SIMULATIONS

In the context of theoretical inquiry, simulations are tools by which theorists examine the consequences of assumptions. In that respect, it is equivalent to logical analysis, which seeks to derive additional propositions from a set of assumptions. Logical analysis, if possible, is always preferable: Consequences asserted as a result of the outcomes of simulations are open to the criticisms that (1) a slightly different instantiation of the assumptions would have produced different results, (2) the outcomes produced are critically dependent on the initial conditions assumed in the model, and (3) the generalizations proposed hold only for the particular space of parameter values examined. Simulations as theoretical tools are quite distinct from simulation put to other purposes such as training or entertainment (e.g., flight simulators).

As a theoretical tool, simulations are typically used for two reasons. First, a proposed model contains probabilistic elements or nonlinear relations among a large set of variables and the overwhelming complexity of possible outcomes makes it impractical or impossible to derive closed-form solutions of key properties. This use of simulations in these circumstances has a long history in social science; for instance, Rapoport in the 1950s used a deck of cards to simulate a link-tracing process on a biased net, a network composed of ties constructed from random and biased forces (1953). The second use of simulations is somewhat more recent, although it has a precursor in Schelling's famous model of segregation (1969). In this arena, agent-based modeling, the nature of the modeling exercise requires that simulations be used to analyze the model's consequences— the aim is to derive complexity at the aggregate level from the interaction of agents following relatively simple rules at the microlevel. Such complexity is "emergent" relative to the lower-level rules of interaction and agent-state change and thus, in principle, not predictable from these rules. Therefore, simulations must be used to detect such emergent regularities. In such a model, there are typically many agents, and often, probabilistic considerations figure in the determination of who interacts with whom and in the determination

of the changes of agent-state change. Logical analysis of such a system is not feasible. The only way to explore consequences is through simulations. Both uses of simulations have been greatly aided by the development of very fast computation easily available on desktop workstations.

A simulations study can be divided into three phases: model setup, model implementation and execution, and inductive analysis of model output. In the model setup phase, decisions must be made about how variables are interconnected or how agents may interact and what rules govern their changes of state. In the implementation and execution phase, the system of agents or variables must be encoded in a computer program and various executions of this program conducted. The output of these executions must then be analyzed for patterns or regularities that can be reasonably attributed to the underlying assumptions about the connections among variables or the behavior constraints on agents encoded in the program. Care must be exercised to avoid the attribution of substantive meaning to regularities that are artifacts of the program implementation. In the best of all possible worlds, the simulation study is convincing because (1) the assumptions about behavior or variable connection are clear and intuitively reasonable or based clearly on existing theory, (2) the program implementation is transparent, (3) a full range of initial conditions and values of basic parameters is explored, and (4) clear regularities emerge and variation in these regularities can be interpretively explained in terms of the model's original assumptions.

Simulations have been called a third way of doing science (Axelrod 1997) because research using simulations has features of both deduction and induction. As does deduction, simulations require that research start with an explicit set of assumptions but no theorems are proved; rather, the output of systematic executions of the algorithmic implementation of these assumptions are then inductively analyzed for patterns and regularities. Unlike induction, however, the data analyzed are not generated by empirical measurements. This third way of doing social science, termed "generative social science" by Epstein and Axtell (1996), relies on the more recent type of simulations, agent-based modeling. Such models have a number of common features. Attention focuses on systems consisting of multiple agents and the emergence of system regularities from local interactions among agents. Agents have internal states and behavioral rules, and the rules may be fixed or changeable through experience and interaction. Agents are boundedly rational; they have only limited information-processing and computational capacity. Agents interact in an environment that provides resources for their actions. Typically, agents and the rules they use thrive or die based on their success in obtaining resources. Agent-based models are the paramount tools for "generative social science," social science in which the key research imperative is to explore what microspecifications of agents and their interaction protocols are sufficient to generate macrophenomenon of interest. The macrophenomena explored cover a wide range: the polarization of attitudes, the articulation of political structures, global performance of organizations, cooperation in social dilemmas by strangers, retirement behavior and social networks, historical change in primitive societies, and labor markets, to name but a few.

SITUATIONISTS

Situationists are members of the Situationist International (SI) (1957–1972), a European avant-garde art movement whose embrace of radical politics gave them a significant role in the student uprisings of the late 1960s. Initially, a breakaway group of the Lettrist International, the SI sought to create "situations," moments of radical disruption in which the possibilities of a different society more attuned to "real" desires, might be envisaged or temporarily realised. Members of the group included Dutch architect Constant Nieuenhuys, a cofounder of the Amsterdam Provos and the painter Asger Jorn; Italian painter Pinot Gallizio; in the United Kingdom, Donald Nicholson-Smith, the poet Alexander Trocchi and art historian T. J. Clark; and in France, utopian architect Ivan Chtcheglov (Gilles Ivain), Michèle Bernstein, Raoul Vaneigem, and Guy Debord. Also associated with the movement (but after its official demise) were "punk" activists, including Sex Pistols manager Malcolm MacLaren, fashion designer Vivienne Westwood, and graphic designer Jamie Reid.

Among techniques developed to explore the possibility of creating new situations were the theory of "unitary

urbanism," which sought to unearth complementary and transforming moments of city life, the *dérive,* a narrative walk or simultaneous walks through the urban environment (sometimes connected by walkie-talkie) designed to stimulate an awareness of the utopian potential available in the built environment, especially its more forgotten corners, and "psychogeography," at once a practice, similar to the *dérive,* aimed at defining the emotional tenor of specific areas and an architectural intervention in urban development aimed at creating previously unheard of new environmental emotions. The ludic influence of Johan Huizinga's theories of play in *Homo Ludens* and the critical urban studies of Lewis Mumford is visible in many of these activities. In all of them, the contrast is drawn between the abstract space of representation, including sociological representation, and the gritty reality of city streets. Abstraction is seen as the intellectual equivalent of the homogenisation of space brought about by the ascent of the commodity to the status of spectacle, pure sign. Similarly, the situationists were concerned to distinguish their *dérive* from the random wanderings of the surrealists, criticising both the class-specific aristocracy of an irresponsible enjoyment and the surrealist concept of chance as a last bastion of freedom. Rather, they recognised the role of planning in urban geography and sought tactics for changing the ways in which the planned and administered environment might be inhabited.

In the late 1950s and early 1960s, the group's interest in practical experiment gave way to a more theoretical and intensely negative assessment of consumer capitalism, a theme captured in the phrase "the colonisation of everyday life" borrowed from Henri Lefebvre, for a time an associate of the SI. The last remaining element of the art practice was *détournement,* the practice of reorienting advertisements, political slogans, and media catchphrases for revolutionary or simply ironic purposes. Much of their art in this period is therefore also sociologically critical of the circumstances of both the art and the society in which they found themsleves. Such was Gallizio's semiautomated industrial painting, sold by the metre, as ironic comment on the commodification of painting and of the self-expression that it was understood to communicate. In a related gesture, Debord's film *Hurlements en faveur de Sade* (*Howlings in Favor of de Sade,* 1952) contains a 24-minute passage of darkness and silence intended to destroy the possibility not only of vision but of the spectacularisation of the self, otherwise unavoidable in the society of the spectacle. This sequence might also be taken to illustrate the situationist thesis that the spectacle makes visible the simultaneous presence and absence of the world that is typical of the world of the commodity in general and of the spectacle of the commodity in consumerism in particular. In this way, Debord's film is a *détournement* of the cinema apparatus. In a postsituationist example, Debord photographed reporters following him after he was implicated

in a society murder, thus denying journalism its claim to truth through anonymity.

From its vanguard beginnings, the SI devoted itself to a root-and-branch critique of the art world that rapidly expanded to embrace the conditions of society as a whole. By the mid-1960s, the group was devoted to a wholesale critique of the Communist and Socialist parties, not simply as betrayers of the working class but as fellow travelers of the society of the spectacle, the integration of representational politics with the consumption of commodities reduced to signs. For many of the group, the analysis of an alienated and fragmented society was material for a hedonistic practice of anarchist pleasure seeking, developed in the case of Raoul Vaneigem into a political platform directed specifically at students and widely disseminated in France during May 1968. For others, the route led toward anarchism and to armed struggle—for example, Mustapha Khayati, who left the SI to join the PLO. Like the surrealists, the situationists embraced the criminal underworld, invoking a *détournement* of the language of social organization into a lexicon of gangs, rackets, and protection.

While the more hyperbolic and sloganeering work published in the name of the SI was devoted to internal strife, to quarrels with rival factions, and to interventions in long-forgotten local campaigns, much of it offered intelligent critique. Science is pilloried for its autonomy from daily life and for the hypocrisy of its claim to serve humanity in a period of vastly expensive projects like the space race. The fragmentation of knowledge into isolated disciplines incapable of a total critique of a total and totalitarian society was a pale imitation of that autonomy. Praising the Paris Commune and the revolutionary anarchism of Barcelona in the Spanish Civil War as models for the self-organization of workers' struggles, the SI advocated the power of riot as both festival and revolution. Professionalized trades unions were accused of a Stalinist triumph of dictatorship by bureaucracy, and the claim was made that the Cold War hid the deep similarities in workers' oppression on either side of the Iron Curtain. The conscious domination of history by the people who make it was to be the core revolutionary project, since without the conquest of history, the proletariat was doomed only to inherit the tawdry wealth of the spectacular commodity—as was the case under reformist governments like the British Labour Party of the mid-1960s. In an influential pamphlet of November 1966 addressed to "The Poverty of Student Life," students were accused of complicity in their own bureaucratization, in the fragmentation of knowledge, and in submission to the disciplines of power. Against these were raised, especially by Vaneigem, the possibility of living according only to one's desires.

In the major works of the SI, Debord's *La Société du spectacle* (*The Society of the Spectacle*) and Vaneigem's

Traité de savoir-vivre à l'usage des jeunes générations, both of 1967, the central preoccupation is with the degradation of everyday life. For Vaneigem, whether cloaked in religion or the false glamour of spectacular consumer goods, the poverty of daily life was based in humiliation and reification, shame for desiring otherwise than permitted, and the objectification of humanity. This objectification leads directly to isolation, while the society of the spectacle provides only an illusion of community and nationhood. Social organization is then only the distribution of constraints, including the production of isolation and alienation, and as such is deeply contradictory, leading either toward despair, apathy, and at least a moral and intellectual suicide or toward the erruption of a spontaneous revolutiuonary revulsion with the cheapness of the world on offer.

The situationists developed a high art of invective, as often as not employed against one another during the series of expulsions and splits that characterised the history of the movement. Such splits were rationalized as the necessary radicalism of a revolutionary theory that rejected as spectacular ideology any attempt to represent the working class. A revolutionary organisation was held to require absolute separation from the "world of separation" characteristic of the division of art from politics and both from life. Such radical negation required in turn a readiness to negate itself, a task to which the Situationist International turned in 1972.

SMELSER, NEIL

Future historians will write about Neil Smelser (b. 1930) as an iconic figure in twentieth-century sociology's second half. Smelser has had an extraordinarily active career, not only as scholar but as teacher and organizational leader. His impressive and varied performances as organizational leader are perhaps less well known, but they speak equally clearly of scholarly power exercised in a more political manner. His roles have included adviser to a string of University of California chancellors and presidents; referee of the nation's most significant scientific training and funding programs, from NSF (National Science Foundation) to the departments of leading universities; organizer of the *Handbook of Sociology* and the *International Encyclopedia of the Social and Behavioral Sciences;* and director of the Center for Advanced Study in the Behavioral Sciences.

In many respects, both Neil Smelser and the social sciences matured together in the last half of the last century. Smelser expanded his areas of research to include sociology, psychology, economics, and history, at the same time that newly synthetic cross-disciplinary programs, area studies, and applied programs appeared. Through his work with commissions and foundations and as a spokesperson for the social sciences, he sought a greater public role for sociology, and helped to foster the gradual infiltration of their findings and methods into other disciplines, practical settings, and popular culture. Smelser's early interest in comparative international studies anticipated their expansion, an increase in international collaboration, and greater awareness of globalization issues. His move from optimism about positivist approaches and functionalism in the 1950s, to a more guarded optimism and plurivocality today has paralleled broader doubts within the academy and greater tolerance for other ways of knowing.

There is one fundamental respect, however, in which Smelser has broken with dominant trends. The last one-third of the twentieth century was marked by increasing fragmentation and seemingly endless specialization. It was an age of centrifugal conceptual forces and centripetal methodological rigor. These post-1960s intellectual developments have unfolded against a background of ideological jeremiads, the continuous reference to social crisis, and alternations between elegies and eulogies to revolutionary social change. Through all this, Smelser has continued to uphold generality and synthesis as worthy scientific goals. He has maintained his intellectual commitment to uniting divergent disciplinary perspectives and even expanded significantly his own disciplinary reach. He has become ever more dedicated to bridging various conceptual and methodological divides. He has also maintained a quiet and impressive serenity about the continuing possibility for progressive social reform and democratic political change.

Neil Smelser's active life as theorist and researcher has spanned more than 50 years. In 1962, at the age of 32, he became editor of the *American Sociological Review,* the most influential editorial position in the discipline. Almost 35 years later, in 1996, he was elected president of the American Sociological Association, in recognition not only of his lifetime achievement but of the influence, both

scientific and organizational, that he continued to wield over those decades.

Smelser began his public life as a *Wunderkind.* Having barely settled into Oxford as a Rhodes Scholar in 1952, he was tapped by Talcott Parsons, his Harvard mentor, to advise him about preparing for the Marshall lectures at Cambridge. Parsons wanted to demonstrate that his newly developed AGIL theory could handle economics. (AGIL refers to the four "pattern variables" in Parsons's theory of social action. In particular, they refer to: A = adaptation; G = goal attainment; I = integration; L = pattern maintenance, later changed to Latency.) Yet he had stopped reading in that discipline before Keynes' *General Theory.* Smelser was *au courrant* with the Keynesian revolution and AGIL besides.

During their collaboration, it was actually Smelser, not Parsons, who suggested the scheme of double interchanges that allowed AGIL to be applied to social systems. This brilliant conceptual innovation formed the core of their jointly written book, *Economy and Society* (1956), which accomplished what its subtitle promised: an integration of economic and social theory. Along with Smelser's later work, especially *The Sociology of Economic Life* (1963), *Economy and Society* laid the foundations for the new field of economic sociology that has become so central to the discipline today. Only three years later, Smelser published the extraordinarily innovative and deeply researched book *Social Change in the Industrial Revolution: An Application of Theory to the British Cotton Industry* (1959), and only three years after that he brought out the equally pathbreaking *Theory of Collective Behavior* (1962).

While Smelser gained great distinction for this rush of early work, he also aroused great controversy. It was high noon for the functionalist paradigm. Smelser was its crown prince and its clear leader in waiting. His work was not only systematic, original, and erudite but intellectually provocative and aggressive. It brimmed with great ambition and utter self-confidence, and it seemed to suggest that, with the emergence of action theory, the solution to sociology's struggles had arrived. Revealingly, the second chapter of *Social Change in the Industrial Revolution* was titled "Some Empty Boxes," and the chapter that followed was titled, "Filling the Boxes." In *Theory of Collective Behavior,* Smelser began with the pronouncement that "even though many thinkers in this field attempt to be objective," they had not succeeded. Because of their failure, "the language of the field . . . shrouds its very subject in indeterminacy" (p. 1). The aim of his study, he proclaimed, would be to "reduce this residue of indeterminacy" by "assembling a number of categories" so that "a kind of 'map' or 'flow chart'" could be constructed of the "paths along which social action moves" (p. 1). While strongly assertive, his goal appropriately was to *reduce,* not eliminate, the residue of indeterminacy.

The youthful Neil Smelser did, in fact, succeed in filling his boxes, forever broadening our view of the industrial revolution as a multidimensional social process—political, economic, familial, cultural, scientific, and very much contingent, all at the same time. He also managed to create an utterly new and fascinating conceptual social map, one that simultaneously separated and intertwined the different dimensions of collective behavior, social structure, and social movements in a value-added manner never before achieved. What he could not do, however, was ensure the continuing sovereignty of functionalist theory. In the history of social science, much more than conceptual precision and explanatory power is involved. Every powerful approach tends to overreach and is partial and to a degree situationally conditioned.

Thirty years after his unabashed and triumphal entrance on the sociological scene, Neil Smelser penned a "concluding note" to his penetrating essay on "The Psychoanalytic Mode of Inquiry" (in *The Social Edges of Psychoanalysis*, 1998). He warned his readers to be careful of their imperialist urge. Was he not looking back with rueful reflection on the grand ambitions and urgent polemics of those early years?

Whenever a truly novel and revolutionary method of generating new knowledge about the human condition is generated—and the psychoanalytic method was one of those—there emerges, as a concomitant tendency, something of an imperialist urge: to turn this method to the understanding of everything in the world—its institutions, its peoples, its history, and its cultures. This happened to the Marxian approach (there is a Marxist explanation of everything), to the sociological approach generally (there is a sociology of everything), and to the psychoanalytic approach (there is a psychoanalytic interpretation of everything) (Smelser 1998a:246).

In the halcyon days of the Parsonian revolution, there had always been a functionalist approach to everything—although few, if any, could rival the power and insight generated by the approaches developed by Smelser himself.

By the late 1960s, the functionalist approach had stalled. Attacked as ideologically conservative, accused of every imaginable scientific inadequacy, functionalism eventually lost its position of dominance. Yet Smelser's postfunctionalist career has also been an extraordinary one. He did not blame the enemies of functionalism for his tradition's weakening. Instead, he targeted the nature of Parsonian thinking itself. He engaged in implicit self-criticism. This required courage and maturity.

Smelser accused foundational functionalism of hubris, of overreaching conceptually, and underreaching empirically. He dressed it down for being one-sided and polemical. After making those observations on the imperialism of every "truly novel and revolutionary method" noted above, Smelser's later reflections continue with the suggestion that

"it is always legitimate to ask about the relative *explanatory* power of the method in settings and circumstances in which it was not invented." Only on the basis of such further reflection will it be possible to be objective about "what are the emergent strengths *and weaknesses* of the method" (Smelser 1998a:246, italics added).

It was just such a commitment to the task of explanation, over and above the allegiance to any particular theory, that allowed Smelser not just to stay afloat but to flourish after the functionalist ship sank. When Parsons published his first collection of articles, in 1949, he called them *Essays in Sociological Theory.* When, two decades later, Smelser published his own, he called them *Essays in Sociological Explanation* (1968). His ambitions were tied to the scientific goals of discipline, not to any particular approach.

In 1997, in his presidential address to the ASA, Smelser developed what has already become the most influential essay of his later career. In "The Rational and the Ambivalent in the Social Sciences," (in *The Social Edges of Psychoanalysis,* 1998), he developed an argument that exposed one-sided intellectual polemics as a simplistic defense against the ambivalence that marks human life. "Because ambivalence is such a *powerful, persistent, unresolvable, volatile, generalizable,* and *anxiety-provoking* feature of the human condition," Smelser suggested, "people defend against experiencing it in many ways." For intellectual life, the "most pernicious" of these defenses is splitting, which involves "transferring the positive side of the ambivalence into an unqualified love of one person or object, and the negative side into an unqualified hatred of another" (1998:176–77, original italics). Smelser went on to directly apply this critical observation to sociology itself. Admonishing his colleagues that "in our search for application of the idea of ambivalence, we would do well to look in our own sociological backyard," he observed that "there is almost no facet of our existence as sociologists about which we do not show ambivalence and its derivative, dividing into groups or quasi-groups of advocacy and counteradvocacy" (p. 184).

In his third major historical-cum-theoretical monograph, *Social Paralysis and Social Change: British Working-Class Education in the Nineteenth Century* (1991), Smelser demonstrated how this advice generalized from the path that he had now chosen for himself. Rather than declaring all preceding theoretical boxes empty and announcing that he would now proceed to fill them in, his new approach made carefully circumscribed criticisms. It proposed a theoretical model based on reconciliation and synthesis. After reviewing Whiggish, functionalist, Marxist, and status group approaches to the history of British working-class education, Smelser suggests that each must be "criticized as incomplete, limited, incapable of answering certain problems, and perhaps even incompatible with the others." The alternative, he writes, is "to develop a perspective that is

synthetic," that "incorporates insights from approaches known to have usefulness" (Smelser 1991:16–18).

From his first, vivid entry into the field of intellectual combat, Neil Smelser exhibited one of the most lucid and coherent minds that ever set sociological pen to paper. As his career continued to develop, he revealed another distinctive capacity: He became one of the most incorporative and inclusive of thinkers as well. In fact, we would suggest, it has been Smelser's penchant for combining opposites— the acceptance of sociological ambivalence without fear or favor—that has perhaps most distinctively marked his intellectual career.

He is one of the most abstract of theorists, yet he became an acknowledged "area specialist" in British history.

He is a grand theorist, but he employed grand theory exclusively to develop explanations at the middle range.

He is a functionalist, but he devoted his theoretical and empirical attention almost entirely to conflict.

He is a liberal advocate of institutional flexibility, but he has written primarily about social paralysis and the blockages to social change (see Smelser 1974). He is a psychoanalyst who has highlighted the role of affect, but his major contributions have attacked psychologistic theorizing and explained how to fold the emotional into more sociological levels of explanation (e.g., Smelser 1998a, 2002; Smelser and Wallerstein 1998).

He is a trained economist, but he has strenuously avoided economism, and he is a persistent student of economic life who has demonstrated how it is thoroughly imbedded in noneconomic institutions (e.g., 1968). He is a systems theorist who devoted his final historical monograph to exploring the unbending primordiality of class.

He is a close student of social values (e.g., Smelser 1998a) who rejects any possibility of purely cultural explanations.

He is a theorist of social structure who eschews any form of structural determinism (1968, 1997:28–48).

He was a protégé of Talcott Parsons whom Parsons's sworn enemy, George Homans, publicly singled out for distinct praise.

By avoiding the defense against ambivalence, Smelser demonstrated a remarkable ability to take the sword from the hands of those who would destroy him. He showed how Marx and Engels could be viewed as conflict-oriented functionalist theorists (see "Introduction" to *Karl Marx and on Society and Social Change*, 1973). He made the gendered division of family labor an independent variable in social change (see *Social Change in the Industrial Revolution,* 1959), decades

before many feminist theorists made arguments along these same lines. He borrowed from Tocqueville the idea of intranscient "estates" (Smelser 1974) to explain that functional positions in the educational division of labor could be understood as status groups seeking the protection of their own power. He used the idea of "truce situations," an idea that John Rex (1961) had introduced as the antithesis to functionalist consensus theory, to explain why the social differentiation, at the heart of functionalist change theory, developed in a back and forth, stuttering motion rather than in a smooth and unfolding way. He explained (Smelser 1998b) how the differentiation between instrumental and expressive activities actually had been continued, not overturned, by the feminist revolution, and how this often corrosive process of social and cultural rationalization could explain the emergence of the new kinds of child-caring institutions and the increasingly difficult and negotiated character of socialization from childhood to adulthood.

Behind these specific and intellectual innovations, two overarching metathemes have animated Neil Smelser's contributions to sociology. First, there is the insistence that social reality must be parsed into relatively autonomous analytic levels that, in empirical terms, are concretely interconnected. As he wrote (1997) in his intriguing, and continuously instructive Berlin lectures, *Problematics of Sociology,* "Even though the micro, meso, macro, and global levels can be identified, it must be remembered that in any kind of social organization we can observe an interpenetration of these analytic levels" (p. 29). There is every "reason to believe," he insisted, that all "levels of reality are analytically as important" as every other. Smelser's empirical and theoretical work consistently displays the deepest agnosticism about assigning causal apriority. His plurivocality is epistemological and insistent. He absolutely refuses to be absolute. He does not privilege any particular sector or level. Here lies the source of Smelser's famous theft from economic price theory (see the *Theory of Collective Behavior*, 1962:18–20)—the notion that causality must be conceived as a "value-added" process. This apparently simple yet, in reality, quite subtle idea represents a seminal contribution to sociological thought. Social structure, beliefs, and emotions are all important, as is every level inside them. These ideas are reflected in the title for a book honoring Neil Smelser, whose authors—all former students—comprise some of the leading figures on contemporary sociology (Alexander, Marx, and Williams 2004). Second, there is a deep sense that social structure can never, under any circumstances, be separated from the analysis of social process, from the study of social movement, from the flux and flummox of social change. Every book that Smelser has written, every article on social structure, every study of beliefs, and every discussion of emotions—has been a study in the constructive and destructive crystallization of structures.

This double preoccupation with plurality and process, in the context of accepting ambivalence and ambiguity, led Smelser in his historical monograph on working-class education to a wonderfully sociological rendering of the British notion of "muddling through."

> Like all such stereotypes, this one demands skepticism and a nonliteral reading. Nevertheless, it can be argued that if any sequence of social change manifested the principle of muddling through, the one I have suited in this volume is a good candidate. . . . Almost every proposal, whether ultimately successful or not, was accompanied by a series of disclaimers. These were that past good work in the area would not be dishonored; ongoing efforts would not be disturbed; what was being added would be no more than a helpful supplement to cover certain gaps; and the claims, rights, and sensibilities of interested parties would not be offended. . . . The aim was to squeeze limited increments of social change by and through them without disturbing them. *[But] the results were often much more than proponents claimed in their modesty. And in the long run, the policy . . . revolutionized the educational system.* The road to that end was marked, however, by a great deal of muddling through. (1991:370, italics added)

Smelser writes here about the ultimate effects of what initially were intended as modest proposals for reform. He might also be speaking about the cumulative effects of the flow of theoretical proposals he has generated in the latter part of his long scientific career. They, too, were accompanied by disclaimers and by the concern not to dishonor past good work. They, too, were launched in a manner designed not to overly disturb ongoing sociological efforts of other kinds, presented as helpful supplements rather than unfriendly displacements. Indeed, Smelser did succeed in his effort not to offend the rights and sensibilities of other sociological parties. All the same, he challenged their claims, and in the long run, his work has had, if not revolutionary, then certainly fundamental intellectual effects. Over the course of 50 years in the sociological trenches, he has muddled through in a remarkable and inspirational way.

That inspiration has been of great importance to the many students Smelser has instructed as a teacher, mentor, and role model. Intellectual legacies lie not only in the substantive contributions of a scholar but also in the work of students touched by their teacher. Having chaired more than 50 PhD committees, served on numerous others, worked with myriad colleagues on joint projects and instructed so many others through his writing, Neil Smelser stands out here. He demonstrated how the division between teaching and research was often too sharply drawn. For the inspired instructor, teaching was a way of exploring new ideas and exercising intellectual curiosity.

Teaching was also a way to communicate the love of ideas and appreciation of the rich intellectual heritage we are bequeathed. In his inspired teaching, Smelser effectively communicated reverence for those giants of social and psychological thought who sought to understand the vast changes in culture, social organization, and personality associated with the development of the modern world. Yet his respect was tempered with critical analysis and the insight that every way of seeing was also a way of not seeing. He honored our intellectual past without being stifled by it.

SMITH, DOROTHY

Dorothy E. Smith (b. 1926) a Canadian sociologist, is one of the most prominent feminist theorists of the twentieth century. Educated at the University of London School of Economics (BSc), the University of British Columbia (LLD), and the University of California at Berkeley (PhD), she was one of the founders of an influential theoretical framework called feminist standpoint epistemology. Smith asserts that certain standpoints can provide a more reliable vantage point from which to assess how power is woven into institutions that contour women's daily activities. Smith's approach situates women's experiences within the local institutional practices that organize their lives. By using this "everyday world" perspective, researchers remain sensitive to women's experiences while also exploring how varying institutional practices such as welfare policy and higher education differentially organize their lives.

Smith's theoretical approach draws on a variety of traditions, including phenomenology and ethnomethodology as well as Marx's historical materialism and poststructuralism. She was on the faculty of the University of Essex, the University of British Columbia, and the Ontario Institute for Studies in Education (OISE). She also served as head of OISE's Centre for Women's Studies in Education. She was recipient of the Jessie Bernard Award for Feminist Sociology from the American Sociological Association, the Kerstin Hesselgren Professorship in Sweden, and the Lansdowne Professorship at the University of Victoria. She was also awarded the Degré Prize Lectureship at the University of Waterloo and the John Porter Lectureship of the Canadian Sociology and Anthropology Association. Her doctoral thesis, completed in 1963, was titled *Power and the Front-Line: Social Controls in a State Mental Hospital.*

In her highly acclaimed book *The Everyday World as Problematic: A Feminist Sociology,* Smith (1987) argues for a sociology that will reveal the everyday practices of people that abstractions typically developed by sociologists both "express and conceal" (p. 213). Theorizing from her own experience as a single mother of two young children, Smith developed the concept of "bifurcated consciousness" to capture the tensions women in particular experience when they enter the textually organized world of academia

that is independent of the everyday world of preschool schedules, visits to doctors, and trips to the parks. As a mode of consciousness, the practice of sociology, requires distancing from the everyday world of child care and meal preparation, among other particularities. Smith argues that these different modes of consciousness are gendered and that women are constructed as the "Other" in the academic world. As a result of consciousness-raising strategies developed by the feminist movement of the late 1960s and early 1970s, women collectively articulated new issues and concerns that called into question the presumed genderless organization of the knowledge production enterprise.

