defense cases from the 1960s through to the present is the change in the NGRI population, affecting treatment needs in both the hospital and the community. While some defendants might have been able to "fake" psychosis in the early decades, this grew less likely as the fields of forensic psychiatry and psychology developed and specialized training became required. Both civil patients and NGRIs have always been prescribed treatments that are thought to be medically appropriate and necessary. Earlier interventions including psychosurgery and electroconvulsive treatment were invasive and performed by physicians While both interventions are still sparingly used today, the most common treatment for all mental illness is medication; like earlier treatments, it is fixed within the professional domain of licensed medical doctors. For inpatients and outpatients alike, some psychosocial treatments have always been available, although the only common treatment is psychotropic medication.

In terms of treatment options in public facilities, there is little difference among patients due to their commitment status. Nearly all jurisdictions maintain maximum-security hospitals, and most NGRIs begin their commitment in these types of facilities but are eventually transferred to less secure, less costly facilities. In some states, these transfers require multiple approvals, but the degree of real oversight is unknown. Most often, security changes are made with internal review boards. Outright release or conditional release of NGRIs is supervised to a greater extent than transfers, and the release process varies in complexity and criteria. Some states require extensive, multitiered reviews, while others allow the committing judge to grant the release. A few states have convened specialized boards to oversee all NGRI release decisions and supervision. If placed on conditional release, NGRIs are required to adhere to the prescribed treatment and can face revocation if they violate the terms of their release. Failure to adhere to treatment, along with psychiatric deterioration, is the most common reason for revocation, not re-offending.

Contemporary Issues and Developments

Today, defense attorneys and defendants alike will not necessarily opt for an insanity defense for a relatively minor offense, even if the defendant meets the criteria for an acquittal. So, while the court decisions of the 1960s resulted in the release of many long-term patients, this trend away from commitment was short-lived. The insanity defense fell into disfavor among defense attorneys, in large part due to closer scrutiny of defendants and stricter release procedures leading to a long period of hospitalization, and among the public, due to perceived fears of this population. There was a parallel influx of nonviolent persons with mental illness into the

communities and the criminal justice system. Whereas between 1966 and 1983 the insanity defense was a viable defense for a wide range of defendants with concern about unusually long commitment, the new laws discourage its use for less serious offenders. The insanity defense with its expected long-term commitment is an attractive defense only for serious offenders who are facing long incarcerations if convicted. This leaves a large portion of persons with mental illness who are being cared for in the community finding themselves in minor scrapes with the criminal justice system.

Two major law and mental health initiatives of the late 20th and early 21st centuries are outpatient commitment and mental health courts, both of which are outgrowths of the real and the perceived influx of nonviolent persons with mental illness into the communities and the criminal justice system. Outpatient commitment is not a new concept, but it has only recently been widely implemented. It is a form of leverage of persons who have a history of treatment noncompliance—accept treatment or be hospitalized. In some states, it is also a form of leverage of the legislature to provide resources for mental health treatment. Most of the early mental health courts accepted only nonviolent misdemeanants. Revisions of these courts and the newer courts began to accept felons as well, but these may be limited to nonviolent offenders. Mental health courts are a form of criminal justice system diversion for defendants with mental illness. It is unknown at this point the degree to which these diversion programs are taking the place of the insanity defense. It is well documented that there is a measured increase in psychotic disorders among jail inmates and the convicted prison population. While this may be due in part to better diagnostic work in jails and prisons, it is unlikely that this accounts for all of the increase. These observed changes parallel the decline in the use and success of the insanity defense. Persons with mental illness who in prior decades were acquitted and provided treatment in mental health facilities are perhaps now receiving treatment in branches of the criminal justice system—outpatient commitment, jail diversion programs, mental health courts, and jails and prisons. How states respond to the increased demand for psychiatric treatment both in and outside the criminal justice facilities is evolving. Some states have extensive "inpatient" and "community" mental health services throughout their prison system. Ironically, these states are often the same states that provide extensive community mental health services in general. At the same time, some states fail to meet the demand at all levels and fail to recognize that good treatment is good security.

Trial Consultant Training

The nature and scope of trial consultant training reflect the array of services that are offered to clients, such as jury research, presentation strategies, and assistance with exhibits. There are no standard academic or professional requirements for trial consultants. Their training varies considerably across the profession, but it tends to involve a relevant academic background, some on-the-job training, and continuing education. Graduate training in the social sciences tends to be quite valuable, typically more than a background in law. However, on-the-job training helps provide competencies and strengthen skills that are difficult to obtain in any other way. Continuing education helps trial consultants remain up-to-date on valuable developments in the industry and advances in methodological, technological, and statistical areas.

Trial consultants provide either a narrow or a wide range of services to their clients, who are usually attorneys but can also include insurers, corporations, or individuals. These services generally include case

consultation and trial strategy, witness preparation, jury-related services, or presentation and technology-related services. Trial consultants who specialize in trial strategy often have a foundation in social psychology and communication and a solid understanding of law and legal procedure. Those who specialize in witness preparation may have a background in theater, communication, or counseling. Consultants who specialize in jury-related services such as jury selection or community attitude surveys typically have experience with social science research methodology and statistics as well as a foundation in social psychology. Finally, trial consultants who specialize in presentation and technology-related services tend to have a foundation in graphic art and communication. Of course, there are trial consultants who offer the full gamut of services. Thus, trial consultant training is quite diverse, reflecting the umbrella of services that consultants may provide and tapping into a range of disciplines.

Academic Preparation

Most successful trial consultants have graduate degrees in the social sciences, with a doctoral degree in psychology (particularly clinical psychology or psychology and law) being quite prevalent. In these types of academic programs, students acquire valuable skills in research design and methodology as well as in qualitative and quantitative data analysis. Graduate programs in the social sciences, particularly psychology, typically provide students with a solid theoretical background as well as research experience. These are particularly important for consultants who provide jury-related services such as mock trials and community attitude surveys. Analytical and communication skills are also valuable skills that can be honed in graduate programs in the social sciences, although other types of training, such as law school, can provide these as well. Some trial consultants assist their clients with mediations and arbitrations, so an understanding of the theories and applications relating to negotiations and conflict management is often helpful.

There is no clear academic path for individuals interested in trial consulting. Currently, there are no known academic programs that are dedicated to training future trial consultants. Appropriate academic preparation depends on the types of services that the individual plans to offer. For example, a person interested in focusing on graphics or demonstratives (e.g., developing day-in-the life videos of someone with a serious disability, designing illustrations to be used at trial) would need different training from someone who is more interested in conducting jury research in the form of posttrial interviews. In 2007, several universities offered masters and doctoral programs in psychology and law, forensic psychology, or related disciplines (e.g., Florida International University, John Jay College of Criminal Justice, and some other institutions offer relevant courses). A few of these programs offer a combined J.D./Ph.D. degree (e.g., University of Nebraska at Lincoln), although it is not clear whether the dual degree constitutes a superior academic path for those interested in trial consulting.

It is important to note that familiarity with the law and legal procedure is crucial, regardless of the nature or scope of the services provided. Attorney clients do not expect trial consultants to be legal scholars, but they do expect a functional knowledge of the law and a solid understanding of legal procedure. A careful read of relevant texts as well as in-court observations of proceedings is strongly advised.

The level of academic training that trial consultants should have depends on the level of responsibility and the type of work. For example, a master's degree in the social sciences should suffice for someone working as an associate or assistant to a more senior trial consultant. A doctoral degree in psychology or the social sciences provides valuable academic preparation for more senior-level positions, as well as the type of credentials that attorney clients often value. It is not clear whether graduate training of any form would be necessary for someone working in graphics or presentation-focused aspects of trial consulting. Proficiency in the appropriate software and graphic arts coupled with a background in communications should be adequate.

On-the-Job Training

Most trial consultants tend to acquire hands-on training by working for a consulting firm. This experience provides an invaluable opportunity to learn about the profession, the business, and the clients. Working with more experienced consultants can help individuals learn about best practices and gather their own sense of what works best. Moreover, many seasoned trial consultants have considerable insight into how jurors respond to certain types of arguments or evidence, particularly if they have worked on a particular type of case for a long time (e.g., medical malpractice cases).

Someone who acquires training under the tutelage of a consultant who has built a practice around certain types of cases would likely acquire specialized knowledge in that area, which is probably difficult to obtain in other ways.

It is in the courtroom that novice trial consultants often obtain considerable insight into courtroom dynamics, trial strategy, appropriate behavior, and the idiosyncrasies corresponding to some state and federal courts. By observing hearings and trials from start to finish, a novice trial consultant who is working as part of a trial team acquires know-how that is probably difficult to obtain in any other way.

On-the-job training can also help individuals learn about the business of trial consulting, including how to market and sell trial consulting services as well as meet the needs of clients. Such hands-on experience helps consultants provide answers to clients' questions. For example, a client may wonder whether jurors will understand the testimony of a scientific or technical expert in a complex civil case. A trial consultant might suggest some witness preparation to help the expert deliver the information clearly and convincingly in a way that fits with the themes of the case and to prepare the witness for cross-examination. The consultant might also recommend some demonstratives or exhibits to help the witness convey complex information clearly and help jurors use the testimony and evidence as intended. Additionally, surrogate jury research might test, among other things, the extent to which mock jurors understood the expert's message and incorporated that evidence into their decision-making process. Of course, clients do not always have unlimited resources, so successful trial consultants learn to devise solutions that meet the needs and fit within the constraints that clients bring to the table.

Trial consultants must also successfully manage clients. Understanding client needs and managing the complex interpersonal dynamics and political issues that can emerge when working among attorney clients, corporate clients, support staff, and others is important. Depending on their practice, trial consultants often find themselves working with multiple clients, such as corporate defendants and insurers, who do not always share the same goals. These are the types of situations that test consultants' skills in diplomacy, conflict management, communication, and critical thinking. As another example illustrating the importance of understanding client needs and politics, trial lawyers sometimes hire trial consultants only to be able to blame them for providing bad advice if the verdict is unfavorable. Such practices are probably uncommon but reflect the importance of being able to understand the trial consultant's role in a particular situation. Generally, trial consultants tend to acquire and hone many of these competencies through hands-on experience.

Finally, some successful trial consultants have built their practice entirely on their experience and have no relevant academic credentials. These consultants present a compelling argument when they point to their repeat clients, who are pleased with the level of services they provide. However, it is likely that in the future, trial consultants who acquired their knowledge and skills exclusively on the job will face increasing challenges in providing cogent answers to questions about statistics and methodology from increasingly sophisticated clients.

Continuing Education

Trial consultants need to update their skill set and remain up-to-date with current best practices and developments in the field and changes in the law. Clients are becoming increasingly sophisticated with regard to social science and technology, so trial consultants are additionally motivated to keep up with professional developments. For continuing education, trial consultants in the United States typically turn to the American Society of Trial Consultants (ASTC). Every year, the ASTC organizes a conference where trial consultants can take "Trial Consulting 101" and can discuss emerging trends and findings with seasoned experts. Other related professional organizations include the American Psychology-Law Society and the Law and Society Association. The annual meetings of these organizations sometimes provide useful information about scientific findings that are relevant to trial consultants (typically relating to jury behavior).

Certification of Trial Consultants

The ASTC has considered the merits and drawbacks of certification for trial consultants. Considering the diverse nature of the services as well as the swift changes that technological advances can bring, the current state of the profession in the United States excludes any professional certification or state licensing.

However, the ASTC has outlined some practice guidelines for some services (e.g., witness preparation, jury selection), and its annual conference provides workshops and sessions designed to disseminate these best practices. As the ASTC moves to identify practice guidelines for additional services (e.g., posttrial interviews), trial consultants should consider the implications of training or education.

Trial Consulting

Trial consulting gained attention in 1971, when "scientific jury selection" was employed by a group of social scientists in the defense of the Harrisburg Seven, a group of war protesters who faced conspiracy and kidnapping charges. Since that time, the field has grown considerably in terms of both the number of professionals in the field and the range of services offered. The educational and professional backgrounds of trial consultants vary, but doctoral-level psychologists make up the largest percentage of consultants. There are arguably no limits to the types of services that trial consultant can provide, but the most common include community attitude surveys, jury selection, witness preparation, focus group studies, mock trials (also referred to as trial simulation studies), demonstrative exhibit preparation and evaluation, content analysis of media for purposes of change of venue or change of venire motions, shadow juries, and posttrial juror interviews.

Consultant Backgrounds and Qualifications

The trial-consulting industry is unregulated, and there are no educational, training, or experiential qualifications required to identify oneself as a trial consultant, jury consultant, litigation consultant, or any other associated title. The American Society of Trial Consultants (ASTC) states that its members come from the fields of communication, psychology, sociology, theater, marketing, linguistics, political science, and law. Although there are no state or national licensing requirements, the ASTC Professional Code states, "The trial consultant fully discloses academic qualification and consulting experience to potential clients, specifies the services provided, and identifies the objectives of each consultation."

Trial Consultants Versus Experts

Trial consultants are typically retained by the attorney(s) representing one party in a case to assist with one or more aspects of trial strategy. Trial consultants differ from experts generally in the type of assistance they provide, although there can be similarities in the research methods they employ and overlap in the information or assistance they provide to attorneys. Whereas experts are hired because of their specialized knowledge of a particular field or subject relevant to a case (e.g., fire analysis, medical disease, accounting methods) and it is anticipated that they may testify at trial, trial consultants are generally hired to provide services that will assist the trial team with the assessment and development of case presentation and trial strategies, and it is typically not expected that they will testify at trial.

Trial-Consulting Services

A wide range of services designed to address pretrial, trial, and posttrial issues are provided by trial consultants.

Jury Selection

Jury selection was one of the first services provided by trial consultants when "scientific jury selection" was employed in the defense of the Harrisburg Seven in 1971, and over the years, there has been considerable debate over the purpose, effectiveness, and ethics of

trial consultants assisting with jury selection. Generally, jury selection involves attempts to identify jurors who are sympathetic or unsympathetic toward a particular party in the litigation. These attempts may be based on intuitive assessments of potential jurors during voir dire or on research-based "juror profiles" that identify demographic and attitudinal factors associated with favorable or unfavorable attitudes toward one or more of the parties and that are developed prior to the trial. Sources of information about potential jurors include juror questionnaires administered by the court in connection with jury pool maintenance and provided to the attorneys shortly before the trial, community attitude surveys, supplemental juror questionnaires, and the observation of potential jurors during voir dire (which can provide information on their verbal and nonverbal behavior).

Among jurists as well as social scientists, there is substantial variability in the weight afforded to jury selection and beliefs about the influence of individual jurors and jury composition on final verdicts. Empirical examinations have found that juror demographic and attitudinal factors account for a relatively small amount of variance in final verdicts (somewhere between 5% and 15%). However, it can be argued theoretically as well as statistically that in cases where the strength of evidence on opposing sides is evenly balanced and the litigation stakes are perceived to be high, even a slight advantage afforded by means of juror profiles or other empirically derived diagnostic information employed during jury selection can be helpful.

The methodological shortcomings of much of the early research on jury selection have been pointed to as possible explanations for the relatively weak relationships that have been found between juror demographic and attitudinal characteristics and final juror verdicts. Jury selection research that has assessed juror attitudes specific to the characteristics of a particular case has found stronger relationships between juror attitudes and final verdicts.

Community Surveys

Community surveys of jury-eligible individuals can be used to develop juror profiles to be used as part of jury selection. They can also be used to assist attorneys in assessing the strength of a case, a range of possible damage awards in civil cases, and the preexisting prejudice in the trial venue against one or more of the parties.

To develop juror profiles, surveys are administered (typically by phone) to a large number of jury-eligible community members in the trial venue or a surrogate venue deemed sufficiently similar to the trial venue. There is no minimum number of required respondents, but as the sample size increases, the margin of error decreases. Consequently, survey data from hundreds of respondents are required to reach margin-of-error rates that are generally accepted as reasonable in social science. The surveys consist of many demographic and attitudinal questions. In addition, a brief summary of the case is provided, and respondents are asked to indicate which side they favor. (This can be in the form of asking respondents to select a "verdict," but that form of measurement is not required.) Data analyses are then conducted to examine whether particular demographic or attitudinal factors are consistently associated with a verdict leaning or case outcome preference in favor of one party or the other.

If a community attitude survey reveals that, in general and across demographic factors and various attitudes, jury-eligible individuals heavily favor one side in a particular case, the trial team may decide to plea bargain or settle the case rather than go to trial. Survey results indicating an unbalanced case can also help place the potential influence of juror demographics and attitudes in an appropriate context.

Community surveys can be particularly helpful in civil cases where damage awards may be large or difficult to estimate. Given the variability typically associated with economic measures, a community survey can be a cost-efficient method of gathering estimates of damages from hundreds of jury-eligible individuals.

When the ability of a defendant to receive a fair trial in the trial venue is questioned, trial consultants can conduct community surveys to assess prejudice in that venue. And these results may be included in a motion for change of venue or change of venire. (Change-of-venue/venire motions are typically submitted by the defense, but community surveys can also be conducted by the prosecution or the plaintiff in a case to counter data presented by the defense.) Prejudice against a party may result from various sources, including pretrial publicity, personal experience with the party, or community gossip and rumor. Generally, personal experience with the party and community gossip do not substantially influence prejudice in the venue unless the venue is very small or sparsely populated. Community surveys can then be designed to assess the content and amount of

knowledge about the parties as well as preexisting beliefs about guilt or liability.

Focus Group and Trial Simulation Studies

Focus group studies and trial simulation studies allow for a more extensive presentation of trial evidence and arguments to a sample of jury-eligible individuals than community surveys do, but the higher costs associated with compensating individuals for their time and travel to some focus group or conference facility typically result in smaller samples being used in focus group and trial simulation studies. The methods and data analysis techniques generally used in focus group and trial simulation studies come from the fields of marketing, communications, and psychology (particularly small-group research). Trial simulation studies are sometimes based on the experimental method, with half the mock jurors being presented a particular factor (e.g., an argument, a piece of evidence, or a trial procedure) and the other half not being presented with the factor. The fact that the techniques used in focus group and trial simulation studies are grounded in the strong research methods of other fields may account for the lack of empirical examination of the effectiveness of these trial-consulting techniques.

Witness Preparation

Another service commonly provided by trial consultants is witness preparation, whether it is preparation for depositions or trial testimony. Based on the findings of research in the fields of communications and psychology on topics such as persuasion, physical attractiveness, deception detection, and communicator expertise, trial consultants can provide feedback and guidance on the verbal and nonverbal behavior of potential witnesses. In addition, trial consultants can conduct case-specific research involving the presentation of particular witness testimony, or different versions of the witness testimony, to a sample of individuals and then gathering data on their perceptions of the witness.

Demonstrative Exhibits

Based on empirical research on models of juror decision making, information processing (including the topics of attention, encoding, and recall), and visual perception, trial consultants can assist attorneys in the preparation of demonstrative exhibits and animations to be presented during trial. In addition, trial consultants can present prepared exhibits or animations to a sample of jury-eligible individuals (in isolation or as part of a focus group or trial simulation study) and gather data on individuals' perceptions of, reactions to, and memory for the materials.

Content Analysis of Media

When substantial pretrial publicity is associated with a case and attorneys believe that it may affect the defendant's ability to receive a fair trial, trial consultants can assess the amount and content of the publicity. This information can then be included in a motion for change of venue or change of venire. (As with community attitude surveys, this service can also be provided to prosecuting or plaintiff attorneys who seek to oppose such a motion.) Both print (i.e., newspapers and Internet publications) and visual (e.g., news stories or clips appearing on the TV evening news) media can be analyzed. The information gathered from the print media can be quite extensive, including the source of the information and the possible bias of the source (e.g., someone who is likely to be perceived as pro-prosecution, someone who is likely to be perceived as prodefense, or someone who is likely to be perceived as neutral), the nature of the information (including whether it is likely to be deemed inadmissible at trial), the total length of the story, the prominence of the information (e.g., Did it appear on the front page of the newspaper? What was the size of the headline?), and the content of any photos or figures associated with the story. Information gathered from the visual media can include the content of the video, the length of the video, the time and day(s) when the story was aired, and any commentary provided by the newscaster. Results from media content analyses can be combined with results from community attitude surveys to argue that the prejudice in the venue has resulted from the existing pretrial publicity and that alternative venues in which pretrial publicity has not occurred need to be sought.

Shadow Juries

The main service that trial consultants can provide during the actual trial (as compared with before the trial) is "shadow juries." This consists of recruiting a small group of jury-eligible individuals to sit in the courtroom throughout the trial and act as if they were

actual jurors in the case. At the end of each day, the trial consultant meets with the shadow jurors to discuss what has been presented at trial that day as well as to date and to gather their perceptions of the strength of each side's case and their reactions to particular witnesses, evidence, exhibits, attorney tactics and presentation styles, and anything else of interest to the trial team. This information is then provided to the trial team before trial recommences the next day, which allows them to adjust trial strategy based on the feedback.

Posttrial Juror Interviews

To understand the ultimate verdict in a case, attorneys often desire to meet with jurors after trial and talk with them about the case and the jury deliberation. This information can provide attorneys feedback on the effectiveness and accuracy of their jury selection techniques as well as the influence of particular arguments or evidence; assist attorneys with similar, pending cases; and serve as a general educational tool. Trial consultants can assist attorneys in developing interview protocols, or they can carry out the actual interviews. Systematic interviews of individual jurors are likely to produce the most complete and reliable data. Obtaining permission from the court to interview jurors and informing jurors about the limits of confidentiality and the use of the data are essential.

Unconscious Transference

Unconscious transference is a memory error that occurs when an eyewitness to a crime misidentifies a familiar but innocent person from a police lineup. Historically, the use of the term *unconscious* refers to the idea that the witness who misidentifies the familiar foil (an innocent person in a police lineup) has no conscious recollection of the previous encounter with the person. A classic real world example involved a case where a ticket agent at a train station was robbed and misidentified a former customer from a lineup. While the customer had an ironclad alibi, the ticket agent maintained that the person appeared all too familiar to him. Failing to recollect that he was a former customer, the ticket agent apparently based his identification on a sense of familiarity alone and incorrectly associated that with the crime. There is evidence that foils who are familiar to an eyewitness are at risk of being misidentified, but the literature suggests that the process through which it happens is not "unconscious," but, rather, involves a conscious recollection of the previous exposure to the familiar foil.

Studies on unconscious transference typically involve asking witnesses to a mock crime to make an identification from a lineup that contains a foil who is familiar or unfamiliar to the witnesses. Using this design, some studies report that a familiar foil is more likely to be misidentified than an unfamiliar foil. Other studies report null results—that prior exposure to a foil does not increase the probability of a misidentification. A reverse unconscious transference effect has also been reported where a familiar foil is less likely to be misidentified than an unfamiliar foil. In the latter studies, witnesses remember the foil as familiar but innocent and quickly dismiss that person as a potential lineup choice.

So why is there such variability across studies? Two critical moderator variables, physical similarity and conscious inferencing, influence the presence or absence of the unconscious transference error. First, unconscious transference is most likely to occur when the familiar foil and the perpetrator are "moderately" similar in appearance. If they look very different from one another, then they are not likely to be confused, regardless of the level of familiarity. Conversely, if their appearance is so similar that they are indistinguishable from one another, then the foil is at risk of being misidentified regardless of familiarity. Therefore, a moderate level of similarity between the foil and the criminal is needed so that when a familiarity component is added, it increases the likelihood of a misidentification, but only for witnesses previously exposed to the foil. Unfortunately, in many studies on this topic, the level of physical similarity between the familiar foil and the criminal was not controlled or measured, making their results difficult to interpret.