Smith first published her critique of the dominant methods of sociology in a 1974 article titled "The Ideological Practice of Sociology." As a corrective to the abstractions developed by sociologists, Smith created a methodological approach to social research called "institutional ethnography" that is designed to explore links between everyday life experiences and broad-based social structural processes. Smith's methodological goal is to examine the social relations that shape everyday life experiences, revealing how local experiences are organized by relations of ruling. Smith (1987) defines *relations of ruling* as a term "that brings into view the intersection of the institutions organizing and regulating society with their gender subtext and their basis in a gender division of labor" (p. 2). The term *ruling* is used to identify organizational practices of government, law, financial management, professional associations, and other institutions that shape everyday life. Smith argues that bureaucratic procedures and textual forms that rationalize the organizational practices create a screen of neutrality that masks the gender, racial, and class subtexts of institutional activities and discourse.

Smith (1999) resists providing content to the standpoint of social actors. For Smith, a standpoint functions like an arrow on maps in malls. Standpoints are sites in and through which to explore the relationships between diverse local sites. Smith's map-making strategy helps an investigator map the activities that coordinate and reproduce oppressive systems. This strategy also provides a useful tool for activist research. It helps capture less formal activities and institutional processes that intersect in particular social or institutional locations. This knowledge can be used as a resource for social change efforts, providing an assessment of how power operates in local practices of ruling or *ruling relations* where activist interventions might be most successful.

In *The Conceptual Practices of Power: A Feminist Sociology of Knowledge,* Smith (1990a) furthers her analysis of "women's experience as a radical critique of sociology" and takes issue with what she terms "the ideological practice of sociology." *The Conceptual Practices of Power* concentrates on the ways relations of ruling are organized through texts and the ideological properties of textual accounts of factual accounts. As two examples of these practices,

Smith demonstrates how statistics on mental illness and constructions of what counts as suicide are inseparable from the professional and bureaucratic practices that give rise to these phenomena. In the first example, she calls attention to the patriarchal relations that inform the production of statistical evidence. She argues that what counts as mental illness is constructed along with the categories used to organize patients' problems into objects of psychiatry. In the second example, Smith draws on Marx's notion of "social relation" to produce a materialist analysis of the social processes that organize factual accounts and define them as "suicide." Implicated in these processes is the increasing bureaucratic and professional push to standardize organizational forms to produce coherence between the clinical encounter, the production of an account of the encounter, and the development of a specific psychiatric syndrome.

In *Texts, Facts, and Femininity: Exploring the Relations of Ruling* (1990b), Smith extends her conceptualization of relations of ruling and the social organization of subjectivity. She discusses her epistemological link to Marx's method of historical materialism and argues that "social forms of consciousness also exist only in actual practices and in the concerting of those practices as an ongoing process" (p. 7). She offers a powerful analysis of femininity as a textually mediated discourse. Smith explains that individuals in diverse locations who do not know each other are coordinated by the same texts and, consequently, new social relations are created.

Despite her interest in discourse and the power of texts to mediate social relations, Smith is critical of postmodernism and differentiates her materialist feminist approach from Foucault's theory of discourse. While Smith (1993) finds value in Foucault's analysis of discourse, she criticizes his emphasis on discourse to the exclusion of nondiscursive processes. As she explains, "There are indeed matters to be spoken and spoken of that discourse does not yet encompass" (pp. 183–84). In contrast to Foucault's "conception of discourse as a conversation mediated by texts," Smith (1999) argues for the incorporation of how people use texts and how texts coordinate an individual's activities with another's or others' activities (p. 158).

In *Writing the Social: Critique, Theory, and Investigations,* Smith (1999) further explicates her critique of postmodernism. For Smith, it is essential that analysis makes "reference to what is beyond discourse" (p. 127). Smith offers a social theory that envisions subjects of investigation who can experience aspects of life outside discourse. Smith's institutional ethnographic approach provides the methodological framework to explore the material consequences of local discourses and institutional practices for social, cultural, political, and economic processes that shape social actors' everyday lives.

SOCIAL ACTION

Social action occurs when thought processes intervene between a stimulus, an actor, and their subsequent response. In other words, it is a process whereby an individual attaches a subjective meaning to his or her action. This is different from reactive behavior in that a simple reaction involves a response to a stimulus with no intervening thought. The concept of social action is of particular importance to sociology because many aspects of the field are built on the principle of understanding the subjective meanings that actors attach to actions and how they come to understand the actions of others (and themselves).

The sociology of Max Weber rested on his concept of social action. He stated that the goal of sociological analysis was "the interpretation of action in terms of its subjective meaning" (Weber [1921]1968:8). This did not, however, lead him to support the psychological study of the mind but, rather, to pursue a sociological study of mental processes. He was not as concerned with the roots of action in consciousness as much as he was interested in the ways in which social structures affected individual action.

The focus of Weber's interest in social action was on the individual. He acknowledged that there were occasions when the collective had to be treated as an individual, but only as "the resultants and modes of organization of the particular acts of individual persons, since these alone can be treated as agents in a course of subjectively understandable

action" (Weber [1921]1968:13). Therefore, in contrast to what the name might imply, social action is in nearly all instances performed by the individual actor and not the social collective.

Weber outlined four basic ideal types of action. The most important to him were the two basic types of rational action because these are the ones most likely to be understood by sociologists. The first of these, means-ends rationality is based on a set of expectations of other actors and their assumed responses to environmental stimuli and other human actors. These expectations are the "means" by which the actor calculates his or her own actions in order to obtain his or her desired "ends." An example of this type of action would be extending one's hand to a new acquaintance with the expectation that that person will shake your hand and the goal of a successful social exchange. The second type of rational action, value rationality, is based on the belief that some actions must be undertaken for their own sake regardless of whether or not they will be successful. The confession of sins to a Catholic priest in hopes of saving one's soul is an example of this type of action.

The other two types of action for Weber have a seemingly more irrational basis. Affectual action is the result of the emotional state of the actor. An example of this would be throwing expensive dinner plates across the room in a fit of rage or acting in socially unprescribed ways in the name of love. Traditional action is rooted in the individual's routine systems of behavior. This would include things such as showering at night versus in the morning, having tea at a certain time every day, or celebrating one's birthday with a cake and candles.

Although Weber outlined four specific types of social action, he made it clear that nearly every instance involved some combination of these four ideal types. For example, celebrating one's birthday with candles and a cake is not only traditional action but could be interpreted as value action as well.

Weber's concept of social action led to a more general action theory. Although it has declined in popularity since the 1930s and 1940s, a number of notable theorists at that time, including Robert MacIver (1931), Florian Znaniecki (1934), and especially Talcott Parsons (1937), all engaged in action theory. It was mostly the work of Parsons, however, that brought action theory to the spotlight.

Parsons did not intend his action theory to explain all parts of social reality. Instead, he recognized that such a theory was limited primarily to the most basic forms of social life. In turn, the most basic component of his action theory is the unit act. The unit act, for Parsons, has four characteristics: (1) an actor must be present, (2) the act must have a goal to which it is oriented, (3) the situation in which the act occurs must be different from the ends that it aims to accomplish (which is not the same as saying the means must be different from the ends; Parsons saw the

means as only one aspect of the situation—the parts over which the actor has control; the other subdivision of a situation is conditions, or those parts over which the actor has no control), and (4) norms and values exist for an actor that orient his or her choice of means to the desired end.

The last element of the unit act is of critical importance in helping to distinguish action from a behavioral response. The contemplation of a choice implies that the actor is engaging in voluntarism, a well-known concept developed by Parsons. Voluntarism does not mean total freedom to do as one wishes but, rather, the ability to choose from among the range or options available, given the conditions or the restraints of the situation.

In Parsons's later works, he almost entirely abandons his idea of the unit act in lieu of a focus on systems, which he sees as composed of and emerging from unit acts. In other words, he moved in a more macro direction and sought to explain those aspects of social reality that he did not feel could be explained by the individual unit act. Nevertheless, he was influential in bringing Weber's ideas of social action to the United States and to further developing them into the field of action theory.

SOCIAL CAPITAL

The term *social capital* refers either to the capacity of an individual to obtain valued material or symbolic goods by virtue of his or her social relationships and group memberships or to the capacity of a plurality of persons to enjoy the benefits of collective action by virtue of their own social participation, trust in institutions, or commitment to established ways of doing things. The former capacity has been called "relational social capital" and the latter "institutional social capital" (Krishna 2000). The common element underlying both types of social capital is social embeddedness. Individual and collective action alike are enabled and constrained by the resources that actors can leverage within and between levels of social structure.

Like the complementary concept of "human capital" (the knowledge, skill, and understanding acquired by persons through training and experience), the concept of social capital stems from an analogy to physical and financial capital. Capital in general refers to finite assets available for purposive deployment in the satisfaction of future wants (rather than present consumption). Capital assets accumulate as stocks. Put to productive use, they generate flows of benefits for the asset holder and his or her exchange partners. Capital assets are said to be "fungible" (interchangeable), "transferable" (conveyable from one place or situation to another), and "alienable" (transferable in ownership). Since social capital is only slightly fungible, mildly transferable, and inalienable, some economists—for example, Kenneth Arrow—reject the analogy to capital theory. However stretched the analogy may be, the concept of social capital captures something that most sociologists consider an elemental truth—that the resources embedded in social structures facilitate individual and collective action, and generate flows of benefits for persons, groups, and communities.

No one knows who first used the term social capital in the ways defined above. Robert D. Putnam nominates L. Judson Hanifan on the basis of the Progressive educator's 1916 essay on community centers. "The individual is helpless socially, if left to himself," Hanifan (1916) observed of the rural poor in West Virginia. "If he comes into contact with his neighbors, and they with other neighbors, there will be an accumulation of social capital, which may immediately satisfy his social needs and which may bear a social potentiality sufficient to the substantial improvement of living conditions in the whole community" (p. 130). The core elements of the concept are clearly present in this quotation: agential capacitation through relationship formation, interdependent asset cumulation, and "social potentiality," the facilitation of collective ends.

Two contemporary social theorists who developed the concept's theoretical potential are Pierre Bourdieu and James S. Coleman. Bourdieu arrived at the concept independently, while Coleman built on economist and policy analyst Glenn Loury's use of the term to designate all the family, class, and neighborhood characteristics that affect actors' investments in human capital. Bourdieu and Wacquant (1992) define social capital as the actual or potential resources at play in the "field of the social"—that is, in the sphere of "mutual acquaintance and recognition" (p. 1991). For Bourdieu, modern society is an ensemble of relatively autonomous fields—for example, the religious field, the linguistic field, the economic field, each with its own strategic logic and specific form of capital—religious capital, linguistic capital, economic capital, and so on. Of these, the most important, the one that exerts the greatest force on the other fields, is the economic. Having limited social capital to the sphere of direct social relations,

Bourdieu devoted his prodigious research efforts to the study of other forms of capital, particularly cultural capital.

Coleman (1988) derived the concept of social capital from the premises of rational choice theory. Starting out from the spare premises of utility-maximizing, resource-bearing actors, each controlling assets of differential value to others, Coleman erected an impressive theoretical edifice extending to interdependent corporate groups ("corporate society"). These premises required him to see social capital as an unintended, emergent phenomenon chiefly found in social structures characterized by "closure." The effective monitoring and sanctioning of behavior that closure provides builds interpersonal trust, generates the authority required for collective action, and allows actors to pool their resources for new projects and endeavors.

Two other theorists of social capital working within the rational choice framework are Nan Lin and Ronald S. Burt. Both emphasize actors' self-conscious investments in social structural arrangements that yield high flows of benefits for themselves and others. Lin's research centers on the ways that social capital facilitates status attainment. In *Social Capital* (2001), he crafted a set of 12 postulates and propositions to integrate the literature in this area. Burt concentrates on the network configurations that confer structural autonomy on strategically located nodes, allowing the occupants of such positions to broker information and control the flow of resources. Burt (2002) theoretically derived four mechanisms (contagion, prominence, closure, and brokerage) that differentially affect the social capitals of actors situated at different nodes. Seamlessly integrating the concept of social capital into his theory of structural holes, Burt advances the proposition that high social capital accrues to positions that span structural holes (defined as weak ties between social networks or subnetworks).

In contrast to the above uses of the term, which concentrate on the empowerment of persons' strategic or instrumental action, political scientist Robert D. Putnam steered social capital research in a decidedly institutional, even communitarian direction. In *Making Democracy Work* (1993), he and his coworkers examined the effectiveness of 20 new regional governments established in Italy in 1970. Some of these new governments failed miserably, while others established successful participatory programs and spurred economic development. After controlling for political ideology, tax revenues, and other conditions, Putnam determined that the best predictor of governmental performance was a strong local tradition of civic engagement, which he measured by a host of social capital indicators, such as membership in voluntary associations and voter participation in elections. In *Bowling Alone* (2000), Putnam applied the same analysis to American communities and states. He found that, overall, social capital had declined significantly since 1960. States and localities that maintained relatively higher levels of social capital, however, were more likely to experience safer and more productive neighborhoods, better student test scores, lower levels of tax evasion, and higher levels of intergroup tolerance.

As in Putnam's work, empirical studies employing the concept of social capital typically involve dependent variables of performance or outcome, indicators of social capital at the relational or institutional level (or both), and various controls. Persons advantaged by higher social capital find better jobs more easily, organize more effective protests, and influence public opinion more decisively. The mechanisms of relational social capital include (1) access to information, organizations, or public officials; (2) the promulgation of effective norms; (3) the cashing in of outstanding interpersonal obligations ("credit slips"); and (4) being in a position to understand conflicting interests or perceptions and thus to broker solutions acceptable to different parties.

In communities where higher levels of trust, cooperation, and participation prevail, common outcome variables include institutional effectiveness and smoother adaptations to changing macroeconomic conditions. The mechanisms of institutional social capital include (1) vertical linkages between levels of social structure; (2) horizontal linkages ("bridges") between local social networks; and (3) the support of outside agencies in devising positive-sum solutions to collective action problems.

During the 1990s, social capital explanations blossomed in the fields of developmental economics, community development, criminology, social welfare, and poverty amelioration. Many of these fields saw the failures of both market-centered and government-centered programs to solve pressing social problems. For many policy-oriented researchers, social capital represents a liberating perspective.

As important as the concept of social capital appears to be for both theoretical and applied sociology, it has no shortage of critics. Many economists reject the analogy to capital theory and doubt whether social capital rises to a factor of production. Methodologists worry that too many diverse mechanisms underlay the concept's effects, that too many diverse indicators measure it, and that its effects are distributed over too many levels of social organization. They consider the concept "fuzzy" (analytically imprecise). Some theorists reject in principle the distinction between social capital and cultural capital. They insist on a joint conceptual construction or on the epistemological priority of cultural capital. Theorists inclined toward rational choice or network explanations lament the concept's extension into the macro realms of institutional social capital. Critical theorists consider the multiplying analogies to capital to be symptomatic of the social sciences' intellectual subordination to bourgeois ideology.

Social theorists long understood that the resources embedded in social structures empower actors (whether persons or collectivities) to conceive and achieve their

projects. In social capital, they found a concept that focuses like a laser on precisely that idea.

SOCIAL CLASS

Few concepts are more contested in sociological theory than the concept of "class." In contemporary sociology, there are scholars who assert that class is ceasing to be useful (Pahl 1989) or even more stridently proclaim the death of class. Yet at the same time, there are also sociologists who write books with titles such as *Bringing Class Back In* (McNall, Levine, and Fantasia 1991), *Reworking Class* (Hall 1997), *Repositioning Class* (Marshall 1997), and *Class Counts* (Wright 1997). In some theoretical traditions in sociology, most notably Marxism, class figures at the very core of the theoretical structure; in others, especially the tradition identified with Durkheim, only pale shadows of class appear.

In what follows, there is first an examination, in broad strokes, the different ways in which the word *class* is used

in sociological theory. This is followed by a more fine-grained exploration of the differences in the concept of class in the two most important traditions of class analysis, the Weberian and the Marxist.

VARIETIES OF CLASS CONCEPTS

Many discussions of the concept of class confuse the terminological problem of how the *word* class is used within social theory with theoretical disputes about the proper definition and elaboration of the *concept* of class. While all uses of the word class in social theory invoke in one way or another the problem of understanding systems of economic inequality, different uses of the word are imbedded in very different theoretical agendas involving different kinds of questions and thus different sorts of concepts. One way of sorting out these alternative meanings is to examine what might be termed the anchoring questions within different agendas of class analysis. These are the questions that define the theoretical work the concept of class attempts to do. Five such anchoring questions in which the word *class* figures centrally in the answers are particularly important.

1. *Class as subjective location.* First, the word class sometimes figures in the answer to the question: "How do people, individually and collectively, *locate themselves and others* within a social structure of inequality?" Class is one of the possible answers to this question. In this case, the concept would be defined something like this: "Classes are social categories sharing subjectively salient attributes used by people to rank those categories within a system of economic stratification." With this definition of class, the actual content of these evaluative attributes will vary considerably across time and place. In some contexts, class-as-subjective-classification revolves around lifestyles, in others around occupations, and in still others around income levels. Sometimes the economic content of the subjective classification system is quite direct, as in income levels; in other contexts, it is more indirect, as in expressions such as "the respectable classes," the "dangerous classes." The number of classes also varies contextually depending on how the actors in a social situation themselves define class distinctions. Class is not defined by a set of objective properties of a person's social situation but by the shared subjective understandings of people about rankings within social inequality (e.g., Warner [1949]1960). Class, in this sense of the word, is contrasted to other forms of salient evaluation—religion, ethnicity, gender, occupation, and so on—that may have economic dimensions but that are not centrally defined in economic terms.

2. *Class as objective position within distributions.* Second, class is often central to the question, "How are people *objectively located* in distributions of material inequality." In this case, class is defined in terms of material

standards of living, usually indexed by income or, possibly, wealth. Class, in this agenda, is a *gradational* concept; the standard image is of rungs on a ladder, and the names for locations are accordingly such things as upper class, upper middle class, middle class, lower middle class, lower class, underclass. This is the concept of class that figures most prominently in popular discourse, at least in countries like the United States without a strong working-class political tradition. When American politicians call for "middle-class tax cuts" what they characteristically mean is tax cuts for people in the middle of the income distribution. Subjective aspects of the location of people within systems of stratification may still be important in sociological investigations using this concept of class, but the word class itself is being used to capture objective properties of economic inequality, not simply the subjective classifications. Class, in this context, is contrasted with other ways that people are objectively located within social structures—for example, by their citizenship status, their power, or their subjection to institutionalized forms of ascriptive discrimination.

3. *Class as the relational explanation of economic life chance.* Third, class may be offered as part of the answer to the question, "What *explains* inequalities in economically defined life chances and material standards of living of individuals and families?" This is a more complex and demanding question than the first two, for here the issue is not simply descriptively locating people within some kind of system of stratification—either subjectively or objectively—but identifying certain causal mechanisms that help determine salient features of that system. When class is used to explain inequality, typically, the concept is not defined primarily by subjectively salient attributes of a social location but, rather, by *the relationship of people to income-generating resources* or assets of various sorts. Class thus becomes a *relational* rather than simply *gradational* concept. This concept of class is characteristic of both the Weberian and Marxist traditions of social theory. Class, in this usage, is contrasted to the many other determinants of a person's life chances—for example, geographical location, forms of discrimination anchored in ascriptive characteristics like race or gender, or genetic endowments. Location, discrimination, and genetic endowments may, of course, still figure in the analysis of class—they may, for example, play an important role in explaining why different sorts of people end up in different classes—but the definition of class as such centers on how people are linked to those income-generating assets.

4. *Class as a dimension of historical variation in systems of inequality.* Fourth, class figures in answers to the question, "How should we characterize and explain the variations across history in the social organization of inequalities?" This question implies the need for a

macrolevel concept rather than simply a microlevel concept capturing the causal processes of individual lives, and it requires a concept that allows for macrolevel variations across time and place. This question is also important in both the Marxist and Weberian traditions, but as we will see later, here the two traditions have quite different answers. Within the Marxist tradition, the most salient aspect of historical variation in inequality is the ways in which economic systems vary in the manner in which an economic surplus is produced and appropriated, and classes are therefore defined with respect to the mechanisms of surplus extraction. For Weber, in contrast, the central problem of historical variation is the degree of rationalization (in this context, the extent to which inequalities are organized in such a way that the actors within those inequalities can act in precise, calculable ways) of different dimensions of inequality. This underwrites a conceptual space in which, on one hand, class and status are contrasted as distinct forms of inequality and, on the other hand, class is contrasted with nonrationalized ways through which individual life chances are shaped.

5. *Class as a foundation of economic oppression and exploitation.* Finally, class plays a central role in answering the question, "What sorts of transformations are needed to eliminate economic oppression and exploitation within capitalist societies?" This is the most contentious question, for it implies not simply an explanatory agenda about the mechanisms that generate economic inequalities but a normative judgment about those inequalities—they are forms of oppression and exploitation—and a normative vision of the transformation of those inequalities. This is the distinctively Marxist question, and it suggests a concept of class laden with normative content. It supports a concept of class that is not simply defined in terms of the social relations to economic resources but that also figures centrally in a political project of emancipatory social change.

Different theoretical approaches to class analysis build their concepts of class to help answer different clusters of these questions. Figure 1 indicates the array of central questions linked to different approaches to class analysis. Weber's work revolves around the third and fourth questions, with the fourth question concerning forms of historical variation in social organization of inequalities providing the anchor for his understanding of class. The narrower question about explaining individual life chances gets its specific meaning from its relationship to this broader historical question. Michael Mann's work on class, especially in his multivolume study of *The Sources of Social Power* (1993) is, like Weber's, also centered on the fourth question. John Goldthorpe's (1980) class analysis centers firmly on the third question. While his work is often characterized as having a Weberian inflection, his categories are elaborated strictly in terms of the requirements of describing and explaining economic life chances, not long-term historical

variations in systems of inequality. For Pierre Bourdieu, class analysis is anchored in a more open-ended version of the third question. Where he differs from Weber and other Weber-inspired class analysts is in expanding the idea of life chances to include a variety of noneconomic aspects of opportunity (e.g., cultural opportunities of various sorts) and expanding the kinds of resources relevant to explaining those life chances from narrowly economic resources to a range of cultural and social resources (called "cultural capital" and "social capital"). "Class" for Bourdieu (1984), therefore, is a much more expansive concept, covering all inequalities in opportunities (life chances) that can be attributed to socially determined inequalities of resources of whatever sort. Finally, class analysis in the Marxist tradition is anchored in the fifth question concerning the challenge to systems of economic oppression and exploitation. The questions about historical variation and individual life chances

are also important, but they are posed within the parameters of the problem of emancipatory transformations.

The rest of this essay examines in some detail how these questions are played out in the Weberian and Marxist traditions, the two most important traditions of class analysis in sociological theory. The concepts of class in these two theoretical traditions share much in common: They both reject simple gradational definitions of class; they are both anchored in the social relations that link people to economic resources of various sorts; they both see these social relations as affecting the material interests of actors; and, accordingly, they see class relations as the potential basis for solidarities and conflict. Yet they also differ in certain fundamental ways. The core of the difference is captured by the favorite buzzwords of each theoretical tradition: *life chances* for Weberians, and *exploitation* for Marxists. This difference, in turn, reflects

the location of class analysis within their broader theoretical agendas.

THE WEBERIAN CONCEPT: CLASS AS MARKET-DETERMINED LIFE CHANCES

What has become the Weber-inspired tradition of class analysis is largely based on Weber's few explicit, but fragmentary, conceptual analyses of class. In *Economy and Society* ([1924]1978), Weber writes:

> We may speak of a "class" when (1) a number of people have in common a specific causal component of their life chances, insofar as (2) this component is represented exclusively by economic interests in the possession of goods and opportunities for income, and (3) is represented under the conditions of the commodity or labor markets. This is "class situation."
>
> It is the most elemental economic fact that the way in which the disposition over material property is distributed among a plurality of people, meeting competitively in the market for the purpose of exchange, in itself creates specific life chances. . . .
>
> But always this is the generic connotation of the concept of class: that the kind of chance in the *market* is the decisive moment which presents a common condition for the individual's fate. Class situation is, in this sense, ultimately market situation. (pp. 927–28)

In short, the kind and quantity of resources you own affects your opportunities for income in market exchanges. "Opportunity" is a description of the feasible set individuals face, the trade-offs they encounter in deciding what to do. Owning means of production (the capitalist class) gives a person different alternatives from owning skills and credentials (the "middle" class), and both are different from simply owning unskilled labor power (the working class). Furthermore, in a market economy, access to market-derived income affects the broader array of life experiences and opportunities for oneself and one's children. The study of the life chances of children based on parent's market capacity is thus an integral part of the Weberian agenda of class analysis.

This definition of class in terms of market-determined life chances is clearly linked to the third question posed above: "What *explains* inequalities in economically defined life chances and material standards of living?" Weber's answer is, In capitalist societies, the material resources one brings to market exchanges explain such inequalities in life chances. But even more deeply, Weber's conceptualization of class is anchored in the fourth question, the question of how to characterize and explain historical variation in the social organization of inequality. Two issues are especially salient here: first, the historical variation in the articulation

of class and status and, second, the broad historical problem in understanding the rationalization of social processes.

Class is part of a broader multidimensional schema of stratification in Weber in which the most central contrast is between "class" and "status" (as well as "party"). Status groups are defined within the sphere of communal interaction (or what Weber calls the "social order") and always imply some level of identity in the sense of some recognized estimation of *honor*, either positive or negative. A status group cannot exist without its members being in some way conscious of being members of the group.

This conceptual contrast between class and status for Weber is not primarily a question of the *motives* of actors: It is not that status groups are derived from purely symbolic motives and class categories are derived from material interests. Although people care about status categories in part because of their importance for symbolic ideal interests, class positions also entail such symbolic interests, and both status and class are implicated in the pursuit of material interests. Rather than motives, the central contrast between class and status is the nature of the mechanisms through which class and status shape inequalities of the material and symbolic conditions of people's lives. Class affects material well-being directly through the kinds of economic assets people bring to market exchanges. Status affects material well-being indirectly, through the ways that categories of social honor underwrite various coercive mechanisms that are in accord with the degree of monopolization of ideal and material goods or opportunities to obtain them.

The contrast between class and status provides one of the axes of Weber's analysis of historical variation in systems of inequality. One of the central reasons that capitalist societies are societies within which class becomes the predominant basis of stratification is precisely because capitalism fosters continual technical and economic transformation.

Weber's concept of class is also closely linked to his theoretical preoccupation with the problem of historical variation in the process of rationalization of social life. The problem of class for Weber is primarily situated within one particular form of rationalization: the *objective instrumental* rationalization of social order. In all societies, the ways people gain access to and use material resources is governed by rules that are objectively embodied in the institutional settings within which they live. When the rules allocate resources to people on the basis of ascriptive characteristics and when the use of those material resources is governed by tradition rather than by the result of a calculative weighing of alternatives, then economic interactions take place under *non*rationalized conditions. When those rules enable people to make precise calculations about alternative uses of those resources and discipline people to use those resources in more rather than less efficient ways

on the basis of those calculations, those rules can be described as "rationalized." This occurs, in Weber's analysis, when market relations have the most pervasive influence on economic interactions (i.e., in fully developed capitalism). His definition of classes in terms of the economic opportunities people face *in the market,* then, is simultaneously a definition of classes in terms of rationalized economic interactions. Class, in these terms, assumes its central sociological meaning to Weber as a description of the way people are related to the material conditions of life under conditions in which their economic interactions are regulated in a maximally rationalized manner. Weber is, fundamentally, less interested in the problem of the material deprivations and advantages of different categories of people as such, or in the collective struggles that might spring from those advantages and disadvantages, than he is in the underlying normative order and cognitive practices— instrumental rationality—embodied in the social interactions that generates these life chances. "Class," in these terms, is part of the answer to a broad question about historical variations in the degree and forms of rationalization of social life in general, and the social organization of inequality in particular.

THE MARXIST CONCEPT: CLASS AS EXPLOITATION

The pivotal question that anchors the Marxist conceptualization of class is the question of human emancipation: "What sorts of transformations are needed to eliminate economic oppression and exploitation within capitalist societies?" The starting point for Marxist class analysis is a stark observation: The world in which we live involves a juxtaposition of extraordinary prosperity and enhanced potentials for human creativity and fulfillment along with continuing human misery and thwarted lives. The central task of the theory is to demonstrate first, that poverty in the midst of plenty is not somehow an inevitable consequence of the laws of nature but, rather, the result of the specific design of our social institutions and, second, that these institutions can be transformed in such a way as to eliminate such socially unnecessary suffering. The concept of class, then, in the first instance is meant to help answer this normatively laden question.