Second, unconscious transference occurs when witnesses incorrectly infer that the familiar foil and the criminal are the same person, a process referred to as conscious inferencing. Conscious inferencing allows the witness to accurately recall the previous encounter with the foil, but not dismiss the person as familiar but innocent. Because the witness thinks the familiar foil and the criminal are the same person seen in two

different places (at the crime scene and the place where they saw the familiar foil), recollecting the previous encounter with the familiar foil only reinforces the misidentification. Several studies have demonstrated that unconscious transference effects can be eliminated by preventing conscious inferencing. This can be done by telling witnesses just prior to making a lineup identification that the familiar foil and the criminal are not the same person, or by presenting a lineup that contains the familiar foil and the criminal. These procedures allow witnesses to distinguish between the familiar foil and the criminal, to realize that they are not the same person, and the result is often a correct, positive identification of the criminal.

The importance of conscious inferencing was also seen in a study with children, where 11- to 12-year-olds were found to be as susceptible as adults to unconscious transference, whereas 5- to 10-year-olds did not make the unconscious transference error. The study reported that the older children engaged in conscious inferencing and thought the familiar foil and the criminal were the same person seen in two different places. The younger children did not exhibit conscious inferencing, nor did they make the unconscious transference error. Therefore, the older children were susceptible to making the unconscious transference error because they had the cognitive ability to engage in conscious inferencing. The younger children were not susceptible to making the unconscious transference error because they lacked the cognitive skill to engage in conscious inferencing.

The discovery of the role of conscious inferencing has affected how the concept of unconscious transference is viewed. There does not appear to be support for the traditional definition of unconscious transference whereby a familiar foil is misidentified and the witness has no "conscious" recollection of the previous exposure to the foil. The misidentification of a familiar foil appears to depend on the ability of the witness to recall where the familiar foil was encountered, followed by an error in inferential processing whereby the foil and the criminal are thought to be the same person. Therefore, recalling the context where the familiar foil was seen appears to be a prerequisite for the misidentification. This process results in the formation of what has been referred to in the literature as a composite memory that is formed by using old information that was previously stored in memory (exposure to the foil) and new information (exposure to the criminal). The composite memory can be thought of as two separate memories that are held together by a contextual tag, which is the inference that the familiar foil and the criminal are the same person. If the contextual tag is broken, then the unconscious transference effect is eliminated. However, if the contextual tag is not broken and the witness misidentifies the familiar foil, then the composite memory may become solidified and very difficult to correct due to commitment effects and the destructive updating of the original memory for the crime. While the unconscious transference concept has enjoyed widespread acceptance in the field, perhaps it is time to give the general idea a more accurate title or description, such as "misidentifying a familiar bystander effect," given that such errors are driven by the conscious recollection of a previous exposure to the familiar foil.

Uniform Child Custody Evaluation System (UCCES)

The Uniform Child Custody Evaluation System (UCCES) provides a method of gathering and organizing information during child custody evaluations. It proposes to standardize the process for evaluations as a remedy for the unsystematic methods and procedures that are frequently employed in these cases. Although it offers a specific process for structuring data collection, it does not specify which psychological tests or

assessment instruments should be used. Research examining the psychometric properties of this system is currently lacking. The UCCES recommends that examiners provide a specific custody recommendation to the court, although the ethicality of addressing this "ultimate issue" is a matter of debate in the field.

Description

Harry Munsinger and Kevin Karlson designed the UCCES to standardize the processes of conducting custody evaluations and providing recommendations to the courts. State laws do not specify what information should be gathered and considered during custody evaluations, and the authors argue that this lack of specificity has led to custody examiners performing dissimilar assessments and providing widely different information to the courts. They suggest that the courts are better served by a standardized process that carefully balances information gathered from parents, children, and collateral sources. Such evaluations in principle should be more predictable and equable, and the courts should be better able to compare recommendations from different experts.

Materials in the UCCES packet consist of a set of 25 forms that the examiner uses sequentially to structure the evaluation. Forms begin with client referral, agreement to conduct the assessment, consent to evaluate minors, and parent personal history questionnaires. Some forms are intended to structure the parent interviews, child interviews, behavioral observations, home observations, and collateral interviews. Other forms seek to structure the examiner's analysis of the validity of individuals' responses during the evaluation, the suitability of joint custody, and the possibility of abuse or neglect. A form is even provided for tracking all communications relating to the case.

The examiner is encouraged to follow a strict set of procedures, beginning with the initial communications with the attorneys and parents. The actual evaluative process begins with gathering historical information from the parents and any other primary caretakers (e.g., grandparents) and the children. The parents are interviewed together during an initial session. The examiner then interviews each parent and child alone over a series of days. The UCCES manual offers various recommendations for performing the evaluation in as consistent and unbiased manner as possible. For example, it strongly recommends alternating the order of parental meetings or interviews at each session to avoid the suggestion of bias.

Although a strict set of procedures is recommended, the UCCES does not constrain the type or number of assessment instruments administered to children or parents beyond recommending that the standard interview forms should be completed. For example, the use of various objective and projective tests that might inform one's understanding of the closeness of the children to each parent is encouraged. When the children are interviewed alone, the UCCES manual specifically recommends administration of the Kinetic Family Drawing test, a projective device scored by measuring the distance between the persons in the drawing.

In addition to the interviews, the UCCES recommends making behavioral observations of parent-child interactions with each parent. The manual does not indicate the types of behaviors or interactions that the examiner should track nor does it provide a specific coding or rating system. Professional surveys have suggested that examiners rarely make use of structured rating systems, nor have any custody-specific methods been developed. Home visits are also recommended to verify that the home situation has been described accurately by the parents (e.g., the environment is safe and clean). Finally, the examiner also may perform "collateral interviews" to gather substantiating information from friends, neighbors, babysitters, and/or other individuals who interact with the family.

After performing the standard information gathering, the examiner reviews the forms and determines a custody recommendation based on the principle of "goodness of fit." The UCCES manual provides a very general operationalization of this legal principle by directing the examiner to consider if the parent lovingly supports healthy individuation and development of the child, encourages and is involved in the child's interests and academics, and has basic competencies with regard to child care. More detailed operationalizations of the goodness of fit standard are referenced in the manual. Finally, a written report is prepared and sent to the court and both attorneys. The authors recommend that the examiner make a specific recommendation of custody for the family.

Psychometric Properties

No information concerning psychometric properties is provided in the UCCES manual. This is perhaps not surprising because the authors consider the UCCES to be a flexible, evaluative process rather than a specific psychological instrument. Nevertheless, whether

UCCES-based recommendations are more reliable or valid than non-UCCES-based recommendations ultimately is an empirical question. A literature search failed to locate any publications specifically evaluating the reliability or validity of custody recommendations made using the UCCES, however.

The authors assume that examiners will use a variety of psychological tests in addition to the UCCES forms, and they exhort clinicians to be aware of the limitations of psychological testing and to adhere to the *Standards for Educational and Psychological Testing* when administering, scoring, and interpreting test data. Despite this caveat, they also suggest that examiners may use various controversial projective tests to inform judgments concerning the child's psychological closeness to each parent. More generally, many of the clinical instruments recommended for use were not designed to address typical custody-related questions, and several authorities have questioned the relevance and utility of these tests for this purpose.

The Ultimate Issue Debate

The "ultimate issue" refers to the legal question that is to be determined by the court in a particular case. Mental health experts continue to debate whether it is ethical to offer ultimate issue opinions more broadly, as well as specifically in relation to custody cases. This debate centers on several concerns, such as that expert witnesses are not necessarily trained in legal issues and, perhaps most important, that experts giving ultimate issue opinions represent an attempt to usurp the fact finder's role as the final arbiter of case dispositions. Some experts, including the authors of UCCES, are comfortable providing such opinions. Others believe that experts are not qualified to make such assertions in court and that it is unethical to do so.

U.S. Supreme Court

The U.S. Supreme Court conducts appellate review hearings of lower-court decisions, relying on written briefs and oral arguments by counsel for the parties to help the justices formulate opinions as to cases' outcomes. The number of petitions from parties seeking to have the Supreme Court grant a hearing on their appeal far exceeds the number of cases the justices are able (or willing) to take on. For the very few cases that reach the Supreme Court, there is a highly structured, formalized process waiting. Should a petitioner succeed in obtaining a hearing, his or her attorneys will be able to submit written briefs and participate in oral arguments. Thereafter, the case will fall entirely within the justices' domain; processing of the case will include an initial justices-only conference, the exchange of draft opinions, and various types of interim decisions by the justices (e.g., on the standard of proof to which the government—if a party to the case—should be held), leading up to a majority's ultimate decision to affirm or overturn the lower-court ruling.

Matters before the Court sometimes involve questions about human behavior. The need for behavioral science knowledge provides opportunities for professional organizations to submit their own briefs addressing relevant research areas. Guidelines and precedents exist for how justices may decide cases, but such parameters are often open to disagreement and justices may even fashion new rules. The interpersonal and cognitive aspects of the justices' own decision making have also been studied. This entry examines the operations of the U.S. Supreme Court, the criteria used by justices in making decisions, the types of rulings issued by the Court, and the role of precedent in Court deliberations, as well as the various interfaces between it and psychological science.

Operations of the Supreme Court

The U.S. Supreme Court does not conduct "trials" in the sense of evidence presentation, cross-examination of witnesses, and original fact-finding. Rather, it conducts appellate reviews (i.e., hearings) of cases from lower appellate courts, such as a federal Circuit Court of Appeals or a state High Court. The one exception to the U.S. Supreme Court's role as an appellate venue, which is very rare, is when the Court takes a case under original jurisdiction, as when there is a dispute between two states. In its typical appellate role, the U.S. Supreme Court will evaluate the soundness of the lower-court decision being appealed, with an eye toward whether the previous court acted properly in applying U.S. Supreme Court precedents, interpreting provisions of the U.S. Constitution, interpreting a statute, and so forth. Ultimately, a majority of the Supreme Court must decide whether to affirm or overturn the lower-court ruling.

An estimated 8,000 petitions for hearing are filed annually to the U.S. Supreme Court. In such petitions, the losing side at the previous level (petitioner) requests a full review and hearing at the Supreme Court, based on the contention that the previous court's ruling contained reversible *procedural* error and that the case raises highly important statutory or constitutional issues. In only about 80 cases per year (based on recent years' practice) does the Court grant certiorari (cert. for short), meaning that it agrees to hear the appeal. For cert. to be granted, at least four of the nine justices must vote to do so.

A case before the nine U.S. Supreme Court justices is highly structured. With the exception of extremely high-profile cases, to which more time may be devoted, a typical Supreme Court oral argument lasts for exactly 1 hour, with 30 minutes granted to counsel from each of the two sides. The justices can (and often do) interrupt attorney arguments to pose questions, with the time consumed by the justices counting as part of the arguing side's 30 minutes. Written briefs submitted in advance by each side, as well as amicus curiae ("friend of the Court") briefs submitted by outside parties, form the basis for the oral questioning. For an outside party to submit an amicus brief, consent must be obtained from the focal parties in the case or from the Court. Greg Stohr (2004) details how the University of Michigan, in preparing to defend its affirmative action admissions policies, actively sought supportive amicus briefs from groups including corporations and retired military leaders to buttress its argument for the importance of diversity in society.

On the next available Friday after oral arguments, a justices-only conference takes place, at which a straw vote is held to see how many justices are leaning toward voting for each side. The most senior justice in the (tentative) majority—with the Chief Justice treated as being first in seniority, regardless of length of service on the Court—has the choice of to whom to assign the writing of the (apparent) majority opinion. Other justices can draft concurrences or dissents, depending on their judgment of the case. Draft opinions are exchanged among the justices' chambers, sometimes for months, with a justice who was originally planning to vote for one side sometimes being won over to the other side; such shifting coalitions may, of course, necessitate a reorganization of the writing of majority and minority opinions. Justices vary in the amount and nature of the work they delegate to their law clerks; the latter tend to have graduated from elite law schools and clerked previously for an appellate judge at a lower level.

Role of the Solicitor General

According to Lincoln Caplan (1987), "the Solicitor General's principal task is to represent the Executive Branch of the [federal] government in the Supreme Court" (p. 3). In some cases, the U.S. government is one of the two focal parties to the dispute, whereas in others it is not. Overall, however, so influential does Caplan consider the Solicitor General (SG) to be that the former's book on the history of the SG's position is titled *The Tenth Justice.* Two ways in which the SG's office has an impact on procedural aspects of Supreme Court cases are (1) its high success rate with cert. petitions relative to others who file and (2) its opportunity to participate in the oral arguments of some cases as a third party with its own block of time, when the U.S. government is not one of the focal parties. In the University of Michigan affirmative action cases mentioned above, for example, the SG was given 10 minutes each in the undergraduate and law school cases. Caplan suggests that, for much of its history, the SG's office has enjoyed a reputation for thorough, impartial legal analysis in its briefs, thus possibly accounting for its influence with the justices.

Decision-Making Criteria

Just as jurors in a criminal or civil case use standards of proof in deciding how to vote in a trial (e.g., "guilt beyond a reasonable doubt," "preponderance of the evidence," "clear and convincing evidence"), federal judges—including those on the U.S. Supreme Court—have a number of guidelines and frameworks for deciding the cases they hear. At a general level, the Supreme Court's role is to interpret the U.S. Constitution and federal statutes. In addition, the Court can establish new rules for deciding future cases. Among the many types of cases the U.S. Supreme Court decides, those involving the Due Process and Equal Protection Clauses of the Fourteenth Amendment to the U.S. Constitution often are among the most high-profile ones. Furthermore, these types of cases illustrate one of the frameworks used by the justices in deciding how they will vote.

As a starting point, a state may pass a law restricting some type of behavior, such as certain forms of sexual conduct or the circumstances under which a woman can obtain an abortion. The initial inquiry would probably ask whether the statute threatened a "fundamental right" or imposed burdens on a "suspect class" (e.g., groups that have historically been subjected to discrimination). If the answer to this inquiry is "no," the statute's constitutionality is then evaluated by the Supreme Court justices (or federal judges on a lower court) according to what is known as the "rational basis" or "rational relations" test, which is considered a relatively easy standard for the government to meet in defending the law. Harry Krause and David Meyer (2003) note that "ordinarily, the Equal Protection Clause requires only that the lines drawn by the government be rationally related to the object of the legislation" (p. 25).

If, however, the Court determines that one or both of the aforementioned triggering conditions—intrusion on a fundamental right or against a suspect class—is met, the government will then be held to the more difficult "strict scrutiny" standard regarding its statute. This standard "presumes that the challenged action is unconstitutional, unless government can rebut . . . by proving that the intrusion on the fundamental right is necessary, or 'narrowly tailored,' to the advancement of a 'compelling' state interest" (Krause & Meyer, 2003, p. 23). A saying has developed reflecting many observers' impression of the government's difficulty in prevailing under strict scrutiny; the standard is said to be "strict in theory, fatal in fact." Regarding Supreme Court justices' ability to devise new standards, the former justice Sandra Day O'Connor's test of whether abortion-related restrictions impose an "undue burden" on women's access to the procedure is one of the most prominent examples in recent years.

A somewhat different, more linguistically related issue concerns statutory interpretation. Justice Stephen Breyer discusses some of the complexities of this seemingly obscure area in his 2005 book *Active Liberty.* The following is one example of such interpretive principles, in which Breyer draws on several different legal sources:

> A canon of statutory interpretation, *ejusdem generis*, says that, if "general words follow specific words in a statutory enumeration," courts should construe the "general words" as "embrac[ing] only objects similar in nature to those objects enumerated by the preceding specific words." (p. 92)

Such "canons of construction" are often discussed in law review articles.

Types of Rulings

Many of the U.S. Supreme Court's best-known rulings are those that appear to bring final resolution to a matter. For example, once the Court's final decision in *United States v. Virginia* (1996) was announced, observers knew instantly that the Virginia Military Institute could no longer exclude female students. Other cases, at the time they are decided, appear to provide finality to an issue, only to have it reemerge years later in a new line of cases. One recent example is how the Court shifted its stance on a constitutional right to privacy of sexual intimacy from *Bowers v. Hardwick* (1986) to *Lawrence v. Texas* (2003). What these cases all have in common, however, is that the U.S. Supreme Court rulings brought closure to the parties at hand, with no need for further hearings.

Not all cases at the High Court are like that. In some, the justices remand the case back down to a lower court for reevaluation in light of some new standard or ruling. A new round (or set of rounds) of hearings and determinations thus takes place in a lower court, far away from the spotlight of the U.S. Supreme Court, to which the case ultimately may or may not return. In *Schlup v. Delo* (1995), for example, the U.S. Supreme Court had to decide if the state prisoner Schlup's habeas corpus claim of new exculpatory evidence should be evaluated by a lower court under the standard of "clear and convincing" evidence (harder for Schlup to prove) or,

simply, greater likelihood than not (easier for Schlup to prove) that the new evidence would be able to sway a "reasonable juror."

In other cases, the U.S. Supreme Court's role is to decide if a lawsuit can go forward at the trial level (e.g., in a U.S. District Court). Subsumed under this larger issue are more specific questions, such as whether the parties bringing suit have legal standing to do so and whether an issue is one that can be properly deliberated and decided in the judicial arena, as opposed to legislative or other nonjudicial venues (if so, the issue is said to be "justiciable"). The landmark legislative redistricting case of *Baker v. Carr* (1962) is illustrative of such cases.

Overturning of Precedents

Many justices and commentators advocate adherence to precedents or *stare decisis*. However, as alluded to above, the Supreme Court occasionally reverses one of its major decisions. Lawrence Wrightsman (2006, p. 232), drawing on the 1992 case of *Planned Parenthood of Southeastern Pennsylvania v. Casey*, summarizes four factors justices may consider when deciding whether to overturn precedent:

- The workability of the [existing] rule
- The extent to which the public has relied on the rule
- Relevant changes in legal doctrine
- Changes in the facts or perceptions of the facts

Interface of Psychological Science and the Supreme Court

The U.S. Supreme Court is relevant in at least two significant ways to the study of psychology and law. First, research on human behavioral processes may be relevant to deciding a case. Second, a substantial body of empirical studies on psychological and other factors appearing to play a role in Supreme Court justices' decisions is rapidly accumulating.

Recent Cases Involving Studies of Human Behavior

Cases being debated in the U.S. Supreme Court may involve issues of human behavior. For example, in deciding whether a governmental practice is, "cruel and unusual" or demonstrative of a "compelling" state interest, some justices on the Court may wish to consult evidence from the social sciences. Accordingly, professional organizations may submit amicus briefs attempting to guide the Court on matters of human behavior. A systematic listing of amicus briefs filed by the American Psychological Association is available on its Web site (listed at the end of this entry). Historically, probably the best known citation of social science research in a U.S. Supreme Court opinion is that in *Brown v. Board of Education* (1954, footnote 11). A sampling of contemporary Supreme Court cases raising behavioral science issues are summarized as follows, for illustrative purposes:

In *Roper v. Simmons* (2005), the Court had to decide whether it was constitutional to impose the death penalty on individuals who committed their crimes while younger than 18. The case, therefore, raised questions of adolescents' cognitive and emotional maturity. In disallowing such executions, the majority opinion cited research from developmental psychology, noting, among other findings, that compared with older individuals, adolescents are more "impetuous" or impulsive. They are also more susceptible to peer pressure and would likely be less able to get themselves out of situations where violence could take place.

Gratz v. Bollinger (2003) and *Grutter v. Bollinger* (2003), companion cases on whether the University of Michigan's admissions policies for its undergraduate and law school programs, respectively, could constitutionally use race as a factor, hinged in part on the University's claim that attending an institution with a diverse student body tended to confer academic and social benefits on majority and minority students. Such a finding would appear to strengthen the argument for a university having a compelling state interest in providing a diverse student body and, potentially, for particular methods used to achieve this objective. Indeed, Justice O'Connor's majority opinion in *Grutter* noted that "the Law School's claim of a compelling interest is further bolstered by its *amici*, who point to the educational benefits that flow from student body diversity."

Supreme Court justices vary widely in their receptivity to psychological and other social scientific evidence. In some of the above cases, such evidence appears to have played a substantial role in the Court's decision making (or, at least, was cited in the majority opinion). In contrast, other justices appear to take a much more negative view. Wrightsman (2006) quotes Justice Antonin Scalia as alluding to "those of us who have made a career of reading the disciples of Blackstone rather than of Freud" (p. 103). Wrightsman also

adds that "this was not the only time that Justice Scalia has gratuitously attacked psychology."

Related to the introduction of scientific information into court cases, another important role of the U.S. Supreme Court has been to interpret the Federal Rules of Evidence as far as standards for the admissibility of scientific evidence (social, as well as physical, science) and technical knowledge into federal trials. Leading cases in this area from recent years include *Kumho Tire Company v. Carmichael* (1999) and *Daubert v. Merrell Dow Pharmaceuticals* (1993).

Research on the Psychology of Supreme Court Decision Making

The cognitive and interpersonal processes that go into the justices' own decision making have been active research topics in their own right. As summarized by Wrightsman (2006), areas of inquiry include pressures toward group conformity (that there appear to be more unanimous decisions, and fewer 8:1 decisions, than would be expected, suggests that such pressures are operative); whether the justices' ultimate votes can be predicted from an analysis of their questioning during oral arguments; and content analysis of justices' written opinions to assess the cognitive complexity exhibited in the opinions and see if situational factors (e.g., being in the majority or dissent) affect levels of complexity. One of the major scholarly projects on Supreme Court decision making in recent years, Washington University's Supreme Court Forecasting Project, has an extensive database online. Guiding such empirical studies are conceptual models known as the legal model, the attitudinal model, and the rational choice model.

V

Validity Indicator Profile (VIP)

The validity indicator profile (VIP) is a measure of response validity that is intended to be administered concurrently within a battery of cognitive tests in a forensic assessment. The VIP has two subtests (verbal and nonverbal), containing 178 items in all. Curve analysis of test responses classifies performance as valid or invalid. Invalid performances are subclassified as inconsistent, irrelevant, or suppression (obvious malingering). The VIP has been validated in several adult samples.

Forensic psychological testing often involves assessment of cognitive functioning. Given the inherent advantages of appearing impaired in many forensic forums (e.g., litigated claims of injury, competency to stand trial), it is important to provide a formal assessment of the validity of test performance. Forensic assessments that conclude that cognitive impairment exists are below the standard of practice if they do not include overt assessment of the validity of presentations in interviews or on psychological tests. A large variety of response validity instruments exist. Most response validity instruments depend on assessment of memory performance. The VIP directly assesses problem-solving ability and vocabulary.

Performance on the VIP is categorized as valid or invalid. Valid performances, referred to as compliant, reflect an intention to perform well and reveal sustained effort throughout the test. Invalid performances are classified as inconsistent, irrelevant, or suppressed. Inconsistent performances reveal evidence of intention to respond correctly but reflect inconsistent effort. Irrelevant performances result from random responding throughout the test. Performances classified as suppressed demonstrate that the individual intended to respond incorrectly on the test and exerted sustained effort to respond incorrectly.

These classifications reflect a model of test validity in which validity is evaluated by a cross-classification of "intent" (intends to respond correctly or does not intend to respond correctly) and "effort" (low to high). Although most "malingering tests" in use are referred to as "effort" tests and employ a dichotomous classification process that generally is construed to mean "malingering" or "not malingering," the VIP employs a fourfold classification scheme to capture elements of these two constructs. Construct validation of this scheme demonstrates that compliant and inconsistent performances could be distinguished on the basis of effort, that inconsistent and irrelevant performances could be distinguished on the basis of intent, and that compliant and suppressed performances could be distinguished on the basis of intent.