The specific strategy in the Marxist tradition for answering the normative question leads directly to the question about historical variation. The normative question asks what needs transforming for human emancipation to occur. The theory of history in Marx—generally called "historical materialism"—lays out an account of the historical dynamics that make such transformations possible and, in the more deterministic version of the theory, inevitable. Again, the concept of class figures centrally in this theory of historical development.

The most distinctive feature of the concept of class elaborated within Marxism to contribute to the answer of these two questions is the idea of *exploitation.* Marx shares with Weber the central idea that classes should be defined in terms of the social relations that link people to the central resources that are economically relevant to production. And like Weber, Marx sees these relations as having a systematic impact on the material well-being of people; both "exploitation" and "life chances" identify inequalities in material well-being generated by inequalities in access to resources of various sorts. Thus, both concepts point to conflicts of interest over the *distribution* of the assets themselves. What exploitation adds to this is a claim that conflicts of interest between classes are generated not simply by what people *have* but also by what people *do with what they have.* The concept of exploitation, therefore, points our attention to conflicts within *production,* not simply conflicts in the *market.*

Exploitation is a complex and challenging concept. In classical Marxism, this concept was elaborated in terms of a specific conceptual framework for understanding capitalist economies, the "labor theory of value." In terms of sociological theory and research, however, the labor theory of value has never figured very prominently, even among sociologists working in the Marxist tradition. And in any case, the concept of exploitation and its relevance for class analysis does not depend on the labor theory of value.

The concept of exploitation designates a particular form of interdependence of the material interests of people— namely, a situation that satisfies three criteria:

1. *The inverse interdependent welfare principle:* The material welfare of exploiters causally depends on the material deprivations of the exploited.
2. *The exclusion principle:* This inverse interdependence of welfares of exploiters and exploited depends on the exclusion of the exploited from access to certain productive resources.
3. *The appropriation principle:* Exclusion generates material advantage to exploiters because it enables them to appropriate the labor effort of the exploited.

Exploitation is thus a diagnosis of the process through which the inequalities in incomes are generated by inequalities in rights and powers over productive resources: The inequalities occur, in part at least, through the ways in which exploiters, by virtue of their exclusionary rights and powers over resources, are able to appropriate surplus generated by the effort of the exploited. If the first two of these principles are present, but not the third, economic oppression may exist, but not exploitation. The crucial difference is that in *non*exploitative economic oppression, the privileged social category does not itself *need* the excluded category. While their welfare does depend on exclusion, there
Figure 2   Core Elements in Weber's and Marx's Class Analysis

Source: Adapted and simplified from Wright (1997:34).

is no ongoing interdependence of their activities. In the case of exploitation, the exploiters actively need the exploited: Exploiters depend on the effort of the exploited for their own welfare.

This conceptualization of exploitation underwrites an essentially polarized conception of class relations in which, in capitalist societies, the two fundamental classes are capitalists and workers. Capitalists, by virtue of their ownership and control of the means of production, are able to appropriate the laboring effort of workers embodied in the surplus produced through the use of those means of production. The Marxist tradition of class analysis, however, also contains a variety of strategies for elaborating more concrete class concepts that allow for much more complex maps of class structures in which managers, professionals, and the self-employed are structurally differentiated from capitalists and workers. For example, Wright (1985, 1997) argues that managers in capitalist firms constitute a type of "contradictory location within class relations" in the sense of having the relational properties of both capitalists and workers.

The exploitation-centered concept of class provides a framework for linking the microlevel question about explaining individual material conditions and interests with the macrolevel question about historical variation and the normative question about emancipatory transformation. What needs changing in capitalism is a system of property relations that confers power on capitalists and enables them to exploit and oppress others. This social organization of class relations is not an expression of a natural law but is one form in a systematic pattern of historical variation. And

the life experiences and interests of individuals living within these relations generate patterns of conflict that have the potential of pushing these historical variations in ways that accomplish the emancipatory transformation.

THE TWO TRADITIONS COMPARED

The contrast between Marxist and Weberian frameworks of class analysis is illustrated in Figure 2. Both Marxist and Weberian class analysis differ sharply from simple gradational accounts of class in which class is itself directly identified within inequalities in income since both begin with the problem of the social relations that determine the access of people to economic resources. In a sense, therefore, Marxist and Weberian definitions of class in capitalist society share much the same *operational* criteria for class structure within capitalist societies. Where they differ is in the theoretical elaboration and specification of the implications of this common set of criteria: The Marxist model sees two causal paths being systematically generated by these relations—one operating through market exchanges and the other through the process of production itself—the Weberian model traces only one causal path, and the Marxist model elaborates the mechanisms of these causal paths in terms of exploitation as well as bargaining capacity within exchange; the Weberian model only deals with the latter of these. In a sense, then, the Weberian strategy of class analysis is contained within the Marxist model.

While the Marxist concept of class may be particularly suited to the distinctively Marxist question about potential

emancipatory transformations, is it still sociologically useful if one rejects that question? There are a number of reasons why elaborating the concept of class in terms of exploitation has theoretical payoffs beyond the specific normative agenda of Marxist class analysis itself:

1. *Linking exchange and production.* The Marxist logic of class analysis affirms the intimate link between the way in which social relations are organized within exchange and within production. This is a substantive, not definitional, point: The social relations that organize the rights and powers of individuals with respect to productive resources systematically shapes their location both within exchange relations and within the process of production itself.

2. *Conflict.* One of the standard claims about Marxist class analysis is that it foregrounds conflict within class relations. Indeed, a conventional way of describing Marxism in sociological textbooks is to see it as a variety of "conflict theory." This characterization, however, is not quite precise enough, for conflict is certainly a prominent feature of Weberian views of class as well. The distinctive feature of the Marxist account of class relations in these terms is not simply that it gives prominence to class conflict but that it understands conflict as generated by *inherent properties* of those relations rather than simply contingent factors.

3. *Power.* At the very core of the Marxist construction of class analysis is not simply the claim that class relations generate deeply antagonistic interests but that they also give people in subordinate class locations forms of power with which to struggle for their interests. Since exploitation rests on the extraction of labor effort and since people always retain some measure of control over their own effort, they always confront their exploiters with capacities to resist exploitation. This is a crucial form of power reflected in the complex counterstrategies exploiting classes are forced to adopt through the elaboration of instruments of supervision, surveillance, monitoring, and sanctioning.

4. *Coercion and consent.* Marxist class analysis contains the rudiments of what might be termed an *endogenous* theory of the formation of consent. The argument is basically this: The extraction of labor effort in systems of exploitation is costly for exploiting classes because of the inherent capacity of people to resist their own exploitation. Purely coercively backed systems of exploitation will often tend to be suboptimal since under many conditions it is too easy for workers to withhold diligent performance of labor effort. Exploiting classes will therefore have a tendency to seek ways of reducing those costs. One of the ways of reducing the overhead costs of extracting labor effort is to do things that elicit the active consent of the exploited. These range from the development of internal labor markets that strengthen the identification and loyalty of workers to the firms in which they work

to the support for ideological positions that proclaim the practical and moral desirability of capitalist institutions. Such consent-producing practices, however, also have costs attached to them, and thus systems of exploitation can be seen as always involving trade-offs between coercion and consent as mechanisms for extracting labor effort.

5. *Historical/comparative analysis.* As originally conceived, Marxist class analysis was an integral part of a sweeping theory of the epochal structure and historical trajectory of social change. But even if one rejects historical materialism, the Marxist exploitation-centered strategy of class analysis still provides a rich menu of concepts for historical and comparative analysis. Different kinds of class relations are defined by the specific mechanisms through which exploitation is accomplished, and these differences in turn imply different problems faced by exploiting classes for the reproduction of their class advantage and different opportunities for exploited classes to resist. Variations in these mechanisms and in the specific ways in which they are combined in concrete societies provide an analytically powerful road map for comparative research. Weber's class concept also figures in an account of historical variation, and one of its strengths is the way in which his conceptual menu draws attention to the interplay of class and status and to historical variations in the forms of rationality governing life chances. These are not issues brought into focus by the Marxist concept of class. On the other hand, the Weberian concept, by marginalizing the problem of exploitation, fails to bring to center stage the historical variability in forms of conflict linked to the central mechanisms of extraction and control over the social surplus.

SOCIAL CONSTRUCTIONISM

The argument that *social constructionism* proposes, with more or less insistence, about objects of social and cultural inquiry is in some sense the "other" to essentialisms of all sorts. To wit: Things—including even nature—are not simply given, revealed, fully determined, and as such, unalterable. Rather, things are made, and made up, in and through diverse social and cultural processes, practices, and actions. Much of the force of social constructionist argument is in this irony—its proposal that some assumedly taken-for-granted phenomenon not only could be otherwise but that its "local" form has a history that can be written to show a collection of interests, actions, and flows of power that have created and that sustain it. It seeks typically to show how some arguably social or cultural thing came about, how it is maintained, and, often by implication, how it might be changed. Social constructionist argument offers critique as a resource against all analyses that say, in effect, "This simply is the way things are and/or always have been." This emphasis on critique becomes particularly pronounced

in work where the line between constructionism and *deconstruction* blurs.

BERGER AND LUCKMANN'S SOCIOLOGY

In *The Social Construction of Reality: A Treatise in the Sociology of Knowledge,* Peter Berger and Thomas Luckmann (1966) build their argument on "classic roots" of Western sociology: the work of Marx, Durkheim, Weber, Schütz, and Mead. But classic roots for some are minor literatures for others, and Berger and Luckmann intended their book as a corrective to what they saw as an overemphasis on "purely structural" argument in the then-popular versions of structural-functionalism in U.S. sociology. They "correct" by forefronting acting and interacting human(ist) beings as the primary agents in the constitution, maintenance, and change of the social.

Berger and Luckmann (1966) contend that "reality is socially constructed and that the sociology of knowledge must analyze the process in which this occurs" (p. 1). They treat this project as one equally relevant to academic philosophy and to everyday life, but their constructionism is distinct from philosophical argument and analysis. Rather than asking ontological and epistemological questions such as "What is real?" and "How is one to know?," Berger and Luckmann shift attention to more specifically pragmatic considerations appropriate to an empirical, by which they mean "scientific," sociology. Central among these are the following: What does a collection of people located at a particular time and in a particular place take to be "real," and how is this construction to be understood as something they do? How are their conceptions linked to relevant social and historical contexts? How are differences in social realities/constructions/worlds across different collections of people understood as implicating those varying contexts? The very existence of difference in such social realities and contexts, they argue, underwrites the need for studying the *social processes* through which such difference has come about and by which it is maintained as well as changed. They assert that the sociology of knowledge "must concern itself with whatever passes for 'knowledge' in a society, regardless of the ultimate validity or invalidity (by whatever criteria) of such 'knowledge'" (p. 3).

Berger and Luckmann (1966) credit Marx with the clearest statement of the social construction of reality argument in that "man's consciousness is determined by his social being," specifically through the human activity of laboring together and the social relationships that emerge and are inextricable from that labor. For them, Marx's famous concepts of substructure and superstructure are seen most accurately "as, respectively, human activity and the world produced by that activity" (p. 6).

Berger and Luckmann (1966) propose their theory as a major redefinition of the sociology of knowledge, making

it and the study of the social construction of reality central to sociological theory. They cite what they call two "marching orders" for modern sociology as at the heart of their argument: Durkheim's advice to "consider social facts as things" and Weber's statement that "both for sociology . . . and for history, the object of cognition is the subjective meaning-complex of action" (p. 18). These "orders" might be restated in their version of social constructionism as follows: Treat socially constructed realities as things, as objective; and see the meaning and action in social life that are these realities as mutually constitutive and contingent. That is, the objects that emerge in and through situated, meaningful social action can come to have precisely the "obdurate" quality that Durkheim used to describe "social facts." These then become habituated and typified in individuals' understandings of themselves, others, and their worlds and are used as resources to create, sustain, and change those objects. "Society is a human product. Society is an objective reality. Man [sic] is a social product" (p. 61). This, they say, is the essence of the social construction of reality.

Also central to Berger and Luckmann's social constructionism are the *phenomenology* of Alfred Schütz and the *symbolic interactionism* of George Herbert Mead. From Schütz, the authors take a stated focus on the natural attitude of *everyday life* and the knowledge therein and attention to how these are taken up, reiterated, and changed in and through the routine interactions and taken-for-granted understandings of the people whose lives are lived in a given locale. For Schütz, this concept of the everyday was an analytical resource with which to focus attention on how the social is continually accomplished by human beings pursuing practical but mundane projects. From Mead comes a sense of the absolute importance of human *social interaction* as symbolic interaction, suffused with and by shared meanings in language that feed back into and shape the ongoing lines of joint and always open action as well as the selves at the center of that action.

Berger and Luckmann (1966) underline the importance of processes of historically situated legitimation in carrying forward and sustaining all such social realities, realities that illustrate what they call institutionalization. *Language* and knowledge are the coordinating and integrating symbolic resources that bring a coherence to the diverse lines of situated human interaction. While the paramount or everyday realities thus constructed are mostly taken for granted by those who produce and are produced by them, "every symbolic universe is incipiently problematic" and routinely requires conscious "maintenance work" by embodied individuals who make it up (pp. 106, 116). From the analyst's view, then, as Berger and Luckmann note, "Says who?" is a critical question: "What remains sociologically essential is the recognition that all symbolic universes and all legitimations are human products; their existence has its base in

the lives of concrete individuals, and has no empirical status apart from these lives" (p. 128).

FOUCAULT'S POSTSTRUCTURALISM

The name and work of Michel Foucault are often linked to social constructionism. While, like Berger and Luckmann, Foucault wrote in conversation with a legacy of Western European, *humanist* thinkers, unlike them Foucault mostly wrote against that legacy—at least as it typically is read in the origin stories of U.S. sociology—and toward what he hoped would be a new way of thinking about human beings in social and historical terms. The proto-heroic humanist subject at the heart of Berger and Luckmann's story—and most other sociological stories—has a much less glorious role to play in the social construction work proposed here.

Drawing on their own intellectual and personal relationships with Foucault, philosopher Hubert Dreyfus and anthropologist Paul Rabinow offer a careful reading of Foucault's difference from the dominant traditions of Western European thought in the social and human sciences. They argue that Foucault was neither a *structuralist* nor an advocate of *hermeneutics*—what they call the two "poles" of the human sciences—but that he sought to develop a "new method" that would preserve "the distancing effect of structuralism, and an interpretive dimension which develops the hermeneutic insight that the investigator is always situated and must understand the meaning of his cultural practices from within them" (Dreyfus and Rabinow 1983:xii). Deeply influenced by Marx but not Marxist or Hegelian, Foucault's new method would eschew the dialectic as explanatory device in favor of a view of history as discontinuous, marked by epistemic breaks rather than linear development. More Nietzschean than Husserlian, Foucault would dismiss the search for deep meaning and truth behind social formations and practices ("texts") characteristic of hermeneutics, seeing the history of Western thought as revealing nothing to give a deep interpretation of (Dreyfus and Rabinow 1983:xxiii–xxv, 123–24, 180–83). Relying on methods that he called archeology and *genealogy,* Foucault sought—especially in his later books—not to provide a new theory of anything but, rather, to encourage a critical understanding of, "a history of," as he put it, "the present." Indeed, the human sciences themselves, and the objects and subjects that populate and define them, became prime targets for this critical and ostensibly new kind of analysis.

If Berger and Luckmann bring forward the importance of the acting and interacting individual in the context of the everyday to better understand how social realities are constructed, Foucault might be seen to diminish considerably what he called the "anthropological" theme that individual people are the prime sources of movement and force—especially through the operation of rational choice and

intentionality—in society and in history. Although he later moved away from claims that the person is fully an effect of discourse, he retained through his last books on the care of the self the view that while not fully determined by prescribed cultural and institutional practices, the space of the resisting and "creative" subject should not be framed in terms of the humanist fantasies of "freedom" or "free will." Indeed, Foucault's skepticism about the optimistic stories in the legacy of humanism sets off his contributions from those carried forward by Berger and Luckmann and others who wrote more from within that tradition (and that also is apparent in the pragmatism of Richard Rorty).

In some of Foucault's most widely read books, we might say that the sources of the social construction about which Foucault writes are differentially distributed across particular *discursive practices,* their objects and subjects, and the individual, acting human beings who both take them up/are taken up by them and who give them life/are given life by them in real time and place. The distinction implied here between the body or bodies acting in time and space, on one hand, and the nature of the objects and subjects given life thereby, on the other hand, is, arguably, one of Foucault's most enduring contributions. In the focus on disciplinary practices, Foucault may be said to show us, in fine-grained empirical detail, the social and cultural machines through which docile and useful bodies and subjects were/are made into objects in service of "society." In his analysis of sexual subjects, he shows us how, through expert knowledge and discourse, culture and society create a "deep inside" essence—sexuality and the desire for sex—as the condition for the discovery of true, "healthy," and useful knowledge about each and every one of us. Here, especially, we see that which was thought to be prior and fundamental proposed, rather, as product and resource for the operation of power and "social good."

In these images of social construction, the individual still acts and interacts, but the choices are circumscribed in advance to serve and reinforce the structures that define the everyday. Although he professed very little interest in a study of the everyday realities so produced or in the meanings they had for those who enacted them—topics of central interest to Berger and Luckmann and "interpretive" philosophies and theories they wrote—Foucault was far from resigned to despair about the possibilities for change and *resistance* in the face of such structures. Most particularly, he did not see the human being in society as fully determined by the subjectivities that serve to embody that being. Perhaps particularly in his distinct but not always fully elaborated conception of *power* as always dynamic and relational, not as a commodity-like thing that some have and others do not, can we see the sense in which Foucault granted the acting individual within a constraining/enabling *subjectivity* or "self" a notable importance in society and history. For Foucault, one is "in" power as long as one is "in play" in relational dynamics with others in social and cultural sites that hierarchically allocate prerogatives, responsibilities, and duties. While there is constraint both from the subjectivities through and in which one takes up/is given an identity in such settings and from the prerogatives and responsibilities that define and link these entities together, the fact that the individual, as human individual, has the capacity to act and thus to act otherwise and in some degree of resistance to those constraints is critical to Foucault's vision. Even in social arrangements that appear to offer one party no power—for example, a woman in an abusive heterosexual relationship—Foucault's concept of power would encourage us to see how her "local" subjectivity could provide resources for possibly effecting change. While he emphasized social construction as operating beyond, around, in, and through the individual—as social and cultural processes and practices—Foucault allocated to the acting individual the possibility for both doing and thinking otherwise, something to which he himself aspired.

Beyond the notion of resistance, in his books on the care of the self, Foucault focuses attention on what he calls a "genealogy of ethics" based on careful study of life in ancient Greece. The problem of ethics there, which for Foucault is the problem of how to develop, how to craft, one's relationship with one's self, is not about resistance and power but, rather, about the ways one might put together a life. That framing does not imply, of course, an absence of social and cultural constraint, but it does bring forward the acting individual, using and adapting, applying, social and cultural codes to the mundane details of life, the space, of course, in which a life is made and made up in countless reiterations.

SUBSEQUENT LINES OF WORK

Constructing Social Problems

Against the commonsense and often social scientific wisdom that social problems exist as obviously undesirable conditions threatening social and cultural stability, health, and happiness, Malcolm Spector and John I. Kitsuse ([1977]2001), in their *Constructing Social Problems,* propose a definition of social problems and a kind of empirical analysis that draws on many of the themes in Berger and Luckmann's work and that have come to exemplify a certain kind of social constructionist theory. Both lines of work might be read in part as humanist responses to the then dominance of structural and functional analysis of social systems apparent in U.S. sociology and the corresponding de-emphasis on situated, ongoing, social interaction. Parallel work in psychology, often referred to as "constructivist," marks similar reactions against a dominant positivism there (see Burr 1995).

Social problems, Spector and Kitsuse ([1977]2001) wrote, are "the activities of individuals or groups making assertions of grievances and claims with respect to some putative conditions" (p. 75). The inquiry should focus on what they called *claims-making and responding activities* by specific persons at and in particular times and places and about things they do not/do like and hope/hope not to change. Here, the analyst is not concerned with evaluating or examining the validity or truth of the claims made about the things in question, which of course has been the conventional sociological assignment. "Even the existence of the condition itself is irrelevant and outside of our analysis. We are not concerned whether or not the imputed condition exists" (p. 76). It is, rather, the viability or "life" of such claims and responses that interest Spector and Kitsuse.

Social problems—and, by extension, all of what can be called "moral work" or "morality" understood as the making of evaluations and judgments—are thus seen as accomplishments that exist in and through claims-making, responding, and related activities. Although this gives prime place to actual language in use and the strategies those who press such claims or respond to them might adopt, Spector and Kitsuse's view also incorporates activities that participants pursue that seem to the analyst to be clearly premised on member definitions of the objects, arrangements, and theories that they imply. Attention thus is given not only to language and *discourse* but to the individual and joint activities that appear to be premised on these member understandings and interpretations.

Spector and Kitsuse's constructionism contains an explicitly *reflexive* flavor. Sociologists themselves are seen as among the primary champions of various definitions of social problems—in both the public and professional arenas in which they can be found—and these definitions easily become topic for the theory and strategy of analysis this constructionism encourages. Indeed, professional and official claims-makers of all sorts have been among the most commonly studied participants in constructing social problems in the large body of research and writing this work has stimulated. Much of the early empirical research using this perspective—studies by Stephen Pfohl on child abuse, by Peter Conrad on hyperactivity, by Joseph Schneider on alcoholism, and by Conrad and Schneider on the medicalization of deviance—focused on such professional and medical claims-makers and their interactions with various lay populations (see Conrad and Schneider 1992).

Sexuality: Identity and Body Constructed

Foucault's writing on the disciplining of the body and the shaping and embrace of subjectivity has had an enormous effect on subsequent research and theory on various aspects of sexuality across the human sciences. Among the clearest of these lines of influence are those found in the

argument that *sexual identity* is socially constructed and that "the body"—and the *sexual body* in particular—and sexuality are "inscribed," "performed," and thus, too, constructed. This work offers examples of the two different ways in which social constructionism seems to be read: as at the more or less rational and intentional direction of an individual self or subject, on one hand, and as the operation of constraining but not fully determinative social, cultural, and historical processes that more or less shape/constitute subjects and their activities, on the other.

Before Foucault—and in U.S. sociology—an early and notable example of the former kind of social constructionist argument dealing with what might be called "gender identity" is Harold Garfinkel's famous case study of Agnes. Arguably paradigmatic of ethnomethodological analysis, Garfinkel drew on detailed interviews with and observations of a male-to-female transsexual to reveal the mundane practices or "methods" that Agnes had to learn and then use in order to be, to exist in the world as, a taken-for-granted, "bona fide" female and woman in society. Garfinkel shows how Agnes worked to achieve this mundane ontology and, in doing so, makes clear just how much all normalized gender identity is an accomplishment produced by and through an ongoing set of intentional practices that are the seen but unnoticed stuff of social and cultural reality. Garfinkel's ethnomethodology and subsequent work in *conversation analysis* helped us see the material real as an achievement in which human beings in local settings put society and culture together using the mundane practices that every society/culture makes available to them. (A parallel kind of analysis that is not particularly about sexual identity and is not seen as ethnomethodological but is, arguably, constructionist in a similar sense, is found in Erving Goffman's work on the presentation of self.)

Against this kind of constructionism, elements of which also can easily be found in writing on the social construction of sexual identity linked to gay and lesbian identity and social movement politics, some feminist scholars have taken up from Foucault and from poststructuralism more generally an analysis of how sexuality and sexualized bodies are inscribed and performed in and through social and cultural regulatory practices that simultaneously produce the very subjects or subjectivities through and in which human beings are said to "have *agency*." Indeed, the very possibility of "agency"—not to mention "rational choice"—is seen here as a cultural and social resource with various but circumscribed possibilities that are always politically charged. The writings of Judith Butler and Elisabeth Grosz, in their emphasis on performativity, materiality, the psyche, and the volatility of bodies have been among the most influential here. In this work, we can see a critique of the version of constructionism that highlights the intentional, choosing, and rational subject. While not erasing the significance of a moving, acting human individual,

this work resituates the notion of human agency within a complex of forces that can be said to "construct" the social and cultural objects under study. Poststructural influence in scholarship on gay and lesbian sexuality has produced congenial analyses, sometimes referred to as queer theory, that aim to deconstruct sexual identity as itself a social construction that regulates and serves that which it seems to critique. In all these latter works, the emergence, force, and consequences of categories of knowledge and their related practices, never simply "used" or "directed" by the familiar humanist subject, are at the center of attention.

Posthuman Actant Networks in Technoscience Studies

A third line of work that can be seen as social constructionist in yet another sense has grown up in the interdisciplinary field of technoscience studies, particularly as found in the work of Bruno Latour and Donna Haraway. Here we come almost full circle from Berger and Luckmann's claim that social constructionism takes knowledge and its categories, their creation, history, complexity, and movement as its central topic of analysis. But this circle is not quite closed. Although Berger and Luckmann claimed that "whatever passes for 'knowledge' in society" should be subjected to constructionist analysis, they were not quite willing to subject their own kind of work—science—to a thoroughgoing or "radical" constructionism. The work referenced here does precisely that.

Pushing the decentered humanist subject even farther afield, this work might be characterized as a *posthuman* or postpersonal constructionism in which the human player does not disappear but, rather, becomes one of a diverse collection of "*actants*" linked together in a network that itself can be seen to construct facts and technoscientific knowledge. In no case is this network directed by the humans who participate in it, although they retain a special importance linked to their particular capacities as users of language and meaning and as those who can ask often difficult moral and ethical questions.

Grounded in early ethnographies of scientists at work at the bench, Latour, Steve Woolgar, and others contributed to what Latour calls an *actor-network analysis* of science. Eschewing much standard sociological explanation, Latour has seen the production of scientific knowledge and the actual work of science as collective accomplishments of a network of actants, only some of whom are human or even alive. Latour saw that scientists rely heavily on the action of the ever-expanding collection of writing machines ("inscription devices"), observations, and laboratory-sited events, and objects that ostensibly stand in for "nature" and on whose behalf the scientists hope to speak as they defend their claims to skeptical colleagues. Successful scientific knowledge becomes that which the scientist and other actant collaborators can defend against all attempts to undermine it as "subjective" or merely a human speaking for herself or himself alone.

Haraway has contributed importantly to this view of technoscience, although she writes as a socialist-feminist sympathetic to poststructuralism and who longs for what she calls a "successor science" that is networked, collaborative, partial, strongly objective, and that seriously seeks to make a better world, with less suffering and more "happiness," for all living beings. Writing explicitly against sexism, racism, and patriarchy, Haraway offers a constructionism that is considerably more open, messy, and unpredictable than versions that locate the rational human actor—historically almost always a white male European or North American—at the center of its story or that give "discourse" a determinative force. From her famous "cyborg manifesto" to later critical analyses of technoscience, Haraway urges an understanding and vision by human actants in this process—among other "material-semiotic objects"—that not only make explicit their own dependencies but that also speak their own implication in the shaping of and responsibilities for the local worlds being built. Haraway wants scientists to ask if the worlds they help to construct are worth living for, for whom this might be more or less the case, and what all life in these worlds is likely to be, being able to admit that while they know, they do not know for sure. Others have pursued work that reiterates and extends various themes of contingency, distributed cognition, and complexity in the networks that can be said to construct and embody technoscientific knowledge.

SOCIAL DARWINISM

Social Darwinism is the application of the theory of natural selection to human society. Alfred Wallace, the theory's codiscoverer, once asked Charles Darwin whether he would follow up his *Origin of Species* with a book on human beings. Darwin replied:

> You ask whether I shall discuss "man." I think I shall avoid the whole subject, as so surrounded with prejudices, though I fully admit it is the highest and most interesting problem for the naturalist. (Cited in Hawkins 1997:20)

Darwin was understandably cautious. But others have felt less constrained, with the result that massive theoretical and political issues have arisen.

Most living creatures, Darwin and Wallace argued, produce many more offspring than are needed to reproduce their numbers. Such multiplication, if left unhindered, meant that "the earth would soon be covered by the progeny of a single pair." However, the numbers of each species remained much the same from one generation to the next. What was taking place?

A struggle for survival and reproduction must be occurring, one between individuals and the rest of nature. No two individuals are alike, each possessing variations that confer advantages and disadvantages in the struggle. Those individuals with particular advantages will be those that develop and reproduce future generations. All this, Darwin and Wallace believed, occurs in the context of inevitable resource shortages. As Malthus had argued in the late eighteenth century, populations grow at a geometric rate while food supplies grow arithmetically. The environment

was therefore active in eliminating those individuals without the characteristics necessary to survive and reproduce.