The categorizations are accomplished by performance curve analysis. The performance curves are a summary of response accuracy plotted against item difficulty. The VIP has two subtests, nonverbal and verbal. The nonverbal subtest includes 100 picture-matrix problems, and the verbal subtest includes 78 word-definition problems. The items within each subtest span a hierarchy of difficulty, from very easy to very difficult. The items are presented in a randomized order of difficulty. The test is typically completed

by paper and pencil, but the publisher also provides a means for computer testing.

The test takers must complete all the items, each of which has two answer choices. Once the test is completed, the answers are scored (0 or 1), and they are reordered by item difficulty. Spans of 10 scores are averaged, using running means, to yield performance curves comprising 91 (nonverbal) or 69 (verbal) points. For example, Items 1 to 10 yield the first running mean, and Items 2 to 11 yield the second running mean. In a VIP performance curve, the *x* value of the performance curve is item difficulty, and the *y* value is mean performance accuracy (running mean value).

When a line is plotted through the running means, the resulting performance curve yields distinctive features that are used to categorize performance. The first general feature is the slope of the performance curve. The curves that have a downward slope from easy to difficult reveal intent to respond correctly. The flat curves reflect irrelevant responding, and the upward sloping curves reflect intent to respond incorrectly. The extent to which these slopes are sustained provide information about application of effort. The first running mean is also an indicator of intent, as that point of the curve reflects performance on the 10 easiest items. These items are easily answered by young children. The test includes items that are not easily answered by most individuals so that a transition from effortful performance to guessing can be observed. The fluctuations in the expected progression of the performance curve from consistent correct responding to guessing, given the ability level of the individual, and identify instances of inconsistent responding. That is, these fluctuations are meaningful irrespective of the inherent capacity of the individual to respond correctly.

For classifications of compliant, inconsistent, and suppressed, it is possible to estimate the intellectual capacity of the individual. The characteristics of the performance curve and the number of items correctly responded to have been correlated with performances on other intellectual measures. It is noteworthy that these features are applicable when individuals intentionally choose incorrect answers and are classified as suppressed.

Validation studies have been reported in four published papers and the test manual. Validation and cross-validation samples have included large numbers of normal adults, neuropsychology examinees, criminal defendants, and persons with serious mental illness. The reported classificatory accuracy of the nonverbal subtest is 66% sensitivity and 90% specificity. The verbal subtest demonstrates 59% sensitivity and 94% specificity.

Verbal Overshadowing and Eyewitness Identification

Verbal overshadowing (VO) refers to situations in which describing a nonverbal experience, such as the appearance of a face, impairs subsequent recognition. In the original demonstration of VO, participants viewed a video of a robbery with a salient perpetrator and were later asked to recognize the perpetrator in a photographic lineup, including seven similar distractors. After viewing the video, half the participants spent 5 minutes writing a description of the robber, while the other half performed an unrelated control task. Remarkably, participants who verbalized the face were significantly less likely to correctly identify the target face among others in the lineup.

Since its original demonstration, considerable research has explored the generality and boundary conditions of VO. VO has been found to generalize to a large variety of other visual experiences, including colors, abstract figures, photographs of mushrooms, and maps, as well as other sensory modalities, including audition (e.g., music and voices) and taste (wines).

In contrast, it is not observed for more verbalizable experiences such as the contents of spoken statements. The boundary conditions associated with VO involve both situation and individual difference variables. An important individual difference variable is expertise, with verbalization impairing performance when perceptual expertise is high (e.g., when individuals have been perceptually trained with a stimulus) and verbal expertise is low (e.g., among individuals with high verbal ability or those trained to describe a stimulus).

A variety of situation variables have been found to mediate VO during the encoding, postencoding, and retrieval phases. With respect to encoding, verbalization is observed with faces of persons from one's own race but not with faces of those of other races (demonstrating a role of perceptual expertise). With respect to postencoding, extensive verbalization produces greater VO than more modest descriptions. With respect to retrieval, VO is more likely to be observed when the distractors are highly similar than when they are dissimilar (and thus more verbally distinguishable). VO is more likely to be observed for faces presented upright than inverted faces (suggesting a role of holistic processing). Despite the prevalence of VO across many domains, a number of researchers have failed to replicate the phenomenon. However, a meta-analysis including 29 studies and 2,018 participants found a statistically significant overall effect, indicating that participants who verbalized a target were 1.27 times more likely than nonverbalizers to misidentify the target. Furthermore, this meta-analysis also revealed that verbalization effects are more likely to be observed when (a) the verbalization instructions induce detailed and elaborate descriptions and (b) there is a minimal time delay between the verbalization and the recognition test.

Currently, it is not entirely clear why VO occurs, and there are three competing accounts proposed to explain the phenomenon. The *content account* asserts that it is the precise contents of what is said during verbalization that interferes with memory. In other words, people create verbalizations that do not quite match up with the original visual memory, thus interfering with future recognition. The content account fits well with the effect of expertise on VO (see above) and helps explain why extensive verbalizations (which tend to include more inaccuracies) are more disruptive, but it fails to account for why many studies have failed to show a connection between the quality of verbal descriptions and recognition accuracy. It also has trouble accounting for why describing one face can interfere with the recognition of a different face. According to the *criterion shift account,* verbalization biases participants toward the target-"not-present" option, leading to reduced recognition accuracy when the target is present. Although this account potentially explains VO results in studies with "not-present" options, it fails to account for the many times in which VO has been observed in the absence of a not-present option. Finally, according to the *process shift account,* verbalization changes the individual's processing orientation from a more holistic strategy to a more local one. If, as is often the case, faces are initially encoded holistically, the verbally induced featural processing strategy may lead to recognition processes that are incommensurate with the manner in which the face was originally encoded. A particular strength of the processing account is that it does not require a link between verbalization quality and recognition accuracy, which as stated above, is often not demonstrated. Although at present there is some controversy regarding the relative merits of the content, criterion, and processing shift accounts of VO, it seem likely that all three accounts have merit. Further research is needed to determine when each one is most likely to apply.

In summary, a large amount of research has shown VO to be a pervasive effect across many types of visual memory and other areas of perception. A recent meta-analysis has shown VO to be a relatively small, but reliable effect on memory. Furthermore, characteristics of the verbalizer, the particulars of the description task, and what occurs between viewing the original stimulus and retrieval of this stimulus appear to play a role in the strength of the VO effect. Although the exact cause(s) of VO remain unclear, that the effect occurs and that it can significantly effect eyewitness memory is beyond dispute. From a practical perspective, the modest size of VO effects combined with its tendency to dissipate over time suggests that investigators should not avoid soliciting verbal descriptions from witnesses. However, investigators may want to avoid asking participants to make identifications immediately after providing extensive verbal descriptions of a perpetrator's face or voice.

Victim Impact Statements

Most states allow victims and/or victims' survivors to speak during the sentencing phase of trials as to the pain they have suffered as a result of the crime. Such proclamations, called "victim impact statements," are extremely controversial. Some legal experts posit that victims and/or victims' survivors have the right to speak publicly about the harm they have endured; other legal experts suggest that such statements encourage the trier of fact to base sentencing decisions on emotion, as opposed to fact. The presence of victim impact statements in capital trials has caused considerable debate, as social scientific research has suggested that juror, defendant, and victim characteristics play a significant role in how such declarations are perceived and, consequently, in juror decision-making processes in death penalty cases. The U.S. Supreme Court has ruled that victim impact statements are constitutional; however, social scientists have issued certain recommendations as to how the prejudicial nature of such statements can be minimized.

Victim impact statements outline the harm they have suffered as a result of the defendant's actions. Since the enactment of the Victim and Witness Protection Act (1982), most states allow the trier of fact (i.e., judge or jury) to take such statements into consideration when determining the sentence of the defendant. Victim impact statements may detail the following: (a) the physical, psychological, and financial impact that the crime has had on the lives of the victim and/or the victim's survivors; (b) the victim or victim's survivor's opinions about the crime and/or defendant; and (c) in murder cases, information about the personal characteristics of the deceased. In most states, victim impact statements cannot characterize the defendant in negative terms, nor can victim impact statements describe the type of punishment the victim or victim's survivors feel is appropriate for the defendant.

The presence of victim impact statements in the sentencing phase of trials is an extraordinarily controversial issue. The primary debate stems from the fact that victim impact statements are not evidence; rather, they simply serve as a context through which the jury should interpret the impact of the crime. Some legal experts have argued in favor of the admissibility of victim impact statements, suggesting that they give victims and victim's survivors a voice in court proceedings, allow for psychological healing and closure, promote sentences that are more reflective of the suffering endured, humanize the person who has been harmed, encourage other victims to come forward, and enhance the perception of procedural justice. Other legal experts have argued against the admissibility of such statements, positing that they foster inconsistencies in sentencing procedures, expose judicial proceedings to undue public pressure, and encourage jurors to base decisions on issues that are irrelevant to the facts at hand (i.e., emotion).

In no type of case are victim impact statements more debated than in capital (i.e., death penalty) trials. Two Supreme Court rulings are pivotal in discussing the impact that victim impact statements are allowed to have in death penalty cases. In *Booth v. Maryland* (1987), the Court concluded that the victim impact statements created a "constitutionally unacceptable risk" and violated the Eighth Amendment's prohibition against cruel and unusual punishment. The Court ruled that in a death penalty case, the jury's decision must be based on the characteristics of the defendant and/or crime and not on the impact of the crime on the victim's survivors. The Court posited that allowing victim impact statements to influence the jury's decision could lead it to base the sentence on juror sentiment, as opposed to the facts presented in court.

In *Payne v. Tennessee* (1991), the Court reversed its earlier decision and changed the role that victim impact statements were allowed to play in capital trials. *Payne v. Tennessee* held that the Eighth Amendment erects no prohibition against the admission of victim impact statements relating to both a victim's personal characteristics and the emotional impact that the crime has had on the victim's survivors. In summary, the Court ruled that such evidence is admissible during the sentencing phase of capital trials if the state legislature chooses to permit it. Finally, the Court concluded that victim impact statements jeopardize capital defendants' right to due process only if such declarations are "so unduly prejudicial that it renders the trial fundamentally unfair."

Social scientific research has suggested that the presence of victim impact statements affects the way in which jurors perceive the victim, the victim's survivors, and the defendant. Previous findings have also concluded that such declarations affect jurors' decision-making processes in capital trials. For example, earlier studies have found that jurors exposed to victim impact statements are more likely to think favorably of the victim and the victim's survivors than jurors who are not exposed to such declarations. Previous research has also suggested that the aforementioned attitudes translate into behavior: Capital defendants are more likely to receive the death sentence when victim impact statements are present than when they are absent.

Psycholegal data have also suggested that victim characteristics appear to affect the way victim impact statements are weighed. Specifically, victims with greater social standing in a community may both be more valued by the victim's survivors and have survivors who are more educated and, consequently, persuasive and eloquent. Consequently, the victimization of a person of higher social status may have more effect on a jury and ultimately influence the extent to which defendants are perceived as blameworthy.

Certain juror characteristics also appear to affect the way victim impact statements are perceived. For example, one study found that death-qualification status (i.e., a jurors' eligibility to hear a capital case based on their attitudes toward the death penalty) enhances jurors' susceptibility to victim impact statements. Specifically, when victim impact statements were presented, death-qualified jurors (i.e., jurors who are eligible to hear a capital case) were more likely to think favorably of both the victim and the victim's survivors.

Because of the prejudicial nature of victim impact statements, social scientists have issued several recommendations. First, psycholegal researchers have suggested that victim impact statements be limited in scope, particularly when describing the victim in ways that emphasize his or her high social status. Second, social scientists have recommended that restrictions be placed on the number of victims' survivors allowed to testify in court, so as to reduce the cumulative effect that such testimony has on the jury. Third, psycholegal researchers have advocated that the jury be prohibited from hearing descriptions of the defendant in dehumanizing terms (e.g., "animal," "monster"). Fourth, social scientists recommend that juries be given more guidance about the purpose of victim impact statements when they are admitted. Finally, some psycholegal researchers suggest countering the effect of victim impact statements with execution impact statements. Such declarations involve informing the jury of the impact that the execution of the defendant would have on his or her survivors and serve to "level the playing field" between victims (who tend to be hyperindividualized) and defendants (who tend to be deindividualized). Although not constitutionally mandated, several states (e.g., Oregon, California) have approved the inclusion of such testimony in capital trials.

VICTIMIZATION

Victimization can be defined as the act or process of someone being injured or damaged by another person. The resulting damage may be physical (e.g., bruises, broken bones) or psychological (e.g., posttraumatic stress disorder [PTSD], depression). Victimization is a frequent event that occurs within an interpersonal context, often involving an abuse of power, such as a parent who abuses a child; an adult child who abuses a frail, elderly parent; or a teacher who sexually abuses a student. Although past research on victimization has tended to be compartmentalized, a more integrative approach is needed not only because of the frequent comorbidity among the different types of victimization, but also because of the shared psychological issues. The shared core psychological issues extending across types of victimization include damage to interpersonal relationships and self. Although victimization may often involve traumatic experiences, trauma may not involve victimization. For example, stepping off a curb and falling and breaking an ankle might be a traumatic event; however, such an event does not define an experience of victimization because it is not an interpersonal event.

To understand victimization, several core themes need to be acknowledged. Contrary to a layperson's perspective, victimization is not a rare event that occurs only in a stranger-on-stranger context. On the contrary, victimization is an extraordinarily frequent event that most often occurs in, and adheres to, the ordinary roles of human life. Although stereotyped conceptions of victimization do occur (e.g., a woman raped by a stranger walking down a street at night) and are damaging and need to be addressed, these types of victimization are not the norm outside the context of a war. Rather, the most significant sources of victimization are those that arise out of our ordinary day-to-day roles, such as those of spouse, parent, child, and friend. Thus, victimization must be understood as an inherent part of human relationships.

Unfortunately, research and writing about victimization is often compartmentalized or balkanized. For example, researchers who study child sexual abuse frequently do not consider the co-occurrence of other forms of victimization, such as physical abuse. Similarly, researchers who study physical abuse may fail to acknowledge the effects of witnessing domestic violence. This has lead to a failure to appreciate the total context of the victimization. Furthermore, such balkanization has led to the failure of researchers to create conceptual models that are organized around general concepts of victimization. Instead, most research and most models of victimization are limited to a particular context. As the field has matured, there is growing recognition that such balkanization can lead to failures to recognize the similarities in these experiences. In particular, such balkanization has prevented researchers from recognizing the common core of the victimization experience: the need to focus on the interpersonal nature and consequence of victimization.

This entry does not discuss victimization that is related to social and political processes such as war. Although war and genocide are grim fields from which victimization springs, such events are beyond the scope of this entry and require their own level of analysis and consideration. Likewise, victimization that is the result of living in a socially disintegrated or impoverished state (e.g., dangerous neighborhoods or extreme poverty), while profoundly damaging to human beings, is not discussed here.

This entry focuses on phenomena that occur in the context of human relationships, particularly those relationships that are defined as the ordinary relationships in which people are involved. The experiences of victimization are defined not simply by who did it and what was done but, instead, by what core psychological process is involved. Such an integrative approach is a useful developmental stage in understanding the phenomena of victimization for a number of reasons. First, more and more researchers are finding that unique, isolated victimization may be rare and that, instead, multiple victimizations of the same person, occurring across time and context, are more typical. In short, there is an enormous amount of overlap among victimized populations in their exposure to what had been seen as distinct and unique victimization situations. As researchers have identified this process, what has come to be understood as a variation of the Matthew Principle is true—"He who has, receiveth; he who has not, receiveth not." That is, victimization has a far higher likelihood of occurring among certain groups and certain people, particularly those previously victimized.

An abused child may be bullied at school and, as an adult, be a victim of domestic violence. Furthermore, the effect of these different victimizations may be more than simply the sum of the individual types.

Finally, the need for an integrative approach is particularly demonstrated by the shared interpersonal nature of the victimization phenomena. If the key facet of the victimization experience that defines it is the interpersonal nature of the victimization, then there is quite likely to be a shared psychological expression of exposure to victimization across types of victimization. An integrative approach allows for the examination of this common core of psychological features attendant to this definition of victimization.

Effects of Victimization

The early research on the consequences of victimization detailed the many psychological consequences of exposure to victimization. Typically, researchers would identify populations previously victimized and compare this population with a nonvictimized population on standardized measures, primarily of psychological disturbance. This research has demonstrated that victimization exposure is a pathogen. In addition to the possible physical effects associated with victimization, there may be psychological symptoms across a range of domains, such as dissociation, depression, anxiety, and interpersonal difficulties. Additionally, specific forms may have more specific outcomes. For example, child sexual abuse may be linked to sexual difficulties. Not only is there a wide range of possible symptoms associated with victimization, but there also is a wide range of severity of response to victimization. With the maturation of the field, particularly with the leadership provided by researchers such as David Finkelhor, emphasis has shifted from specific psychological symptoms and the recognition of PTSD to core psychological issues or processes that are affected by victimization. These core psychological issues include damage to interpersonal relationships and self.

One of the accomplishments of the several decades of research into the consequences of exposure to violence and victimization is the recognition that PTSD is often a specific consequence of victimization. This recognition has brought considerable attention to the role of trauma in the lives of human beings and an awareness that exposure to trauma, particularly chronic, repetitive trauma, creates a unique kind of psychological response that does not fit the typical understanding of PTSD and, instead, requires an understanding of not only trauma and its response but also trauma and the task of adjusting to chronic exposure to trauma. This has led researchers to identify different types of PTSD, described as complex PTSD, to distinguish it from the diagnosis of PTSD as given in the *Diagnostic and Statistical Manual* (fourth edition; *DSM-IV*).

Likewise, in the lives of children, there is a greater recognition that the responses of children to chronic, repetitive stressful events cannot be subsumed under the diagnosis of PTSD, which was developed primarily in the crucible of wartime experiences of soldiers. Thus, in the current scientific community, there is an appreciation that the unique adjustment capacities and responses of children and adolescents require some new types of diagnostic nomenclature. In particular, the notion of a developmental trauma disorder has been brought into the scientific community by several people and is being considered for inclusion in subsequent editions of the *DSM*. The finding that should be emphasized, however, is that trauma exposure is a unique and particular pathogen that occasions a range of responses in humans. In part, these outcomes can be captured by the diagnosis of PTSD; however, the range of responses needs a more articulated and specific set of diagnostic categories to be able to delineate the variety of responses and syndromes observed in children, adolescents, and adults.

The fact that victimization typically occurs within the context of an interpersonal relationship has profound consequences for understanding the consequences of victimization. Such victimization elicits unique interpersonal, emotional, and developmental issues. Humans form their working models of the world in the context of relationships. It is how we come to understand what we may expect from other people and how we learn to interact with others. Thus, the consequences of victimization, particularly victimization that occurs in the context of central human relationships, are far reaching and may affect later relationships.

As originally proposed by John Bowlby, our core attachment figures are the lens through which we develop our understanding of the world. The theory of the world we form in these relationships, thus, becomes the template against which we judge subsequent experiences and by which we shape our own actions in the world. When these models are damaged or distorted by victimization, the primary consequence is that all subsequent interactions are affected by the accommodations that the victim has to make to the

experience of victimization. For example, as a result of abuse by a parent, a child believes that all relationships are potentially hurtful. The child then enters into all subsequent relationships with a sense of mistrust and an expectation that rejection and harm will soon follow. The microenvironment that the child has created, in turn, may lead to these expectations being fulfilled.

Thus, at the heart of the victimization experience is the damage done to the victim's sense of trust and his or her ability to create a safe, attached relationship. The betrayal of victimization is considered to be one of the most difficult processes for humans to incorporate into their expectation of the world as being a benign or benevolent place. Particularly, when victimization is repetitive and ongoing, there is no opportunity for the development of a secure base in any attached relationship.

This damage to the attachment's schema occurs along with changes in other cognitive schemas. The way in which the world is experienced and interpreted is transformed by victimization exposure. Cognitive schemas, particularly with the perception of relationships, are transformed in negative ways. Roland Summit was among the first to explain these changes in cognitive schemas through his description of the accommodation syndrome, wherein the experience of victimization fixes and makes rigid subsequent interpretations of reality.

The core cognitive schemas of relationship are all profoundly influenced by the experience of victimization. Finkelhor has summarized for a developmental approach, in particular, how this damage is mediated through four core conditions: (1) repetitive and ongoing victimization occurs, (2) the victim's core relationships are altered, (3) victimization is added to other stressors, and (4) victimization occurs during a critical developmental stage. That is, if victimization is repetitive, if the nature of the victim's relationship with core attachment relationships is damaged by the victimization, is added on to other stressors, and occurs at a critical period, then these serve as moderators that contribute to the power of the victimization experience through the powerful degradation of development processes.

In terms of critical developmental tasks that can be affected by victimization, perhaps the most core cognitive schema affected is that of the self. Early child development requires the development of a sense of self. One of the core functions of this self is the ability to manage one's emotions, physiological arousal, basic daily living tasks, as well as managing and regulating affect. In particular, affect regulation is perhaps the most critical task for all humans. The experience of victimization may have a particularly critical influence on children's ability to regulate their emotional responding to the world. Victimization occurring during adulthood has the effect of undermining acquired competencies and forcing a kind of psychological regression. A very typical experience in adult victimization is for the victim to lose significant psychological developmental accomplishments and regress to previous levels of dependence. There may be a corresponding failure to be emotionally autonomous and self-regulating. There is considerable research that demonstrates that these experiences, moreover, have the power to foreclose the future accomplishment of a developmental task by the consequence of victims being burdened by psychological symptoms and/or accommodating to the victimization by a disengagement from the social world and a lack of confidence in their own self-efficacy.

As described by Finkelhor and Angela Browne, the damage to the self also may include feelings of stigmatization and powerlessness. The person may feel responsible and to blame for what happened. For example, the physically abused child and battered wife may feel deserving of the abuse. Furthermore, given the nature of the interpersonal relationship, the victim may feel too ashamed to report the experience. For example, an elderly person abused by an adult child may feel too ashamed to report the experience. Victimization also may be accompanied by a feeling of powerlessness. The stalking victim, for example, may feel a loss of control over his or her life.

As was previously noted, victimization is not usually an isolated event, and this is important in understanding the consequences of victimization. Finkelhor suggests that there is an additive effect when victimization occurs in the context of other stressors. He also notes that if victimization occurs during a critical period of development, it can interrupt successful task resolution of a developmental stage. Finkelhor's model, defining the moderating effects of damaging context, is a useful attempt at bringing understanding of the psychological processes to the specific understanding of the victimization effects. There is now an increasing body of literature that does confirm most of Finkelhor's suggestions, particularly those having to do with multiple victimizations and the cumulative effect of victimization co-occurring with other stressors.

In summary, victimization is a frequent event with profound consequences on human adjustment. To have a more nuanced psychological understanding of victimization, the interpersonal context of the experience

must be included in our theoretical and practical models of those who have been victimized.

Victim-Offender Mediation With Juvenile Offenders

Policymakers, social workers, and researchers have long been reflecting on how to respond to youth crime. In recent years, the concern that traditional approaches stemming from retributive and rehabilitative models of justice may no longer be viable responses to criminal acts has increased the interest in alternative measures and approaches originated within the restorative justice model. Central to this model is the notion that a criminal act is an offense against a victim within the context of a community, as opposed to a violation against the state. Thus, a criminal act engenders a conflict among people and harms the victim; justice cannot be achieved unless that conflict is solved and that harm repaired. Based on this view, the offender along with other individuals affected by the criminal act (e.g., victim, community members) actively participate in the resolution of the conflict, with the help of a fair and impartial third party. Several measures have been developed within the restorative model; of these measures, the oldest and most frequently adopted is victim-offender mediation (VOM).

This entry provides a definition of VOM, describes its goals, and outlines the key components of the VOM process, including the role of the mediator. It then discusses the relation between VOM and the criminal proceeding in the juvenile justice system. It also summarizes evidence on the type of cases that are likely to be mediated and the motivations behind victims' and offenders' decisions to participate in VOM and describes victims' and offenders' perceptions of the VOM process. It also reviews the evidence concerning the relation between participation in VOM and later recidivism among juvenile offenders. Reflections on the present and the future of VOM practice and research are offered as conclusive remarks.

What Is VOM?

VOM is a process through which victims of crimes meet the offender in a structured and safe environment. As a practice, VOM involves a face-to-face meeting between the victim and the offender in the presence of a trained mediator. The goal of VOM is to create the opportunity for the victim and the offender to engage in a dialogue addressing their informational and emotional needs. The VOM process cannot begin until the offender acknowledges his or her responsibility for the offense. Thus, VOM does not deal with issues revolving around establishing the truth about the occurrence of the offense but focuses on the consequences of the offense.

The importance of conflict resolution distinguishes VOM from other forms of mediation (e.g., mediation in custody cases or in divorce cases) in which the emphasis is placed on reaching a settlement rather than on addressing the emotional consequences of the facts in questions.

What Happens During VOM?

In most of the VOM programs, prior to the actual mediation, the mediator contacts and meets separately with the victim and the offender. During these sessions, the mediator evaluates whether the parties are willing and able to engage in VOM; the mediator also prepares the parties for the subsequent meeting (e.g., by correcting unrealistic expectations). To avoid feelings of rejection

that may induce a sense of revictimization, the victim is typically contacted after the offender has already agreed to take part in VOM.

During the actual VOM meeting, the victim and the offender talk to each other about the crime, discuss the effects of the crime on their lives, and describe their feelings about it. At times, more than one mediation meeting is necessary to complete the process. In some practices, family and community members join the victim and the offender in the meetings (i.e., family group conferencing, conferencing).

As a result of the VOM process, the victim and the offender may choose to create a mutually agreeable plan to repair any material and psychological damages that resulted from the crime. Research indicates that VOM is largely successful, and an agreement between the parties is reached more than 90% of the times. The reparation plan may include direct compensation to the victim, work for the victim, and community service. Research suggests that when reparation plans are generated within VOM, reparation is completed more frequently than when reparation is court imposed.

What Is the Relation Between VOM and the Criminal Proceeding?

In the United States, there is great variability in the relation between VOM and the criminal proceeding. In some cases, VOM is attempted as a diversion measure, as when a juvenile case is diverted to mediation services in the early stages of a criminal proceeding and does not reenter the juvenile justice system, assuming that the mediation agreement is completed. In other cases, VOM is the condition for probation following an admission of guilt accepted by the court. Finally, in some cases, VOM is attempted in the postadjudication phase. Such variability exists in other countries as well, such as those in the European Union, except that VOM is not a common practice in the postadjudication phase. Furthermore, the practice of VOM in Europe is frequently an inherent part of the criminal procedure (at certain stages of the proceeding, the case may be referred to a mediation service), so that if the mediation process is successful, there will be a tangible impact on the case sentence. The variability observed appears to depend largely on the characteristics of legal and policy tradition specific to each country rather than on considerations pertaining specifically to the practice of VOM with juvenile offenders.

Who Participates in VOM and Why?

Participation in VOM depends largely on the criteria for case referral and, critically, on the parties' willingness to partake in the process. Various referral criteria have been used, such as the age of the offender, whether the offense is more or less severe, or whether it was committed by a first-time offender. Traditionally, VOM has mostly involved juvenile offenders who had committed crimes against property and minor assaults. However, more recently, there has been a tendency to broaden the scope of VOM and extend this practice to more serious offenses and to adult offenders, although it should be noted that the seriousness of the offense may deter victims' participation.

Victims' and Offenders' Motivations

Research indicates that approximately 60% to 70% of victims who are offered the opportunity to partake in VOM do so. When asked what motivates their decision to undergo the VOM process, victims express a desire for restitution and a desire to see the offender held accountable, learn about the reasons behind the offender's actions, share the pain caused by the crime, help the offender change, and avoid court processing.

High percentages of participation are also observed among juvenile offenders. With respect to motivations, there is some indication that juvenile offenders choose to participate in order to take responsibility for the criminal acts they have committed, apologize to the victim, and move on with their lives.

To date, little is known about the motivations behind the decision not to participate in VOM. Victims seem to emphasize either the triviality of the offense or, at the other end of the spectrum, the fear that the VOM meeting may not be safe. As for offenders, there is initial evidence that they may opt out of VOM because their lawyers advise them against participating. Indeed, the admission of responsibility for a crime, a necessary condition for VOM, raises issues of legal safeguards for juveniles.

Victims' and Offenders' Perceptions of VOM

A number of studies have examined the consequences of participating in the VOM process for victims and

offenders. Specifically, extant investigations have focused on individual participants' satisfaction with VOM and perception of fairness of the process. The picture emerging across these investigations is clear: The vast majority of victims and offenders report being satisfied with the process and with the resulting agreement (i.e., between 80% and 90% according to some reports).

Victims' Perceptions

Results from research suggest that victims who meet with their offenders are more likely to be satisfied with the criminal justice system's response to their case than victims of comparable offenses who do not meet their offender and whose case undergoes criminal prosecution. The main factors associated with victims' satisfaction are that the victim deemed the restitution plan as fair, appreciated the role of the mediator, and had a strong inherent motivation to meet the offender. This latter factor, together with the consideration that participation in VOM occurs only on a voluntary basis, highlights the possibility that self-selection may be a key component of long-term satisfaction. Thus, long-term satisfaction may be accounted for by preexisting differences between individuals who agree and individuals who do not agree to partake in the process. Although it is possible that individuals who view the outcomes of VOM more positively hold more favorable views of it in the first place, which makes it difficult to isolate the effects of VOM per se, the close connection between the voluntary nature of VOM and its outcomes underscores the fact that choice and direct participation are germane to the restorative justice approach and its effects.

Offenders' Perceptions

Results from research also indicate that participating in VOM is also largely positive for juvenile offenders who report having understood their mistakes and the consequences of their mistakes for the victim; furthermore, feelings of internal change have been reported. Nevertheless, a tendency to use the VOM process instrumentally as a way to conviction has also been observed.

Recidivism

VOM and other measures grounded in the restorative justice model have met with unprecedented interest in the past decade. This interest in part reflects the disaffection toward more traditional approaches that are deemed to have failed to reduce the prevalence and recidivism of youth crime. A number of studies have examined whether participation in VOM is associated with decreased prevalence and severity of recidivism in youth crime. The outcomes of these studies have been summarized in recent meta-analytic work and indicate that juveniles who underwent VOM were less likely to re-offend a year after VOM, and when they did so, the new offenses were less severe than those that originally resulted in VOM participation.

These results have been considered promising evidence in favor of the efficacy of VOM in reducing youth crime. However, these studies suffer from some methodological limitations. For one, only in a small subset of them were juvenile offenders randomly assigned to VOM as compared with other intervention measures. If the cases were referred for VOM because they were considered particularly amenable to this form of intervention, the differences in recidivism may reflect inherent differences between the VOM group and the comparison group. Furthermore, even when randomization procedures were employed, participation in VOM was still voluntary. This intrinsic characteristic of the process makes it difficult to evaluate the effects of VOM in an unbiased fashion.

The Future of VOM

Over the past three decades, VOM has witnessed increasing interest in several parts of the world. VOM is appealing because it is rooted in shared values of solidarity, reparation, and a sense of justice, while it holds the promise of becoming an effective measure for reducing and preventing youth crime and for increasing citizens' sense of security.

To maintain such a promise, extant research results should be confirmed by more extensive investigations employing rigorous designs, including studies in which individuals are randomly assigned to VOM, experimental and control groups are measured on key variables pre- and post-VOM, and the effects of VOM are followed up longitudinally over several years.

Victim Participation in the Criminal Justice System

As a result of a number of developments—including the rise of restorative justice—victims in common-law jurisdictions now have far more input into the criminal process. Victim participatory rights are currently recognized as an important component of criminal justice proceedings. Research has shown that victim participation in justice can help victims who want to be included in proceedings and that victim participation does not result in difficulties or create problems for the smooth operation of the criminal justice system. However, because victim participation in sentencing decisions challenges traditions and established patterns within the criminal courts, these rights sometimes encounter resistance in their implementation. As legal cultures are transformed, however, and victims are increasingly perceived as a legitimate party in proceedings, victim participation can become an acceptable practice and a way to inject restorative justice elements into adversarial justice systems. Ultimately, it is the underlying value system and ideology that will determine whether victims are meaningfully integrated into proceedings. Attempts to integrate victims outside the adversarial criminal justice system through restorative justice schemes have worked for some victims, but they do not serve those who wish to remain within the protective structure of adversarial systems.

This entry reviews the historical development of the role of crime victims in common-law criminal justice systems. It presents and assesses research on the impact of these changes on victims and the criminal justice system. Emerging alternative perspectives and schemes to integrate victims in proceedings are then discussed. The entry concludes by noting some implications for criminal justice policies regarding crime victims.

Victims' Role in Criminal Proceedings

In adversarial justice systems, a criminal trial entails a conflict between two adversaries—the state and the defendant, and the search for the "truth" is conducted before an impartial adjudicator—the judge. In earlier centuries, crime victims had to assume the responsibility of pursuing the offender and bringing him or her to justice. Over time, this state of affairs changed. With the centralization of power and creation of the concept of "the King's peace," victims lost their active role in justice. The state began to prosecute a defendant on behalf of the community, and the crime victim was relegated to the role of witness for the prosecution.

For most victims, even their role as witness never materializes. Most criminal incidents do not result in a trial as a result of the attrition of cases. The police may fail to make an arrest, or the prosecutor may decide not to file a criminal charge. If a charge is filed, it may be stayed or withdrawn. In the vast majority of cases, the offender ultimately pleads guilty, and the case proceeds to sentencing without a criminal trial being held. Unlike continental legal systems, which provide victims with a formal role in criminal proceedings, adversarial legal systems do not accord victims any formal standing in the prosecution of "their" offenders. Victims have little influence over whether (or how) the state chooses to proceed against the alleged perpetrator. Thus, until fairly recently, crime victims were denied any input into the sentence of the offender. Yet the state highly depends on victim cooperation, without which a criminal prosecution is unlikely to succeed.

Changes in the Role of Crime Victims

Until the 1970s, crime victims were considered the "forgotten persons" of criminal justice—invisible to and neglected by the system. The lack of victim standing in criminal proceedings, and the consequent insensitivity to the needs of crime victims, led to victim

dissatisfaction and alienation from the criminal justice system. Surveys of crime victims in a number of countries revealed complaints related to the lack of information about the case as well as frustration due to the lack of input into the proceedings. These findings provoked campaigns by victims' rights groups to bring about changes in the criminal justice system.

In response to the victim movement, Western countries have passed legislation creating various victim rights and have established a wide range of services for victims of crime. Victims now have the right to receive information about the status of the case in which they are involved, and they also have the right to apply for financial compensation and psychological assistance. More recently, many jurisdictions have provided victims with participatory rights throughout the criminal process, beginning with the arrest of a suspect and ending with the prisoner's release from prison. Although most rights and benefits that facilitate victim participation in justice have been generally accepted, the right to actively participate in the judicial process and to have a voice in proceedings has proved controversial and continues to be the subject of heated debate.

Emergence of Participatory Rights for Crime Victims

Research and practice have shown that while some victims prefer to stay out of the criminal justice system, many others wish to participate. The need to accord victims participatory rights has been recognized by many national committees established to study victims in the criminal justice process (e.g., the President's Task Force on Victims of Crime, 1982, in the United States and the report of the Standing Committee on Justice and Human Rights, 1998, in Canada). Similar reports have been published in other jurisdictions.

The international community has also recognized the need to integrate victims into the criminal justice process. In 1985, the United Nations Seventh Congress on the Prevention of Crime and Treatment of the Offender adopted a declaration that required that victims be allowed to present their views and concerns at appropriate stages of the criminal justice process. Victims also enjoy significant rights in proceedings before the International Criminal Court in the Hague. That court hears cases involving the most serious crimes committed against many hundreds of crime victims.

Many states in the United States have enacted victims' bills of rights that vary in scope from mandating that criminal justice officials simply show respect toward victims, to establishing a victim's right to be present and heard, to allowing victims to sit at the prosecutor's table during trial. In several states, victims' rights are achieved by specific statute, but a number of states have adopted constitutional amendments to give victims' rights greater permanence and visibility. The majority of the states also allow for victim participation in sentencing and parole hearings. The states also provide for victim participation in plea bargaining. However, the extent to which victims are allowed to participate in plea discussions varies widely, with no state providing victims with a veto over plea agreements.

Reforms addressing the circumstances in which victims are afraid or reluctant to provide testimony or input into proceedings (such as domestic violence cases) have also been adopted. These laws (or statutory amendments) require the police to make arrests regardless of whether the victim signs the complaint. Similarly, prosecutors are allowed to proceed with a case even if the victim refuses to cooperate (this is known as a "no-drop" policy). Mandatory arrest laws and no-drop prosecutorial policies recognize that victims of domestic violence are especially vulnerable to retaliation from the perpetrator if they press charges. These laws therefore remove this decision from victims. Mandatory charging and prosecuting policies thus create a potential conflict with the principal goal of victims' advocates: to give victims a say in important criminal justice decisions that affect their lives. Accordingly, some battered women's advocates and feminist scholars have criticized the mandatory element of these policies on the grounds that they further disempower the crime victim.

Victim Impact Statements at Sentencing

Sentencing attracts more interest than any other stage of the criminal process. Victims look toward a sentencing court to vindicate their suffering and to mark the crime by imposing an appropriate penalty on the convicted offender. It is therefore not surprising that it is at the stage of sentencing that victims are most interested in providing input. Of all the participatory reforms, victim input into sentencing decisions, or victim's right to submit victim impact statements (VIS), have attracted the most opposition.

The VIS—as the concept is referred to in the United States and Canada—or the victim personal statement (VPS)—its counterpart in England and Wales—is a statement in which the victim describes the impact of the crime on his or her life, including physical, social, psychological, and financial harms. The VIS may be delivered at the sentencing hearing either in writing, orally, or visually (in countries or jurisdictions that allow victim allocution or presentations through a video). Judges are encouraged, or in some jurisdictions required, to take the VIS into account when determining sentence.

Arguments for Victim Participation at Sentencing

Advocates of victims' rights to participate in the criminal justice process have advanced a variety of arguments, some moral, some penological, and others practical in nature. The idea of victim participation recognizes victims' wishes to be treated as a party to the proceeding. Allowing victims to participate in the criminal process reminds judges, juries, and prosecutors that behind the "state" there is an individual victim with an interest in how the case is ultimately resolved. It is argued that providing victims with input promotes proportionality in sentencing because victims can provide accurate information about the seriousness of the crime. Victim participation may also lead to increased victim satisfaction with the judicial process and cooperation with the criminal justice system. This, in turn, may enhance the system's effectiveness in bringing offenders to justice. It may also increase perceptions of the fairness of proceedings, because it will also allow victims to be heard. The use of VIS may also promote psychological healing by helping victims recover from the emotional trauma associated with their victimization. Finally, it may also alleviate some of the feelings of helplessness that can arise as a result of the crime and the inability on the part of victims to express themselves to judicial authorities.

Objections to Victim Participation

Objections to victim participation at sentencing range from assertions that vengeful justice will result to predictions that the system will grind to a halt as a result of the additional time needed to process cases. Opponents of victim participation are reluctant to expose the court to public pressure (created as a response to the victim input), from which it should properly be insulated. There are also concerns that the victim's "subjective" account of events may take precedence over the allegedly "objective" one pursued by the court. The legal profession has found the prospect of allowing material that may be highly emotional in the courtroom unacceptable and argues that a victim's input into sentencing is irrelevant to any legitimate sentencing considerations, lacks probative value in a system of public prosecution, and is likely to be prejudicial. Permission to deliver a VIS in person—exercising victim allocution right—has been regarded as particularly objectionable, as an oral version in a very serious crime may be very moving for the judge and this may increase sentence severity or promote sentencing disparity. Objections also included arguments that victim input violates the fundamental principles of the adversarial legal system, which do not recognize the victim as a party to the proceedings. Including victims would transform the trial between the state and the defendant into a tripartite court proceeding (state-victim-offender). Such practices, it was argued, belong only in the so-called continental legal systems with adhesive prosecution or *partie civil* procedures or to restorative justice schemes.

Research Findings on the Effects of Victim Participation

Victim Input Into Sentencing

Research provides answers to some of the questions raised in the debate about victim input into sentencing. Although far from conclusive, this research suggests that (a) victim participation does not result in delays or clog the criminal justice system by protracting the time taken to arrive at an adjudication; (b) victim participation does not always or necessarily result in harsher punishment of offenders; (c) victim participation has the potential to increase victim satisfaction with the judicial system; (d) many judges see a benefit in receiving crime impact information directly from the victim by means of VIS; (e) victim statements seldom include inflammatory or prejudicial material that may bias the court against the defendant; and (f) the implementation of victim input laws is still problematic, as a result of which many victims do not benefit from these reforms.

Research has demonstrated that in practice, many victim-related reforms never reach victims. Victims either are unaware of their rights to participate or elect not to exercise them. Studies also reflect considerable

confusion about the nature and purpose of VIS. Victims often do not understand the true purpose of VIS or may claim that they did not fill out such statements when, in fact, they did. This may be because victims are questioned by a seemingly endless array of people and may become confused about the purpose of particular interviews. Some jurisdictions have overcome this problem by having victims prepare their own VIS rather than merely provide the information to the investigating officer (in some countries, probation or victim assistance staff).

In common-law jurisdictions, it was observed that only a minority of all victims participate by submitting a VIS. Analysis of court files and surveys of criminal justice professionals, such as prosecutors and judges, confirm that most sentencing hearings take place without the benefit of an impact statement from the victim. The likelihood of an impact statement being submitted will depend on the nature and seriousness of the crime, as well as many other variables. Victims of serious violent crimes are more likely to submit VIS.

Impact of VIS on Victims' Welfare and Satisfaction With the Justice System

Findings on the effect of providing input into sentencing are inconsistent with respect to the issue of victim welfare and satisfaction and suggest, at best, modest effects. The lack of evidence on satisfaction, however, may simply reflect a problematic implementation of the law. The level of satisfaction may also vary with the type of offense committed. In some cases, filing VIS heightens victims' expectations that they will influence the outcome. When that does not happen, victims may be less satisfied than those who do not submit a statement. In contrast, research has shown that in the continental criminal justice systems (which allow victims a party status and let them provide significant input into the proceedings, victims who participated as subsidiary prosecutors or acted as private prosecutors were more satisfied than victims who did not participate. These differences suggest that in jurisdictions in which victims have more input into proceedings, levels of satisfaction with justice are higher.

Restorative Justice, Therapeutic Jurisprudence, and the VIS

Victims have benefited greatly from the worldwide rise of interest in a new paradigm in justice known as *restorative justice.* Restorative justice programs have been created in many nations, both developed and developing. These programs exist at all stages of the criminal process, from pretrial conferences involving victims and perpetrators to restorative programs that arrange meetings between victims and prisoners. All restorative justice programs share the same goal of attempting to achieve something more than simply punish the offender.

This approach to addressing crime assigns a prominent role to the victim. Restorative justice advocates argue that victims are better served by an attempt to reconcile, where appropriate, the victim and the offender. When this occurs, the offender accepts responsibility for the offense, expresses remorse for the crime, and often makes some practical form of compensation to the crime victim. Under a purely retributive justice system, which privileges punishing the offender, the benefit to the victim—beyond seeing the offender punished—may be negligible. Another new approach, known as *therapeutic jurisprudence*, addresses the legal participants' psychological welfare. This perspective also offers an alternative to the conventional retributive model of criminal justice, one that assigns a very prominent role to the victim.

Although some researchers have questioned the extent to which restorative justice proceedings serve the interests of victims, this approach does focus attention on the connection between victims' participation and their welfare. The importance of victims' voices in proceedings, on the one hand, and victims' roles in the reentry of offenders (which is the ultimate purpose of restorative justice), on the other, has been increasingly recognized in justice practices around the world. This change is due in part to victim advocates' efforts on behalf of victims and in part to research findings that challenge prevailing beliefs and myths about victims' interests, motives, and the consequences of input into sentencing. Research has questioned the common assumption that victims are vengeful by showing that they can also be forgiving or merely expressive about what they perceive as injustice (a lenient sentence or a lack of compensation). Research indicates that many crime victims, particularly victims of serious offenses, are eager to describe their victimization experiences. They want a voice to communicate a sense of the harm they have sustained rather than wishing to influence the sentence that is ultimately imposed.

Videotaping Confessions

The Innocence Project, an organization dedicated to exonerating the wrongfully convicted by means of DNA testing, has to date been responsible for freeing 197 people from unjust imprisonment. By examining the particulars of wrongful conviction cases, the Innocence Project has also identified several factors contributing to these miscarriages of justice. One such factor is false confessions, which can occur when innocent suspects succumb to the intense psychological pressure that is a ubiquitous feature of today's police interrogations in the United States. In fact, false incriminating statements made by suspects during detention played a role in more than 25% of the wrongful-conviction cases in which the Innocence Project has been involved. In response to these troubling facts, many scientific, legal, and political leaders have called for mandatory videotaping of custodial interrogations. Proponents argue that videotaping interrogations will discourage the police from using highly coercive techniques to elicit confessions, and the resulting audiovisual record will permit later trial fact finders to more accurately assess the voluntariness and veracity of suspects' statements. However, policies requiring videotaping should be carefully considered so as to minimize the potential drawbacks of the procedure as suggested by psychological research.

Law Enforcement's Mixed Reactions to Videotaping

Over the past 25 years, there has been considerable ambivalence within the law enforcement community concerning the videotaping of interrogations and confessions. Long before the first DNA exoneration case in 1989, the police in some jurisdictions took the initiative and began experimenting with the videotape recording of at least portions of the questioning of detained suspects. For example, by the early 1980s, the district attorney's office in one borough of New York City had access to approximately 3,000 videotaped admission statements. According to statistics maintained by that office, videotaping produced an 85% guilty-plea rate and a nearly 100% conviction rate. In contrast, other jurisdictions have adamantly resisted the call for mandatory videotaping of custodial interrogations. Those in law enforcement opposing the videotaping movement have argued that the cost of equipment, storage, and transcription of videos is an undue burden for jurisdictions with limited budgets. Moreover, they fear that suspects will be hesitant to talk in the presence of a camera; judges and juries will disapprove of certain legally permissible interrogation tactics commonly used (e.g., lying about the amount and kind of evidence incriminating a suspect), thus rejecting the confession evidence as unreliable; and requiring videotaping will impugn the integrity of law enforcement agencies that have worked diligently to earn a reputation for honesty.