Turning now to *social* Darwinism, human characteristics can also be seen as resulting from struggle to survive. Herbert Spencer, for example, looked forward to a society in which individuals are free to realize their full potential. A long evolutionary process would take place, leading to a race in which people found fulfilment in aesthetic and spiritual matters rather than in the materialism of Spencer's own day. Those individuals not adapting and developing in this way would slowly die out. Note, however, a divergence between Spencer's views and those of Darwin. Spencer had no Malthusian fear of overpopulation, believing that humans have the capacity to adapt to environmental and social change. There are also differences between social Darwinists. Spencer believed that state intervention would delay the improvement of the human species, while William Sumner, the influential Yale Social Darwinist, increasingly saw a need for social reform.

The transfer of evolutionary ideas to human beings is an intellectual and political minefield. There are five themes here; the politics of knowledge, the question of "struggle," the notion of "progress," the assumption of direction, and an "end" to which evolution is developing.

As regards knowledge, the theory of natural selection can easily be seen as a product of its era and knowledge recruited to distinctive political ends. "The struggle for survival," for example, can be seen as a transposal of the social struggle (all too apparent in Darwin's Britain) to the non-human world. Similarly, the "successful" variations are no less than the human success stories of middle-class Victorian society again transposed to the natural world. Similarly, Malthus's theory of necessary resource shortages is by no means the objective and scientific theory as he claimed. Wallace, though clearly influenced by Malthus, was also sympathetic to Owen's socialism. Such a politics argues that "resource shortages" are not inevitable. They are a product of social and property relations.

Similarly, forms of social evolutionism were well established before Darwin's *Origin*. Herbert Spencer coined the phrase "the survival of the fittest" some 10 years before the publication of *The Origin*. As applied to humanity, he meant the struggle between *races* to survive, the demise of the weakest leaving the strongest to "keep up the average fitness to the conditions of life." Here again was an apparently objective science being used to enhance an overtly political programme. Social Darwinism is sometimes seen as a "neutral instrument," albeit one capable of being recruited to by a range of political positions. Such adoption by a range of causes is a matter of historical fact. But to describe the theory as "neutral" or "objective" is probably being overdeferential to this "science."

These issues remain important today. "Neo-Darwinism" in the form of sociobiology also claimed to be an objective

form of knowledge. (This time the organism, including the human organism, is seen as a carrier of and reproducer of "selfish genes" into future generations [Dawkins 1989].) But this perspective, too, can be seen as a product of its day, the "selfish gene" being no less than the selfish person of neoliberalism transferred back to the natural world. But all this said, the theory of natural selection as developed by Darwin and Wallace remains largely intact. It was a social construction (what theory is not?), but many biologists would argue that it still describes real causal mechanisms affecting both the natural and the human worlds.

The "struggle for survival" is a problematic second theme. So, too, is the linked question of "human nature." Darwin was again cautious over these matters; recognising in *The Descent of Man* that the struggle to reproduce can take a number of forms, including various forms of cooperation. Yet social Darwinism is often equated with liberalism, with attempts to prosper, and with an idea of human nature that focuses on the individual at the expense of his or her social and environmental context. Such an interpretation led to early support for social Darwinism from influential classes in North America. But alternative understandings were made in other societies. Prince Kropotkin, the Russian anarchist, argued strongly in his 1902 book *Mutual Aid* that the fundamental feature of all nature, including human nature, was mutualism and cooperation. The lesson of Darwin here was that this propensity needed active support in capitalist societies devoted to individualistic competition. Mutualistic and solidaristic interpretations of Darwin were also more common in other societies, including France.

We should also note different understandings of both the struggle to survive and of human nature in our own day. *The Bell Curve,* published in 1994 by Herrnstein and Murray, represents a contemporary form of Social Darwinism. They argue that intelligence is the prime means by which human beings succeed in modern knowledge-based societies. Some groups, particularly black people, are seen as possessing inherently low levels of intelligence. White people are better endowed and Asians have, it is argued, higher intelligence levels than both these groups. Social stratification and social success are again, therefore, seen as largely the result of individuals' assumed internal characteristics. Society, according to this position, is itself "natural." Here is another example of a science (in this case a science measuring "intelligence") that is easily recruited to a particular kind of politics. And it is a "science" that is itself highly contested by many social and natural scientists. They would especially question oversimple notions of "intelligence" and would argue that intellectual capacities are best seen as developing during a person's early lifetime.

Closely linked to the "science" of intelligence is the fact Social Darwinism has often been linked with eugenics. This is the attempted speeding up of human evolution, the selection of the "best" humans and the neglect or even killing of the supposedly "inferior." These concerns have recently resurfaced with the rise of biotechnology and cloning. Embryos deemed to be "unfit" can be modified or even destroyed. Such "unnatural selection" must be of major concern, but it is important to stay focused on the more subtle, often unintended, effects of the social and "natural" environment on people's well-being.

"Progress" is a third theme. Sumner, like Spencer, argued strongly for a sense of "progress" emerging from the struggle to survive. If human beings were allowed to realise their capacities, societies' high levels of "civilisation" would eventually be achieved. As is often still assumed, science was seen as the main means by which such progress was to be achieved. The most "intelligent" people are taken to be those best able to advance science and hence society at large. Progress, according to this perspective, therefore had distinct normative connotations. It has close links with the philosophical and sociological ideas of Georg Hegel and Auguste Comte. Progress, entailing increased scientific knowledge (including knowledge of the self) is equated both with increased civilisation and the creation of freed, emancipated selves.

Darwin was aware of the difficulties here but did not always resolve them. He claimed the "science" of natural selection to be value free. Yet much of his language describing evolutionary change implicitly adopted a notion of progress. Note, for example, the following from *The Origin:*

> The inhabitants of each successive period in the world's history have beaten their predecessors in the race for life and are higher in the scale of nature; and this may account for that vague yet ill-defined sentiment, felt by many palaeontologists, that organisation on the whole has progressed. (1859:345)

Darwin also espoused aspects of Lamarckian thinking, especially in *The Descent of Man.* According to this view, acquired characteristics could be inherited by later generations. As people continued fighting for survival, and so long as governments and philanthropists did not interfere, the most favourable characteristics would emerge and be passed to later generations. Progress was again the most likely outcome.

The progress question closely links to the fourth theme, that of directionality. Spencer and much of early sociology adopted a strong notion of direction. For Spencer and writers such as Emile Durkheim, the direction of social change is away from homogeneity toward structured heterogeneity. Directionality is also a feature of much historical materialism. For Karl Marx and Friedrich Engels, European history is divided into four distinct eras; tribal, classical, feudal, and capitalist. Communism would be the final, most "progressive," outcome. Note in Marx and Engels the significance of class struggle with each society being an embryonic version of the following social form. Note also the implication in much social theory that all societies inevitably follow the

same direction. Such understandings borrowed more or less explicitly from evolutionary thought. The transition from the simple to the complex was raised to a point of cosmic significance by Spencer, an understanding that applied to the human, biological, and physical worlds. Contemporary sociologists such as Niklaus Luhmann also maintain that society is increasingly characterised by autonomous "subsystems," with the result that modernity is increasingly "unsteerable." Analogies are still made between biological and social evolution. But paradoxically, and most unfortunately, these make little contribution to the increasingly urgent task of understanding how human societies are rooted in their ecological environments.

Finally, note the related theme of teleology. Marx and Engels argued that one of Darwinism's main gains was "the death of teleology"—an end to any notion that an organism or society is the result of any predetermined end. In important ways, this was achieved, with Darwinism delivering an apparently fatal blow to Christian accounts of origins. Nevertheless, there remain traces of teleology. Darwin's notion of a multiplicity of "species, genera and families of organic beings" all having "common parents" has distinct biblical overtones. Indeed, evolutionary theory is arguably another science offering itself as a God-surrogate and demanding constant uncritical adulation. Such a view can, however, be used to marginalise the real scientific insights made by Darwin, Wallace, and others.

Future work linking evolutionary and social thought must consider humans and other species as an evolved species with distinct powers. But these potentials must be seen as realised or constrained by different social and political contexts. Critical realism, as developed by Roy Bhaskar and others, is a useful way forward. It recognises the reality of causal mechanisms operating in the natural worlds (natural selection being an example) while insisting on these theories being critically assessed and taking account of how such mechanisms combine with social relations and processes to produce the societies we actually observe and experience.

SOCIAL DILEMMA

A social dilemma is formally defined as an incentive structure in which a deficient outcome is collectively achieved when each individual (in a group of two or more people) makes choices in accordance with a dominating strategy. A strategy is dominating if the *personal* consequences of behaving according to it are superior to the consequences of behaving according to all other strategies, regardless of the behavior of others in the group. The outcome is considered to be "deficient" when that outcome is preferred less than other outcomes by all members of the group. The commons dilemma, a social trap, the public goods problem, and the free-riding problem are all used to refer to a social dilemma. Real-world examples of social dilemmas range from an arms race between superpowers, the overharvesting of regenerating natural resources, protective trade policies, traffic jams, the use of modern amenities that create global warming, and so on. In these examples, the choice that follows the dominating strategy—often called the choice of "defection," or "free-riding" in some contexts—is the one that brings forth the most desirable outcome *for the individual.* Using the example of the arms race, the individual consequence for choosing to increase military power is military advantage. Using the example of overharvesting resources, the individual consequence for choosing to overharvest is the immediate profit reaped from ooverharvesting. However, if each person follows the dominating strategy and makes the choice of defection, the *collective outcome* is less desirable an outcome than if the individuals had followed another strategy and made an alternative, cooperative choice. For example, everyone benefits more if both superpowers disarm than if both expand their military power. Furthermore, everyone benefits more if the fishermen refrain from overharvesting than if they overharvest, and so on.

The current use of the term *social dilemma* summarized above is relatively new. However, the study of social dilemmas began much earlier, in the 1950s. Robyn Dawes used the term when he reviewed experimental work that had previously been described as "*n*-person prisoner's dilemmas." Social dilemmas were originally conceptualized as a group version (or *n*-person version) of the prisoner's dilemma, which usually involves only two people. The

name "prisoner's dilemma" (PD) comes from a story of two individuals suspected of a crime. Two suspects who have been arrested for a serious crime are being interrogated by a district attorney. The district attorney does not have enough evidence to convict either of the suspects of the crime. Therefore, the district attorney needs a confession from at least one of the suspects. He offers a deal to each "prisoner" independently. If one of the prisoners confesses and the other prisoner does not confess, the one who confesses gets acquitted and the one who does not confess gets the maximum penalty. If both prisoners confess, both are charged with the serious crime but both will receive a lenient penalty. If neither prisoner confesses, each prisoner is charged with a minor offense (not the serious crime) and receives a minor penalty. Both prisoners face a choice between confessing and not confessing. The dominating strategy is confessing, since individually, each prisoner is better off by confessing than by not confessing no matter what the other does. For example, Prisoner A is better off when he confesses (lenient penalty for the serious crime) than when he does not confess (the maximum penalty for the serious crime), if Prisoner B confesses. If Prisoner B does not confess, A is again better off by confessing (no penalty) than by not confessing (penalty for a minor crime). However, when each takes this dominating choice of confessing, each receives a lenient penalty for the serious crime, whereas each prisoner could have avoided that penalty by not confessing.

Social dilemmas and prisoner's dilemmas have attracted the attention of researchers in various fields of the social sciences. Early empirical works, however, have been conducted mostly by a group of social psychologists called experimental game researchers. Early experimental studies of social dilemmas examined games set up in a laboratory that served as a miniature model of real-life problems such as the problems mentioned earlier. Recently, thinking of experimental games as miniature models of real social problems has been replaced by more theoretically driven approaches. Below, major factors studied in the early experimental gaming tradition are briefly summarized. Next, an overview of the theoretical issues concerning *cooperation* in social dilemmas is provided.

FACTORS AFFECTING BEHAVIOR IN SOCIAL DILEMMAS

Experimental game researchers produced an impressive list of factors that affect the cooperation-defection choice in experimental games. The list includes both individual-level factors as well as structural factors.

Individual-Level Factors

Gender. Contrary to the naive view that women are more cooperative than men, experiments on social dilemmas produced mixed results. In some studies, women are more cooperative, and in other studies, no gender difference in cooperation emerged. Yet in another set of studies, men are found to be more cooperative than women. The naive belief that females are more cooperative than males may be attributed to the fact that the nature of the tasks females face in society makes their "cooperation" more visible than the tasks males face in society.

Social Value Orientation. The individual-level factor that has been most extensively studied is what is referred to as "social value orientation" or "social motivation." Social value orientation is defined as an attitude toward self and an interdependent other. An individual's social value orientation is represented by a combination of positive and negative attitudes toward self and other. Put differently, an individual's social value orientation can be conceptualized as the degree to which an individual is concerned with his or her own welfare and with another person's welfare. Three major types of social value orientation have been studied. *Individualists* are concerned with their own welfare and have little or no concern with the welfare of the other. *Cooperators* are concerned with the welfare of both self and the other. *Competitors* are those who prefer positive "relative gain" even at the expense of their own welfare. Theoretically, other types of social value orientation can exist. However, studies of social dilemmas have repeatedly shown that these three types are the dominant modes of social value orientation. Facing social dilemmas, cooperators tend to behave in a cooperative manner, whereas individualists and competitors tend to behave in a noncooperative manner.

Trust and Expectations. One of the most consistent findings in experimental studies of social dilemmas is that there *is* an effect of the expectations of other people's behavior on the player's own behavior. That is, players who expect that other players are cooperative tend to cooperate themselves, and those players who expect that other players are not cooperative tend not to cooperate themselves. This finding is worthy of attention since individuals profit more from noncooperative behavior than from cooperative behavior *no matter what other individuals do* (see the definition of social dilemmas mentioned above). Thus, from a rational theoretic perspective, individuals who face a social dilemma situation should be indifferent to others' behavior. Despite this rational-choice theoretic prescription, an overwhelming majority of subjects do pay attention to other people's behavior and adjust their own behavior to the observed or expected behaviors of others.

Dean Pruitt and Melvin Kimmel propose the goal/expectation theory of cooperation to explain the effect of expectation on an individual's behavior. According to this theory, individuals who experience undesirable consequences of

mutual defection come to prefer mutual cooperation to mutual defection but hesitate to cooperate unless they expect that others will not take advantage of their willingness to cooperate. They are "cautious cooperators" who are willing to cooperate if others do as well but are careful not to be victimized by free riders. Unconditional cooperation, that is, cooperation even when other people are not cooperating, is rarely observed in social dilemma experiments. Some students who study the effect of an individual's social value orientation suggest that the difference in social value orientations reflects the individual's general trust in other individuals. For "cautious cooperators" who believe that others are also willing to cooperate, initiating cooperation is more desirable than unilateral defection that will eventually destroy the possibility of achieving mutual cooperation. On the other hand, for those who believe that others are not willing to reciprocate, mutual cooperation is an impossible dream. Individual differences in general trust, or trust in other people in general, is thus suggested to affect individuals' proclivity to cooperate in social dilemmas. This suggestion has been consistently confirmed by a large number of studies.

Culture. Scholars expect that cooperation in social dilemmas is easier to achieve in a collectivist society than in an individualist society, since people in a collectivist society value the welfare of the group over their individual welfare. This prediction has received a mixed but generally negative support empirically. Toshio Yamagishi argues that within-group cooperation in a collectivist society is institutionally grounded, and thus people in a collectivist society cooperate at a high level in the everyday practice that takes place within institutional arrangements. On the other hand, when experimental participants face an artificially created social dilemma situation in a laboratory stripped of the institutional context surrounding everyday social dilemmas, people in collectivist cultures tend to be less trustful of others and thus less cooperative than those in individualist cultures.

Other Factors. Other individual difference factors such as group identity, information, morality, and prior experience have also been studied.

Structural Features

The ways in which structural features of the social dilemma affect an individual's cooperative behavior have been extensively studied.

One-Shot Versus Repeated Play. Achieving mutual cooperation is easier in repeated games than in one-shot games. In a one-shot game in which two players interact only once and never play the same game again, players have no means to influence their partner's behavior. When the same game is repeatedly played between the same two partners, however, one player can affect his or her partner's choice by adopting a certain strategy such as the tit-for-tat strategy. The tit-for-tat strategy is one in which a player cooperates when and only when his partner cooperated on the previous round. This strategy, despite its simplicity, has proven very effective in inducing the partner to take cooperative actions. In repeated games in which players' behavior involves "noise," another strategy called Pavlov is found to be more effective. The Pavlov strategy is one in which a player maintains the same behavior as long as the outcome is satisfactory and switches the behavior when the outcome is not satisfactory.

Incentives. The incentives that characterize a social dilemma have two components: (1) temptation for defection—how much more an individual gains by not cooperating—and (2) gain of cooperation—how much more each individual gains when all individuals cooperate compared with when none cooperates. Both are known to affect an individual's behavior in a social dilemma. Cooperative behavior decreases as the size of temptation for defection increases, and cooperative behavior increases as does the gain of cooperation. Furthermore, the former effect (of the size of temptation) is stronger than the latter effect (of the size of the gain of cooperation).

Size of Incentives. Despite the fact that defection is the dominating strategy in social dilemmas, the prediction of no cooperation (or complete defection) is seldom supported by experimental research. A sizable proportion of subjects, between 30 and 60 percent, cooperate even in one-shot games. The lack of support for the rational choice theoretic prediction of no cooperation is sometimes attributed to the weak incentives used in the experiments. Several experimental studies examined the effect of incentive size on cooperation. Some studies, comparing imaginary incentives and monetary incentives, find a higher level of cooperation when real money is at stake than when imaginary money or points are at stake. Other studies find the opposite. The size of the monetary reward is found to have no effect on the average level of cooperation. Experimental economists examined the effect of monetary size on game players' choices using the ultimatum game. They found that choice behavior is not affected very much even when the monetary stake was increased to an amount equal to a few months of the average cost of living in Indonesia and in Moscow.

Communication. The positive effect of communication and face-to-face interaction on cooperation in social dilemmas has been well documented. Similarly, cooperation level is found to be higher when subjects' choices are known to others than when their choices are anonymous.

Group Size. When there are more partners, it is difficult to detect who is cooperating and who is defecting. Furthermore, the effectiveness of one's action is distributed across many partners so that one's action does not have a strong impact on specific others. Finally, strategic actions may have negative "externalities." If a player decides to defect in a reciprocal manner in order to punish a defector, other cooperators might interpret his or her strategic action as exploitive, and might try to punish him or her by defecting themselves. This may produce a conflict spiral often observed in the repeated social dilemma experiments. While the largest difference lies between dyads and three-person groups, group size generally has a negative effect on cooperation.

Sanctions. The most straightforward means to enhance cooperation in social dilemmas is administrating selective incentives or sanctions. Experimental studies of sanctioning behavior in social dilemmas consistently demonstrate the positive effect of sanctioning on cooperation. The use of sanctioning as a means to enhance cooperation in social dilemmas, however, faces the second-order dilemma concerning the administration of sanctions. Logically, a higher level of sanctioning—the sanctioning of those who do not participate in the administration of sanctioning—is required to solve the problem of sanctioning. The sanctioning of nonsanctioners is required to maintain the "second-order sanctioning." Such a situation can create an infinite regress of ever higher-order sanctioning activities.

Other Factors. Other structural factors that have been extensively studied in social dilemmas include the territorialization or privatization of a common resource, leadership, resource variability, power distribution, type of behavior (contribution to a public good versus restraining from overuse), and the binary choice of cooperation and defection versus a varied level of cooperation.

THEORETICAL APPROACHES TO EXPLAINING COOPERATION IN SOCIAL DILEMMAS

As mentioned above, the cooperation rate is usually higher in repeated games than in one-shot games. And yet, many participants in social dilemma experiments do cooperate even in one-shot games that are anonymously played with strangers. There are currently two broad approaches to explain cooperation in such games. One is the social value orientation approach, according to which some people are endowed with a value that honors cooperation even when no gain is expected. This explanation of cooperation in one-shot games, however, immediately raises another question as to why some people have such a value and others do not. The second approach to explain cooperation in these games may be broadly called the evolutionary approach. This

approach seeks a "hidden" adaptive advantage in behaving cooperatively or reciprocally. Most studies from this perspective focus on advantages associated with some form of conditional cooperation or reciprocal cooperation.

Reciprocity. As mentioned earlier, most of the participants in one-shot games care about other people's behavior and behave in a reciprocal manner to the expected behavior of others. A correlation between the player's own behavior and his or her expectation about other players' behavior is one of the strongest findings in the social dilemma experiments. This correlation may be caused by a projection of the player's own behavior onto others. However, experiments of one-shot, sequential PD games, in which the first player makes a decision and then the second player who is aware of the first player's decision makes a decision, consistently demonstrates that people do behave in a reciprocal manner even in one-shot games. The social value orientation cannot explain such reciprocal cooperation, since those who have internalized the welfare of others should cooperate regardless of their partner's choices. Yamagishi and his colleagues argue that reciprocity is a "default" decision heuristic that is triggered when people face an interdependent situation. They further argue that having such a default response is adaptive since it helps individuals establish mutually cooperative relations at a relatively minor cost incurred by forgoing free-riding opportunities.

Strong Reciprocity. Some researchers think that humans behave not only reciprocally but also *strongly reciprocally.* Strong reciprocity translates into an inclination to punish defectors even in one-shot games. This approach seeks the adaptive advantage not in reciprocal behavior *per se* but in the reciprocity-punishment complex. This approach logically suffers from the problem of the infinite regress of higher-order sanctions mentioned previously. Most researchers who adopt this approach, however, claim that the cost of higher-order sanctioning is smaller than that of the first-order sanctioning (i.e., the cost sanctioning nonsanctioners is smaller than sanctioning defectors), and thus it is easier to solve the higher-order dilemma than the dilemma of cooperation and defection.

Selective Play and Ostracism. Another approach to explaining cooperation in social dilemmas is exit and ostracism. Students of social dilemmas have traditionally dealt with isolated relationships, and the wider context in which relationships are embedded has not been seriously examined. In the traditional research paradigm, players are locked in a particular relationship and do not have the option to leave it and join another relationship. Moreover, players do not have the option of kicking out undesirable members from their group. This traditional research paradigm is called the "forced play" paradigm because players are "forced" to

interact with a particular set of partners. We sometimes face interdependent situations of this kind. An example is the U.S.–U.S.S.R. relationship during the Cold War. However, most personal as well as formal relationships entail at least some room for mobility. Although the exit option was included in some early studies of social dilemmas, it was not until the late 1980s that social dilemma researchers (although small in number) began systematic research efforts to explore the theoretical implications of the option to leave the relationship and choose a new partner. The resulting research paradigm may be called the "selective play" paradigm. Theoretical and empirical research using some form of the selective play paradigm, including the option for ostracism, generally indicate that cooperation in social dilemmas is easier to maintain when people who face a social dilemma can leave the group or when they can ostracize uncooperative members.

Signal Detection and Mimicry. The option to ostracize or to avoid interacting with uncooperative players requires that people have an ability to detect noncooperators. Evolutionary psychologist Leda Cosmides argues that humans are evolutionarily endowed with a cognitive module specialized for watching for and detecting noncooperators. However, cheater detection ability faces an arms race with the ability to mimic on the part of the defector. A game theoretic account of the arms race between signal detection ability and mimicry predicts that mimicry loses when and only when it is too costly to do so. Some of the evolutionary-based abilities found in animals to detect signals of cooperators may be replaced among humans by institutional arrangements to provide accreditation and references. Reputation is one mechanism that supports selective play and ostracism as solutions to the social dilemma problem.

SOCIAL EXCHANGE THEORY

Social exchange theory is one of the major theoretical perspectives in sociology. It takes its place alongside social systems theory, symbolic interactionism, structural-functionalism, and conflict theory. Three of the major exchange theorists are George C. Homans, Peter Blau, and Richard M. Emerson. This general perspective has roots in a number of disciplines in the social sciences, including the fields of psychology, sociology, anthropology, and micro-economics. Some of the early theoretical influences came from pragmatism, utilitarianism, behaviorism, and functionalism. Other sources of influence include the major works of several social psychologists and cultural anthropologists. From psychology, the work of John Thibaut and Harold Kelley, notably their prize-winning book *The Social Psychology of Groups* (1959, 1986), is closest to the analysis developed by exchange theorists in sociology, especially Homans and later Emerson. The other major influence on theories of social exchange that derived from psychology was behaviorism. It had a strong impact on the development of Homans's theory of social behavior as exchange and the early work of Richard Emerson and later the work of Linda Molm. In cultural anthropology, the works of Claude Levi-Strauss, Bronislaw Malinowski, and Marcel Mauss were especially influential.

The first formal treatment of social behavior as exchange in sociology appeared in George Homans's article published in 1958 in the *American Sociological Review.* This was also a major topic in his presidential address on "bringing men back in" at the American Sociological Association meetings. He was reacting to the growing dominance of Parsonianism and the focus on large-scale social systems in sociological theory. Homans argued that theory should focus on the subinstitutional level of analysis, specifying the determinants of "elementary" social behavior that formed the bedrock of groups and organizations. For him, this meant a primary emphasis on the actions of individuals in direct interaction with one another in contrast to the study of institutions and institutional behavior driven by

social prescriptions or normative elements in society, the focus of Parsons. Homans believed that the subinstitutional elementary forms of social behavior could "crack the institutional crust," forcing changes in the institutionalized ways of doing things. Rebellion, revolution, and even more modest forms of social change often take this form. They provide the impetus for social change.

Homans' most sustained work on social exchange is his book *Social Behavior: Its Elementary Forms,* published in 1961 and revised in 1974. In this book, he lays out his propositions of elementary social behavior. These propositions are based to a large extent on the work of his Harvard colleague, B. F. Skinner and his ideas about reinforcement processes as determinants of behavior and behavioral change. Skinner defined social exchange as the exchange of activity, tangible or intangible, and more or less rewarding or costly, between at least two persons (Homans 1961:13). Influenced by deductive theorizing and logical positivism, Homans believed that many important aspects of social behavior could be derived from five simple behavioral propositions. He embraced reductionism, arguing that the behavior of collectivities could be reduced to principles of elementary behavior. For Homans, nothing emerged in social groups that could not be explained by propositions about individuals, together with the given conditions under which they were interacting.

Homans's primary focus was the social behavior that emerged as a result of mutual reinforcement of two parties involved in a dyadic exchange. His theoretical consideration of distributive justice, balance, power, status, authority, leadership, and solidarity is based on an analysis of direct exchange. Two main criticisms of Homans's work were that it was too reductionistic (i.e., it took the principles of psychology as the basis for sociological phenomena) and that it underplayed the significance of the institutional level of analysis and the social processes and structures that emerge from social interaction. These criticisms were addressed in the subsequent work of Peter Blau and Richard Emerson.

Blau (1964, 1986), in his well-known book, *Exchange and Power in Social Life,* developed a much more extensive treatment of the links between microlevel social behavior and the groups, organizations, and institutions it constitutes. For Blau, relationships between the elements of the structure create emergent processes that evolve from the interaction of the parts but that are not reducible to properties of these individual elements. Thus, a major difference between the perspectives of Homans and Blau is the latter's recognition of "emergent" processes at more complex levels of social organization. Blau framed his micro-exchange theory in terms of rewards and costs as did Homans, but he took a more utilitarian approach. Social exchange, for Blau (1964), "refers to voluntary actions of individuals that are motivated by the returns they are expected to bring and typically do in fact bring from others"

(p. 91). Blau defined exchange behavior as behavior explicitly oriented to the ends that can be achieved through interaction with others (Blau 1986:5). The microlevel exchange theory in Blau's work represents one of the first attempts to apply utilitarianism derived from microeconomics to social behavior. Later efforts include those of Gary Becker, a Nobel Prize–winning economist.

Blau focused primarily on the reciprocal exchange of extrinsic benefits and the forms of association and emergent social structures created by this kind of social interaction. In social exchange more than in economic exchange, the exact nature of the obligations to return the favor or resources of value is often not specified in advance. There is a general expectation of some future return, but it is frequently based on reciprocity norms rather than explicit negotiation. Subsequently, this form of social exchange has been identified as reciprocal or "non-negotiated" exchange in contrast to negotiated exchange in which there are explicit, often binding terms of trade.

Principles of social attraction were used by Blau to specify the conditions under which behavior leads to the initial formation of exchange relations. Social exchange processes give rise to differentiation in social status and power based on the dependence of some actors on others for the provision of valued goods and services. Much of the remaining focus of his book is on the structure of social exchange and emergent social processes at the group and organizational level. His explicit attempt to build a theory of social structure on the basis of a microlevel theory of exchange was influential in Emerson's work, although they used different theoretical strategies. Blau's discussion of dependence as a determinant of power drew on Emerson's (1962) early work on power. In addition to his effort to build a macrosocial theory of structure on the basis of a microsocial theory of behavior, Blau identified generic social processes and mechanisms that he viewed as operative at various levels of social organization. These included cooperation, collective action, legitimacy, opposition, and conflict. His work set the stage for a number of subsequent developments in exchange theory.