In the past 15 years, two large surveys have been conducted to assess the extent to which law enforcement agencies were videotaping at least some interrogations and/or confessions and their reactions to this procedural modification. The first was a report to the National Institute of Justice in 1992 by William Geller, who estimated that approximately one-third of law enforcement agencies serving populations of 10,000 or more recorded interrogations, or parts thereof, on some occasions in the late 1980s. Importantly, Geller found that the police, who had experience with videotaping, expressed strong support for the practice. As a member of the San Diego police put it, "Not using video would be like not using state-of-the-art fingerprint analysis

equipment. If better technology comes along, and its cost is reasonable, the police should experiment with it if there is a reasonable chance that it can assist them in their work" (p. 153).

The second report by attorney Thomas Sullivan in 2004 similarly found positive responses from those departments videotaping custodial interrogations. The following are some of the reasons mentioned by officers in Sullivan's report for embracing the videotape practice: It eases the public's concerns for how suspects in custody are treated; it eliminates the need for extensive note taking, so that officers can better observe suspects' nonverbal behavior; videotapes serve as a useful teaching tool for demonstrating appropriate interrogation techniques; and subsequent viewing of videotapes can reveal incriminating information missed during the live interrogations. Sullivan believes that once the police try videotaping, they will not want to go back to older methods, and he argues that the widespread acceptance of this practice will "benefit suspects, law enforcement, prosecutors, juries, trial and reviewing court judges, and the search for truth in our justice system" (p. 28).

Compelled Recording of Interrogations by Court Order or Legislative Statute

The electronic recording of interrogations was mandated for the first time in the United States by the Supreme Court of Alaska. The court's ruling issued in 1985 was based on the state constitution's due process clause. The justices reasoned that "recording . . . is now a reasonable and necessary safeguard, essential to the adequate protection of the accused's right to counsel, his right against self-incrimination and, ultimately, his right to a fair trial" (*Stephan v. State*, 1985). Nine years later, the Supreme Court of Minnesota also ruled for compulsory videotaping, stating that "an accurate record makes it possible for a defendant to challenge misleading or false testimony and . . . protects the state against meritless claims" (*State v. Scales*, 1994). Decisions by state Supreme Courts in Massachusetts, New Jersey, and New Hampshire fell short of ruling that their state constitutions mandate recording of interrogations. Nevertheless, in each of these states, the highest court held that failure to offer a custodial recording at trial could be a basis for the presiding judge to suppress any purported confession offered by the prosecution. Furthermore, should the judge admit an unrecorded confession into evidence, it was held that the jury would be instructed to exercise great caution in the weight given to the prosecution's claim that the defendant made self-incriminating statements. These decisions have generally led many police departments in these states to implement custodial recordings to avoid the possibility of their confession evidence being thrown out or having it greatly diluted by unfavorable jury instructions.

In 2004, Illinois became the first state to require by statute complete custodial recordings. Following Illinois's lead, Maine, New Mexico, Wisconsin, and the District of Columbia have since enacted similar recording legislation. Several additional states have prorecording bills currently under legislative consideration.

Possible Drawbacks of the Videotaping Practice

As the foregoing discussion suggests, all indications are that the videotaping of in-custody interrogations will become a standard law enforcement practice. It is therefore prudent to consider any possible downsides associated with the videotaping procedure or with the manner in which it might be specifically implemented.

Recap Bias

One concern is the potential prejudicial effect of the police choosing to record the suspects' final confession but not any of the interrogation that preceded it. Both Geller and Sullivan noted in their survey reports that such "recap videotapes" are not unusual. Recap videotapes are potentially problematic for two reasons. First, recaps may convey to trial fact finders that the confession was more voluntary than they would otherwise perceive it to be if the interrogation in its entirety was available for them to observe. Second, recaps often are recorded after suspects have been asked to recount their stories multiple times. By the time the camera is rolling, their statements may be accompanied by little of the emotion and agitation that might have been present the first time they revealed the self-incriminating information. Recap videotapes, then, may make suspects appear far more callous and unremorseful than is in fact the case, which in turn could bias the jury against them. Awareness of this issue has led most courts and legislative bodies that have made custodial recordings

compulsory to spell out clearly that the entire interrogation must be recorded—from the *Miranda* warning to the end of the session.

Fundamental Attribution Error

Even if judges and jurors have the opportunity to view an entire interrogation videotape, it may still be an extremely difficult task for them to accurately assess whether or not a confession was voluntarily given. A vast amount of research on social judgment demonstrates that observers tend to attribute people's actions to internal causes (i.e., to their dispositions or intentions) even when external forces or pressures in the situation (e.g., orders from an authority figure) could readily account for their actions—a phenomenon known as the fundamental attribution error. The U.S. Supreme Court in *Lego v. Twomey* (1972) expressed the view that jurors are readily capable of differentiating voluntary from involuntary confessions and thereby discounting the latter. However, the pervasive tendency for people to commit the fundamental attribution error should serve as a warning that the task of evaluating the voluntariness of suspects' statements made during an in-custody interrogation designed explicitly for the purpose of extracting a confession is not necessarily as straightforward as it might seem. Consistent with this point, laboratory research has shown that mock jurors asked to consider a suspect's self-incriminating statements, which came on the heels of very obvious high-pressure tactics on the part of an interrogator (e.g., he waved his gun in a menacing manner), were unable to completely discount the confession in rendering their verdict.

Differentiating True From False Confessions

As noted at the outset, one of the primary reasons why proponents of the videotaping practice are so insistent about the need to adopt this approach is their belief that a videotape record of an interrogation will make it possible for judges and juries to more readily catch false confessions that make their way into the system. Years of scientific studies on people's ability to accurately distinguish truthful from untruthful statements, however, indicate once again that commonsense notions may be largely incorrect. The consensus among researchers who study the detection of falsehoods is that people generally do little better than chance when it comes to separating lies from the truth. Even those who receive special training to increase lie-detection skills seldom show significant improvement; alarmingly, they sometimes perform worse after training than before.

An especially disturbing implication of the literature on lie detection for the videotaping practice is that people perform relatively worse when they rely primarily on visual cues, particularly those emanating from a person's face, when trying to make veracity judgments. Consistent with this pattern, a recent study found that people were better at differentiating true from false mock confessions when they listened to an audio recording or read a transcript of an interrogation than when they viewed a full videotape version that featured a close-up of the suspect's face. People tend to believe that they can tell from closely observing another person's face whether he or she is speaking untruths, but the scientific evidence suggests otherwise.

Camera Perspective Bias

A final issue concerning the videotaping practice that should be taken into account is the perspective of the camera when the interrogation is initially recorded. This may appear at first to be an inconsequential factor, but a growing body of research indicates that it may have profound effects on the conclusions drawn by triers of fact who later evaluate videotaped confessions. A considerable body of research indicates that an observer attributes unwarranted causality (influence) to objects and other people when they stand out in his or her visual field or are the focus of his or her attention—a phenomenon referred to as illusory causation.

Based on such demonstrations, Lassiter and his colleagues (2006) hypothesized that videotaped confessions recorded with the camera focused on the suspect would lead observers to assess that the suspect's statements were more voluntary and conclude that the suspect was more likely to be guilty than if the camera focused on the interrogator or on both the suspect and the interrogator equally. Two decades of research have confirmed this hypothesis. Videotapes that show both the suspect and the detective in profile (an equal-focus camera perspective) produce evaluations that are comparable with those based on more traditional presentation formats—that is, audiotapes and transcripts. Lassiter and his colleagues have therefore recommended that any legislation requiring videotaping of custodial interrogations should also specify that an

equal-focus camera perspective be used at the time of the initial recording.

Violence Risk Appraisal Guide (VRAG)

The violence risk appraisal guide (VRAG) is an actuarial instrument that assesses the risk of further violence among men or women who have already committed criminal violence. On average, it has yielded a large effect in the prediction of violent recidivism in more than three dozen separate replications, including several different countries, a wide range of follow-up times, several operational definitions of violence, and many offender populations. It is the most empirically supported actuarial method for the assessment of violence risk in forensic populations.

The VRAG is a 12-item actuarial instrument that assesses the risk of violent recidivism among men apprehended for criminal violence. It was developed on 618 male violent offenders assessed pretrial in a secure psychiatric hospital; about half of them returned later for treatment, whereas the others were imprisoned. Most of the approximately 50 variables considered for the VRAG had predicted criminal or violent recidivism in previous research, and a few were nominated by clinicians. All variables were scored from institutional records by researchers blind to outcomes and were from four domains: childhood history, adult adjustment, referral offense details and circumstances, and assessment results. The outcome was whether, according to criminal records, there was a criminal charge for subsequent violence in an average of 7 years' access to the community; 31% of the offenders met this recidivism criterion.

Many candidate variables predicted recidivism, but multiple regression selected the best combination for the VRAG. Several steps maximized the likelihood that the VRAG's predictive validity would replicate—requiring that each item uniquely predict violence, ensuring the inclusion of items from all four domains, and requiring that items predict recidivism in each of several subsamples (randomly selected halves, treated and imprisoned subjects) plus the entire sample. Item weights were based on the bivariate relationship between each item and recidivism. The VRAG items in descending order of the weights are the Hare Psychopathy Checklist–Revised, elementary school maladjustment, a diagnosis of personality disorder, age (negatively related), having been separated from one or both parents prior to 16 years of age, failure on a prior conditional release, nonviolent offense history, never having married, a diagnosis of schizophrenia (negatively related), victim injury in the referral offense (negatively related), alcohol abuse, and not having a female victim in the referral offense. The VRAG can be used when as many as 4 items are missing and scored by prorating.

The VRAG predicted violent recidivism in the development sample with a high degree of accuracy—the area under the relative operating characteristic (ROC) was .76. (The ROC area is a measure of effect size equivalent to the common language effect size—the probability with which a randomly chosen violent recidivist will have a higher score than a randomly chosen nonrecidivist.)

The original sample (plus additional men who had not been released at the time) was followed again at 10 years' average opportunity. The violent recidivism rate was .43 and the ROC area .74. There have been more than 36 replications with nonoverlapping samples, and the VRAG's average ROC area is .72—a large

effect by conventional standards. Under optimal conditions (high reliability; not dropping, replacing, or modifying items; fixed and equal follow-up durations), the VRAG yields ROC areas of approximately .85. The VRAG has been shown to generalize across outcomes (number of violent re-offenses, institutional violence, very serious violence, self-reported violence, general recidivism, overall severity of violent recidivism, rapidity of violent failure), follow-up times (12 weeks to 10 years); countries (seven in North America and Europe), and offender populations (mentally disordered offenders, sexual aggressors, violent felons, developmentally delayed sex offenders, emergency psychiatric patients, wife assaulters, and juvenile offenders). Some data suggest the VRAG predicts violence among women, but there are few studies on this.

The VRAG scores range from −26 to +38; the mean in the development sample was 0.91 (SD = 12.9), and the standard error of measurement was 4.1. Each score has been associated with one of nine categories, each with a known likelihood of violent recidivism in 7 years and increasing linearly from 0% in the lowest category to 100% in the highest. There are also norms for 10 years of opportunity. Each VRAG score is associated with a particular percentile so that the violence risk of an individual assessee is evaluated according to his or her standing relative to a large sample of violent offenders. Replications of the VRAG have generally reported that the obtained rates of violent recidivism matched the predicted likelihoods for each category. If the average score of the sample is similar, the follow-up duration is approximately the same as for the norms, and the outcome is operationalized similarly.

The recommended basis for scoring the VRAG for research and individual assessment is a comprehensive psychosocial history addressing childhood conduct, family background, antisocial and criminal behavior, psychological problems, and details of offenses. Adequate psychosocial histories include more than past and present psychiatric symptoms and rely on collateral information (i.e., material gathered from friends, family, schools, correctional facilities, the police, and the courts). Scoring the VRAG is not a clinical task in its typical sense because it does not require contact between the assessor and the person being assessed. Nevertheless, compiling the required psychosocial history clearly is a clinical task, and expertise is required to score VRAG items from psychosocial histories.

The VRAG scores are static inasmuch as they do not change with time or treatment (although they might change when rescored after offenders commit further violent offenses). Current research is aimed at identifying which changes in personal characteristics or circumstances make a valid additional contribution to the assessment of violence risk based on static variables. At this point, however, no such "dynamic" variables have been identified in assessing which offenders are at risk of committing violence. There is some evidence that they might aid in predicting when violence is imminent. In concurrent testing, actuarial tools such as the VRAG have consistently outperformed structured and unstructured clinical judgment. Although requiring resources and expertise, the VRAG is the most accurate and empirically supported actuarial method for assessing the risk of violent recidivism in forensic populations.

Violence Risk Assessment

Violence risk assessment is a decision-making task that transpires in numerous legal and clinical settings in which the possibility of a person's future violent behavior is of concern. Common contexts in which violence risk assessment occurs include involuntary

civil commitment, release from prison or forensic hospital, sentencing, transfer of youths to adult court, and sexually violent predator determinations. The formal study of violence risk assessment proliferated after the seminal research studies and legal decisions in the 1960s and 1970s established that despite the legal demands for and constitutionality of risk assessments, little empirical evidence could be garnered in their support. Researchers soon focused on identifying promising risk factors for violence and, more recently have been developing and evaluating structured violence risk assessment measures intended to improve on unstructured clinical prediction.

The Purpose and Application of Violence Risk Assessment

The purpose of violence risk assessment differs somewhat across applications, but at its core, it is the estimation of the likelihood of future violent behavior posed by an individual. In some settings (i.e., treatment discharge planning), risk assessment also includes a specification of the risk factors present in a case and the risk management or intervention strategies that would be necessary to mitigate risk. In other settings (i.e., sexual predator determinations, prison security-level classification decisions), less attention is given to the specific *nature* of the risk factors that underlie a risk assessment than to the end result (an estimate of *level* or *amount* of risk).

Almost invariably, risk assessments transpire within legal contexts. One exception would be the duty to protect that many mental health professionals have in the context of private psychotherapy. Even here, however, a mental health professional is subject to common law and has ethical duties to identify high-risk patients. At some point in their careers, most mental health professionals will be faced with a client or patient who poses a risk of violence.

In terms of applications, violence risk assessment commonly is employed for release decisions from prisons and psychiatric facilities (both civil and forensic). Although specifics differ across jurisdictions, release may be contingent on a decision that a person does not pose an undue risk to public safety. In some such applications, efforts are made to gear the risk assessment toward identifying risk factors that would be important to target in violence-reduction treatments. Violence potential is also relevant in the civil commitment context, in which persons must not only be mentally ill but also pose a risk to others (or self) to be detained involuntarily. In criminal sentencing contexts, risk assessment can be used to inform decisions about whether a person should receive a custodial or a community sentence. In more extreme manifestations, it may be used in the determination of whether a person is sentenced to death. An increasingly common use of risk assessments is to determine whether a person meets statutory criteria for being declared a "sexually violent predator"; that is, a sexual offender who poses a substantial risk to reoffend in a sexual manner may be committed for treatment after serving a term of incarceration. Other countries use risk assessment within the context of indeterminate sentencing statutory provisions. Furthermore, risk assessment often is used when persons are admitted to prisons, youth detention centers, or psychiatric facilities, to determine the security level of their placement and/or their risk-relevant treatment needs. There are numerous other legally relevant contexts in which risk assessment figures prominently (i.e., child abuse evaluations, custody and access evaluations, judicial interim release decisions, immigration hearings).

Risk assessments typically are done by persons within the human services fields, such as psychology, psychiatry, social work, nursing, or substance use counseling. Personnel within prison systems (i.e., correctional classification officers) also engage in a type of risk assessment for offenders admitted to penal systems.

History of the Scientific Study of Violence Risk Assessment

Although the clinical and legal tasks of violence risk assessment have been occurring in some form for centuries, the contemporary scientific study of violence risk assessment has its roots in important legal decisions and empirical studies that occurred between the mid-1960s and late 1970s. During this time, important legal decisions such as *Baxstrom v. Herold,* a 1966 decision of the U.S. Supreme Court, found the extant process underlying postsentence confinement of the so-called mentally disordered dangerous offenders unconstitutional and ordered hundreds of such persons, all of whom had been declared to be "dangerous," to be released from confinement or transferred to less secure institutions. The sociologist Henry J. Steadman took advantage of the opportunity to study the fate of these persons and reported that there were very few who subsequently committed new violent offenses, suggesting that the accuracy of the determinations of dangerousness was

low. Despite these developments, other legal decisions upheld the constitutionality of clinical predictions of violence. Furthermore, the 1976 groundbreaking case of *Tarasoff v. Regents of the University of California* went so far as to impose a positive legal duty on psychiatrists and psychologists to forecast the potential violence of patients under therapy in some circumstances.

In the early 1980s, Professor John Monahan summarized what he called the "first generation" of empirical studies on the prediction of violence. He concluded that clinical predictions were not very accurate, in particular leading to an unacceptably high false-positive error rate. He also called for a "second generation" of research that would focus on identifying meaningful risk factors for violence and using empirically based procedures for making risk assessments. Since that time, researchers have indeed identified numerous meaningful violence risk factors, such as substance use problems, psychopathic personality features, anger, impulsivity, antisocial peers, antisocial attitudes, previous violence, young age at first violent act, stress, treatment nonadherence, lack of social support, and some features of mental illness.

Although there has been no well-recognized declaration of a "third generation" of risk assessment research, efforts since the early to mid-1990s have capitalized on what was learned from risk factor research that has led to the construction and evaluation of risk assessment measures that compile and integrate numerous empirically validated risk factors. A further movement has included increased emphasis on the reduction of risk or prevention of violence, as opposed to solely estimating the likelihood of future violence. For this reason, a single definition of violence risk assessment is elusive. The two primary contemporary approaches to risk assessment, discussed below, adopt somewhat differing conceptualizations of the task.

Contemporary Approaches to Violence Risk Assessment

There are two primary approaches to violence risk assessment—structured and unstructured. The structured risk assessment typified first-generation research on risk assessment and remains commonly used today. However, unstructured risk assessment, sometimes called clinical prediction, is based primarily on clinicians' discretion and lacks rules that guide the risk factor selection or integration process. As such, it is vulnerable to decisional biases and widely varying quality across clinicians. For these reasons, although research supports that it can achieve statistically significant predictive levels, this differs across clinicians. Furthermore, most research indicates that it has lower reliability and predictive validity than more structured approaches to risk assessment. Therefore, a purely unstructured, discretion-based approach to risk assessment cannot form the basis of defensible risk assessment.

To increase the reliability and validity of risk assessments, researchers focused on developing and evaluating structured approaches: *actuarial decision making* and *structured professional judgment (SPJ).*

Actuarial Decision Making

The actuarial approach has a long history in psychology in terms of prediction. It is defined by the application of algorithms (equations, score cutoffs, decision rules) to the combination of risk factors to reach a predictive decision, thus improving the consistency and accuracy of such decisions. It also tends to incorporate risk factors that have been selected through empirical means (i.e., those items that add independently and incrementally to the prediction of the outcome). Therefore, at least within development samples, the risk factors used to make decisions have empirical support. Meta-analytic research suggests that actuarial prediction is more accurate than unstructured clinical prediction in approximately 50% of research studies, by about a 10% increase in hit rate.

Problems have been noted with actuarial approaches. Perhaps most important, actuarial measures that rely on statistical selection of risk factors and decision algorithms are subject to predictive degradation when used in new samples, and hence their generalizability is potentially tenuous. Therefore, cross-validation is a vital component of actuarial measure development, and evaluation and must be performed prior to the use of such measures. Furthermore, there is a tendency for actuarial methods to emphasize time-invariant risk factors that are less relevant to violence risk management and reduction aims than time-varying, or dynamic, risk factors. Because there has been a strong conceptual shift in the violence risk assessment field from a purely predictive model to a risk management or harm-reduction model, the predominantly predictive focus of some actuarial methods has been criticized. Although identifying risk level can indicate the *intensity* of necessary intervention, the failure to include risk factors that can serve as treatment targets reduces the relevance of actuarial

prediction for informing the *type* of treatment that would reduce risk. These limitations have led some researchers to express concern about this method of decision making and to develop another approach—SPJ.

Structured Professional Judgment

The SPJ approach shares some features with typical actuarial approaches, such as specifying risk factors with empirical support that are to be considered in a risk assessment and providing operational definitions and coding rules for risk factors. These features are intended to facilitate its reliability and predictive validity. However, the SPJ approach allows professional judgment at the point of making final decisions. It provides guidelines for such decisions but does not impose strict cutoffs or algorithms derived from a particular sample because of their potential predictive degradation and instability across samples. Evaluators are encouraged to consider the relevance of risk factors to the given individual being evaluated and to make decisions of low, moderate, or high risk based on the number, pattern, and relevance of such risk factors, as well as the probable degree of intervention that would be necessary to mitigate risk. The other distinguishing feature of SPJ is its explicit emphasis on risk management and the importance of bridging assessment and management. It does this through including time-varying risk factors and by providing guidelines for linking risk factors to risk management strategies, the point of which is not only to provide the means of assessing the likelihood of future violence but also to facilitate risk reduction and the prevention of future violence.

The SPJ approach has been criticized for allowing professional judgment to form part of the final decision-making process. Critics argue that this reduces its reliability and validity. However, those studies that have compared actuarial and SPJ measures or the structured judgments produced by SPJ with the numeric use of SPJ measures have generally found that SPJ decisions fare as well or better than actuarial decisions. Criticism also has been directed toward the publication of some SPJ measures prior to the accumulation of evaluation studies. Developers counter that SPJ measures are professional guidelines that are based on the empirical literature. They do not rely on empirically derived, potentially unstable algorithms that are in need of cross-validation, and hence, they do not require the same type of validation. Both arguments have merit. However, specific SPJ measures ought to have empirical support for their interrater reliability and predictive utility (of risk factors and risk judgments) prior to recommendation for use in practice.

Voice Recognition

Voice recognition, or "earwitness" identification, has not received the amount of research or public interest that eyewitness identification has received in recent years. A 1983 survey of British legal cases, however, found more than 180 cases at that time in which voice

identifications were used as evidence. But a growing body of research suggests that the use of voice identifications in court is just as dangerous, if not more so, than reliance on eyewitness identification. Research consistently shows that voice recognition is less accurate than face recognition under similar circumstances and that the same factors that affect eyewitness reliability can also create problems for the earwitness. Potential jurors, however, often overestimate the accuracy of voice recognition in forensic contexts.

Voice Recognition in the Courtroom

Perhaps the most famous use of voice recognition evidence in a criminal trial was in the trial of Bruno Richard Hauptmann, executed in 1936 for the kidnapping and murder of the infant son of the aviator Charles Lindbergh. The Lindbergh case was called the trial of the century, and one of the most dramatic moments in the trial was when Lindbergh himself took the stand. Describing the night of the ransom drop-off 3 years before the trial, Lindbergh spoke of hearing a voice from 100 yards away while he waited in his car for a friend to hand over the ransom. When Hauptmann was arrested 29 months later, Lindbergh was brought to the police station to listen to Hauptmann repeat the words of the kidnapper: "Hey doctor! Over here, over here." Lindbergh testified under oath that he was certain that Hauptmann's voice was the voice of the kidnapper. Experts still disagree over whether the jury reached the correct verdict in finding Hauptmann guilty.

Voice identification has played a role in at least one well-publicized case of erroneous conviction in Canada. In October 1984, a 9-year-old girl named Christine Jessop disappeared from her home in Ontario and was found dead almost 3 months later. She had been stabbed to death, apparently shortly after her disappearance. The investigation quickly focused on a neighbor, Guy Paul Morin, who was arrested in April 1985. Although Morin had a strong alibi, he was brought to trial in 1986 and was initially acquitted. But in Canada, the prosecution can appeal an acquittal, and Morin was retried in 1991. The second trial lasted almost 9 months, and the second jury found Morin guilty.

Although many errors occurred in the investigation of Christine Jessop's death and the trials of Guy Paul Morin, one dramatic piece of evidence at the trial came from Christine's mother, Janet. She testified that on the night of Christine's funeral, she heard an unknown male voice crying out near her home, "Help me, help me, oh God, help me!" She later identified this voice as that of her neighbor, Morin, with whom she had spoken over the fence just a few times. The prosecution claimed that Morin experienced a fit of remorse after the funeral and cried out in emotional agony from his home. While we cannot know the role that this testimony played in the jury's decision, one thing is clear: The wrong man was ultimately convicted. DNA testing revealed several years later that Morin could not possibly be the killer, and he was exonerated in 1995. The real killer has never been found.

Earwitness Research

Morin's voice was mistakenly identified by a casual acquaintance. Lindbergh, in contrast, was called on to identify a voice that he had heard only once. Both types of identification have forensic relevance. Usually, voice identifications are made in situations in which the witness or victim was unable to see the perpetrator's face because of darkness or because the perpetrator wore a mask. Sometimes, the victim of a crime may recognize the perpetrator's voice as that of a former co-worker or even a relative. The victim tells the police that he or she recognized the voice, and the identified person becomes the main suspect. Many cases in which voice identification is used as evidence, however, involve the identification of a stranger's voice. In such cases, when a suspect has come to light, a voice lineup may be played for the witness, usually in the form of a tape-recorded series of short clips of several parties speaking. The witness is asked to indicate whether any of the voices is the voice of the perpetrator. A voice showup may also be used, in which the witness is asked to listen to only one voice and to indicate whether this voice is the voice of the perpetrator. For example, witnesses to a bank robbery in North Carolina were asked to listen to a tape-recording from a previous convenience store robbery, in an effort to gather evidence that the two crimes were committed by the same person.

Why would such identifications result in errors? As with face recognition by eyewitnesses, it is important to recognize that memory for a voice does not operate like a tape recorder or a video camera. A listener encodes certain salient features of a voice into memory (e.g., pitch, loudness, accent, or unusual pronunciation or cadence) when it is heard, but later recognition of the voice as familiar is also heavily influenced by context, expectations, and logical reasoning. For example, if you answered your telephone right now, your identification of the voice at the other end of the line would

depend partly on your actual auditory memory for voices and partly on your expectations of who might be calling you, your knowledge of people who know your phone number, and even considerations such as the time of day. And almost all of us have had the experience of picking up the telephone, expecting a particular caller, "identifying" the voice as that of a friend or relative, only to realize minutes later that the caller is actually a stranger who has dialed a wrong number.

In a typical earwitness experiment, participants listen to a recorded statement of a particular duration and may or may not be informed that they will be asked to recognize the voice later. After a period of time, the participants are exposed to a voice lineup consisting of several different voices and are asked to choose the voice that had uttered the original statement. Participants also often rate their confidence in their choice or are asked whether they are certain enough to testify in court regarding their identification. In a study by Daniel Read and Fergus Craik, for example, college students heard a series of statements, including a male target voice saying, "Help me, help me, oh God, help me!" (the words heard by Christine Jessop's mother) and were asked to rate the emotionality of each statement. They did not know that they would be asked to recognize any of the voices in the future. At a class meeting 17 days later, the same students were asked to listen to a series of 20-second, conversational utterances by 6 male speakers and to choose the one that had uttered the statement in question. The target voice was one of the voices in the lineup. Pure guessing would have resulted in a chance performance level of 17% (1 out of 6). In fact, the accuracy of the students in the study was only 20% correct, no better than chance.

Most studies also incorporate a "target-absent" lineup to measure the likelihood of a false identification when the lineup does not contain the actual perpetrator. Such research points out the danger of misidentifying an unfamiliar voice as familiar; even with a relatively lengthy exposure to a distinctive target voice, false identification rates in such a target-absent lineup can be as high as 90% to 100%.

Factors Influencing Voice Recognition Accuracy

The likelihood of correctly identifying a voice depends on a number of factors or *estimator variables*, many of which also influence eyewitness accuracy. Limited exposure to a voice can lead to decreased accuracy; the longer the time that the perpetrator spends talking, the more likely the witness is to properly encode the voice characteristics. It is important to recognize, however, that witnesses are likely to overestimate the length of time that the perpetrator spent speaking. A 30-second speech sample, for example, is typically remembered as having lasted from 90 seconds to more than 2 minutes. The amount of time that passes between initially hearing a voice and then being tested for recognition is also critical. The longer the delay between exposure and testing, the greater the chance of error becomes, particularly errors in the form of false recognitions of innocent persons' voices. Background noise can interfere with the witness's ability to encode voice characteristics. The proximity of the witness to the speaker is also important, with closer proximity being associated with greater accuracy.

The ability to see a perpetrator's face may also adversely affect the recognition of the perpetrator's voice, a phenomenon known as the face overshadowing effect. It is thought that a witness pays relatively more attention to the face when it is visible, resulting in decreased voice identification accuracy. Studies have shown, however, that instructions to pay attention to the voice do not significantly reduce the face overshadowing effect, suggesting a process that may not be under the witness's conscious control. Use of voice recognition evidence in situations where the perpetrator's face has been visible, then, is considered unreliable.

Studies of eyewitness identification consistently find superior performance in recognizing faces of one's own race as opposed to faces of another race. There is a similar finding in voice recognition research regarding accents and languages. English speakers, for example, have been shown to be more accurate in recognizing unaccented English-speaking voices than heavily accented English-speaking voices and least accurate in recognizing voices speaking in a foreign language. Language familiarity, then, has a significant positive effect on voice identification accuracy. (Gender, on the other hand, has no consistent relationship to voice recognition.)

Stress can also decrease the accuracy of voice recognition. When viewing videotaped crimes in the laboratory, research participants typically make more errors in both face and voice recognition when violent threats are made or a weapon is present. Our ability to pay attention to all aspects of our surroundings is limited under any circumstances, and under conditions of stress it becomes more limited. When threats are made, it is more important to our survival to listen to and remember the content of the spoken message rather than the vocal qualities of the speaker.

Voices may easily be disguised, further decreasing the ability of a witness to accurately recognize a voice. When a witness hears a voice raised in anger during the commission of a crime and subsequently attempts to recognize the speaker saying something in a normal tone, accuracy is decreased. Whispering is an extremely effective way to disguise a voice, because it covers up many distinctive vocal characteristics such as pitch.

Earwitness accuracy may also be related to the age of the witness. Studies tend to show that very young children are not as accurate in recognizing voices as children above 10 years of age, who often perform comparably with adults. Speaker identification accuracy also decreases after the age of 40, probably related to increases in hearing loss for older persons. Furthermore, blind persons are not superior to sighted persons in their ability to recognize voices or other natural sounds, in spite of popular opinion to the contrary.

Common sense tells us that recognizing the voice of an acquaintance, friend, or family member should be easier than recognizing the voice of a stranger. To a certain extent, research supports this conclusion. However, studies of the recognition of familiar voices find a wide range of accuracy levels, depending on the specific circumstances of the event. Although some studies find a high degree of accuracy (more than 95%) in recognizing familiar voices, studies often show accuracy rates of less than 70%, and sometimes significantly lower. Daniel Yarmey and colleagues, for example, compared participants' recognition of highly familiar voices (immediate family members or best friends), moderately familiar voices (co-workers, teammates, or friends), or low-familiarity voices (casual acquaintances) and found that accuracy for identifying voices of low and moderate familiarity was only about 65% and participants misidentified the voices of strangers as being familiar almost 40% of the time. Thus, according to Yarmey, when a witness claims to recognize a perpetrator's voice as that of a familiar person, police officers should not simply take this statement at face value but should construct a voice lineup to test the witness's ability to identify the voice in question.

Unfortunately, the most salient indicator of voice recognition accuracy for a juror is often the witness's confidence in the courtroom. Studies consistently show that voice identification accuracy is almost completely unrelated to confidence. Extremely confident witnesses are often wrong in their identification of a voice, and accurate witnesses often show little confidence in their identifications. Furthermore, jurors are likely to overestimate the likelihood of any voice identification being accurate. When psychology students, for example, are asked to estimate the percentage of accurate identifications in circumstances mirroring actual laboratory and field studies, they consistently give unrealistically high accuracy predictions. While it may not be surprising that laypersons have little knowledge of the problems associated with earwitness identification, a recent British study indicated that police officers were no more knowledgeable than the general population regarding voice recognition issues.

Voice Identification Procedures

In another parallel with eyewitness research, the use of one-person showups in voice identification has been criticized as unduly suggestive. In a study by Daniel Yarmey and his associates, a young woman approached citizens individually in a public place and interacted with them for about 15 seconds each. The participants were given a voice identification test approximately 5 minutes after the encounter. When the test was a one-person showup as opposed to a lineup to six voices, innocent suspects were significantly more likely to be identified. Accurate identifications of the real speaker's voice were rare in both conditions.

Within the United States and, for the most part, internationally, there are few standardized procedures for use in forensic voice identification. Researchers at the Netherlands Forensic Institute have proposed the development of guidelines for voice lineup construction, similar to the guidelines in use in many police departments for eyewitness lineups. They advocate a minimum of five voices in the lineup in addition to the suspect, with foils being chosen for similarity to the suspect's sex, age, accent, socioeconomic background, and vocal characteristics, such as pitch and speed of speaking. They also recommend the use of double-blind administrators and standardized instructions for the earwitness—recommendations that are becoming common in the realm of eyewitness procedure but need stronger advocacy in the voice recognition arena.

Voir Dire

Voir dire is a legal proceeding during which attorneys and/or judges question prospective jurors (called *venirepersons*) to determine their fitness for jury duty. The purpose of voir dire is to uncover bias; the procedure is designed to identify and eliminate members of the venire panel who are unable to be impartial and who do not meet statutory requirements of jury service. The format and scope of voir dire questioning varies across jurisdictions and the discretion of the trial judge. Research on voir dire is limited and primarily concerns its effectiveness, the relative effectiveness of extended versus minimal voir dire, and the factors influencing juror honesty during voir dire questioning.

Purpose of Voir Dire

Voir dire, a term derived from Middle French which means "to speak the truth," is a pretrial legal proceeding. During voir dire, the members of the jury pool, known as the venire panel, are questioned by the judge, the attorneys, or both. Questioning may be directed toward the group as a whole or administered privately to individual jurors. Based on their responses to this questioning, prospective jurors are chosen for removal from the jury. The legal purpose of voir dire is to uncover any existing jury bias and to protect against the possibility that the defendant receives an unfair trial. This questioning process is designed to eliminate both jurors who do not meet the statutory requirements for jury service and those who are unable or unwilling to set aside preexisting biases and remain impartial. The Sixth Amendment of the U.S. Constitution guarantees all defendants the right to a speedy and public trial by an impartial jury of their peers, and thus the judge must determine whether service by any of the venire members would result in a constitutional violation.

The impaneling of an impartial jury requires that venire members answer demographic and attitudinal questions, as well as questions regarding their familiarity with the case, the litigants, and anyone else involved in the case. Jurors who express an inability to be impartial may be excused from jury service through a challenge for cause or a peremptory challenge. However, it is possible that the judge may alternatively attempt to "rehabilitate" biased jurors or secure public commitments that they will ignore their biases. Rehabilitation is attempted when jurors indicate that they could have difficulty remaining impartial to both sides of the case. These jurors may be asked if their preexisting attitudes will interfere with their ability to be fair and follow the law. Jurors who agree to set aside their biases and decide the verdict based on the evidence are considered "rehabilitated" and fit for jury service. Although the objective of voir dire is to identify jurors who hold opinions or biases that would make them unfit or ineligible for jury service, the voir dire proceeding may also be used for other purposes. Attorneys may attempt to ingratiate themselves with the jury, instruct the jury on the relevant law, or obtain public assurances from jury members that they can be fair during voir dire.

Procedural Elements of Voir Dire

The format of voir dire proceedings and the number and scope of voir dire questions vary widely across states and jurisdictions. The format of voir dire, the level of attorney involvement, and the nature of questioning are ultimately determined by the trial judge. In some instances, only minimal voir dire is allowed, and the judge conducts all questioning of the venire panel; attorneys have a minor role, and questioning is typically conducted in a formal manner. In addition, the questions are superficial in nature and primarily concern the

prospective jurors' ability to serve as impartial jurors. Federal court adheres to this format of voir dire. Extended voir dire typically allows for a greater number of questions, more case-specific questions, and greater involvement of the attorneys in the questioning. The questioning format also varies according to the discretion of the judge. Questions may be posed to the venire members as a group, or members of the venire panel may be questioned individually, out of earshot from the remainder of the panel.

Attorneys from each side of the case may recommend the elimination of venire members by issuing an objection to a particular prospective juror's presence on the jury in the form of a challenge. There are two categories of challenges: challenges for cause and peremptory challenges. The trial judge is responsible for either granting or denying both types of challenges.

When issuing a challenge for cause, an attorney must communicate to the Court the justification for the challenge. The challenges for cause are intended to eliminate prospective jurors who do not meet the legal requirements for jury service. For example, federal law mandates that jurors must be 18 years or older and U.S. citizens to serve on a jury. In addition, impartiality is another requirement for jury service; jurors must agree to set aside preexisting opinions and promise to decide the case based solely on the evidence presented during trial. Thus, challenges for cause are designed both to eliminate jurors who do not fit the statutory requirements of jury service and to excuse those who express an inability or unwillingness to follow the law in a given case. Both prosecutors and defense attorneys are granted an unlimited number of challenges for cause.

The second mechanism for removing members of the venire panel is through the use of peremptory challenges. The peremptory challenge differs from a challenge for cause in that attorneys are not routinely required to provide justification for the objection. Peremptory challenges may be used to excuse prospective jurors who meet the legal requirements for jury service. Indeed, an attorney may expend a peremptory challenge to excuse a prospective juror whom the attorney believes to be unfavorable to their case but who is not eligible for an excusal for cause. With some exceptions, attorneys may base peremptory challenges on any number of factors, including occupation, physical appearance, and even nonverbal behavior in the courtroom. The number of peremptory challenges allotted to attorneys is limited, and attorneys are usually granted a greater number in high-profile cases. In addition, in some cases, defense attorneys may receive more peremptory challenges than prosecuting attorneys. There are some restrictions to an attorney's use of peremptory challenges, however. Peremptory challenges may not be used to excuse a member of the venire panel because he or she is a member of a cognizable group. Case law maintains that jurors may not be excluded based on their race (*Batson v. Kentucky*, 1968), sexual orientation (*People v. Garcia*, 2000), gender (*J.E.B. v. Alabama ex rel. T.B.*, 1994), religion (*State v. Fulton*, 1991), or socioeconomic status (*Thiel v. Southern Pacific Co.*, 1946). Despite these rulings, limiting the implementation of peremptory challenges, it is widely acknowledged that the inappropriate use of peremptory challenges, especially with regard to the race or ethnicity of prospective jurors, still occurs.

Voir Dire as a Safeguard

Voir dire is widely considered to be a legal safeguard, helping ensure that verdict decisions are based on evidentiary considerations and not the preexisting attitudes of individual jurors. Voir dire is especially important in cases in which there are concerns about the existence of juror partiality, such as cases that have received a great deal of pretrial media attention. In these types of cases, jurors may hold attitudes that could interfere with their ability to weigh the evidence in a fair manner. For example, if jurors have been exposed to media coverage of a case, it is possible that they may have already formed opinions about the guilt of the defendant prior to the trial. Similarly, research has demonstrated that there are certain types of cases about which jurors have strong attitudes, such as death penalty and child sexual abuse cases as well as cases in which a defendant enters an insanity plea. Research has demonstrated that attitudes toward the death penalty and attitudes toward the insanity defense are related to verdicts in these types of cases. For example, research indicates that jurors who are proponents of the death penalty are more likely to render a guilty verdict than jurors who are opposed to the death penalty. This research indicates that for cases in which jurors hold biases or strong preexisting attitudes, juror judgments are not solely based on the strength of evidence.

For voir dire to be an effective procedure for eliminating biased jurors from the panel, several conditions must be met. First, attorneys must be able to construct questions that accurately assess juror attitudes and tap into juror bias. In addition, jurors' attitudes must be related to their verdict decisions. Finally, jurors must respond honestly to questions posed to them during voir dire.

Research on the Format and Effectiveness of Voir Dire

Perceptions and opinions about the voir dire procedure are mixed; while some have described it as an essential part of the trial process, others claim that the time and financial resources consumed by this process contribute to a lack of efficiency in the legal system. As the Sixth Amendment guarantees each criminal defendant the right to an impartial jury, it seems certain that some form of voir dire is a legal necessity to assess the venire panel for preexisting biases. However, some critics maintain that the information obtained during the voir dire process is not sufficient or appropriate for identifying juror bias. Therefore, many have argued for a reduction in both the time and scope of voir dire and attorney involvement in the process. Although research on actual voir dire proceedings is limited, an observational study of voir dire in four felony cases found that approximately half the discussion during voir dire concerned jurors' ability to fulfill their role and remain impartial. The findings in this study suggest that attorneys can be effective at challenging members of the venire panel, who are generally biased against their side. However, it is premature to draw conclusions based on these data as the sample of cases observed was very small.

In addition to debate over voir dire in general, there is controversy concerning the length and scope of voir dire and the level of attorney participation. Proponents of extended voir dire claim that it is necessary to adequately assess juror bias and to provide both parties with enough information to properly exercise peremptory challenges. However, critics of extended voir dire argue that it wastes valuable time and monetary resources in light of the nation's large backlog of cases. These critics argue for minimal voir dire and limited attorney involvement and claim that the high status of judges and the serious nature that surrounds the questioning will encourage jurors to be forthcoming with information. In addition, opponents of extended voir dire claim that attorneys abuse the voir dire procedure by using it for purposes other than assessing juror bias. Indeed, according to critics, these inappropriate uses include ingratiation and establishing rapport with the jury, obtaining public commitments from jurors prior to the start of the trial, and prematurely presenting case arguments. The most central critique of extended voir dire is that it does not result in a more effective elimination of biased jurors than does minimal voir dire. In addition, although extended voir dire has been shown to reduce perceptions of defendant culpability compared with minimal voir dire after juror exposure to pretrial publicity, research has failed to find evidence that extended voir dire is superior to minimal voir dire in reducing the biasing impact of pretrial publicity on juror judgments.

Despite the failure to demonstrate the superiority of extended voir dire over minimal voir dire as a safeguard, there is evidence to suggest that extended voir dire may be the preferable format for obtaining honest answers from jurors. Although it is possible that minimal voir dire in which a judge conducts the questioning may be more efficient than extended voir dire in terms of time and cost, existing data suggest that judge-conducted voir dire may be less likely to assist in the identification of biased jurors than attorney-conducted voir dire. Mock jury research has demonstrated that participants are more honest and forthcoming when voir dire questioning is performed by an attorney rather than by a judge. This finding is also supported by research on information disclosure in interview settings, which demonstrates that when there is a great amount of social distance between the interviewer and the interviewee, the interviewee may feel pressure to respond in an "acceptable" manner rather than responding honestly. The status differential between judges and jurors is larger than that between attorneys and jurors, suggesting that prospective jurors would be more likely to provide honest responses to questioning by attorneys rather than by a judge. Attorneys are free to move around the courtroom and decrease their physical distance from the venire panel, whereas the large social distance between judges and prospective jurors is exacerbated by the placement of the judge behind the elevated bench.

In addition, research on social interactions also demonstrates that people are more willing to disclose information to people who appear friendly and warm than to those who seem detached and reserved. Judges are compelled by their role to maintain a formal and proper demeanor during trial proceedings, and although they may act in a kindly manner toward the venire members, it would be inappropriate for judges to attempt to curry favor with the jurors. Conversely, attorneys may take advantage of their partisan role and act in a warm, friendly, and sociable manner toward the venire panel. This type of behavior toward the prospective jurors may also work to limit the perceived social distance between attorneys and jurors and to increase disclosure and honesty during voir dire.

Although attorney-conducted voir dire may be a mechanism for eliciting honest information from

jurors, there are other obstacles that may impede juror honesty during voir dire. There are several features of voir dire that may serve as demand characteristics, or aspects of the situation that communicate to jurors what behavior is considered appropriate and acceptable. For example, the situational aspects of voir dire communicate to prospective jurors that the judge is in a position of authority, and it is likely that the high status of the judge makes the norm to obey authority salient in this situation. The judge is dressed in a ceremonial black robe, seated at an elevated bench, and addressed as "Your Honor," highlighting his or her elevated status and official role. Stanley Milgram's classic research on obedience to authority has demonstrated the potential for this social norm to influence behavior. In addition, several aspects of the voir dire setting communicate the seriousness of the procedure. The courtroom setting is formal and ritualistic. It is likely that ideals such as fairness and impartiality are made salient by the situational aspects of the voir dire procedure. As jurors most likely agree with these ideals, it may be difficult for biased jurors to admit their biases in response to questioning by a judge.

The expectations that attorneys and judges have about jurors' level of preexisting bias may influence the manner in which they question prospective jurors and influence juror honesty. This is known as the experimenter expectancy effect. Research in this area suggests that when experimenters have a prediction about the results of an experiment, this prediction can be unconsciously communicated to participants, which generates hypothesis-confirming behavior from the participants. It is possible that because judges must ignore their personal biases when presiding over a case, they believe that jurors also possess the ability to put aside preexisting prejudices for the trial. Thus, it is possible that if judges expect that jurors will be impartial, this expectation could be inadvertently communicated to jurors, resulting in dishonest answers from the prospective jurors in response to questioning.

As mentioned earlier, for voir dire questioning to be effective in allowing for the elimination of biased jurors from the venire panel, jurors must answer the questions posed to them during voir dire honestly. However, during voir dire, the common legal practice of juror rehabilitation may be an additional impediment to the honest reporting of juror bias during voir dire. Indeed, when prospective jurors admit to harboring bias, the judge often asks if they can put their biases aside and decide the case based on the evidence. The Supreme Court ruling in *Mu'min v. Virginia* (1991) simply requires an affirmative response to these questions to demonstrate juror impartiality. Other rehabilitation tactics include reminding the prospective jurors of the grave importance of their civic duty and that the law requires jurors to ignore all preexisting biases and opinions. It is possible that prospective jurors feel pressure to comply with a request from the judge and are uncomfortable reporting that they would be unable to be fair and impartial. It is likely that prospective jurors find it difficult to respond honestly to inquiries about bias.

Waiver to Criminal Court

Juvenile transfer to adult court is the process by which some youths who are viewed by juvenile court judges as inappropriate for the juvenile justice system are transferred to adult court. The decisions to transfer a youth to adult court are typically based on concerns about public safety balanced against considerations of youth development. The rationale for waiver is fourfold: (1) separate severely antisocial from amenable youths, (2) ensure public safety, (3) remove youths unlikely to be amenable within the juvenile court time frame, and (4) hold mature adolescents accountable for their conduct. There are various mechanisms for waiver, including juvenile waiver, prosecutorial filing, and automatic and reverse transfer. The standards applied in each transfer mechanism are typically based on the criteria outlined by Judge Abe Fortas in *Kent v. United States* (1966). These standards are used by judges in determining whether a youth should be transferred to adult court.