Homans and Blau popularized exchange theorizing in the late 1960s and early 1970s, but sustained empirical research on the topic did not begin until the mid-1970s largely as a result of the influence of Emerson's (1972) more formal theoretical work, based on his earlier treatment of power-dependence relations. Emerson built a conception of social exchange around his fundamental insights concerning power in social relations. He, like Blau, made power and inequality central to his treatment of exchange processes. And, like Blau, he viewed his theory of social exchange as the initial step toward building a general theory of social structure. The structures of primary interest were the networks formed as a result of the connections among a set of actors engaged in social exchange with one

another. Two of Emerson's distinct contributions to exchange theory in sociology are his fundamental insight into the relational nature of power and his extension of exchange theory to analyze the social networks created by exchange relations. Subsequent work by Markovsky, Willer, Skvoretz, Lawler, Molm, Bonacich, Friedkin, and others built on these developments.

For Emerson, the relationship between power and social structure was the central theoretical problem in social exchange theory. From his earliest work in social exchange, Emerson (1962) defined power in relational terms as a function of the dependence of one actor on another. The *power* of actor A over actor B in the A*x*:B*y* exchange relation (where *x* and *y* represent resources of value) increases as a function of the value of *y* to A and decreases proportional to the degree of availability of *y* to A from alternative sources (other than B). These two factors (resource value and availability) determine the level of B's dependence on A and thus A's power over B. That is, *the power of A over B is a direct function of B's dependence on A in the A:B exchange relation.* The more dependent B is on A, the more power A has over B. Embedding this relationship in a network of exchange opportunities creates the basis for a structural theory of power in exchange networks.

This relational conception of power has two central features that helped to generate a large body of research on social exchange networks. First, power is treated explicitly as relational, not simply the property of a given actor. Second, power is potential power and is derived from the resource connections among actors that may or may not be used. Exchange relations are *connected* to the extent that exchange in one relation affects or is affected by the nature of the exchange in another relation. The connection according to Emerson can either be positive or negative. A *negative* connection means that exchange in one relation reduces the amount or frequency of exchange in another exchange relation involving one of the same parties (e.g., the A-B and B-C exchange relations are negatively connected at B if exchange in the A-B relation reduces the frequency or amount of exchange in the B-C relation). A connection is *positive* if the amount or frequency of exchange in one relation increases the amount or frequency of exchange in an exchange relation involving at least one of the parties to both exchanges (e.g., the A-B relation is positively connected to the B-C relation if exchange in the A-B relation increases the frequency or amount of exchange in the B-C relation). These are modal cases, however; exchange in two relations may also be "mixed" involving both positive and negative exchange connections relating to different aspects (or dimensions) of exchange. Exchange in more complicated networks often involves both positive and negative connections (see Cook, Emerson, Gillmore, and Yamagishi 1983).

Emerson expanded this important direction of development in exchange theory in subsequent publications formulating what is now known as exchange network theory. In his work with Cook (e.g., Cook and Emerson 1978), Emerson argued and experimentally demonstrated that power was clearly a function of relative dependence. Moreover, dependence was a feature of networks of interconnected exchange partners whose relative social power was the result of the shape of the social network and the positions they occupied. While Cook and Emerson concerned themselves with other exchange outcomes, particularly commitment formation, it was the connection between the use of power and the structure of social networks that became the central focus of social exchange theorists for over two decades.

The key assumptions of exchange theory, summarized recently by Molm and Cook (1995:210), include the following: (1) Behavior is motivated by the desire to increase gain and to avoid loss (or to increase outcomes that are positively valued and to decrease outcomes that are negatively valued), (2) exchange relations develop in structures of mutual dependence (both parties have some reason to engage in exchange to obtain resources of value or there would be no need to form an exchange relation), (3) actors engage in recurrent, mutually contingent exchanges with specific partners over time (i.e., they are not engaged in simple one-shot transactions), and (4) valued outcomes obey the economic law of diminishing marginal utility (or the psychological principle of satiation). Based on these core assumptions various predictions are made about the behavior of actors engaged in exchange and the effects of different factors on the outcomes of exchange. The power-dependence principle, in addition, allows for the formulation of predictions concerning the effects of increasing the value of the resources involved in the exchange and the availability of resources from alternate sources.

One of the most consistent findings in the experimental research on social exchange is that relative position in a network of exchange relations produces differences in the relative use of power, manifest in the unequal distribution of rewards across positions in a social network (Bienenstock and Bonacich 1993; Cook and Emerson 1978; Cook et al. 1983; Friedkin 1992; Markovsky et al. 1988; Markovsky et al. 1993; Skvoretz and Willer 1993). While several competing microtheories connecting network structure and power use have emerged over the past two decades, these competing perspectives converge on the prediction that power differentials relate to actor's network positions in exchange networks (see Skvoretz and Willer 1993:803). The theories differ, however, in the causal mechanisms at work in converting differentials in network position into actual power differences. The Graph-Theoretic Power Index approach uses elementary theory and focuses on the role of exclusion in networks (Markovsky et al. 1988; Markovsky et al. 1993; Skvoretz and Willer 1993). Core theory borrows from game theory and focuses on specifying the viable coalitions

among exchange partners (Bienenstock and Bonacich 1992, 1993). Equidependence theory is based on power-dependence reasoning and specifies equilibrium points at which the dependence between partners reaches a "balance" (Cook and Yamagishi 1992). Finally, expected value theory (Friedkin 1992) is based on a probabilistic logic and looks at the expected value of exchanges weighted by their likelihood of occurrence (For a detailed discussion of the relative merits of these theories and their predictive abilities see Skvoretz and Willer 1993. For thorough discussions of each of these alternative formulations see the *Social Networks* special issue edited by Willer [1992]).

Bienenstock and Bonacich (1993) developed an approach to the analysis of exchange in networks of social relations based on game theoretic concepts such as the "core" (a solution set). Different network structures not only produce different power distributions, but also, different coalitions emerge as solutions to exchange. This argument implies that the structural arrangement of actors in relative position to one another can be an impetus for some subsets of actors to exchange more frequently than others. Bienenstock and Bonacich (1993) find that the core typically makes effective predictions about the frequency of exchanges as well as relative power differences among the actors in the network.

Cook and Yamagishi (1992) argue that social exchanges in a network proceed toward an equilibrium point at which partners depend equally on each other for valued resources. This "equidependence" principle has implications for partner selection as well as for exchange outcomes. They identify three different types of relations that can emerge from a network of potential exchange relations (which they refer to as an opportunity structure). Exchange relations are those in which exchanges routinely occur. Nonrelations are potential partnerships within the network that are never used and that if removed from the network do not affect the predicted distribution of power. Finally, latent relations are potential exchange relations, which also remain unused but which if removed affect the subsequent predicted distribution of power across positions in the network. The existence of latent relations can be important because they may be activated at any time as an alternative source of valued resources. When they are, they modify the distribution of power in the network.

Friedkin (1992) also argues that some relations involve more frequent interaction than others, depending on the structure of the alternative relations in the exchange network. The expected value of a particular exchange weighted by the probability of the occurrence of that exchange determines the payoffs for each exchange. The fact that some relations are used more than others is central to Friedkin's explanation of how power becomes differentially distributed across positions in a network.

The Graph-Theoretic Power Index (GPI), developed by Markovsky and Willer, predicts resource acquisition by actors in positions in exchange networks. It is a key element of what has come to be known as network exchange theory (Markovsky, Willer, and Patton 1988). GPI is based on the probability of particular partnerships being formed (see Markovsky et al. 1993:200–04 for a detailed explanation). Markovsky and his collaborators argue that some types of structures have more of an impetus toward the exclusion of some parties from exchange than do others. (In Emerson's terminology, networks that are negatively connected lead to more exclusion because they include alternatives that are competing sources of value.) Some network structures can be characterized as weak-power networks and others as strong-power networks. The main difference between these two types of networks is that strong-power networks include positions that can exclude particular partners without affecting their own relative power or benefit levels. One implication of this distinction is that strong-power networks will tend to have lower levels of behavioral commitment between exchange parties than will weak-power networks, because strong-power structures allow the arbitrary exclusion of some partners (Markovsky et al. 1993) facilitating power use.

Recent developments in Network Exchange Theory developed by Markovsky and Willer include efforts to study network dynamics, coalition formation, and the links of exchange processes in networks to other social processes like the emergence of status differences and the legitimation of inequality. In addition, Markovsky has recently worked on the linkages between the study of exchange networks and complexity theory, a rapidly developing field of interdisciplinary research.

Molm started with Emerson's two central propositions: Power is relational and power is a function of dependence, but her program of research took a direction that was distinct from the other positional theories of social exchange noted above. First, Molm focused on exchanges that are not negotiated but that are reciprocal acts of contingent giving (e.g., Molm, Peterson, and Takahashi 1999). In reciprocal exchange, actors do not bargain over the division of a finite pool of resources (or a fixed range of positive returns); rather, exchange is a process of "gift giving" or the simple act of the provision of a valued resource or service, and exchange relationships develop over time through repeated acts of reciprocal giving. The failure of reciprocity results in infrequent exchange. Second, power is not solely tied to the legitimate use of authority. Power may take the form of coercion or punishment. Whereas the other theories view the use of power as wielding structural influence through the threat and/or practice of exclusion from exchange (especially when there is a power-imbalance in the network), Molm considers how actors may impose punitive sanctions or negative outcomes on one another. The threat or practice of exclusion is most effective in networks in which there is a large power difference between the actors. And actors who

are most dependent (least powerful) are most likely to be excluded from exchange in certain networks (e.g., networks in which there is a monopoly structure).

Molm's (*Coercive Power in Social Exchange,* 1997) work demonstrates that not all power use is structurally motivated. Punishment power is not used unwittingly in the same way in which exclusion can produce the unconscious use of reward power in negotiated exchange contexts. Power use can also have strategic motivations. Punishment power may be used much less frequently, but when it is used, it is most likely to be employed purposively to influence the future actions of an exchange partner. The less frequent use of punishment power results from the risk that the target of punishment will simply withdraw from the relationship altogether. Molm extends exchange theory by investigating alternative sources of power. Power use based on the application of punishment is distinct from power use that involves differential rewards. Molm's research also demonstrates how coercive power is constrained by the structures of dependence. The primary force in exchange relations is the dependence on rewards, which motivates both the use of punishment as well as reward power.

Since those involved in ongoing exchange relations frequently have control over both rewards and punishments (even if it is only the withholding of rewarding behaviors) Molm's research facilitates the investigation of more complex exchange situations. In addition, Molm has begun to specify the nature of the precise mechanisms that relate structural determinants of power with the actual use of power by those in various positions of power, something previous theorists had not yet accomplished. Norms of fairness or justice and attitudes toward risk play a central role in this analysis. Conceptions of fairness constrain the use of power under some conditions, especially the use of coercive power, and risk aversion makes some actors unwilling to use the structural power at their disposal for fear of loss. In more recent work, Molm, Takahashi, and Peterson (2003), analyze the relationship between different forms of social exchange (e.g., negotiated versus reciprocal exchange) as a key factor in predicting exchange outcomes. The relative importance of fairness, risk aversion, and the strategic use of power varies, depending on whether or not the exchange is negotiated directly between the parties involved or it involves reciprocal, non-negotiated exchange instead.

Lawler and his collaborators (e.g., Lawler and Yoon 1996) have recently developed a new theory of relational cohesion based on principles of social exchange. The focus of this work is to examine the conditions under which social exchange relations emerge from opportunities for exchange and lead to the emergence of positive emotions about the exchange relation. These positive emotions may subsequently lead to relational cohesion, commitment, or solidarity. Positive emotions develop based on positive evaluations of the outcomes of exchanges between actors and the frequency of their exchange. Low frequency and unfavorable (or less favorable) outcome exchanges are much less likely to lead to commitment to the relation, to positive feelings about the exchange and to feelings of cohesiveness or solidarity (i.e., what Lawler terms a "we-feeling"). This line of research returns to some of the earlier anthropological concerns about the nature of the links between exchange and solidarity in social relations. In addition, it expands the scope of exchange theory to include the emotional bases of exchange, commitment, and cohesion.

Empirical research on social exchange theory has also focused more recently on the effects of important factors such as uncertainty and risk on the nature and structure of social exchange (including the work of Molm). Facing uncertain environments actors involved in exchange are more likely to seek to form committed exchange relations (Cook and Emerson 1978; Kollock 1994; Lawler and Yoon 1996) or networks of trusted exchange partners. A significant effect of the emergence of commitment in many networks is that it reduces the extent to which actors seek exchange with alternative partners and thus serves to reduce power inequalities both within the exchange relation and within the network in which the relation is embedded (Rice 2003). Kollock's (1994) work demonstrates that uncertainty not only results in commitment formation as a means of reducing uncertainty, but also tends to be correlated with perceptions of trustworthiness of the actors involved in the exchange relations. Recent work on trust in social exchange relations treats trust as an emergent property in certain types of exchange settings.

Yamagishi, Cook, and Watabe (1998) report that trust emerges in exchange relations under conditions of high uncertainty when actors begin to form commitments to exclusive exchange relations in an attempt to avoid the possibility of exploitation by unknown actors who enter the exchange opportunity structure. Given low uncertainty, actors are much more likely to continue to "play the market" and to avoid forming commitments to specific partners in order to maximize their access to valued resources. (Uncertainty in these experiments refers to the likelihood of being exploited by a new partner in a network of exchange opportunities that changes over time.) In recent research on trust, uncertainty, and vulnerability to exploitation are often defined as two of the key elements of situations in which trust considerations are paramount (e.g., Heimer 2001). Cook, Rice, and Gerbasi (forthcoming) identify the types of economic uncertainty that lead to the formation of trust networks for exchange. Trust networks, if they become closed networks, actually may retard the transition to market economies under high economic uncertainty such as that characteristic of Eastern European countries and other countries making the transition from socialist to capitalist economies. Other implications of social exchange theory for economic relations are explored in Cook et al. (forthcoming).

New applications of social exchange theory to macrolevel social structures and processes are a fitting tribute to Blau's enduring influence on the development of exchange theory, despite his own skepticism about the links between microlevel theories of exchange and macrolevel social structures and processes.

SOCIAL FACTS

In his work on *The Rules of Sociological Method* ([1895] 1982), the French sociologist Durkheim defined social facts as ways of acting, thinking, and feeling that were external to individuals and exercised a constraint over them. Although the concept of social facts is closely identified with Durkheim, it is also relevant to the understanding of any type of social theory that treats society as an objective reality apart from its individual members. In general, it can be distinguished from theoretical paradigms that place a greater emphasis on social action or individual definitions of reality.

According to Durkheim, social facts are general to the whole society and have a distinctively collective character. They constitute the distinctive subject matter of sociology. They are often embodied in social institutions, such as religions, kinship structures, or legal codes. These institutions are the primary focus of sociology as a science. However, social facts can also appear as social forces of more diffuse type—for example, in the mass behavior of crowds and other forms of collective action or in the collective tendencies manifested in statistical rates of social phenomena such as suicide and crime.

Durkheim stated that the sociologist should treat such social facts as things. The sociologist must study these social facts as realities in their own right, with their own objective laws of organization, apart from the representation of these facts in the individual's consciousness. In Durkheim's view, if society does not exist as a distinct level of reality, then sociology has no subject matter. The social and the psychological are distinguished as different and independent levels of analysis. For Durkheim and his followers, this meant examining both the social substratum, or distribution of groups in space, as well as the collective representations or collective psychology shared by most members of society.

Durkheim also distinguished between the normal and the pathological within the sphere of social facts. Phenomena such as crime and suicide are normal for a society if they correspond to its type of social organization and level of development. For example, crime is normal in a society that also prizes individual innovation, and no progress would be possible without the actions of those great criminals who represent in their individual person the new cultural tendencies and provide a focus for new outlets for emerging currents of public opinion. In his book *Suicide*, Durkheim ([1897]1951) examined social suicide rates as a type of social fact. He argued that suicide rates varied regularly with differing social circumstances, and he proposed a theory of four social causes of suicide, two of which were particularly central to modern society. Egoistic suicide resulted from the lack of integration of the individual into social groups and was the most common type of suicide in modern society. Based on his examination of suicide rates, Durkheim constructed a formula that stated that the rate of egoistical suicide varies inversely with degree of integration of familial, religious, and political society. Durkheim thought that familial, religious, and political ties were generally weakened in modern society and, therefore, suicide rates were higher. He argued generally that society needed to supplement these weakened ties with new and stronger ones rooted in important emerging realities such as the occupational or professional group.

Anomic suicide resulted from failure of social norms to regulate the individual's wants, needs, and desires. It was found especially in periods of rapidly changing or fluctuating economic circumstances but could occur in other forms, wherever individuals' normal standards of conduct and expectations were suddenly disturbed. For Durkheim, both of these social causes operated independently, apart from the individual incidence of suicide, and pointed to a level of social facts that could be understood only sociologically.

Since his book's publication, Durkheim's work has been faulted for its underestimation of the interpretive aspects of the classification of actions as suicides and also for its neglect of the role of motives and intentions in the understanding of individual suicides. In a later study titled *The Causes of Suicide*, another member of the Durkheim school, Maurice Halbwachs (1930), had already placed a more equal emphasis on the psychological as well as the social dimensions of suicide and, thus, counteracted the school's inherited objectivism. Jack Douglas's (1967) work on *The Social Meanings of Suicide* reviews this tradition of research. He questions the validity of an objectivist account of suicide as a purely social phenomenon and calls for a study that does justice to the complexity of the socially embedded meanings connected with acts of suicide.

Durkheim and the members of his school investigated a wide range of other social facts, including family and kinship structures, the division of labor, religion and magic, systems of symbolic classification, and the dynamics of whole societies. Their focus on studying social facts as objective realities led them to emphasize social morphology—that is, the study of the number, distribution, and social arrangement of populations in space and over time. This approach combined the disciplines of geography, history, and demography into a synthetic sociological analysis of what they called the social substructure. Among the Durkheimians, Maurice Halbwachs wrote most extensively on social morphology, although all the members of the school, including Durkheim himself, used this perspective in their explanations of social phenomena.

The emphasis on social morphology was part of a more general methodological principle in which Durkheim argued that the causes of changes in social facts are to be sought in historically antecedent social phenomena. For example, in *The Division of Labor in Society*, Durkheim (1893) examined the transformation of whole societies from mechanical to organic solidarity. Mechanical solidarity was based on likeness among its members due to a strongly developed collective consciousness and was organized around segmental groups, primarily extended kinship structures. Organic solidarity was based on the mutual interdependence of performances in a complex division of labor. Increased division of labor and organic social solidarity also promoted greater individuation and a decreased influence of the collective consciousness. This overall transformation from one type of solidarity to another was caused by changes in social morphology, in particular, an increase in the total population volume, a greater number of persons in given territories (i.e., material density), and an enhanced degree of communication and interaction among groups (i.e., moral or dynamic density). At the same time, Durkheim identified a modern pathological form that he titled the anomic division of labor. In this type of social organization, the division of labor failed to create social solidarity because of the absence of sustained contact between segments in the division of labor. It is noteworthy that this explanation of social change operates entirely at the level of interrelated social facts.

In his study on *Seasonal Variations in Eskimo Society*, Durkheim's (1904–1905) close collaborator, Marcel Mauss,

found a similar cause of change in religious ritual, law, family organization, economic life, and other aspects of Eskimo society in the seasonal variation of population concentration and dispersion and their concomitant effects on moral density. In their study of *Primitive Classification*, Durkheim and Mauss (1901–1902) argued that the central categories of thought and elementary forms of classification of objects in the world in primitive societies corresponded to the social organization of those societies and could be understood without reference to individual psychology. In a related study of "The Preeminence of the Right Hand," Robert Hertz (1909) argued that the unequal evaluation placed on the right versus the left hand was not rooted as much in biological realities as in social and especially religious definitions of the sacred versus the profane. This study subsequently generated a large literature on dual systems of classification that ultimately helped give rise to structuralist theories of culture and society.

Although the concept of "social facts" is associated with Durkheim and his school, and with the positivist tradition generally, other social theories that emphasize the constraint of objective social conditions over individuals share something in common with this view. Marxist social theory has a strong positivist or objectivist dimension in its focus on forces and social relations of production that confront individuals as objective conditions of existence. Although Marx noted that individuals make history, he added that they did so under conditions independent of their will. Social existence determines consciousness rather than the other way around. In Marx's writings, individuals appear largely as representatives or personifications of social classes or objective economic forces. When Marx does emphasize the role of actors in history, they are usually collective actors such as social classes like the bourgeoisie or the proletariat. Capitalism as an economic system dominates the experience of both worker and capitalist. The capitalist's individual motives are unimportant in understanding capitalism. They are merely representatives of the economic dynamics of the system. However, Marx sometimes strikes a more activistic chord, for example, when he speaks of the revolutionary action of the proletariat as a necessary part of the historical transformation from capitalism to communism. This ambiguity divided later Marxists (e.g., Gramsci and Althusser) over the question of the deterministic versus voluntaristic implications of Marx's work. This division was enhanced with the discovery of the writings of the young Marx, with their more humanistic emphasis on individual alienation and their Hegelian language of self-consciousness. These writings seemed to contradict the economistic and deterministic emphasis of his mature writings.

Emphasis on the objective reality of society and factual character of social existence helped generate a variety of functionalist and structuralist approaches to social theory. Although Talcott Parsons began his work with a theory of social action, he rapidly moved toward the development of a macrosociological, structural functional theory that all but eliminated the study of individual action and actors. This theory emphasized the role of common values in creating social integration and, in consequence, examined the individual largely in terms of the successful (or unsuccessful) socialization and internalization of these values. When individual action was emphasized, it was thought to take place within a culturally determined set of choices among institutionalized value orientations—what Parsons called the schema of patterned variables. For example, the choice between universalism versus particularism, or achievement versus ascription, is a culturally defined choice in which individual actors may choose their particular orientations to action but do so within a cultural system that has already valorized one or another of the competing value orientations.

In *The Social System*, Parsons (1951) also began to develop a theory of social systems that focused on the idea that any social system, including whole societies, needed to accomplish four basic functions in order to survive (i.e., adaptation to environment, goal attainment, social integrative, and cultural pattern maintenance). The analysis of the interchanges among institutions (e.g., economy, polity, household, school, law, etc.), serving these four functions became a major focus of theory building and was applied by Parsons to a variety of concrete problems. For example, in *Economy and Society*, Parsons and Neil Smelser (1956) provided a detailed analysis of the economy as a social system and charted its internal interchanges as well as its relations with other noneconomic systems. In *Family, Socialization and Interaction Process*, Parsons and several collaborators (1955) also examined the social system of the family, in particular, the distribution of instrumental and integrative roles among men and women. His followers developed this perspective in varying directions, including most notably Kingsley Davis and Wilbert Moore, in their attempt to demonstrate the functional necessity of social stratification in society and the aforementioned Smelser who extended this approach to social change in the industrial revolution and to the study of collective behavior. All these studies focus on the objective analysis of social and cultural systems without significant reference to individual agency as a constituting factor.

Robert K. Merton's functionalist theory also emphasized the study of objective social structures and their consequences. Merton focused on the distinction between the manifest (i.e., intended and foreseen) and latent (i.e., unintended and unforeseen) functions of social structural arrangements. In his influential essay "Social Structure and Anomie," published originally in 1938 in the *American Sociological Review*, Merton traced the ways in which an anomic American social structure inordinately emphasized the goal of success and downplayed the role of legitimate means to that goal or limited access to their achievement by

the lower classes. As a result, this particular social structure promoted a variety of role adaptations, including criminaloid innovation, ritualist withdrawl of effort, full-scale retreat from social engagement, and rebellion against established values and norms. Merton and his students generally adopted a more flexible functionalist method than Parsons. This allowed them to discuss a variety of internal dynamics of "middle-range" social phenomena (e.g., conflict, bureaucracy, reference groups) that escaped the more wholistic and systematic functionalism of Parsons. However, the Mertonian brand of functionalism remained devoted to an image of society as an objective social phenomenon susceptible to analysis without substantial reference to the motivation of individual actors.

Later twentieth-century French social thought produced a particularly large number of variations on Durkheim's sociological objectivism, including the structuralism of the anthropologist Claude Lévi-Strauss, the historical investigations of the *Annales* school, especially the work of Braudel and his followers, the work of Michel Foucault, and the writings of Louis Althusser.

Lévi-Strauss drew heavily on linguistic models to create structural theories of kinship, myth, and culture generally. His theories eliminated individual experience and response in favor of establishing the reality of enduring, perhaps even eternal human structures. Human experience and expression in differing cultures could then be viewed as variations on these structures, but operating strictly within their confines. The second generation of *Annales* historians rejected the study of history in terms of actors and events and emphasized structures of the *longue duree,* especially the stabilizing influence of objective environmental forces, including even climate, and enduring socioeconomic and civilizational structures. This approach is best exemplified in Fernand Braudel's (1949) work on *The Mediterranean* but also in the studies of Immanuel Le Roy Ladurie, whose examinations of the economic and social impact of climatic fluctuations has entertained the possibility of a "history without people." Michel Foucault's studies also attempt to establish a history without the individual subject. His studies of madness, changing forms of knowledge, the clinic, and the prison trace fundamental shifts or epistemological breaks in the discourses about these topics without necessarily searching for causal sequences or viewing the changes as emerging from the actions of individuals. Instead, actors instantiate the words and deeds made possible by the reigning discourses. These various approaches to society, culture, and history reach perhaps their fullest development in Louis Althusser's structuralist Marxism. Althusser rejected the early humanist in favor of the later scientific Marx. He created a structural theory of society that entirely eliminates any effects of human agency in favor of the self-evolving character of internally dynamic socioeconomic and political structures.

The objective, scientific study of social facts is generally opposed by social theorists who emphasize human agency and social interaction. For example, Max Weber's social action theory; the symbolic interactionism of George Herbert Mead, Herbert Blumer, and their followers; phenomenological sociologists such as Alfred Schütz; and several related perspectives can be opposed to theories that emphasize the objective reality of social facts. Weber's work rests on an assumption of "methodological individualism," which insists that all objective social processes—for example, relations of power and authority—can in principle be reduced to the actions of individuals. Mead, Blumer, and their followers view society as a process rather than an object and see human beings as creators of systems of meaning through the use of symbols in social interaction. For both Weber and the symbolic interactionists, these symbolic systems need to be interpreted by the actors involved as well as by the sociological investigator—in the latter case, through a hermeneutic retrieval of meanings. Schütz's approach suggests that we begin with the taken-for-granted knowledge and conceptions of everyday life of actors and build our scientific concepts about social processes from that starting point. In general, when the objective structures of society are emphasized by interpretive sociologists, they are thought to be a moment in a larger necessary process of objective creation and subsequent reappropriation of meanings and institutions.

There have been many efforts to combine the objective study of social facts inherited from the Durkheimian, Marxian, structuralist, functionalist, and related traditions with an equal focus on the subjective experience and response of actors. The work of Peter Berger and Thomas Luckmann, Anthony Giddens, and Pierre Bourdieu are particularly worth mentioning. In *The Social Construction of Reality*, Berger and Luckmann (1966) traced the social processes of objectivation, institutionalization, socialization, and internalization through which culture and society are first created as an objective and even alien reality but then reappropriated and reinterpreted in new ways by individuals. Bourdieu's (1972) book, *Outlines of a Theory of Practice*, emphasized the concepts of habitus, practices, and reproduction. He views social and cultural structures as inherently embodied in actors without seeing any opposition between social facts and actors' experiences. Actors reproduce structures through their practices while at the same time making these structures real and removing their purely objective status as externalities. In general, sociologists today increasingly emphasize the equal significance of what Giddens (1984), in his book *The Constitution of Society*, calls "structure" and "agency." In his view, social structures provide the symbolic and institutional resources required for human agency to actually exist, yet actors working within these structures also simultaneously renew and transform them through their very action.

Although these and other efforts at synthesis have produced fruitful results, it is not clear that they have fully resolved the basic dilemma involved in the creation of a systematic social theory that must do justice to both the objective realities of historical economy, society, and culture and the equally compelling reality of individual experience and response. This is a dilemma perhaps inherent in sociology as a social science.

SOCIAL INTERACTION

Social interaction is the process through which two or more social actors reciprocally influence one another's actions. Although it may involve corporate actors of varying size, from pairs of individuals acting in concert to complex organizations, it commonly refers to processes of mutual influence among individuals. Individuals always influence one another's action in some form when in one another's immediate physical presence but may also do so through varied media of communication when spatially and temporally separated. However, until recently, the study of social interaction or what is commonly called *microsociology* has focused primarily on its face-to-face varieties.

Social interaction is the critical link between the individual and society. It is the medium through which culture and society directly influence individuals and through which individuals collectively produce and reproduce culture and social arrangements. However, social theories vary greatly in the relative emphasis they place on social interaction. Many suggest that patterns of social interaction directly reflect participants' psychological characteristics, internalized cultural values and social norms, or the influence of larger social entities and structures. Although these theories generally recognize that processes of social interaction constitute and uphold social arrangements and systems, they imply that the processes and outcomes of social interaction are largely predictable from anterior or other external factors. In contrast, other social theories argue that social interaction cannot be deduced from anterior or external factors and requires direct investigation.

Erving Goffman was the strongest advocate for treating social interaction as a subject in its own right. Goffman repeatedly argued that the orderliness of social interaction could not be reduced to the psychology of participants. Whatever is in individuals' minds, according to Goffman, they must make their behavior understandable to others. That requires an orientation to expressive conventions and consideration of the meanings one is likely to convey to others through either upholding or violating those conventions. For Goffman, social interaction involved not a meeting of minds but moves in an orderly game of collective definition.

Goffman also argued that what are commonly called social structures, such as diffuse social statuses or organizational positions, influence patterns of social interaction only indirectly. He maintained that social interaction consists of processes and structures specific to it. According to Goffman, there is only a "loose coupling" between interactional practices and encompassing social structures. The introduction of social structural factors into social interaction requires their translation and transformation into interactional terms. Hence, patterns of interaction cannot be directly deduced from social structural factors without consideration of the rules of their transformation into interaction specific processes and structures.

Goffman's own analyses of social interaction focused on the dramatic character of its definitional dynamics and its ritual order or structure. Goffman argued that social actors reach a working consensus about the definition of the situation that governs their interaction by mobilizing a variety of expressive resources, such as their appearance, voices and bodies, physical objects, and the fixed equipment of the setting. They thereby enact characters, stage scenes, and play through social narratives using techniques similar to those used by theatrical actors. Goffman also argued that an implicit but complex code of ritual conventions governed the interactional dramas of everyday social life. According to Goffman, much expressive conduct is ritual in both the ethological sense of being stylized and virtually automatic and, borrowing from Émile Durkheim, in the religious sense of expressing respect and regard for objects of ultimate

value. Goffman argued that interactants ritually express respect and regard for each other's self or "face," as if it were sacred. He demonstrated how social actors do so by avoiding intrusion on one another's various self-territories, such as personal space and private information, and by celebrating their past or anticipated relations with one another.

Goffman's analyses of social interaction provide a compelling answer to one of the central questions of social theory: What is the basis of social order? Individuals who hope to influence one another must make their actions understandable to one another. To do so, they must subject their conduct to the constraints of mutually understood expressive conventions, such as the grammatical rules of spoken language or the ritual prescriptions and proscriptions of interpersonal conduct. Failure to do so results in misunderstanding or not being understood at all. Hence, engagement in effective social interaction and enlistment of others in one's own endeavors necessarily involves an implicit commitment to an expressive order that is the foundation of all social order.

To demonstrate the anchorage of social order in interaction rituals, Goffman concentrated much of his attention on interaction in public places. The individuals who populate such places, at least in contemporary urban settings, often have widely varied personal and social characteristics and little, if any, knowledge of and, hence, grounds for trusting one another. Yet as Goffman illustrated time and again, their public encounters are commonly orderly, routine, and unremarkable. Such routine and orderly public interaction demonstrates that individuals, despite their many differences and lack of familiarity with one another, are mutually oriented to similar expressive conventions and committed to upholding what Goffman came to call "the interaction order."

According to Goffman, "the interaction order" is not a product of blind conformity to informal norms of public interaction. He recognized that public actors routinely violate the ritual conventions of social interaction both inadvertently and for a variety of practical reasons. Yet he showed that violations are commonly followed by apologies and explanations or what he called "remedial work." The seeming offender thereby acknowledges the potential offense and demonstrates his or her understanding of and commitment to the ritual conventions of interaction, despite the apparent evidence to the contrary. In addition, Goffman demonstrated that the ritual expectations governing interaction serve as enabling conventions that render both conformity to and violations of them mutually meaningful. For example, the implicitly understood prohibition against staring at strangers makes stares from strangers menacing, flirtatious, or otherwise meaningful. The ritual prescriptions and proscriptions of interaction are not invariant norms but constitute a common idiom of expression that social actors strategically use for a variety of expressive purposes.

Those whom Goffman inspired have primarily focused their attention on strategic uses of the ritual idiom of interaction in public places. Following Goffman's advice to study the varied ways individuals treat and are treated by others and then deducing what is implied by them through that treatment, many have concentrated on how patterns of interaction both express and reproduce cultural conceptions of different categories of people and relations among them. For example, they have shown how adults commonly deny children the same expressions of respect and regard in public places that they grant one another. Adults thereby imply that children are less than full-fledged persons, and the young commonly respond to that treatment in ways that confirm adults' unflattering conceptions of them. Others have documented the varied ways that men publicly harass women by violating their self-territories and right to be let alone. Men thereby expressively assert their dominance over public places and situationally disadvantage women who must tolerate men's uninvited overtures, evaluative remarks and gazes, and attempts to extract personal information. Still others have shown how whites tend to respond to African Americans, especially younger males, with obvious suspicion and fear in public places, often provoking hostile and intimating responses. The result is a kind of interactional choreography of the tension and misunderstanding that embodies the state of race relations in contemporary American society, both expressing and reproducing those strained relations.

Other students of social interaction have examined how individuals infuse usually impersonal and anonymous public encounters with sociality and intimacy. For one, Lyn Lofland has detailed how public encounters are not limited to fleeting relations, as when one stranger asks another for directions or the time, or routinized ones, such as those between taxi drivers and their fares or the panhandler and potential donor. What has been called quasi-primary relations of transitory sociality are also common in public places when strangers recognize that they share a common interest, a common social identity, a common focus of attention, or territory. For example, unacquainted dog owners often stop for a friendly chat about their canine companions, gay men may mutually recognize their special "kinship," unacquainted onlookers sometimes exchange critical commentary on street art and performances, and seatmates on buses and users of laundromats may engage in conversation for the duration of their time together. Longer-lasting intimate-secondary relations are also common among those who routinely encounter one another in public places. The regular customers and staff of diners, bars, and coffee shops; regular riders of bus or subway routes; and regular shoppers and retail clerks may begin to exchange personal information and, over time, a degree of intimacy, however circumscribed. In any case, this diversity of relations in public arguably provides residents of urban settings

at least some of their sense of belonging, place, and community.

Those who followed Goffman's lead into the study of public interaction have also demonstrated, in a variety of ways, that the social glue of what Durkheim called collective ideas and sentiments is anchored in ritual patterns of interaction. In both public and less accessible places, individuals dramatically enact presumed differences among people and reproduce collective conceptions of stages of life, gender, race, and other social distinctions. They honor one another's privacy but seek out and celebrate sociability with others. Each encounter that goes beyond the fleeting and routine creates what Durkheim called collective effervescence, fellow feeling, and collective identification.

The interactional production and reproduction of collective identity is most apparent among those who establish relations of continuing interaction. Using the example of little league baseball players, Gary Alan Fine has shown how members of interacting groups create distinguishing styles of appearance, their own argot or specialized language, inside jokes, and collective myths that constitute a distinctive group culture that Fine terms "idioculture." Those distinctive cultural practices expressively mark the group's boundary, distinguish those who are "us" from "them," and encourage a sense of personal identification with the group. This and other examples illustrate that social interaction is the source of cultural creation and change and of social solidarity, whether among small groups of friends or larger communities.

The apparent connection between social interaction and solidarity has led some students of interaction to consider how built environments encourage or discourage casual contacts. Most have concentrated their attention on how suburbanization, the policies that promote it, and the consequent demise of corner stores, neighborhood bars, and other urban gathering places have diminished opportunities for unexpected encounters and casual interaction among residents. Although largely speculative, they argue that the diminishment of those opportunities also diminishes residents' sense of community identification and solidarity.

Inspired in part by Goffman but more significantly by *ethnomethodology,* conversation analysts have conducted more detailed studies of social interaction than other followers of Goffman's lead. Conversation analysts extend the ethnomethodological concern with the taken-for-granted but methodical procedures of everyday social life to the study of conversational interaction. They maintain that an adequate understanding of the methodical procedures of conversational interaction requires studious attention to its empirical detail. They argue that those details are often lost in and concealed by the glosses and summaries of observational field notes and insist on the necessity of audio and/or video recording and detailed transcription of social interactions. Conversation analytic transcripts include interactional details such as phonetic representations of pronunciation and notations of simultaneous talk, inhalations and exhalations, and length of silences, often in fractions of seconds.

Conversation analysts have identified a number of processes and structures of conversational interaction based on these empirical materials. They include the procedures of opening and closing conversations, of introducing and developing topics, and of turn allocation in conversation. The study of turn taking in conversation has been particularly revealing. It demonstrates that speakers commonly demonstrate some understanding or appreciation of the prior turn or turns of talk in their current turn. That allows the previous speaker or speakers to assess how well she or he has been understood and to attempt clarification of any misunderstanding in subsequent turns of talk. The turn-taking structure of conversational interaction thereby serves as a general mechanism for the continual achievement and maintenance of mutual understanding, providing, in the words of one conversation analyst, the very architecture of intersubjectivity.

Conversation analysts have also studied what they call the preference format of conversational interaction, using the expression "preference" in a precise and peculiar sense. They use that expression to refer not to conversationalists' motivations or to statistical regularities but to the way responses to certain kinds of turns at talk are delivered. Preferred responses are delivered in a straightforward manner and without delay while dispreferred responses are delayed, qualified, and/or explicitly explained or justified. Conversation analysts' investigation of such "preference formats" tends to confirm Goffman's observations about the ritual and cooperative character of social interaction. For example, acceptance of invitations, offers, and requests is the preferred response, while refusal is dispreferred. The delay, qualification, explanation, and/or justification of a refusal are mechanisms of avoiding insult and conflict. Hence, conversational interaction exhibits a systematic bias in favor of cooperation, social solidarity, and order.

Conversation analysts initially limited their attention to the organization of mundane, everyday conversations but have more recently investigated the distinctive features of conversational interaction in particular institutional settings. These studies suggest that the ways conversational organization in such settings diverge from that of mundane conversation serve "to talk" those very institutional contexts of interaction into being. For example, in mundane conversations, any conversationalists can select himself or herself as the next speaker when the current speaker approaches the end of her or his turn at talk, but participants in classroom discussions usually honor the teacher's right to allocate turns at talk by waiting to speak until recognized by the teacher. It is in large part that restrictive organization of turn taking that distinguishes classroom discussion from

the casual conversations that commonly occur in classrooms before and after classes and that makes it possible for students easily to disrupt classroom discussions by speaking "out of turn."

SOCIAL MARKET ECONOMY (*SOZIALE MARKTWIRTSCHAFT*)

The term "social market economy" was coined at the end of the 1940s by Alfred Müller-Armack, a German economist and social theorist of the so-called Freiburg School of Law and Economics, a neoliberal branch, often referred to as "ordoliberals." Walter Eucken is known as the founder of "ordoliberalism," and Wilhelm Röpke, Alexander Rüstow, and Karl Böhm have been other prominent representatives of this group. The idea of a social market economy became a leading political and economic ideologem for the rebuilding of the German society after World War II, closely attached to the myth of the German *Wirtschaftswunder* and the name of Ludwig Erhard. Reviewing general social debates as well as studying the relevant scientific discussions, it is not easy to distinguish the definition of the social market economy from "welfare society" and

various concepts concerning "social state regulations" (*Sozialstaatlichkeit*). There is consensus, however, that social market economy combines principles of competitive democracy—that is, a free market economy—with the idea of an active state regarding standards of social equilibration and responsibility. According to Alfred Müller-Armack, systemic mechanisms (i.e., the "automatism" of the market system) enforce "guidelines" by "meaningful" regulations reflecting general social and human values. The goal of such regulations is to find a "new balance between the divergent interests of social security and economic freedom" (Müller-Armack 1966:236).

Eucken and his followers argued for supplementing the private law society with an institutional guarantee of open markets to ensure that market competition can display its central function as "the most ingenious instrument to emasculate power" (Böhm 1961:22). In its German reality after 1948, social market economy is based on three main areas of societal governance and political regulations. First, it covers rules of guaranteeing qualitative competition; second, it embraces arrangements regarding social security, health care, and so on; third, it is backed by the institutionalization of the so-called labor-capital compromise (industrial conflict).

Thus, social market economy has to be grasped as a societal project to bridge the systematically built-in contradictions between the dynamics of liberal market economy, on one hand, and the institutionalization of standards regarding social values on the level of societal community, on the other. A broader understanding of the idea of social market economy focuses not only on macrolevel national economic policies but also on ethics and on issues of a specific social philosophy concerning the role of the state, the regulative functions of the intermediate organizations and institutions, and the "positioning" of—respectively, the "embedding" of—individuality.

THE HISTORICAL CONTEXT OF THE EMERGENCE OF THE SOCIAL MARKET ECONOMY

The project of a social market economy arose against the background of the developments and historical experiences of Germany between the late 1890s and the first half of the twentieth century. One can observe philanthropic and state legal reactions to the new social challenges of industrial capitalism, urbanization, and proletarization in all European societies during the nineteenth century—starting with special legislation in England even before 1850. Germany was a "latecomer" to industrialization and, as a relatively newly established nation-state, developed an intense and elaborated social debate over these issues. In contrast to other European countries, the so-called *Soziale Frage*—"how to integrate the working class into a bourgeois society?"—became a core element of the German

nation. Against the background of a controversial debate under the regime of Fürst Bismarck, the "Deutsches Reich" introduced the most advanced social state regulations of the time concerning health care, unemployment pay, and social welfare, on the one hand (*Sozialgesetzgebung* [social legislation] 1883–1889). On the other hand, it initiated suppression of the social protest by the police and launched tough laws against socialist movements in the country (*Sozialistengesetze* [socialist laws]

(1878). Bismarck's welfare state led to a configuration of corporatist interest intermediation as a central element of coordinated capitalism.

Nation building and the political debate during the so-called Weimar Period were very much profiled by the *Soziale Frage* and the industrial conflict issue. The fate of the Weimar Republic was linked to two controversies: First, there was an emphasis on the building of a modern, more or less Western-oriented civil society versus strong and aggressive feudal and militaristic traditions. Second, there were the efforts toward a societal institutionalization and regulation of the capital-versus-labor conflict. The programmatic and political actions of the Weimar Parties referred mainly to these two areas of society building. Class abatement was seen as a main task of welfare-state action beyond inquest particularism. Interestingly, the conservative revolt ending the Weimar Period targeted the party pluralism as well as the "irresponsible" social costs of the welfare system. One of the intellectual starting points of early ordoliberal thinking in the 1930s has been the experience of a specific "failure of the state" (*Staatsversagen*) and the "corporatism" of the Weimar Republic facing the needs of a modern market economy.

From the very beginning, the specific German approach toward regulating industrial class society via an active state had an emphasis not only on social integration and social pacification but on economic performance, too. Because Germany had no colonies and an inferior position regarding natural resources, social pacification, vocational training, and the "production" of a state-loyal and skilled labor force became essentials of the German way toward industrial modernity.

THE FOUNDATION OF THE FEDERAL REPUBLIC OF GERMANY

Social policy discussion and societal decision making regarding labor organization and economic development did not start in a historical situation of "tabula rasa" after 1945 but was built on a tradition of substantial "social state regulations" and a broad theoretical debate regarding welfare issues and class abatement well before the end of the 1920s. As profound as the ideological changes and political regulations of the Nazi Regime may have been, main elements of the power structure and its institutional framework

still worked or were quickly restored at the end of World War II. The pre-Nazi union movement quickly regained power on the factory level, and Germany had a relatively developed institutional setting regulating labor politics and labor law (e.g., labor courts) as well as chambers of commerce and industry. Returning emigrants and a young generation of intellectuals started enthusiastic debates on the future structure of the German society. Among the leading intellectuals there was no doubt that some sort of "socialist" governance system should be implemented to resist "fascism," on one hand, and to avoid the social misfits and imbalances of "crude capitalism," on the other. Even the Christian Democratic Union (CDU), which was prominent for its "free-market" position later, favored socialist elements for the socioeconomic order of the new Germany (*Aalener Programm,* which proclaimed steel industry, coal, and mining as state-owned economic assets). It is necessary to recall that the concept of *Soziale Marktwirtschaft* entered the debate not by way of left-wingers but through moderate conservative discussants as a program to curb socialist and interventionist aspirations.

Doubtless, the emphatic energy was centered on the idea of the market—the free market controlled by a strong state but *not* managed or manipulated by an interventionist state. Literature shows an almost theologian association, as Philip Manow (2002) stresses:

> Ordoliberalism thus transferred the idea of "Staatskirchentum" to the economic sphere: The economy was supposed to function freely, according to its own "liturgy" of a free competition and efficient resource allocation, but the state was supposed to oversea and protect this free and undistorted functionate against all undue interference. The authoritarian leanings of ordoliberal thought thus drew heavily upon the protestant concertion of the proper role of the state. (p. 13)

However, intellectual modeling of socialist ideas for (re)building societies after 1945 has not been only a German topic. Everywhere in Europe more or less socialist models for the reconstruction of economy and society were on the agenda. This is true for Great Britain, France, and also for Italy. Despite the attraction of the prosperous material culture in the United States, the example of American capitalism did not get much credit among European social theorists immediately after World War II. The rise of the Cold War, however, laid ground not only for political anti-communism but also for rigid opposition against socialist ideas in general. The debate on society building got caught at the beginning of open confrontation between the two political blocks. The events in Greece and Yugoslavia and especially the Korean War influenced and restricted substantially the intellectual dispute and political reasoning throughout Europe and, due to the peculiar border situation,

in West Germany in particular. Against this background, the idea and the concept of social market economy clearly bridged "free market economy ideology" and the European—and especially German—tradition of social policy. Alfred Müller-Armack formulated the idea, and Ludwig Erhard became its symbol of realization.

The main structural elements characterizing the realization of the social market economy concept are the following:

- The organization of efficient regulations on competition, fighting, and limiting distortions and deterioriation of market procedures through monopolization and trusts and the like. However, the basic idea was not to call for the state as economic actor but to call for an active state in terms of ensuring "contextual direction."
- The implementation of an elaborated social security system and of various welfare society standards guaranteeing a relatively high level of minimum income for all, including health care, unemployment and sickness payments, and other procedures of "social state" qualities (*Sozialstaatlichkeit*); favoring especially in these areas the active—regulating and caring—state. These welfare-institutions turned out to be "real" identifying qualities for social market economy through the 1960s and 1970s.
- The institutionalization of the industrial conflict and especially the stabilization of independent unions not only as an economic bargaining power but as an element of the political structure of society. Of particular importance are regulations concerning codetermination of workers and workers' interest organizations on enterprise and branch levels (*Mitbestimmungsgesetze* [laws of codetermination] 1951/52, 1972). The institutionalization of industrial conflict did not fit the original ordoliberal doctrines pushed by Eucken, Rüstow, and others, but surely it became essential historically, to the working concept of social market economy in Germany from the 1950s on.

During the 1950s, the more puristic ordoliberal concepts fused with welfare state achievements. The cartel law, the central bank law, and the pension reform were enacted in 1957; principles of liberal economic order and elements of a corporatist welfare state were implemented simultaneously. The social market economy model is strongly related to what has been discussed by Ralf Dahrendorf and others as the career of the social democratic consensus scenario in postwar industrial societies in Europe.

Screening the situation of social policies and labor strategies after World War II, we find variations of this social democratic consensus. Of particular relevance for theoretical and political debate has been the Swedish model (a model that has its roots in the late 1920s), but the French model of "planification" has provoked special interest, too. The different phases of social disputes and, especially, industrial conflicts in postwar Italy fueled ambitious

modeling and provoked intellectual curiosity as well as tough controversies. Great Britain—apparently the "hero" of the Anglo-Saxon heritage of liberalism and free-market economy—had a rather interesting postwar history of state-regulated welfare economy. As different modes of regulating industrial conflicts and economy in general were implemented in all industrial societies during the twentieth century, the workers' codetermination of regulations became a special "qualifying" element of the German system of industrial conflict management. The introduction of the social market economy transformed the "negative integration" of the working class (Güenther Roth) into some degree of positive conflictual partnership.

SOCIAL MARKET ECONOMY AS THE GERMAN SUCCESS STORY

The success of the German social market economy lies in its continuous generation of competitive production and productivity by way of effective workers' involvement (*Leistungsbereitschaft* [readiness to perform]) and a widely shared culture of rationalization, on one hand, and in its "catalyser" function in producing stable relationships between the different-interest parties in economic conflict, on the other. The social effectiveness of the social market economy system and its obvious economic efficiency, ideologically backed by a relatively high legitimacy of an "active state," were the foundations of what was seen from outside as the "German model," especially during the 1960s and 1970s. Low strike losses, high-quality production, the influx of millions of the skilled refugees from Eastern Germany, and the import of hundreds of thousands unskilled workers ("guest workers") from Italy, Spain, the Balkan countries, and Turkey made possible the so-called German *Wirtschaftswunder* during the first two decades after World War II, which realized high growth rates and impressive productivity gains (the gross domestic product doubled during the 1950s and labor productivity rose on an annual average of 5.7 percent). This "miracle" did hide systemic tensions and contradictions. Growing world markets, increasing competitiveness of German products, low defense expenses—these and other factors contributed to the peculiar configuration of the German economic and social success story. Strike figures, productivity, economic growth, and terms-of-trade figures show that in almost all relevant data sets, Germany took a favorable position in the statistics.

Only in the late 1960s did a short recession interrupt a continuous positive economic development. This short economic crisis showed the integrative function of the German system of industrial conflict regulation. Even though wildcat strikes gave evidence that even the German consensus model was based on antagonistic structures, the conflict histories in France and in Italy demonstrated to the

European public that the German model of social integration and economic progress had considerable advantages regarding the overall "benchmarking" between the early industrialized nations in an increasingly competitive world market.

This success story received admiration from outsiders and sometimes was looked on with envy and mistrust from European neighbors—but overall, it was welcomed as a historical development that stabilized German society politically and guaranteed its strong Western ties. There is no doubt that a socially and economically unstable and therefore unreliable German Federal Republic would have been a difficult burden for the European unification process and the East-West confrontation.

Germany could build its new economy under the military shield of the United States and NATO and with considerably fewer defense expenditures and input into military research and development than other countries. Therefore—like Japan—the German economy could concentrate on consumer and investment products with a strong export orientation. It might be disputed therefore as to what degree the social market economy system alone guaranteed progress and prosperity in Germany during the postwar decades or to what degree the externally "sponsored" economic growth-dynamics stabilized the model of the social market economy. Obviously there has been a positive interaction (*Wechselwirkung*).

The German path of economic and social development continued through the mid-1970s and was then redesigned due to qualitatively new challenges and uncertainties related to new technologies, globalization, new economic power structures, and the world financial markets. During the late 1970s and the 1980s, the German mode of capitalism lost its reputation, as the German economy increasingly showed the same problems as other Western Nations.

At the end of the twentieth century, the classic model of industrial society as conceptualized by economists, historians, and the first generation of sociologists in the late nineteenth century, was called into question. What is currently on the agenda of the political and social science discourse is first the future of the so-called Taylor-Ford regulation model, which has essentially characterized the process of industrialization for the last 60 years or so; second, the future of European variations of social welfare societies, which were established in the postwar period; and third, the impact of globalization—the emergence of the "global age" (Martin Albrow).

SOCIOECONOMIC CHANGES AND CRITICAL ARGUMENTS SINCE THE 1970s

Along with the trend toward "globalization" and "internationalization," economies increasingly experience strong pressures regarding mobility of capital investment, flexibility of labor use, and decentralization of production,

research, and development activities in order to reduce costs. The key formulas are lean management, just-in-time-production, global sourcing, global marketing, and global production. National institutions lose some of their earlier regulative importance. Globalization has more impact on activist states like Germany as the state loses its capacity to direct economic activity within its borders and is on the defense against Anglo-Saxon-style capitalism.

Moreover, "internal" factors like demographic developments and changes of the social structure (composition of workforce regarding gender, education, age, etc.). as well as new sociocultural standards of consumption and leisure, generate new framing conditions for modeling the built-in tensions and contradictions for policies focusing on economic efficiency and social effectivity.

Relatively early, critical analysts have spotted weak points of the German model regarding economic efficiency and market competition: highly legalized and regulated work relations, rigid unions that back inflexibility of work input and block industrial change, the increasingly unbearable social costs, and the welfare costs endangering prosperity in the long run, creating a "negative progressive circle" of economic data dynamics. The positive aspects of the German social market economy fade against its negative aspects. During the 1980s, the world economic scenario and developments at the national level reduced the attractivity of the German model considerably: More and more, export-oriented German producers were faced with strong competition on many important markets—for example, on the important U.S. market—from Asian competitors, especially from Japanese industry. The classical "super-aditum" of German industrial production on the world market—the label "Quality Made in Germany"—lost its particular profit value. Especially the machine tool, textile, and chemical industries could no longer rely on "Made in Germany." Even the auto industry—traditionally the most important product symbolizing German engineering—had to face fierce competition from Japanese competitors. With its highly regulated labor market, relatively strong legalizations regarding many products (especially biotechnics and the like), and its high labor costs, Germany lost its former strong position as an attractive economic place for foreign investments, too.

Negative effects of formerly positive enterprise cultures and consensus policies at the firm level, such as recruitement of long-term, high-quality workers, trust in local economic networks, and so on, showed up more and more as elements of inflexibility and as problems for innovation and structural change. The very qualities of the German success story (Hans-Joachim Braczyk et al.) became the foundations of the German economic difficulties in the 1980s: trust relations, long-term regional cooperation, and the tradition of conflictual cooperation in industrial relations. Demographic developments challenged modern social

welfare systems in most European countries—and also in Japan—but hit the German situation harder, as the legalized demands regarding social transfer payment became more and more costly.

The fall of the Iron Curtain after 1990 and the integration of former East Germany (GDR) into the West German societal model proved to be a crucial test area regarding the German model. The enlargement of the institutional and normative system of West Germany's social state principle (*Sozialstaatlichkeit*) combined with the integration of a very problematic, inefficient economic structure has been a "fantastic" economic macro-experiment. The integration of the GDR resulted in a massive de-industrialization and destruction of economic resources, on one hand, and in the production of huge costs for the welfare society institutions, on the other. In effect, this pushed the German model to its limits. The size of the German economy and its still-strong industrial core as well as the good name of "DM" (Deutschmark) helped resist to some degree the very serious economic challenges. However, since the beginning of the 1990s, the German economy has been in a critical condition, displaying over 4 million unemployed, reduced profit margins in many branches, and the slowdown of investments in new technologies and new products. The situation has not improved much since then. Three indicators expose the critical condition of Germany's economy at the end of the twentieth century:

1. The German economy is still very much oriented toward heavy industry, manufacturing, and machine tool and vehicle engineering, and it remains relatively underdeveloped in industries associated with the postindustrial economy, such as biotechnology, knowledge service, and so on. These facts are seen as an important weakness by some observers. In Germany, more than one-third of the working population is still engaged in the so-called industrial sector, compared with only about one-quarter in the United States. Despite some problems of statistical equivalencies, there is no doubt that the German economy with its strong position in automobile production and machine tool industry is still more industry oriented and less service oriented than other modern economies.

2. Flexibility of labor is progressing only very slowly in Germany, in contrast to the United States and Japan and also, for example, the Netherlands. Institutional and cultural support for traditional work patterns such as the "normal working day" and long-term work contracts is still strong. Labor costs are also at the highest level compared with other nations, while the comparative advantage of a high-quality labor force diminishes with the expansion of lean production methods. Overall, the German labor market is rather resistant to the introduction of new types of low-income work with flexible time arrangements and new income configurations to reintegrate the long-term unemployed.

3. The positive interaction of free-market conditions with state interventionists' welfare policies obviously has turned into a negative spiral. Against this background, there has been an ongoing debate over the last few years about the *Standort Deutschland* (Germany's position as an attractive location for investment) versus the *Modell Deutschland* (the German model). Recent government rhetoric and a wide range of economic literature and, in particular, strategic arguments made by entrepreneurs has been aimed at remodeling the German model. The workers' interest organizations have definitely lost power. The model of the social market economy was put on trial as there was a broad consensus between experts and leading social politicians that facing first the Japanese success story and second—from the 1990s on—the new American success story, German socioeconomic doctrines had passed their best times.

SOCIAL MARKET ECONOMY, EUROPE, AND GLOBALIZATION: REFORM OF DISSOLUTION

Economic data in the 1980s and especially in the 1990s clearly show the diminishing attraction of the German model. In terms of growth dynamics and employment, Germany has fallen behind most of its European and global competitors—and some experts labeled Germany as "the sick man of Europe," pointing to a 0.7 percent growth rate in 2001 and 2.7 percent of GDP fiscal deficit in 2002.