Since the inception of the new juvenile justice system, psychology has played a role in the evaluation of juvenile offenders. Psychology's link to the waiver process is important because it increases the likelihood that individual characteristics will be considered prior to waiving jurisdiction of youth. An important component of the evaluation is for mental health professionals to suggest what types of treatment might allow for prosocial change. With respect to policy, psychologists can inform the courts about new mechanisms or ways of processing and treating severe offenders that would allow for potential change in their problem behavior and their healthy development.

This entry discusses the rationale for waiver, the various mechanisms for waiver, the standards that are applied by judges in determining whether a youth should be transferred to adult court, and the criteria that underlie each standard. In addition, it describes the relationship between psychology and the waiver process and highlights the contribution to evaluation that mental health professionals can make by suggesting what types of treatment might allow for positive change. Psychology can also help inform policy on the waiver process.

Historical Purposes of Waiver of Jurisdiction

The rationale for and the juvenile court's interest in upward waiver for certain juvenile offenders is fourfold. First, the juvenile justice system was initiated to rehabilitate delinquent youths. Transfer mechanisms have always been available to avoid the inclusion of youths whose potential dangerousness might detract from the rehabilitative efforts of programs that were designed to benefit errant children and adolescents. Thus, the waiver mechanism was used as a safety valve to remove certain youths who were thought to detract from a system that was intended to treat and improve youths who were believed to be amenable to intervention.

Second, the juvenile justice system is responsible for protecting the public. In most states, the juvenile justice system must release youths in its custody when they reach a certain age (typically 17 or 18 years), depending on the laws pertaining to particular offenses. If it is thought that a juvenile is unlikely to be rehabilitated prior to turning 18 (the most common age after which

the juvenile justice system no longer has jurisdiction), the law allows juvenile court judges to waive jurisdiction. This then alleviates any potential threat the child or adolescent might pose to public safety with regard to escape from less secure facilities or at the time of mandatory release.

Third, when a youth's rehabilitation is considered unlikely, it has been argued that the state has an interest in avoiding the use of its limited rehabilitation resources. Historically, waiver has been an acceptable legal mechanism for avoiding the use of existing resources when even the usually effective treatments would be unlikely to result in rehabilitation. However, the courts are also expected to think of creative ways to help youths change their behavior.

Fourth, until the waiver and transfer laws were enacted, it was legally presumed that all juveniles below a certain age (typically 18 years) were insufficiently mature to be held criminally responsible for their antisocial acts. Youths below this age were automatically treated as juveniles under the parens patriae philosophy. This guiding principle remains as a presumption, but one that is debatable depending on the juvenile's level of maturity. Thus, juveniles may be transferred if they are viewed as mature participants in a criminal act. Maturity is often considered in conjunction with risk of future offending and treatment amenability.

Mechanisms for Transfer: Routes to and From Juvenile Courts

There are different mechanisms by which the justice system achieves transfer. Transfer mechanisms can be grouped into three categories: judicial (upward) waiver, statutory exclusion, and direct file. Transfer mechanisms are determined by state law, and states may use any combination of mechanisms to meet perceived societal needs and policy goals.

Judicial waiver is the most common method for transferring cases to adult criminal court, with 45 states allowing for transfer of certain types of cases on the basis of juvenile court judges' decisions about the appropriateness of transfer. Under this method, juvenile court judges make a determination as to whether the juvenile should be tried in juvenile court or transferred to adult court. Juvenile court judges may consider a range of factors in making this decision, including psychological evaluations that address the psychological characteristics of the youth as they pertain to *Kent* criteria.

Two other mechanisms by which youths may be transferred to criminal court for trial exist. These mechanisms, which were introduced in the 1990s, include statutory exclusion and prosecutorial direct file. At present, 29 states provide a statutory exclusion. In these states, offenders above a certain age or accused of certain types of crime (serious offenses such as murder and assault) are automatically outside the jurisdiction of the juvenile court. In these cases, the charge is filed directly in adult criminal court without any input from juvenile court judges, a formal juvenile hearing, or an evaluation of the youth's characteristics. This mechanism, which is available in 25 states, removes the discretion of the juvenile court judges from the transfer process entirely.

The second transfer mechanism, which was adopted in 15 states in the late 1980s and early 1990s, is called prosecutorial direct file. This mechanism allows prosecutors to file charges against youths in either juvenile or criminal court for certain types of offenses. Similar to automatic transfer, prosecutorial direct file does not allow for a hearing at the juvenile level, nor is there any evaluation of the youth prior to the prosecutor's filing of the case directly in adult criminal court. Recent estimates of the percentage of juveniles transferred to adult court under each type of transfer indicate that although newer routes have been introduced, judicial transfer from juvenile courts remains a relatively common mechanism for transfer. Waiver rates differ based on the types of crimes committed and what is occurring in various communities with respect to the level of juvenile violence.

A protective transfer mechanism is now in place in some states if a decision error occurs during the transfer process. In some states where criminal courts receive transferred youths by statutory exclusion or direct file, judges may view the youths as amenable to treatment in the juvenile justice system and/or possibly too immature to be processed in adult criminal court; at this point, juvenile court judges have the opportunity to reverse the transfer or decertify the youths. This option is available in 25 states and serves as a safety net for youths who are inappropriately transferred to criminal court. It is interesting that in some states where judicial transfer from juvenile courts (upward waiver) is used, reverse transfer is an option. However, this special case of the reverse transfer is rare and only occurs in 6 states. In sum, the reverse transfer process, available in 25 states, serves as a protective mechanism for youths who are inappropriately transferred to adult courts (e.g., if they are immature, amenable to treatment, or incompetent to stand trial); however, this mechanism typically requires that some authority (attorney and/or the

judge) recognize the decision error and plan a pretrial hearing in criminal court, which then allows the criminal court judge to transfer jurisdiction and send the youths back to juvenile court.

There is also the potential for blended sentencing, wherein the trial occurs in one setting, but sentencing occurs in a different setting or combination of settings. Such a system may result in the imposition of both juvenile and criminal sanctions for the same offense. All these mechanisms are attempts to balance the need for protecting society against the recognition that children may possess diminished capacity compared with adults and therefore deserve a judicial process that takes such factors into account.

Legal Standards for Transfer to Adult Court

With each of the mechanisms for transfer, it is required that the judge apply a "standard" to determine whether or not the youth should be tried in adult court. The laws controlling waiver of court jurisdiction require hearings to address whether evidence supports the statutory criteria for waiver. Many states have two to three levels of legal standards for waiver of jurisdiction. The first is a set of simple threshold conditions that must be met before going further (e.g., age, being charged with a certain offense, having a special history of prior offenses). If the threshold measures are met, then courts in most states can proceed to the point at which they apply one of typically three standards, which are often referred to as (1) *public safety* or *danger to others,* (2) *amenability to rehabilitation,* and (3) *the best interest of the child/community.* Many of these standards have a similar meaning. Specifically, they are attempting to balance the development of the youth against the protection of society. For instance, the *danger to others* standard requires that youths not be waived to criminal court unless they present a serious risk of harm to others. The same standard would generally be applied in reverse waiver (requiring that the youth not present a serious risk of harm if the waiver were approved). The amenability to rehabilitation standard allows the court to waive jurisdiction and remand the youth for criminal court trial only if the youth is found to be not amenable to rehabilitation within the resources of the juvenile court (as stated in *Kent v. United States*) and/or "is not a fit and proper subject" for juvenile custody. Each of these criteria mentioned above are drawn from the eight criteria listed in *Kent v. United States*. The best interest of the child/community standard requires that the juvenile court judge consider issues such as dangerousness and amenability and attempt to provide the best placement for the youth. Finally, it appears that increasingly states do not list a broader standard but rather list the specific *Kent*-like criteria to be considered before transferring a youth to adult court. All three standards exist because of a concern for risk of harm to the public.

Criteria Underpinning the Standards: The *Kent* Criteria

Under each standard within state statutes, there is a set of criteria that judges consider to address the legal standard. Many of these factors listed in state statutes mimic *Kent* criteria. Specifically, in *Kent v. United States*, the U.S. Supreme Court recommended eight factors, and most states have etched some permutation of these factors into the statutes or case law. The *Kent* criteria can be separated into straightforward legal criteria and others that are psychological or psycholegal in content. For example, some *Kent* criteria—such as whether the case has prosecutorial merit or the desirability of trial in criminal court because the case involves adult associates—are primarily factors that the judges can easily determine without any psychological input. Therefore, forensic clinicians do not need to provide input pertaining to direct legal factors. Other elements of *Kent* that concern danger to others, sophistication maturity, and amenability to treatment are pertinent psychological constructs for which judges often request psychological evaluations and input.

Psychology's Link to Juvenile Waiver Considerations

Historically, clinical forensic psychologists have been central participants in the evaluation of youths who were facing transfer. Psychologists are often asked to provide information about the risk the youths pose to society, their level of maturity, and the degree to which they are amenable to treatment. If the youths are amenable, psychological reports and/or testimony then are responsible for providing a road map for change and, in relation, recommend where this change could occur. Traditionally, these questions have been answered by clinical interview alone. More recently, juvenile assessment tools have been designed for the assessment of young offenders that may be helpful in guiding assessment in this area. For example, the Structured Assessment of Violence Risk for Youth, the Youth Level of Service/Case Management Inventory

(YLS/CMI), and the Risk-Sophistication-Treatment Inventory (RSTI) are all measures that could be used to examine youths and provide information that is relevant to the courts regarding youths who are being evaluated by the courts. In addition to these measures, Thomas Grisso also provides a structure for the evaluations that might be used. While the aforementioned measures provide structure to the evaluation process, they do not supplant the need for extensive knowledge about adolescent development and the need to keep abreast of the current literatures on transfer, risk of violence in youth, maturity, and treatment amenability.

The role of psychology in the waiver of youths has been substantial for two primary reasons. First, psychologists are able to provide relevant psychological information on youths that allows for the individual assessment of youths rather than automatic or direct file procedures that do not consider individual differences. In addition, psychologists' reports and testimony provide an opportunity not only to describe the youths but also to determine and delineate what needs to change.

Second, the role of psychology has been to aid in the eventual development of policy. Research and scholarly papers thus far have suggested that one way to improve transfer evaluations is to have the evaluations conducted frequently. At present, single-point predictions are limited because they capture the youth at one moment in time but do not incorporate future data. This may not be particularly helpful as the youth grows. Thus, the concepts of youth violence prevention, management, and treatment need to be infused into contemporary thinking on juvenile evaluations by juvenile and adult court decision makers. This conceptual development suggests the need for identifying, measuring, and monitoring changeable risk and readiness for treatment factors in youth because these factors are the most promising targets for reducing problem behavior in youth. Maturity and amenability are two concepts that are changeable and may affect the potential for problem behavior in youth over time, but single-point predictions do not allow for the development of these concepts over time. One such policy change might be to adopt the blended sentence option more frequently so that youths can be monitored over longer periods of time before making an ultimate decision about transfer.

Weapon Focus

The weapon focus effect is the tendency for witnesses who observe an armed criminal to direct their attention toward the weapon so that they fail to encode and remember information about the perpetrator's physical appearance as accurately as they would have if no weapon had been visible. This effect can have important consequences for the investigation of a crime, as the police often rely on witnesses' descriptions of a perpetrator as they attempt to identify a suspect.

In lab experiments investigating weapon focus, researchers typically expose participant-witnesses to slide sequences, videos, or live enactments in which a target person holds a weapon (in the experimental condition) or a neutral object (in the control condition), although sometimes in the control condition the target is empty-handed. Several kinds of weapons have produced the effect, including a handgun, carving knife, switchblade knife, meat cleaver, liquor bottle, and syringe. Usually witnesses' performance in a condition

with a completely visible weapon is compared with performance in a condition with no weapon, but in some studies researchers have manipulated the amount of exposure time or the degree of visibility.

The primary dependent variable, witnesses' memory of the target's appearance, has been measured using two different methods. First, witnesses may attempt to describe the target's physical features (e.g., height, hair color) and clothing by responding to open-ended or multiple-choice questions. Many studies have demonstrated that a weapon's presence impairs the accuracy of witnesses' descriptions. A second method is to ask witnesses to identify the target in a lineup. The weapon's influence on this less sensitive measure is weaker, with a few experiments reporting null results.

Although memory of the target's appearance is the main interest in most studies, a weapon's presence can harm the ability to remember other aspects of the target as well. For example, witnesses exposed to a weapon may find it more difficult than controls to recall the semantic content of verbal statements made by the target.

If witnesses in the experimental condition focus on the weapon to a greater extent than controls focus on the neutral object, one might expect this difference to be revealed by eye movements and by memory for the object. Consistent with these expectations, researchers found that witnesses made more frequent and longer eye fixations on an object held by a target in a slide sequence if that object was a gun rather than a nonweapon. Additionally, although only a few studies have investigated memory for the object, those that do exist generally indicate that witnesses can identify and describe a weapon better than a neutral object.

Some researchers have used field studies rather than lab experiments to explore the weapon focus effect, usually by interviewing witnesses to actual crimes or examining police reports. Some, though not all, of these investigations have yielded null results. Perhaps these findings are at odds with those obtained in lab experiments because field studies are more realistic. Alternatively, the discrepancy could be attributed to field researchers' difficulty in surmounting daunting methodological obstacles. For example, determining the accuracy of witnesses' reports is problematic because there is often no complete, objective record of the scene they observed. Also, researchers must struggle to eliminate potential confounds with the weapon's presence, such as exposure time, retention interval, the witness's vantage point, the perpetrator's behavior, and differences in police response (e.g., the police might question witnesses to crimes involving weapons more thoroughly than witnesses to weaponless crimes). Nevertheless, field studies are a valuable complement to lab research, and they offer the possibility of greater ecological validity.

Two different explanations for the weapon focus effect have been discussed in the literature. The first interprets it as a consequence of the psychological arousal or anxiety that the sight of a weapon is supposed to create. The idea is that as a witness's anxiety rises to a point above the optimal level, attentional capacity shrinks so that the witness focuses mostly on central cues (e.g., the weapon, because it is the source of the anxiety) at the expense of peripheral cues (e.g., the perpetrator's clothing and facial features). This hypothesis is contradicted by several findings: Memory of the target is not affected by (a) the level of threat that the armed target directs toward another person, (b) the degree of threat associated with the object held by the target, or (c) having a confederate holding a syringe threaten the witnesses by telling them that they would receive an injection as part of the experiment. Moreover, the weapon focus effect occurs even when witnesses rate their anxiety as low.

An alternative explanation proposes that weapons seem unusual or unexpected within many contexts. Furthermore, it is known that unusual objects within visual scenes attract attention. Consistent with this account, research has shown that an unusual object, such as a stalk of celery or a toy Pillsbury doughboy, can have the same impact on memory of the target as a weapon.

One prediction that follows from the unusualness explanation is that a weapon should fail to elicit the typical weapon focus effect if it appears within a context in which weapons would be expected. For example, a gun held by a target at a shooting range would not be out of place. A test of this prediction revealed that, as hypothesized, a weapon focus effect did not occur in that setting.

An interesting question with both theoretical and practical implications concerns the mechanism by which weapons attract attention. Specifically, do weapons capture attention automatically? If so, witnesses would have relatively little awareness of and control over their attentional focus. However, if the answer is no, potential witnesses (e.g., bank tellers and convenience-store workers) could perhaps receive training that educates them about the weapon focus effect and teaches them to watch the perpetrator rather than the weapon as a crime unfolds. Recent data suggest that educated

witnesses can overcome the weapon focus effect, which implies that weapons probably do not capture attention automatically.

WITNESS Model

Formal (mathematical and computer simulation) models have been developed and applied in a wide range of areas in psychology. The application of formal models can be helpful for clarifying theoretical assumptions, generating precise predictions, and testing the adequacy of theoretical explanations by comparing theory-generated predictions with human-generated data. This entry describes a computational model called the WITNESS model that has been developed for eyewitness identification. The WITNESS model assumes that lineup members are compared with an error-prone memory representation of the perpetrator and that identification decisions are based on a weighted combination of absolute and relative match information.

Eyewitness identification research has a clear and immediate real-world application. Given the converging evidence that mistaken identification is the primary factor contributing to wrongful conviction, it is important to understand the causes of mistaken identification and develop techniques to minimize its occurrence. Toward that end, eyewitness identification research has provided several important insights into the factors that cause or are associated with eyewitness errors and has been instrumental in efforts to reform the procedures by which identification evidence is obtained.

It is also important to understand the psychological processes that underlie eyewitness identification decisions and errors. Here, the questions are not about what happens, but rather *why what happens happens.* Toward that end, it can be useful to develop and test comprehensive, mathematical models of the memory and decision processes that underlie eyewitness identification. One model that has recently been developed for eyewitness identification decisions is called the WITNESS model. This entry will present a brief overview of the WITNESS model and how it is applied to eyewitness identification.

The WITNESS Model

The WITNESS model makes a few simple assumptions about the memory and decision processes that underlie identification decisions and produces response probabilities that can be compared with data. The comparison between responses generated by the model and responses generated by human witnesses provides a means of evaluating the assumptions of the model.

These assumptions are straightforward. First, the model assumes that any event or stimulus may be represented as a vector of features, $f_1, f_2, f_3, \ldots, f_M$. For eyewitness identification, the critical stimulus is the perpetrator of the crime, represented in the model as a vector $\mathbf{P}$. Memory, denoted as a vector $\mathbf{M}$, is an incomplete and error-prone representation of the perpetrator. Specifically, in the model, a given feature of the perpetrator $\mathbf{P}_j$ is stored correctly with probability s and stored incorrectly with probability $1 - s$.

Lineup members are also represented as vectors of features. An important aspect of eyewitness identification generally and the WITNESS model specifically concerns the similarity relationships between lineup members (denoted by vectors $\mathbf{L}_1, \mathbf{L}_2, \mathbf{L}_3, \ldots, \mathbf{L}_N$), the perpetrator ($\mathbf{P}$), and the witness's memory of the perpetrator ($\mathbf{M}$).

According to the model, when the lineup is presented, the witness compares each lineup member with his or her memory of the perpetrator. The result of this comparison process is a number of match values, each one indicating the similarity between lineup member ($\mathbf{L}_i$) and the witness's memory ($\mathbf{M}$) of the perpetrator, denoted $m(\mathbf{L}_i, \mathbf{M})$. Thus, for a six-person lineup, there will be six match values.

Of course, these match values do not specify the decision that the witness will make. The witness must apply a decision rule that considers the match values

so as to make a decision. In the WITNESS model, the decision to make an identification is based on the best match and the next best match. Specifically, the evidence in favor of identifying the best match is given by a weighted combination of the value of the best match and the difference between the best match and the next best match. This is illustrated below as

$$EV_{ID} = w_b(\text{BEST}) + w_{b-n}(\text{BEST} - \text{NEXT}),$$

where BEST is the value of the best-matching lineup member and BEST − NEXT is the difference between the best-matching and the next best-matching lineup member. Thus, a person may be identified if he or she is a very good match to memory or if he or she is a much better match than anyone else in the lineup. These two ways of making an identification are similar to the distinction between absolute versus relative judgments made by Gary Wells in 1984. The degree to which the identification is based on absolute versus relative judgments depends on the values of the weights w_b and w_{b-n} (where w_b and w_{b-n} must sum to 1.0). A high value of w_b is consistent with an absolute judgment, whereas a high value of w_{b-n} is consistent with a relative judgment. According to the model, the witness makes an identification if EV_{ID} is above a criterion c and makes no identification if EV_{ID} is below c.

Applications of the WITNESS Model

In fitting the WITNESS model (or any model) to data, the model's parameters are free to vary. Of course, the parameters should vary in ways that are sensible. A few examples of how the model's parameters vary with experimental manipulations are illustrated below.

Observation and Memory

The changes in the conditions of observation and memory are produced in the model by variation in the storage parameter *s*. The value of *s* will be higher to the extent that the witness has a better opportunity to view the perpetrator, and the delay between the crime and the presentation of the lineup is shorter. Thus, values of *s* reflect both the failure to store information in memory at the time of the observation and the failure to retain that information over time. When there is less accurate information about the perpetrator in memory, the match values become noisy and converge, making it less likely that the witness will correctly identify the perpetrator and more likely that the witness will identify an innocent person. Any factor that affects the storage or loss of information in memory would be modeled in terms of lower values of *s,* including shorter exposure durations, longer retention intervals, high levels of stress and fear, and distraction due to weapon focus effects.

Lineup Composition

Police officers usually select foils (innocent persons in a lineup) based on their similarity to the suspect in the lineup. In the model, the critical parameter is $S(F, S)$—that is, the similarity between the foils and the suspect. Specifically, $S(F, S)$ is the proportion of features shared by both the suspect and the foil. The suspect should be more likely to be identified when $S(F, S)$ is low and less likely to be identified when $S(F, S)$ is high. In the extreme, the model predicts that if $S(F, S)$ is very low, the suspect may be very likely to be identified, whether he or she is guilty or not.

Lineup Instructions

Because the suspect may be innocent, it is important to instruct the witness that the true perpetrator may or may not be in the lineup and that the witness is not obligated to make an identification. These instructions are called *unbiased* because they are unbiased with respect to the guilt or innocence of the suspect. A *biased* instruction implies or explicitly states that the perpetrator *is* in the lineup and that it is for the witness to identify him or her (disallowing a "None of the above" response). It is not surprising that biased instructions result in a higher identification rate, irrespective of whether the suspect is guilty or innocent. The problem, of course, is that as the identification rate increases (without any change in the accuracy of memory), the likelihood that an innocent person will be misidentified also increases.

One way to model the effect of instructions is to lower the value of c (the decision criterion) for biased instructions and raise it for unbiased instructions. However, it is not the only way to model instruction effects. One could assume that biased instructions result in changes in the weights. For example, the biased instructions could have their effect by inducing witnesses to make identifications even if the best match is not that high, provided that he or she is a better match than anyone else in the lineup. In the model, this shift would be instantiated as a decrease in w_b and an increase in w_{b-n}.

The Importance of Mathematical Models

Why is it important to develop mathematical models for eyewitness identification? Mathematical and computational models can be particularly useful when the behavior of interest arises from the confluence of many complex, underlying processes. Eyewitness identification decisions certainly fit that description. For example, a witness's identification accuracy may change with the passage of time, not only because information is lost from memory but also because the witness may make adjustments in his or her decision processes (e.g., lowering the decision criterion as match values drop due to the loss of information over time).

Also, models provide a way of evaluating ideas within a common framework. As noted earlier, when a witness is given biased instructions, the change in the witness's willingness to make an identification could be due to a change in decision criterion or a change in the balance of absolute and relative information used to make the decision. Competing explanations can be compared within the model to see which explanation gives the best account of the experimental results.

Models such as the WITNESS model can lead to new discoveries and new ideas and can challenge well-accepted views. Such models generate quantitative predictions that can be compared with data, allowing precise specification, clear predictions, and straightforward evaluation of the model. When models are compared in this way, theories that seem intuitively plausible sometimes fail quite badly and theories that seem intuitively wrong sometimes fit data quite well.

Witness Preparation

The term *witness preparation* refers to any type of advice or training given to someone who is going to give sworn testimony with the intention of helping improve the quality of their testimony. All persons who might testify in court are potential candidates for witness preparation, including civil and criminal case defendants, plaintiffs, victims, experts, eyewitnesses, and other lay witnesses. Witness preparation may be used to prepare witnesses to testify during trial, but it is also used to prepare them to testify in pretrial depositions and hearings. Witness preparation is carried out by attorneys in most cases, but psychologists, communication specialists, acting coaches, and other consultants assist attorneys in preparing witnesses in some cases—especially high-profile cases.

The two main goals of witness preparation are to educate witnesses about the testimony process and to improve their communication skills. Whether carried out by attorneys, psychologists, or other consultants, witness preparation can be thought of as a behavioral intervention designed to improve communication skills and foster an appropriate level of confidence about testifying. This entry provides an overview of the techniques used to prepare witnesses to testify in court and a summary of the small, but generally supportive research literature examining its use.

Witness Education

Most people who undergo witness preparation training are novice witnesses who have little or no experience testifying. Sometimes, these witnesses know little about the nature and process of courtroom testimony, such as where they will sit in the courtroom, who will ask them questions, and what the questions will be like. These circumstances often contribute to feelings of anxiety and fear in novice witnesses. Research suggests that one way to reduce witnesses' feelings of anxiety about testifying is to educate them about the testimony process by having them participate in a testimony simulation. A testimony simulation can also be

thought of as a testimony rehearsal or a dry run. In a testimony simulation, the witness responds to the types of direct and cross-examination questioning that their attorney expects them to experience in the courtroom. Ideally, the direct examination questioning in the testimony simulation is conducted by the attorney who will question the witness in court, while an unfamiliar attorney conducts the cross-examination testimony.

Although many witnesses are apprehensive about testifying and unsure about how well they will be able to testify, some witnesses are extremely eager to testify and overly confident about how likely jurors are to believe their testimony. In these instances, witness education can be used to induce a realistic amount of anxiety in the witness. For example, some criminal defendants want to testify in their defense because they feel that they can simply explain or argue away all the evidence that the prosecution has amassed against them. These defendants see testimony as an opportunity to tell their story, the way they see it, and tend to argue and become defensive in response to challenging cross-examination questions. Testimony simulations can be used with overconfident witnesses to provide a realistic example of what it is like to be cross-examined and to show them that their "I'm right, you're wrong" approach to testifying is not likely to be persuasive in the courtroom.

Testimony Delivery Skills

Testimony delivery skills are the verbal and nonverbal behaviors that witnesses use to create a desired impression on those observing their testimony, including jurors, judges, and attorneys. Although the type of impression that an attorney wants a witness to create can vary considerably from witness to witness, ranging from confident and in control (e.g., a falsely accused executive) to indignant and upset (e.g., a sexual harassment victim who has been persecuted for coming forward), all attorneys want their witnesses to appear honest and to be believed. Most testimony delivery skills are intended to help witnesses appear honest and believable.

Critics of witness preparation may ask why honest witnesses need to be taught to appear honest. Nearly, all cases that go to trial or come close to going to trial involve multiple versions of the same event or set of events. Witnesses disagree about what happened, who did what, when they did it, and why. When this happens in the courtroom, jurors, judges, and other decision makers must decide which witnesses to believe. Unfortunately, people are not very accurate at telling when other people are being honest and when they are being deceitful. Indeed, years of research has shown that most laypeople have no better than chance accuracy at detecting deception. One reason why most people are inaccurate lie detectors is that they base their inferences about deceitfulness on behaviors that are not clearly associated with lying. The most common layperson beliefs about deceitfulness are that liars fidget, shift their posture, make poor eye contact, stammer, and frequently say "uh" and "um." None of these behaviors are consistent indicators of lying, although they are all signs of nervousness. Honest witnesses who show these and other signs of nervousness while testifying are at a risk of being seen as deceitful simply because they are nervous, flustered, or uneasy. There are many reasons why honest witnesses appear nervous while testifying, and witness preparation is used to help honest but nervous witnesses avoid looking like liars in the eyes of jurors.

The most important testimony delivery skill for witnesses to master is to be completely honest. Witnesses who attempt to present only selected pieces of the story often get called on the incompleteness of their answers and end up facing the types of aggressive and challenging cross-examination questions from opposing attorneys that tend to elicit behavioral signs of nervousness. Moreover, witnesses who are caught being less than 100% forthcoming in one area of their testimony will likely have all their testimony seen as dishonest, regardless of the quality of their other testimony delivery skills. One witness preparation technique that is used to help witnesses avoid appearing deceitful in their testimony is to have them review all previous statements, testimony (e.g., deposition, pretrial hearing), and other case material related to the case. Witnesses often give statements and deposition testimony many months or even years before trial, and reviewing this material allows witnesses to be completely consistent in their story. The merit of this technique is based on the assumption that the witnesses were completely honest in their previous statements and testimony. Although there is a risk that reviewing earlier statements and testimony can create a false sense of confidence or accuracy in witnesses, being uncertain about the content of previous testimony makes honest witnesses vulnerable to appearing unreliable simply because they do not remember relatively minor details of their previous statements.

Other testimony delivery skills that are emphasized by attorneys and consultants during witness preparation training are to listen carefully to the question being asked and to respond only to the content of that question. Witnesses should understand that the attorney will ask another question if he or she wants more information. Witnesses should also be comfortable with saying, "No" and "I don't know" when those are appropriate answers, and they should not guess or provide an answer simply because an attorney repeatedly asks for the same piece of information. Thus, witnesses should avoid using phrases such as "I think" or "I guess." Witnesses should also avoid using rehearsed statements or answers because they appear unnatural and witnesses may become so whetted to rehearsed statements that they rely on them throughout their testimony and repeat the same statements in response to many different types of questions.

Witness preparation is also used to teach a number of nonverbal communication skills. Witnesses are taught to make eye contact with attorneys and jurors, maintain good posture, and avoid looking at the attorneys who called them when asked a difficult question by opposing counsel. Witnesses are also instructed to speak clearly and to avoid speaking too quickly or too softly. Witnesses are encouraged to be expressive and comfortable with showing genuine levels of emotion; however, they are also taught to avoid overly dramatic emotional displays and signs of anger and defensiveness.

Witness Preparation Training Techniques

The most common witness preparation training regimen involves an iterative process of instruction and testimony simulation. The first step in the training process is to instruct witnesses about the basic format of courtroom testimony, such as the difference between direct and cross-examination. At this stage, witnesses are also given basic advice about giving effective testimony, such as being honest, listening carefully to the questions that are asked, and responding only to the questions that are being asked. The next step in the preparation process is to have the witness participate in a testimony simulation, undergoing both direct and cross-examination questioning. Additional instructions for improving the quality of testimony are then made by the attorney or consultant, based on the witness's performance during the simulation. Some attorneys and consultants prefer to make recommendations during the testimony simulation, while others prefer to wait until the testimony simulation is completed. If needed, a second testimony simulation can then be used to evaluate how well the witness was able to follow the most recent set of recommendations.

Some consultants videotape testimony simulations and use the recordings to show witnesses the strengths and weaknesses of their testimony. However, some attorneys prefer to avoid videotaping testimony simulations because there is always a chance that videotaped material may become discoverable to opposing attorneys. Although attorneys can argue that videotapes such as these should be protected as an attorney work product, especially when the witness is their client, many prefer to avoid the risk of creating discoverable material and do not allow videotaping of the testimony simulations.

Does Witness Preparation Work?

Witness preparation research is relatively uncommon, with only four published witness preparation studies in existence. Two of these studies examined the efficacy of relatively brief (15 minutes) witness preparation training programs that were designed to inform eyewitnesses about the purpose of direct and cross-examination and to encourage them to think about how they would answer specific questions that they might be asked when testifying. The participants in both the eyewitness studies were undergraduate research participants. The other two witness preparation studies examined a longer training program (1–2 hours) with criminal defendants. Training in these studies was designed to improve the defendants' use of verbal and nonverbal communication skills by having defendants watch videotapes of their testimony and practice improved communication skills with a researcher playing the role of a defense attorney. One of the criminal defendant studies used volunteer research participants as mock witnesses, and one used real criminal defendants as participants.

Despite variations in methodology, findings from the four existing witness preparation studies converge to provide generally positive support for witness preparation. Witnesses who were prepared to testify were generally seen as more confident, certain, and composed. Prepared witnesses also tended to report being more confident in their testimony, and simply participating in simulated testimony questioning has been found to reduce witness anxiety about testifying.

Coaching and Unethical Training

The term *witness coaching* is often used to denote instructions or training that are unethical or illegal. For example, it is unethical and illegal for attorneys to knowingly encourage witnesses to commit perjury. Although it is clearly improper for an attorney or consultant to instruct a witness to lie, the line between improving testimony quality and changing testimony content is not always clear. Social science research suggests that the content of witnesses' recollections and their confidence in them can be influenced by suggestive questioning, corroborative or contradictory information from others, and continued retelling of their experiences. Thus, the process of witness preparation may inadvertently influence what witnesses have to say when testifying. This potential risk of witness preparation training must be weighed against the potential risk of a truthful witness being seen as dishonest because he or she was not prepared to testify. Ultimately, it is up to ethical attorneys and consultants to ensure that their training techniques are used to allow witnesses to give truthful testimony and not to subtly influence what their witnesses have to say.

Wrongful Conviction

The emergence of forensic DNA analysis in the late 1980s has enhanced the criminal justice system's ability to find the truth. In addition to facilitating the identification and conviction of the guilty, the DNA testing has also exposed a large and growing number of cases in which innocent people were convicted of crimes they did not commit. For the first time, the criminal justice system now has a body of cases in which there is scientific proof that the truth-finding mechanisms of the system failed. Jump-started by the DNA cases, recognition of wrongful convictions has expanded to include cases without any DNA as well. The study of these wrongful convictions has revealed numerous causes of errors related to the way evidence is collected and cases are tried. A commonality shared by almost all the wrongful conviction cases is the presence of a variety of cognitive distortions or biases that can lead investigators, litigators, judges, and juries astray.

Scope of the Problem

The American criminal justice system has historically prided itself on taking great precautions to guard against wrongly convicting the innocent. The American courts and commentators have long espoused a philosophy of caution, expressed in the maxim that it is better to let 10 (or 100) guilty people go free than to convict one innocent person. Nonetheless, there has never been real doubt that the system occasionally errs.

Even prior to the DNA revolution, scholars sought to identify wrongful convictions. In 1932, Edwin Borchard identified what he believed to be 65 wrongful convictions in serious cases. More recently, in 1987 and 1992, Hugo Bedau, Michael Radelet, and Constance Putnam identified more than 400 wrongful convictions in cases potentially subject to capital punishment. These and other similar efforts, however, were subject to challenge by skeptics, who doubted innocence in some of the cases, and even when accepted, the cases were largely dismissed as anomalies rather than symptoms of systemic flaws.

The DNA cases changed this. The DNA cases presented unassailable scientific proof of error. They also demonstrated that errors have occurred not just in those cases where proof of guilt appeared tenuous but also in cases where the evidence of guilt had appeared overwhelming. Moreover, they revealed that wrongful convictions are more prevalent than previously thought and that they reflect systemic flaws.

Determining a precise wrongful conviction rate is very difficult, as it is impossible to identify the whole body of erroneous convictions. To compound the problem, establishing an acceptable definition of "wrongful

conviction" is itself difficult, especially in cases that lack dispositive DNA or other conclusive scientific evidence. Not everyone "wrongly convicted" is actually or completely innocent. Rather, some individuals who are released from their convictions because of procedural errors or inadequate evidence to prove their guilt—and who are thus *legally* innocent—might nonetheless be *factually* guilty. And though they are legally innocent, they may not be *completely* innocent since, for example, they may be guilty of a lesser charge. Distinguishing between these categories can be challenging.

In recent years, however, new evidence has identified a significant number of individuals who were in fact completely innocent but were nonetheless convicted. Between 1989 (the year of the first DNA exoneration in the United States) and 2006, at least 189 people who had been convicted of serious crimes in America were exonerated by postconviction DNA testing. Although significant, this number reflects just the tip of what is certainly a much larger iceberg. As important as DNA can be, it is present in only a small percentage of all criminal cases, and it is preserved and available for postconviction analysis in just a fraction of that total. Hence, the DNA exonerations reveal only a small percentage of all wrongful convictions.

Examining media and other published accounts of cases, Samuel Gross and colleagues have identified 340 cases of proven wrongful convictions in serious felonies between 1989 and 2003. In each case, the wrongful conviction was established by an official governmental act finding the person not guilty through one of several procedures: dismissal of the case by the prosecution or court in light of new evidence of innocence, an acquittal after a retrial, or a pardon based on innocence. As Gross notes, even this group is substantially underinclusive, because it relies on the happenstance that the defendant was able to discover convincing new evidence of innocence and the chance that the researchers found the case to include it in the study.

Looking at the one group of cases for which there exist fairly reliable data on proven exoneration *rates*—capital rape-murders—Michael Risinger has developed what might be the most empirically sound estimate of a wrongful conviction rate. Risinger calculates an error rate in capital rape-murders of approximately 3.3% to 5%.

Causes of Wrongful Convictions

Examining these wrongful convictions has revealed several recurring causes of factual error in criminal cases. The causes include, among others, eyewitness error, false confessions, unreliable jailhouse snitch or informer testimony, witness perjury, faulty forensic science, police misconduct, prosecutorial misconduct, and ineffective defense counsel.

Among these, eyewitness error is by far the most prevalent, occurring in anywhere from approximately 60% to 84% of the exoneration cases. Eyewitness error typically does not involve untruthful witnesses but rather well-meaning, honest witnesses who are simply mistaken about their memory of the perpetrator or the crime. Considerable psychological research has demonstrated the fallibility of eyewitnesses and identified factors that can contribute to eyewitness error. Eyewitness memory is susceptible to contamination and distortion by suggestive police identification procedures or postincident information. For this reason, eyewitness evidence is sometimes analogized to trace physical evidence; as with trace evidence, the fragile nature of the evidence demands care in collecting and storing the evidence. In eyewitness identification cases, care must be taken to minimize suggestiveness and contamination of eyewitness memories.

False confessions are also prominent among the causes of wrongful convictions. Although it is counterintuitive to imagine that an innocent person would confess to a crime he or she did not commit, the wrongful conviction cases demonstrate that false confessions are present in up to nearly one quarter of exoneration cases. High pressure, confrontational police interrogation tactics, such as those included in the Reid Technique of interrogation (which is taught in some form in most police jurisdictions in the United States), which is believed to be effective at eliciting confessions from the guilty, also can induce innocent people to confess. Social science research suggests that under such interrogation tactics, false confessions can be the product of rational choices.

Jailhouse informer or snitch testimony typically involves testimony offered by an individual who was, or claims to have been, incarcerated with the defendant and who claims that the defendant confessed or made incriminating statements to him or her while they were incarcerated together. Courts have long recognized that such witnesses are very unreliable, both because their criminal background suggests that they might have little regard for the truth and because they have an incentive to fabricate. Jailhouse informers often are motivated by explicit or implicit promises, or even unilateral hopes, of leniency or benefits from the

prosecution in their own criminal cases if they provide useful information against another.

Numerous wrongful convictions have also rested, at least in part, on fraudulent or mistaken forensic science. Occasionally, these errors are the product of deliberate fraud. A number of high-profile instances of such fraud have been reported in recent years, in which crime laboratory analysts reported incriminating scientific test results when in fact the analysts either obtained no results, obtained nonincriminating results, or did not even run the tests (a type of fraud referred to as "dry labbing").

More typically, however, laboratory analysts have made honest errors. In some instances, the purported forensic science has itself been fundamentally unreliable and nonscientific. To take one example, microscopic hair comparison, which was a staple of criminal prosecutions for many years, has very little scientific foundation and has now been exposed by DNA analysis as frequently incorrect. Accordingly, many crime laboratories no longer conduct microscopic hair examination.

In other instances, laboratory analysts may be influenced by expectation effects. Research has shown that when laboratory analysts are informed of the results that are expected or about other evidence in a case, this nondomain information can influence the analysts' interpretation of ambiguous data. When told that other evidence includes or excludes a suspect, for example, analysts are more likely than otherwise to conclude that their scientific analyses are consistent with that other information.

Police and prosecutorial misconduct involves overreaching in a variety of contexts. The most common type of prosecutorial misconduct involves failure to comply with the constitutional mandate that prosecutors must disclose to the defense all material exculpatory evidence in their possession. In part, a prosecutor's failure to comply with this mandate reflects the very difficult demands that the adversary system imposes on prosecutors. Since a prosecutor's responsibility to convict the accused naturally encourages him or her to view the evidence in an inculpatory light, it is too much to expect that the same prosecutor would simultaneously view the evidence from the defendant's perspective and recognize its exculpatory value.

Finally, inadequate defense counsel is a frequent cause of wrongful convictions. Indigent legal services are chronically underfunded, and the result frequently is inadequate defense investigation and a lackluster challenge to the state's case at trial. When the defense is inadequate, the adversarial system fails to function as designed to weed out erroneous charges or protect the innocent.

These individual causes of wrongful convictions often work in conjunction with one another to produce a faulty assessment of guilt. A mistaken eyewitness identification, for example, can convince the police of a suspect's guilt. Once convinced of guilt, the police may then set out to develop the evidence needed to obtain a conviction. They might aggressively interrogate the suspect to obtain a confession, producing incriminating statements from the suspect, leading the police and prosecutors to interpret innocent responses in an inculpatory manner, or even inducing the suspect to confess falsely. The police and prosecutors might also seek an unreliable jailhouse informant to bolster their case. Laboratory analysts, informed of the state's theory of guilt, might interpret ambiguous data to support that conclusion. Or the police and prosecutors might otherwise cut corners or bend the rules, in the belief that doing what it takes to convict a guilty person serves the interests of justice. The result of this process is that initial assessments of guilt are reinforced, and the confidence of eyewitnesses, the police, prosecutors, and ultimately courts is bolstered in their judgments about the defendant's guilt.

Cognitive Distortions and Biases

Regardless of the particular errors in a given case, a commonality in most wrongful convictions is the effect of several cognitive distortions or biases in producing a kind of "tunnel vision" that impedes accurate assessment of the facts. The most prominent is confirmation bias—the natural human tendency to seek, interpret, and recall information in ways that support existing expectations, beliefs, or hypotheses. Numerous studies have shown that when testing a hypothesis, people tend to seek information that confirms the hypothesis. In studies, people demonstrate a preference for evidence that will confirm their hypotheses over evidence that will disconfirm them, even though the latter is frequently more probative. By seeking only information that is consistent with their hypotheses, people fail to discover evidence that might disprove their hypotheses and reveal that their confirming evidence was merely coincidental. In a criminal case, this means that investigators tend to look for evidence that is consistent with their theory of guilt but tend not to look for disconfirming evidence—that is, evidence that would exonerate a suspect.

People similarly have a natural tendency to *recall* and *interpret* information in a manner that confirms their beliefs. Research shows a general tendency to overweight positive or confirmatory evidence and underweight negative or disconfirmatory evidence. In criminal cases, this tendency means that investigators and prosecutors are likely to ignore or minimize disconfirming evidence—deeming the evidence irrelevant or the witness unreliable—while overrelying on confirming evidence—interpreting ambiguous data as inculpatory and judging incriminating witnesses and information as highly relevant and reliable.

Compounding these tendencies are phenomena such as belief persistence, also known as belief perseverance. Research shows that people are naturally disinclined to relinquish initial conclusions or beliefs, even when the bases for those initial beliefs are undermined. For example, once convinced of guilt in part because of an initial assessment that crime scene hairs bore microscopic physical characteristics that "matched" a suspect's, investigators or prosecutors in numerous cases have persisted in their belief of guilt even after new DNA testing has proven conclusively that the hairs did not come from the defendant.

Such tunnel vision is also reinforced by other cognitive biases, such as hindsight bias, or the "knew-it-all-along effect." Hindsight bias refers to the tendency that people have to use information obtained after an event to conclude that the eventual outcome was inevitable or more predictable than it actually was. With knowledge of an outcome, people's memories tend to elaborate or emphasize evidence that was consistent with the outcome and minimize or discount evidence that was inconsistent.

In criminal cases, once the police, prosecutors, and courts conclude that an individual is guilty, hindsight bias would suggest that the suspect was an obvious and inevitable suspect from the beginning. In hindsight, evidence against that individual is enhanced. That hindsight assessment in turn reinforces the commitment to focus on that person as the culprit.

Similarly, hindsight bias can affect a witness's assessment of or confidence in his or her identification of a suspect. For example, if an eyewitness had a fleeting glimpse of a perpetrator, that witness likely had a poor image or memory of the perpetrator. But if the witness subsequently viewed clear images of the suspect in a photo spread or live-person lineup and attempted an identification, the witness might replace the poor memory of the perpetrator from the crime with the clear image of the suspect from the photo spread or lineup. Although the identification might be wrong (given that the witness actually had a poor view and memory of the suspect), the witness might in hindsight draw on the clear image from the photo spread or lineup to conclude confidently that he or she had a good view and memory of the suspect and made an accurate identification, especially if the witness received any confirming feedback after making the identification.

Hindsight bias can also have a profound impact on judges called on to review the validity of convictions in postconviction proceedings or on appeal. Typically, such courts are required to assess whether any errors committed by the prosecutor, the court, or defense counsel might have made a difference in the outcome of the case. Hindsight bias makes it naturally difficult for courts to imagine that any error might have affected the outcome. The outcome of the case—the defendant was found guilty beyond a reasonable doubt—tends to appear, in hindsight, to have been inevitable and appropriate. Under these circumstances, it is difficult for courts to conclude that any but the most egregious errors might have made a difference. This, in part, helps explain why courts can be extremely reluctant to reverse convictions, even in the face of strong evidence of error.

Reforms

The increasing awareness in the criminal justice system of the problem of wrongful convictions has also led to an increasing interest in reforms to reduce the rate of such errors. Policymakers are interested in reforms to prevent wrongful convictions, not just because each such case is an injustice to the wrongly convicted but also because every time an innocent person is wrongly convicted, the true perpetrator eludes prosecution. Both basic fairness and public safety demand reliability in the criminal justice system. A variety of official commissions and policy-making bodies have been created in a number of jurisdictions to examine the wrongful conviction cases and develop recommendations for reforms to minimize such errors.

To date, the most progress in implementing reforms designed to minimize wrongful convictions has been made in the areas of eyewitness error and false confessions. In particular, extensive psychological

research has produced a well-developed series of recommendations for improving eyewitness identification procedures. A number of law enforcement agencies throughout the country are now implementing some or all these recommendations.

Some of the more significant eyewitness identification reforms include ensuring that witnesses are properly instructed that the perpetrator might not be present in any given lineup or photo array, so that the witness does not feel compelled to pick someone in every case; properly selecting lineup or photo array "fillers" (nonsuspects) so that the suspect does not stand out; presenting no more than one suspect in any given lineup or photo array; conducting the identification procedure in a "double-blind" manner—meaning that neither the witness nor the detective administering the procedure knows which individual is the suspect—so that the detective cannot even inadvertently cue the witness as to which individual to pick; and presenting photographs of lineup members sequentially, rather than simultaneously, so that the witness must rely on absolute judgments drawn from the witness's memory rather than relative judgments based on comparing one lineup member or photograph with the others.

The most significant reform designed to prevent false confessions is a requirement that all custodial interrogations be electronically recorded from start to finish. Recording serves several purposes. It deters the police from engaging in improper coercive tactics that can produce false confessions. It also creates a clear record of what was said and done, so that lawyers, judges, and juries can more fully and accurately consider the reliability of any statements elicited during an interrogation and indeed help fact finders determine accurately what the suspect said, in his or her own words, without interpretation or paraphrasing by police witnesses. Electronic recording also protects the police from spurious claims of misconduct in the interrogation room and produces powerful evidence to help convict the guilty when a suspect freely and convincingly confesses or incriminates himself in a recording that can be played for the jury.