Nevertheless it should be noted that in social science debates and in popular discussions neither the Japanese success story nor the new Anglo-Saxon success story led to a complete dismissal of the idea and the model of social market economy in Germany. The controversial debate among experts and politicians regarding Rhinish capitalism versus Anglo-Saxon capitalism involved considerable polemics at the beginning. Through the 1990s, it developed more and more into a sophisticated discussion reflecting various options of systemic aspects of different socioeconomic developments and regulations (Friedrich Buttler). The evidences of systemic problems of "classical" welfare policies were put on the agenda as well as the not less systemic problems resulting from neoliberalism.

The historical defeat of the "real socialism" and the difficulties of softly adapting European social welfare achievements to the new challenges of global economy and the impact of new technologies, on one hand, and undeniable deficiencies and social risks of "pure" capitalism, on the other, force current debates into new perspectives. Key words are *deregulation* versus *reregulation, shareholderism* versus *stakeholder values,* and *globalization* versus *regionalization.* Surely there is need for new answers to old problems and for answers to new problems: the ecological question, nonintended consequences of global economic processes and strategies, the troubles with the "new economy" at the end of the twentieth and the beginning of the

twenty-first century, particular economic risks related to financial "bubble" phenomena, and a new quality of international terrorism after September 11, 2001.

On the level of social theory, new emphasis is put on "communitarianism" (Rawls, Walzer et al.) and on the role of the state as a regulator in global economic relations as well as on the increasing impact of nongovernmental organizations (NGOs) on the international level and the role of international organizations (World Bank and World Trade Organization), as well as the ILO (International Labour Office) in Geneva. The fabulous career of the notion of "governance" and its normative disciple "good governance" in relevant socioeconomic literature stands for a new interest in grasping the tensions between free market economy principles and the institutionalization of social justice and social equilibration related to basic social and human values. As the idea of and the demand for a "world government" still remains highly poetic, discussions on the further institutionalization of international and transnational rules and standards regarding labor force use and nature resource management have progressed. After a short period of unquestioned dominance of the Anglo-Saxon model of socioeconomic deregulation, the current debate is much more cautious and ambivalent about this, and there is "curiosity" in modeling a new economic efficiency that includes *social* effectivity. Reflecting the economic and worldwide turbulences at the beginning of the twenty-first century, it does not seem risky to predict that the debate about social market economy will gain new ground in the coming years. Eventually, social scientists will excavate the original concepts "designed" by Walter Euken, Alexander Rüstow, Alfred Müller-Armack, and others.

Struggling with serious problems, the German economy has faced during the last 10 to 15 years, there should be the historical chance for further developing a social market economy that works. The recent economic history of the Netherlands, Denmark, and other countries impressively demonstrates that European welfare societies have laid down rather solid grounds for reshaping themselves without betraying the basic social philosophical and political ideas and ideals that led to their creation after the catastrophes of the economic crisis in the 1930s. There is evidence that the German social market economy will undergo important changes during the coming years—reform of the health care system, new labor arrangements like the Volkswagen 5000 × 5000 model, and strategies for flexibility of income and work time regulations.

Many experts' judgment is clear: The German state that now spends almost 50 percent of the national income (and most of this for social transfers and social security) cannot and will not survive macro-economic challenges ahead. Surely, resistance of vested interests, the reluctance of the incumbent politicians, and the "imago" of the caring state in Bismarckian tradition will be tough. However, the recently fashionable formula "new social market economy" will have to be materialized sooner or later. And there are a lot of issues waiting for disagreement: strengthening consumers' purchase power versus favoring firms' investment activities, lowering business taxes versus public expenses, and so on.

FINAL REMARKS: SOCIAL MARKET ECONOMY, GLOBALIZATION, EUROPEAN UNIFICATION

The German project of a social market economy is one of the models representing the tradition of European capitalism and welfare society development after the Second World War. Notwithstanding internationalization of economic activities, new labor market realities due to immigration and demography, and new modes of economic organization on national, European, and international (and even transnational) level—the issue of the state's role in developing and/or stabilizing political and cultural identity will not vanish from the social sciences catalogue of controversies. The debate on adequate alignment of a state interventionism versus free-market dynamics referring to institutions and generalized ideas regarding well-being and standards of communal life will stay on the agenda of society building in Europe and elsewhere. For sure, in the near future, the notion of social market economy will not be identified as a doctrine but more or less as a "project" directed toward the balance of different societal interests—more precisely, as *one* project among others mirroring the multiplicity of developing capitalisms (Soskice et al.). Against the background of globalization and international competition, social market economy will face alternatives regarding the conduct of civil society—and as the ideas and political concepts of social market economy will "process" in future, social market economy will be opposed by more individualist, Anglo-Saxon-type, free-market-oriented conceptions of the civil society. Certainly, the most important "advancement" of the German social market economy model is to be expected with its integration into the emerging European political, economic, and social order. In many respects, the German "status" of social market economy will give way to overriding European strategies and policies. Thus, nowadays the debate on social market economy becomes part of the broader intellectual and political discussion concerning the basic construction principles of the "European House"—that is, the building of a "European home state" as laid down in the Presidency Conclusion of the Lisbon European Council in March 2000, under the headline: "Modernizing the European Social Model by Investing in People and Building an Active Welfare State."

SOCIAL MOVEMENT THEORY

Social movement theory attempts to explain the origins, growth, decline, and outcomes of social movements. Current theory builds on several different approaches: European *new social movement* theory and North American *collective behavior, resource mobilization,* and *political process* theories. The field has expanded enormously and made important theoretical advances in the past 30 years. Current theory is at a stage of synthesizing ideas from different approaches, tackling neglected problems, defining scope conditions, and devising new research agendas. Although much social movement theory has been developed through studies of movements in Western countries, research is increasingly conducted in other parts of the world, and theories are beginning to incorporate this work as well as to deal with the globalization of social movements. Key areas of social movement theorizing include movement organization, political opportunities and processes, culture, and social psychology.

ORGANIZATION IN SOCIAL MOVEMENTS

Resource mobilization theory brought organization to the forefront of social movement theorizing. Although earlier collective behavior theories recognized organization as a factor in the rise of social movements, they tended to explain movement mobilization by focusing on determinants such as discontent and the emergence of generalized beliefs. Early resource mobilization work identified the "social movement organization" (SMO) as a key entity within movements. More recently, movement analysts have examined a broad range of "mobilizing structures" in social movements, including movement organizations, social networks, preexisting organizations, and alternative institutions. Scholars have analyzed and debated the ways in which preexisting organizations affect movement emergence and maintenance, the effects of different types of SMO structures on strategy and outcomes, interorganizational cooperation and competition, and the changing organizational composition of movements.

Resource mobilization theorists have viewed organization as critical to both the emergence and maintenance of movements. A variety of preexisting organizational forms, such as social networks and established institutions, are involved in the process of mobilization. Preexisting organizations connect new recruits to movement participants and provide leaders and frames that can be adapted for collective action. New social movement theorists such as Alberto Melucci emphasize how movements develop out of the "submerged networks" of everyday life. Through interactions in small groups, individuals experiment with new

cultural forms and develop collective identities, creating the cultural bases for collective action.

To explain movement survival and change, scholars have examined the evolution of various types of organizational structures, including social movement organizations and other organizational forms within social movement communities. After the decline of a period of visible movement activity, movements are sustained through various means. In some cases, movement organizations that attract an exclusive group of participants with a shared culture or that are staffed by professionals keep a movement alive during slow periods. In other cases, a loosely knit movement community, including cultural groups and alternative institutions, sustains a movement during periods of scant political action. One of the interesting avenues of current research is an examination of the ways in which movements move into institutional and cultural domains, creating social changes and spreading movement ideology to these arenas.

Studies of organizational structures are critical to our understanding of social movement strategies and outcomes. In a seminal study, William A. Gamson (1975) demonstrated how organizational characteristics, such as bureaucratization and centralization, affect a challenging group's ability to remain mobilized and achieve movement goals. Further research has continued to specify the advantages and disadvantages of different types of organizational structures, including both the internal characteristics of movement organizations and networks among participants and groups within and across movements. In a study of efforts to unionize California farmworkers, Marshall Ganz (2000) shows how organizational structures that create connections to constituents, opportunities for meaningful and open deliberations among leaders, and leadership accountability are associated with the capacity for effective strategies. Research also suggests that linkages between national and local organizations and connections between a movement and other social movements result in more effective strategies than those employed by movements without such ties.

Studies of interorganizational dynamics have demonstrated the importance of looking at the effects of organizations and movements on one another. Sidney Tarrow's (1998) analysis of "cycles of contention" points to the importance of early movements in demonstrating political opportunities and creating models of protest for movements that come later in a protest cycle. Research suggests that the size of social movement industries and the social movement sector, consisting of all movement industries, is important; the expansion of a population of organizations creates legitimacy for protest strategies and also generates competition among organizations. The ideological composition of movement industries is also significant; radical organizations may have both positive and negative "radical flank effects" on more moderate organizations within a movement. One effect of radical organizations, as Herbert Haines

(1984) found in his analysis of radical flank effects in the civil rights movement, might be to increase funding for moderate organizations. Researchers have also analyzed the ways in which movements influence one another through shared activists and organizational, tactical, and ideological influences.

Movement organizations operate within multiorganizational fields consisting of other movement organizations as well as other types of organizations, such as established voluntary organizations. These organizations cooperate or compete with one another and influence one another's goals and tactics. Analysts have looked at the ways in which internal characteristics of movement organizations as well as overlapping memberships and other ties among organizations facilitate cooperation or encourage competition. They have also examined the ways in which mesolevel groups and organizations coordinate the actions of individual actors. Although macrolevel environmental factors are also important, organizational analyses show that the ways in which organizations are structured, and the nature of connections among groups, affect cooperation and competition within and among movements.

The characteristics of a "social movement industry," consisting of all SMOs working for the same general goals, change over time, affecting mobilization, strategies and tactics, and outcomes. The number and size of organizations in a movement expands or shrinks, and the forms of movement organizations change. For example, some movement organizations become more professionalized over time; some become influential within institutions; and some become decentralized and submerged. Research suggests that organizationally dense movements are likely to generate more protest. Movement industries that contain formalized and professionalized organizations are most likely to persist but are not necessarily more conservative in their strategies. Besides political movement organizations, social movement communities consist of a variety of organizational forms, including cultural and institutional entities. The impact of movement industries and communities on the culture and organization of other domains is a pressing concern for social movement theory.

POLITICAL OPPORTUNITIES AND PROCESSES

While resource mobilization theory focuses our concern on organizational dynamics, political process theory (which might be considered an extension of the resource mobilization approach) brings to center stage the interactions of states and social movements. *Political opportunities* are elements of the political environment that affect perceptions as to the likelihood that collective action will succeed or fail. There has been much debate over the concept of political opportunity, and scholars have proposed various factors as components of the "political opportunity structure."

One key issue is how broad the concept should be and, particularly, whether cultural factors should be included. Some scholars argue for a narrowly political use of the concept, lest it lose all meaning, and some propose distinctions between cultural and political opportunities. Tarrow's (1998) elaboration of the major elements of political opportunity, which is confined to key political variables, is widely employed. In his schema, political opportunity includes the extent of openness in the polity, shifts in political alignments, divisions among elites, the availability of influential allies, and repression or facilitation by the state (pp. 77–80).

A focus on political opportunities directs our attention to the structural obstacles and opportunities for collective action in various political systems. Critics have argued, however, that the approach neglects agency in its focus on political opportunities as structures. Movements are not only influenced by political opportunities; they also create opportunities for themselves and other social movements. Although some elements of political opportunity, such as characteristics of state institutions, are relatively stable, other dimensions, such as policy changes, are more subject to movement influence. Movement strategies are critical to political processes because collective action can produce new opportunities and because movement leaders must perceive and interpret opportunities. However, perceptions of opportunities are influenced by organizational structures, and both agency and structure are clearly important in understanding the creation and impact of political opportunities.

Another important issue for political process theory is the role of political opportunities in the emergence of social movements. Political opportunities are often viewed as encouragements to collective action; when opportunities expand generally, we are likely to see a "cycle of contention" such as the widespread protest of the 1960s. Movements that are "early risers" in a protest cycle open up opportunities for later movements by exposing the vulnerabilities of opponents (Tarrow 1998:77). Doug McAdam (1996:32–33) argues, however, that in reform movement cycles, there is not necessarily an increase in system vulnerability for "spin-off" movements. In fact, political opportunities may contract for movements that come later in a cycle as the state is preoccupied with the demands of the early movements. McAdam suggests that the diffusion of protest tactics, ideologies, and organizational forms may be more important to the emergence of spin-off movements than are political opportunities.

Theorists have also recognized that *threats* as well as opportunities mobilize movements by outraging constituents and increasing the costs of failing to act. Thus, favorable conditions for *mobilization* are different from opportunities for winning *new advantages*. Adherents flock to movements during times of threat, when they feel their contributions are most needed and when they feel emotionally upset or outraged, but they are more difficult to mobilize when there is less opposition to movement goals and conditions are more advantageous for making gains. The appearance of a *countermovement* to oppose movement goals is particularly effective in stimulating movement participation. Assessment of political opportunity and its effects is therefore complicated and involves analysis of the interactions of challengers and a variety of other actors within changing political contexts.

McAdam, Tarrow, and Tilly (2001) argue for a dynamic model of mobilization in which opportunities and threats are not objective structures but are subject to attribution by potential challengers. They contend that the political process model is overly static, failing to capture the interactions among multiple actors involved in attributing threats and opportunities, appropriating sites of mobilization, constructing meanings, and devising collective action. To develop a more dynamic approach, McAdam et al. call for identification of the mechanisms and processes underlying contentious politics. Although this approach has not yet achieved the authors' goal of revolutionizing the field, political process researchers are clearly moving toward the development of more dynamic, interactive models that identify common patterns in the workings of contentious politics. Comparative analysis of movements in different types of political and cultural contexts is critical to this research agenda.

CULTURE AND SOCIAL MOVEMENTS

Criticisms of resource mobilization and political process theorists for focusing too heavily on political organization and interactions with the state have resulted in a "cultural turn" in social movement theory. This new emphasis on culture returns to some of the themes from collective behavior theory and also incorporates ideas from new social movement theory into social movement research. Three of the major topics addressed are the cultural conditions and opportunities that encourage movements, the internal cultures of movements, and the cultural outcomes of movements. A large literature on social movement *framing* and a growing body of work on *collective identity* are central to social movement theorizing about culture.

Collective action frames are ways of presenting issues that identify injustices, attribute blame, suggest solutions, and inspire collective action. *Master frames* perform similar functions on a larger scale, making them useful to a number of different movements and organizations. Preexisting organizations and institutions are a source of cultural meanings and leaders, who adapt meanings and create collective action frames based on their experiences in such institutions. By drawing on cultural resources and developing frames that can be used to mobilize participants and win new advantages, movements then create cultural

opportunities for subsequent movements. The availability of master frames, developed within both preexisting organizations and movements, helps to account for the growth of protest cycles (Snow and Benford 1992).

Master frames and other elements of culture cannot, however, simply be selected or manipulated at will. Social movement culture necessarily draws on the larger culture, which can both facilitate and constrain movement frames and strategies. Existing political discourse sets boundaries on the range of issues considered appropriate for meaningful public debate and policy action. If current political discourse does not include understandings that can be expanded or adapted as collective action frames, it is difficult for movements to create effective frames. Large-scale changes may be needed before movements can spread new discourse. Although theorists often treat cultural and structural opportunities as distinct, there are important connections between cultural and structural changes.

As in the case of political opportunities, both agency and structure are important to our understanding of cultural dimensions of movements. Large-scale cultural changes open up ideological space for social movements, but participants must actively develop and disseminate new cultural understandings. Thomas Rochon (1998) suggests that cultural change often occurs through a two-step process: New ideas and values are first developed "within a relatively small, interacting, self-conscious critical community" (p. 57) and later spread to a wider public by a mass movement. An important question for social movement theorists is how such critical communities develop in different types of cultural and political contexts. In some times and places, lack of "free space" or civil society may constrain the emergence of social movements as much as lack of political opportunity.

Once social movements arise, they not only influence public discourse, but they create their own internal cultures, which influence movement growth, survival, and strategies. In addition to generating collective action frames, movements develop values, collective identities, rituals, and discourse. Research on the women's movement has been particularly important in demonstrating the role of culture in sustaining movements and in shaping their organizational structures and strategies. During abeyance periods, feminism is found in the submerged networks of institutional and cultural venues as well as in surviving political organizations. Protest may take the form of discourse aimed at cultural and institutional as well as political targets. Shared political identity, nurtured through movement culture and the submerged networks of movement communities, is critical in keeping feminism alive.

Internal movement cultures foster the development of collective identities, which influence movement emergence, recruitment, strategies and tactics, and outcomes (see Polletta and Jasper 2001). As new social movement theorists

have emphasized, large-scale socioeconomic changes such as urbanization make it possible to mobilize around new identities such as homosexuality. New identities are shaped within networks and institutions, and recruitment to movements builds on these structures and identities. Collective identities are incorporated into the frames that movement organizations devise to mobilize activists, and they influence the choice of strategies and tactics. Depending on their collective identities, activists prefer certain organizational forms and tactics. Identities may also be used strategically, with differences between activists and mainstream actors emphasized or de-emphasized depending on the political and cultural context. The deployment of movement identities through collective action frames and tactics potentially changes the broader culture by introducing new ideas, values, and lifestyle choices to the public.

In focusing on goal achievements such as the passage of legislation, early resource mobilization theory tended to neglect the cultural consequences of movements. Recently, however, theorists have attempted to assess outcomes such as changes in public discourse and the placing of issues on the public agenda as well as changes in everyday life, such as gender relations. For example, changes in consciousness brought about by the women's movement influenced the decisions of women to run for public office in the early 1970s, and the rhetorical strategies of Quebec nationalists influenced aboriginal peoples in Canada to use similar discourse. In both cases, cultural changes had political implications, demonstrating the importance of analyzing the interactions between "culture" and "politics" rather than treating the two as separate domains.

THE SOCIAL PSYCHOLOGY OF SOCIAL MOVEMENTS

Concepts such as framing and collective identity suggest the importance of social psychology in movement theory. And, indeed, a renewed interest in the social psychology of social movements accompanied the cultural turn in movement theory. Lack of attention to social psychology by early resource mobilization and political process theorists was in part a reaction to those collective behavior theories that depicted movement actors as irrational and their actions as strictly expressive rather than instrumental. In distancing themselves from such approaches, scholars emphasized continuities between collective protest and institutional action, rational choices over emotional reactions, and organization over spontaneity. They tended to neglect even those collective behavior theories that made no assumptions about the irrationality of participants in emphasizing grievances and emergent norms. By the 1980s, however, social movement theorists began to return to social psychology as theorists attempt to synthesize approaches and address neglected topics.

A number of theorists who turned to social psychology criticized rational choice theory as an inadequate conception of human motivation and group relations. By treating individuals as rational actors making separate choices, critics argue that rational choice theory fails to explain differences in participation, levels of involvement, and ongoing commitment. In response to such criticism, some theorists have worked to revise rational choice theory, moving "away from models of individual decisions toward models of group mobilization processes" (Snow and Oliver 1995:585). Others have turned to alternative social psychological concepts to address key questions regarding individual motivation and commitment.

Bert Klandermans (1997) examines the processes involved in recruiting individuals to social movements and maintaining or losing their commitment, including the generation of collective action frames, the transformation of discontent into action, and the erosion of support. In doing so, he attempts to combine resource mobilization and political process approaches with social psychological concepts, connecting different levels of analysis. Collective action framing involves both the societal level *construction* of pools of beliefs through public discourse, persuasive communication during mobilization campaigns, and consciousness-raising during episodes of collective action and the individual level *appropriation* of frames through cognitive information processing and interpersonal interactions. The mobilization of participation involves the interaction of structural and social psychological factors. Movements reach out to potential supporters through networks, demonstrations of effectiveness, and persuasive communications, while individuals make calculations about costs and benefits and the likelihood of movement success. Disengagement results from insufficient gratification and a decline of commitment on the part of individuals, which is related to both macrolevel factors, such as shifts in public opinion, and the mesolevel structures that keep individuals connected to movements.

Collective identity, consisting of "an individual's cognitive, moral, and emotional connection with a broader community, category, practice, or institution," (Polletta and Jasper 2001:285) is an important concept for understanding the participation, ongoing commitments, and departures of individuals from social movements. Individuals who share a preexisting sense of common identity with a group are likely to participate in collective action, although collective identity does not necessarily precede movement involvement; identities are also created and reinforced after recruitment through interactions within movements. Taylor and Whitter (1992) argue that collective identity is constructed within movement communities in three ways: (1) through the erection of *boundaries* differentiating challenging group members from dominant groups; (2) through the development of *consciousness* as a group with common interest opposed to the dominant order; and (3) through *negotiation* of new ways of thinking and acting, both privately and publicly.

Individuals who continue to participate in the process of constructing collective identity are likely to remain committed to a movement, whereas those who no longer feel identified with the group are likely to withdraw. Collective identities change with shifts in movements and organizations, such as the influx of new activists (Klandermans 1997:136). Activists entering movement organizations at different times, under different political conditions, are likely to have different collective identities, and long-lived organizations typically need to negotiate conflicts among cohorts. Although some theorists have discussed collective identity primarily in terms of cognitive beliefs and interests, others have noted "the emotional satisfactions of collective identity" (Polletta and Jasper 2001:290). Many individuals participate in collective action because they find the experience emotionally rewarding and because participation allows them to act on personal values.

Until recently, the emotional aspects of collective action were neglected as social movement theorists focused on the instrumental, politically targeted actions of collective actors and shied away from any implication that social movement participants are irrational. However, new scholarship argues that rationality and emotion are not dichotomous, and that we need to recognize the role of emotion in individual decisions to participate in collective action, framing processes, collective identity, and protest tactics. Empirical research is beginning to demonstrate how emotions are central to organizational, political, and cultural processes. For example, Deborah Gould (2002) analyzes the ways in which emotions were critical to the development of ACT UP and militant AIDS activism. She shows how the negative political opportunity structure of the 1980s helped to change gay and lesbian ambivalence into anger, and how ACT UP's "emotion work" affected its interpretation of the AIDS crisis and fueled militant direct action.

CHALLENGES FOR SOCIAL MOVEMENT THEORY

Social movement theory has advanced greatly in the past 30 years, yet fundamental theoretical challenges remain. One of the key unresolved issues has to do with the very nature of the phenomena studied by social movement theorists. McAdam et al. (2001) argue that social movements should be treated as one form of "contentious politics" along with revolutions, nationalism, and strike waves. These forms of "collective political struggle" are all episodic and public interactions among claimants that involve governments as either claimants, targets, or mediators. The "public" part of this definition of contentious politics excludes "claim making that occurs entirely within well-bounded organizations, including churches and firms" (p. 5).

At the same time, McAdam et al. challenge the distinction between institutionalized and noninstitutionalized politics, arguing that the parallels and interactions between conventional and nonconventional contentious politics need to be analyzed.

Other scholars have also proposed broadening the scope of the social movement field, offering different takes on the problem. Mayer N. Zald (2000) suggests that we think of movements as including all actions shaped by ideological concerns or as "ideologically structured action." This approach would connect collective action to culture and allow theorists to explore, at the microlevel, how individuals develop and maintain commitments and, at the meso- and macrolevels, how movements penetrate institutions, political parties, and government. Although Zald focuses on extending movement analysis into political parties and government agencies, his approach is in line with research on movement activity within institutions and with efforts to locate movements within loosely shaped movement communities and the structures of everyday life. Zald shares McAdam et al.'s (2001) view of the connections between social movements and institutionalized actions, but in contrast to them, he includes nonpublic activity within bounded organizations as ideologically structured action.

David A. Snow (2002) argues that the concept of "contentious politics" advocated by McAdam et al. (2001) is too restrictive in that it excludes social movement activity that is not connected in some way to the state, such as religious movements and self-help movements. He warns that the emerging dominance of the contentious politics approach hinders consideration of alternative conceptualizations such as Zald's ideologically structured action approach. Snow proposes that we think of social movements as collective challenges to systems or structures of authority, including governmental units, but also various types of nongovernmental structures such as corporations, universities, and religious denominations. This approach directs students of social movements to examine cultural and institutional as well as political challenges, and to compare processes of change in different arenas.

The challenge of broadening the scope of social movement theory is related to central theoretical problems facing social movement scholars, including the need to connect levels of analysis and organizational, political, cultural, and social psychological processes. To adequately explain movement mobilization, strategies and tactics, and outcomes, social movement theory needs to examine the ways in which microlevel transformations and reactions are connected to mesolevel organization and macrolevel cultural and political structures. How are perceptions of political opportunities affected by organizational structures and cultural understandings? How do social psychological reactions vary across political and cultural contexts? How does movement organization affect culture and organization in other domains? These and other key questions require detailed empirical examinations of movement processes across levels of analysis.

Most important, social movement theory needs to examine these processes dynamically, showing how interactions among collective actors, their targets, and other actors change over time along with organizational, political, cultural, and social psychological developments. This poses both methodological and theoretical challenges. Case studies continue to be an important means for examining movement growth, development, and change, but other methods are also required, including comparative studies of movements in different countries. McAdam et al. (2001) argue that episodes of contentious politics in a wide variety of settings need to be compared so that underlying mechanisms and processes of change, rather than general laws, can be identified. This approach holds great promise, but critics note that the precise nature of mechanisms and processes remains unclear. Thus, social movement theorists continue to search for ways to examine the dynamic, interactive workings of social movements in different historical, political, and cultural settings.

SOCIAL RATIONALITY

The term *social rationality* covers a family of conceptions of goal-directed behavior that have one feature in common: they proceed from the assumption that each individual's ability to pursue goals more or less intelligently and the way goals are pursued (the mode of rationality) are strongly influenced by social conditions. This conception stands in contrast to "natural rationality" in which the individual's ability to pursue goals more or less intelligently is assumed to be naturally given and the same for all. The latter even holds for a great number of "bounded rationality" approaches in which human biases in judgment and limitations in calculatory ability are explicitly admitted. Important assumptions of the natural rationality approach include the veridicality of expectations, common knowledge (i.e., cognitive coordination) of interacting individuals, and ordered preferences as naturally given. All these assumptions are challenged by social rationality approaches.

Social rationality assumptions are quite old in sociology. For example, Simmel and Weber worked explicitly with such a conception. However, goal-directed behavior was sidelined in sociology for some time in favor or role-playing behavior, and economists used increasingly natural rationality conceptions, often as a simplifying assumption for the sake of tractability and deductive rigor. As a consequence, when sociologists began to pay more attention to goal-directed behavior again (in the 1970s), they often borrowed the conception of natural rationality from economics and game theory, which led to a predominance of natural rationality assumptions in "rational choice sociology" (with James Coleman as a major proponent). In the meantime, social rationality approaches have developed and begun to spread in sociology. There is no single dominant approach yet, but most of the approaches have learned a great deal from natural rationality approaches and from cognitive and evolutionary psychology. In that sense, they have evolved far beyond the beginnings in classical sociology.

A direct result of this difference in assumptions is that in the natural rationality approaches, social and cultural conditions can improve or diminish the joint goal pursuit (also called "collective" rationality or Pareto optimality) but not individual rationality. By contrast, for social rationality approaches, social and cultural conditions can affect positively or negatively *both* individual and collective rationality. This has important consequences for the kind of social arrangements (especially institutions) being considered and for the interdependence among these arrangements. For example, in social rationality approaches, humans are assumed to be forward looking, but they don't naturally look far into the future. The ability to consider the far future (often called "farsightedness" and "rational expectations" in natural rationality approaches) is thus assumed to depend on social arrangements that make it easy to do so by (1) standardizing events and (2) making it possible to predict classes of contingencies. A school system, for instance, and institutions that make it stable over time, allow parents to anticipate possible choices and contingencies far into their child's future. There is no "natural" farsightedness involved. Creating social arrangements for the improvement of collective rationality is often dependent on having arrangements for enhanced individual rationality in place. Institutional design for the improvement of collective rationality is an important task for sociology. However, it presupposes a high level of individual sensitivity to incentives and thus a high level of individual rationality that responds to changes in incentives. Yet contrary to the assumptions in natural rationality approaches, expectations are often not veridical, preferences are often not ordered, and there is no cognitive coordination. Thus, the social conditions under which expectations are more or less veridical, preferences are more or less ordered, and cognitions of interacting partners more or less coordinated must be investigated, and that is one of the tasks of social rationality approaches.

Social conditions can affect virtually all aspects of individual rationality, from the mode of rationality to the abilities that jointly constitute the core of rationality (such as the ability to generate expectations and learn from experience,

the ability to set goals, the ability to "define" situations, and the ability to substitute and the ability to create nongiven alternatives), to the motivation in goal pursuit (such as improvement versus maximization). Especially important is the influence of goals on the criteria of goal achievement and thus on the "mode" of rationality (such as calculativeness, appropriateness, and emotional "rightness"). Social influences on goals thus become particularly important for the way people will go after goal realization. Recent developments in psychology that trace the impact of motivations (emotions and goals) on cognitions ([self-] categorization, interpretation, social perception, beliefs) are highly relevant for sociological work on social rationality, especially for tracing the social influence on rationality through the influence of social arrangements on emotions and goal salience. The same can be said about evolutionary psychology. In this sense, the traditional disciplinary lines are far less clear than, say, 20 years ago. This also holds for the borders between sociology and economics. Social rationality approaches are decidedly not radically "sociological." Contrary to the conception that rationality itself is entirely a social construction (which leaves no theory of action), social rationality approaches generally share the assumption that human beings are endowed with rationality, and that social conditions will affect it positively or negatively and will affect its mode but not "create" it. Thus, the very dispositions to give meaning to situations (e.g., through framing effects and the use of simple heuristics), to generate expectations, to set goals, and to look for (given and nongiven) alternatives, allows social rationality approaches to actually use these features in theories of action. Sociobiology and evolutionary psychology have greatly aided this view by showing how social influences in the past can find their way into "hardwiring" now and how, in turn, this hardwiring makes people wide open for ongoing social influences on rationality. On its basis, even the core elements of rationality, including its seemingly noncalculative modes, can be interpreted as being generated socially in the course of evolution *and* the daily course of interaction.

SOCIAL SPACE

The past few decades have seen a renewed interest in space as a concept for social theory. This "spatial turn" has occurred at a time when ever-denser flows of goods, capital, information, services, and people around the globe have led to what Karl Marx called the "annihilation of space by time" or, to put it more carefully, time-space compression. This thinking is in line with the dominant strand of sociological thinking throughout much of the twentieth century, which has seen the process of differentiation of modern society being inextricably linked to emancipation from spatial factors. In a nutshell, theorists such as Georg Simmel and Émile Durkheim assumed that space would gradually lose in significance as abstract forms of social organization (*Vergesellschaftung*), such as monetarized exchange, become more pervasive.

Yet the resurgence of theorizing on space raises the question whether modernity, late modernity, or postmodernity is indeed characterized by a decoupling of space and time. It could be hypothesized that even time-space compression may not lead to a disappearance of space but to a regrouping of space-time orders. After all, space—very much like the much more theorized concept of time—is a crucial element of *Vergesellschaftung.*

Social science concepts of space have been influenced by and built upon mainly two distinct, ideal typical understandings derived from physics—absolutist and relativist (Albert Einstein). The *absolute* understanding of space is based on a Eucledian view and posits a dualism between space and social life and bodies. According to this view, space exists as a contextual background condition, independently of social action and human perceptions. Social action thus proceeds within an unmovable and fixed space. This sort of container is not thought to be part of social action. By contrast, a *relative* understanding views space as constituted by the structure of the relative positions of the bodies and objects to each other. Accordingly, spaces do not exist independently of social relations defined by the positions of actors, social action, and social goods such as status and power. Social relations flow into the production of spaces, their formation, and their institutionalization.

ABSOLUTIST CONCEPTS OF SPACE

Three distinct concepts can be identified in the absolutist vein of thinking about space, viewing it as territory, as place, or as form.

Space as territory has figured prominently in early twentieth-century approaches to political science and sociology. Geopolitics was a specific form of geodeterminism. This idea has been largely discredited by political practice; especially the national socialist quest for "living space"

(*Lebensraum*). Nevertheless, geopolitical views raise important questions about the potentially exclusive character of social space as political space. The political theory of sovereign nation-states assumes that states can fulfill their integrative function as the final arbiter in making collectively binding decisions only because there is no second state occupying the same territory. The modern form of state organization with territorially defined, territorially fixed, and mutually exclusive state formations is based on the existence of a public sphere with central authorities exercising legitimate use of force and external sovereignty. Over the past decades, this historical configuration has been called into question by newer developments of global governance, such as international regimes and supranational organizations.

Early versions of urban sociology did not embrace territorial determinism. The classic approach of the Chicago School of Sociology posited that people adapt to their urban environment and configure group settlements or communities in what are seen as natural areas. This human ecology approach results in an ideal typical model of the city, which can be modeled as a series of concentric circles. This allowed for the development of concepts such as segregation and succession of groups. In short, the social ecology approach assumes a "synomorphy" of physical and social distance. Yet the concept of space was never explicitly developed.

Space as place can be found in time-space geography, developed by Torsten Hägerstrand and his associates, who came to be known as the Lund school of geography. In this concept, all actions are mapped as local activities. The goal is to trace the spatial expression of everyday, or even lifetime, routines and practices and to thus identify the impact of space on the average day or life course of an average person. Since time-space geography emphasizes the measurement of social activities within the daily environment of persons, it conceptualizes space as a physical environment. The "stations," at which persons carry out their activities, define the "momentary thereness" of "interrelated presences and absences." From here, it is not far to a decidedly behavioral and individualist perspective according to which movement in space involves *mental maps*. Such maps can be thought of as the result of learning and are socially impregnated. Mental maps include topographic representations of places and distance and value judgments—for example, positive and negative images. These cognitive maps imbue places with meaning.

Space as a form transfigures the concept of space into an epistemological tool. This approach is vaguely based on Immanuel Kant who held that space and time are basic "intuitions" and who argued against the view that space has its own reality. Kant held that space is a principle of order, a *conditio sine qua non,* which precedes all experience. Very similar to Kant, Georg Simmel viewed space as existing independently and prior to human cognition. Simmel

also viewed space as a mere "form," akin to forms such as social groups, poverty, and conflict. He considered only the "content" of social ties to be sociologically relevant. Society originates, according to Simmel, if the isolated elements are put together into certain forms. Therefore, space is a formal condition but has no relevance as a cause for processes of *Vergesellschaftung.*

Absolute concepts of space have been useful in answering questions about the placement of persons and groups in places and territories, the impact of macrostructures on human behavior, and the mutual conditioning of action and structure. The movement of actors in space exists, but spaces are not moving; space is fixed. An absolutist understanding of space does not pose questions about the social constitution of space going beyond place and territory. Furthermore, the existence of places and territories is taken for granted. It is not considered how places and territories may also be a product of the constitution of spaces. Also, keeping space as a background condition does not suffice to explore how several spaces intersect in or occupy the same place. This is where the relativist understanding of space comes in. The relativist understanding of space has guided thinking concerned with the constitution, construction, formation, and development of social space. The relative positions of elements involved in the production of space—depending on the view, for example, positions of material objects, places, ties between individual or collective actors—offers a convenient vantage point for conceptualizing space as the duality of presence and absence, space as sites of power and resistance, space as flows, and space as glocalization.

RELATIVIST CONCEPTS OF SPACE

Relativist accounts of social space go beyond a purely physical viewpoint that would look at the placement and relationship of "bodies" in space. They also encompass "action," a sphere conventionally attributed to "time."

In his theory of structuration, Anthony Giddens picks up this thread and uses the concept of space as a device to conciliate the age-old problem of agency and structure. Giddens does not juxtapose societal structures to the actor as objective realities. Rather, he sees structures—defined as recursively reproduced social practices—to flow into the very actions, which in turn create structures. Giddens's theory places social action and structures in a spatial-temporal order. Social practices "take place" in time and space and persons construct their own places. While time-geography treats physical environment as a restricting variable only, Giddens contends that these processes may simultaneously be enabling and restricting to social actors. The place of modern societies is the nation-state. This means that Giddens transcends time-geography in emphasizing the structuration of place and space by power and representation

as resources. Overall, the theory of structuration offers a connection between social integration and system integration, expressed spatially as the difference between presence and absence—*space as the duality of presence and absence.* Giddens conceptualizes the problem of social order as one of "time-space distanciation." In his analysis of globalization Giddens is interested in how processes of social integration—such as trust, intimacy, and family—change, when distant and "absent" structures influence "present" in everyday places. Yet the mechanisms mediating between the present and the absent remain hidden.

The notion of *space as power and resistance* highlights how "presence" and "absence" have mixed in new and volatile ways in processes through domination and countermovements. According to Henri Lefebvre ([1974]1991), social space is a social product. Through time-space colonization; abstract space (*l'espace abstrait*) has been imposed on the concrete space of everyday life (*l'espace vécu*). In a conceptualization reminiscent of Jurgen Habermas's "colonization of the life world," Lefebvre identifies the two master processes: commodification and bureaucratization of and through space. In terms of bureaucratization through space, the state is the master of space in subjecting social life to systematic surveillance and regulation. However, the very outcomes of master processes are always contested terrain, as there are efforts toward the production of a genuinely public and democratic space.

While the concept of time-space colonization describes the reconfiguration of space as caused by exogenous factors that destroy the lifeworlds of persons, what could be called time-space disorientation emphasizes endogenous factors, a crisis of capital accumulation, the move from modernity and postmodernity, and the ensuing crisis in representation. For the lifeworld, this means that commodities and images change radically. Everyday routines become pervaded by global relations and communication. It also involves the transformation of locality so that places are revalorized: Products and images may even profit from global differentiation (as David Harvey describes in *The Condition of Postmodernity*, 1990) Another change in locality is the spread of "nonplaces" (a term developed by Marc Augé in *Non-places: Introduction to an Anthropology of Supermodernity*, 1995), such as holiday clubs, hotel chains, and supermarkets, which are largely devoid of the characteristics of place—namely, space defined by unique history, set of relations, and identity. Instead, these nonplaces are stifling the creative lifeworld by placing uniformity and bureaucratic manners on persons. The differentiation between "place" and "nonplace" should be seen as an ideal typical distinction in the Weberian sense, not least because nonplaces are sites that, in principle, offer opportunities for social ties to be restored and resumed.

Time-space dislocation also raises the identity question "to what space/place do we belong?" Some authors place the decentered or fragmented subject in "in-between spaces" or "third spaces." On a collective level, imagination creates communities of sentiment, groups that imagine and feel things together. "Imagined communities" composed of people who were never in face-to-face contact, constituted the perquisite for the formation of nation-states. Communities of diasporic people now crossing the borders of nation-states carry the potential of moving from shared imagination to collective action (Arjun Appadurai 1996). Processes such as international migration create a new instability in the creation of subjectivities, challenging the narratives of nationally bounded communities.

Space as flows questions the boundaries of societal units such as national states. Some notions in this vein consider the nation-state as anachronistic and emphasize the unbounded space of flows. They overlook the manifold tendencies of reconfiguring political spaces. One of them is the formation of transnational spaces within and across national territories, such as global cities. Technology enables a faster exchange of goods, ideas, and services as well as making travel faster. Persons interact in simulated environments. Place disappears. At the same time, close distance as a bodily experience turns into informational distance. In a macroperspective, global cities are nodes in the space of flows. A partial decoupling of cities from their national economies and states can be observed. Nonetheless, global cities are a mélange of parts of different cities. This suggests that various spaces may intersect in one and the same place, producing a new "power-geometry" (Doreen Massey). Picking up this thread, others have seen Los Angeles as "the quintessential postmodern place," in which developments and changes occurring around the globe are reflected and duplicated in this city (Edward Soja 1989). The "landscape" of Los Angeles is represented from a series of vantage points through which Soja contemplates variations of abstract geometries.

In contrast to space as flows the concept of *space as "glocalization"* (Ronald Robertson 1995) treats space as concomitant processes of generalization and specification, of globalization and localization. The production of space can be considered a dialectical process. On one hand, globalization allows a displacing from concrete territorial places (*space of flows*). On the other hand, global flows have to be anchored locally in specific places (*space of places*). Space is conceived as a relational process of structuring relative positions of social and symbolic ties between social actors, social resources and goods inherent in social ties, and the connection of these ties to places.

On a macrolevel, the reconfiguration of social space is visible, for example, in the political realm. In a process of "unbundling" territoriality (John G. Ruggie 1993), various types of functional regimes have come to intersect territorially defined nation-states. Such institutions include common markets, border-crossing political communities and inter- and supranational organizations. Nonterritorial

functional space-as-flows and territorial nation-states as space-of-places are the grids wherein international or global society is anchored. Such ruptures render the conventional distinction between internal and external increasingly problematic because there are various tiers of making collectively binding decisions. It also calls into question the concept of state sovereignty as an expression of a single fixed viewpoint and the research strategy of "methodological nationalism," which takes for granted national states as containerlike units, defined by the congruence of a fixed state territory, an intergenerational political community, and a legitimate state authority. In its stead, multilayered systems of rule, such as the European Union, demand a multiperspectival framework.

On a mesolevel, the dialectics of flows and places go hand in hand with the possibility of transfer of resources in space. Financial capital, for example, is distinctly more mobile than social capital. It is therefore often seen as the prototype of a global good. By contrast, social capital, such as networks of solidarity and trust, are place-bound, local assets, which can be rendered mobile across space only by social ties in kinship groups, organizations, and communities that connect distinct places. Any conceptualization of space across borders would therefore depend on the type of ties and (social) goods to be exchanged. Glocalization then means, first, that the local is produced—to a large extent—on the global or transnational level. Second, the local is also important in reconfiguring place. An empirical example for this approach is "transnational social spaces." Transnational social spaces consist of combinations of ties and their contents, positions in networks and organizations, and networks of organizations that can be found in at least two internationally distinct places. The concept of transnational social spaces probes into the question by what principles geographical propinquity, which implies the embeddedness of ties in place, is supplemented or transformed by transnational flows. This raises the question about the transaction mechanisms embedded in social ties and structures, such as exchange, reciprocity, and solidarity.

SPACE AND TIME: SOCIAL RELATIONS AND CHANGE

To conclude, the social sciences have used space in manifold ways, ranging from a conceptual tool to a metatheoretical concept. The same seems to be true for its twin sibling, time. Space and time share important commonalities and distinctions. Both refer to social action and social institutions, based on relations between positions in processes. The analysis of social processes requires that both actors and their (physical) environment are treated holistically, not separately. In Norbert Elias's thinking, each change in "space" implies movement in "time" and vice versa. For example, one cannot be perfectly immobile in a room while time is passing. One's heart is beating, cells are dying and growing—change is continuous in "time and space." In the end, space and time may be expressions of two sides of the same coin. Space relates to relations between positions within sequences of events and action, abstracting from the fact that these relations are forever changing. Time, by contrast, is taking into account that such relations are continuously changing.

SOCIAL STRUCTURE

The idea of social structure is closely linked to an intellectual tradition that goes back to the work of Émile Durkheim, as well as to the structural functional theory that owes such a deep debt to his work.

Famously, Durkheim distinguished between nonmaterial and material social facts. All social facts are external to and coercive over individuals (or, at least, should be treated that

way). Nonmaterial social facts (e.g., norms, values, social institutions) exist in the realm of ideas, while material social facts have a real, material existence. One type of material social fact is a social structure. Thus, social structures can be defined as real material social facts that are external to and coercive over actors. For example, the state is such a social structure, as is the market in the realm of the economy.

Durkheim's work played a key role in the development of both structural functionalism and structuralism. The latter, however, is based on Durkheim's later work (e.g., *The Elementary Forms of Religious Life*) and moves off in a different direction in search of the "deep" structures that undergird social thought and social action. Thus, structural functionalism played a key role in developing the notion of social structures (and social institutions), according it a central role in social analysis.

As the name suggests, structural functionalists were interested in the "functional" analysis of social structures. That is, they were interested in analyzing the consequences of given social structures for other social structures, as well as the larger society. The American sociologists Talcott Parsons and later Robert Merton provided the most extensive elaborations of the structural functionalist theory. Parsons developed a complex theory in which he argued that social systems are regulated by four functional needs: adaptation, goal attainment, integration, and latency (often abbreviated with the acronym AGIL). To survive, a social system must be structured to ensure that these needs are adequately and efficiently met. Although, as a student of Parsons, Merton shared many of the basic assumptions of structural functionalism, he was also critical of its more extreme functionalist views. For example, in contrast to the assumption that all elements in a social structure are functional for a society, Merton claimed that certain social beliefs and practices could be dysfunctional, or even nonfunctional. In elaborating this concept of dysfunction, he drew on Durkheim's famous concept of "anomie" to argue that certain social structures can lead to deviant behaviors. Critics outside the structural functionalist paradigm argued that structural functionalists tended to ignore agents or to see them as being controlled by social structures. Thus, structural functionalism was an extreme example of the tendency of some social theories to treat actors as what Harold Garfinkel called "judgmental dopes."

Of course, it is possible, even desirable, to look at the *relationship* between social structures and actors without giving priority to the former (or the latter as did, for example, phenomenologists, symbolic interactionists, and the like). Indeed, a great deal of recent social theory can be seen as according roughly equal weight to social structures and actors. Prime examples are Anthony Giddens's structuration theory and Pierre Bourdieu's work on the relationship between habitus and field. Indeed, the whole idea of structuration (a term that is sometimes also associated with Bourdieu's approach) is that what are termed here (although not necessarily by Giddens) as social structures cannot be examined without simultaneously examining the agents who are involved in them and who are their creators.

In George Ritzer's integrated sociological paradigm, the argument is made that there is a need for a paradigm that focuses on the dialectical relationship among four "levels" of social analysis. The macro-objective level encompasses social structures (and more generally Durkheim's material social facts) and the macrosubjective encompasses social institutions (and Durkheim's nonmaterial social facts, more generally). These levels must be looked at in relationship not only to one another but also to the microlevels—microobjective (behavior, action, and interaction) and microsubjective (mind, self, thought, the social construction of reality). The key point from the perspective of this discussion is that social structures cannot be examined in isolation from all these "levels" of analysis.

Thus, social structure remains central to social theory, but the long-term trend has been away from treating it in isolation from the rest of social reality. Rather, today social structure is seen as one aspect of the social world that must be seen in relationship to all other aspects. It affects, but is affected by, all the others. Thus, contemporary social theory has a more balanced view of social structures and their role in the social world.

SOCIAL STUDIES OF SCIENCE

Social studies of science, or science studies, is a transdisciplinary research field that investigates historical, political, cultural, conceptual, and practical aspects and implications of the sciences. Because modern sciences are deeply intertwined with technology, the more comprehensive

name science and technology studies (STS) is often used to identify the field. Regardless of which name is used, it is widely understood that social studies of science cover a broad range of historical and contemporary developments associated with natural and social science, pure and applied mathematics, engineering, and medicine. Social studies of science draw on the literature, concepts, and methods of philosophy, history, and sociology, but such studies make up an emergent field in its own right and not a branch or subfield of any other established social science or humanities discipline. The field has dedicated journals and professional associations, and numerous universities have STS departments, programs, and research centers. Participants in the field often hold appointments in history, sociology, anthropology, philosophy, and other university departments, but their research typically has a hybrid character.

Social studies of science include a number of different theoretical orientations. Some of these are offshoots of pre-existing schools of social theory. For example, during its heyday in American sociology, structural functionalism was the dominant approach to sociology of science (as represented by Robert Merton's and his students' research on institutional norms and rewards in science). Boris Hessen, J. D. Bernal, and other Marxist scholars and scientists also had leading roles in the early development of social studies of science, especially in Europe. More recently, critical theory, symbolic interactionism, ethnomethodology, semiotics, cognitive psychology, feminist cultural studies, poststructuralist literary theory, and various approaches to globalization have been represented in social studies of science and science policy. Two approaches that developed within the field in a distinctive way are the *sociology of scientific knowledge* (SSK) and *actor network theory* (ANT). These and some of the other current approaches often are labeled as *constructionist* or *constructivist* treatments of scientific knowledge.

THE STRONG PROGRAMME AND SSK

SSK developed in the early 1970s and was strongly influenced by the writings of Thomas Kuhn, Paul Feyerabend, and other influential critics of positivist and logical empiricist philosophies of science. Several members of the Edinburgh University Science Studies Unit (which was founded in the 1960s) had a leading role in a successful effort to reorient the sociology of knowledge to engage the material practices and contents of the sciences. Leading figures in the Edinburgh School (also known as the "Strong Programme" in the *sociology of knowledge*) included David Bloor, Barry Barnes, David Edge, Steven Shapin, and Donald MacKenzie, who published a series of programmatic arguments and social-historical case studies starting in the early 1970s. In 1970, Edge and Roy MacLeod cofounded the journal *Science Studies* (renamed

Social Studies of Science after a few years), which provided an outlet for the new approach and became the leading journal in the field.

The "strength" of the Strong Programme lay in its proposal to extend the sociology of knowledge to cover even the most robust mathematical procedures, physical laws, and scientific facts. Conceived in the early twentieth century, the sociology of knowledge was an empirical research program that aimed to explain the historical formation and social distribution of collective beliefs and ideologies. Instead of evaluating the truth or rationality of beliefs, sociologists of knowledge endeavored to explain the connections between particular beliefs and the characteristics of the social groups that held them. Persons promoting a doctrine typically emphasize its intrinsic truth and rationality, but a sociologist of knowledge attempts to be noncommittal about inherent truth of a belief, while examining the history, socialization practices, and collective interests in the community of believers. Karl Mannheim, an early exponent of the sociology of knowledge, endowed the perspective with broad scope to cover religious and metaphysical systems, political ideologies of all kinds, and controversial scientific theories. However, Mannheim made an exception for the most robust, generally accepted scientific and mathematical knowledge. Mannheim held that because such knowledge no longer bears the imprint of the cultural and historical conditions of its emergence, the sociology of knowledge had no basis for explaining it as a function of particular traditions and practices. He recognized that modern science and mathematics were historically and culturally "conditioned," but he argued that "existential factors" were "merely of peripheral significance" for explaining the status of such knowledge (Mannheim 1936:271). Proponents of the Strong Programme refused to accept the idea that selected facts, laws, and procedures, which are currently accepted as invariant, rational, and true, should be exempted from social and cultural explanation. To set up the possibility of such explanation, Bloor, Barnes, and other adherents to the Strong Programme recruited philosophical arguments about the conventionality of mathematical practices, the theory ladenness of observation, the tacit underpinnings of experimental method, the incommensurability of competing paradigms, and the underdetermination of theory choice by empirical evidence. Such philosophical arguments were used to suggest that the resolution of controversies and the formation of consensus in scientific communities was not due to evidence alone. Empirical study of particular cases would then be used to identify historical conditions, social interests, and collective alignments that may have had some influence on the relevant scientific communities.

The Strong Programme is often summarized by a set of four principles that were formulated by David Bloor (1976) in his influential *Knowledge and Social Imagery:* causality,

impartiality, symmetry, and reflexivity. Although studies associated with the Strong Programme rarely adhered to all four principles (e.g., many SSK studies do not advance clear-cut causal explanations), and the effective meaning of each principle left much to the imagination, the *symmetry* principle was frequently cited as an emblematic feature of the "new" sociology of knowledge. As Bloor defines it, symmetry means that the same general type of explanation should be used for any belief studied, regardless of whether it is held to be true or false. This idea flies in the face of the "sociology of error"—the commonplace idea that erroneous (and also unverifiable) beliefs are to be explained by reference to social and psychological causes (mass persuasion, cultural tradition, vested interests, personal bias, compensation for low status, false consciousness, etc.) and that true beliefs are to be explained by reference to their correspondence to reality and/or their derivation from rational procedures of inquiry. Symmetry, together with the principle of *impartiality,* is a methodological heuristic and not an ontological position. It does not imply that all "knowledges" are equally valid; it simply counsels the sociologist of knowledge to put aside judgments about the validity of a doctrine or practice when seeking to explain why it is *held* to be valid by particular historical and social groups. So, for example, existential factors (socialization institutions, regional cultures, traditions, local authorities, etc.) can be cited to explain belief in evolution and natural selection as well as ascription to special creationist doctrines. To follow through with such explanations does not imply that the competing doctrines are equally good or equally true or that both deserve an equivalent place in biology textbooks. Instead, it implies only that socialization, tradition, and so forth, explain the social distribution of the particular beliefs, regardless of their ultimate truth. Proponents of SSK hold that the ultimate truth of a conviction is irrelevant to an effort to explain why particular communities happen to hold it.

SOCIAL HISTORICAL AND ETHNOGRAPHIC STUDIES

SSK includes two predominant forms of case study, one of which is social-historical in scope and the other ethnographic in design. Typically, social-historical case studies focus on specific episodes of scientific change and/or controversy. These include relatively recent controversies about gravity waves, cold fusion, and solar neutrinos, as well as more remote historical controversies about the discovery of oxygen, the germ theory of disease, or the theory of relativity. Cases include marginal or rejected science (phrenology, spontaneous generation, cold fusion, etc.) as well as established theories and empirical discoveries. Many case studies have a conceptual focus: (1) tracing historical changes in notions of experience, experiment,

matters of fact, and objectivity or (2) challenging established conceptions of experimental test or replication. *Ethnography* is a method for studying the beliefs and practices of contemporaneous groups. It is perhaps best known as an anthropological method for studying exotic "tribes" and attempting to elicit and document cultural practices and understandings characteristic of the tribes studied. The related, but lesser known, sociological approach of *participant observation* is no less significant for suggesting themes and methodological strategies for ethnographic studies to science. Participant observation is a method for studying groups, often living within the sociologist's society, whose beliefs and activities are unusual, "deviant," exotic, or in some other way interesting from the point of view of sociologists, their readers, and their students. Like an ethnographer of an exotic tribe, a participant observer attempts to describe a way of life "from within," and extensive contact with the relevant group is necessary to develop a degree of fluency, skill, and mutual trust necessary for gaining deep access to that way of life.

Another sociological orientation, *ethnomethodology,* also influenced ethnographic (as well as some of the sociohistorical) studies of science. Like ethnographers and participant observers, ethnomethodologists integrate their research methods with the discursive and embodied production of the practices being studied. The engagement with the practices studied tends to be more intimate and detailed than one typically finds in other ethnographic and participant observation approaches. Some of the earliest ethnomethodological studies by Harold Garfinkel and his students reflexively examined social science research practices for transliterating and codifying data. Years later, ethnomethodologists turned their attention to the situated practices of natural scientists, mathematicians, and computer programmers. Such studies attempt to describe the coordination of discursive and representational practices and to elucidate how such practices constitute stable ways of life. Unlike many of their colleagues in social studies of science, ethnomethodologists eschew causal explanation, cognitive modeling, social and cultural criticism, and global theorizing. They are more interested in describing how the practices they study reflexively deploy social as well as technical concepts, models, discourses, theories, and ideal types (see Lynch 1993).

ACTOR NETWORK THEORY

Several ethnographies of scientific laboratories were conducted in the late 1970s, the best known of which was Bruno Latour and Steve Woolgar's (1979) *Laboratory Life: The Social Construction of Scientific Facts,* a study at Salk Laboratory in San Diego. Their book was notable for its bold and explicit argument about the "construction" of a particular biochemical "fact" and also for its adoption of vocabularies from literary theory to describe how laboratory

practices using "inscription devices" make fugitive microbiological phenomena visible, stable, transportable, and resistant to "deconstruction." Latour and several of his colleagues later developed "actor network theory" (ANT), an entire ontology of scientific and technical innovation (see Latour 1986). ANT shares with ethnomethodology an orientation to the "local" or "endogenous" production of society, but it places far stronger emphasis on the semiotic inscription, translation, transportation, and stabilization of marks, graphisms, and other literary traces and representations of scientific practices and phenomena. The key move is to connect the practices and products of science from their point of production (the laboratory or field site) through multiple, globally distributed networks of literary reproduction. Studies taking up the ANT approach attempt to "follow" chains and networks of association through which literary traces travel on their way to publication and dissemination; chains and networks that handle, translate, transform, and reproduce inscriptions, thereby constituting the global infrastructures in which science and society are coproduced in a dynamic and contingent way.

Consistent with the ANT emphasis on distributed networks of scientific production (often organized around "centers of calculation" that articulated standards and controlled expensive means of production), and also stimulated by trends in anthropology, it became popular in social studies of science to pursue multisited ethnographies, which "follow" global developments, sequences of practical transformation, and social networks related to a phenomenon of interest. So, for example, current controversies about global climate change involve a complex array of scientific researchers working in several specialties, as well as members of government and nongovernment organizations, industrial spokespersons and lobbyists, and various specialized and popular media. Although it may be desirable to seek in-depth understanding of the different—and competing—points of view of the constituent actors, to do so requires interviews and documentary research at multiple research sites. In studies of contemporary (or very recent) cases, such research tends to blend the aims and methods of social historical research with those of ethnography.

A distinctive, though disconcerting and unevenly adhered to, aspect of ANT is its radicalization of the theme of symmetry from SSK. Symmetry in SSK is the methodological principle of giving the same (social) form of explanation to (allegedly) true as well as false beliefs. ANT compounds SSK's methodological indifference to truth and falsity with an ontological indifference to the status of any given "entity" as "social" or "natural." So instead of framing technical innovation as having been "caused" in linear fashion by "social" antecedents or "conditioned" by social circumstances, ANT abandons the effort to discriminate types of cause and, instead, "explains" innovations by tracing out hybrid networks of association composed of human and nonhuman "actors" ("actants" in the jargon of semiotics). This monistic ontology can be viewed as an alternative (perhaps a mirror image) of the more prevalent scientistic monism in which social actions, cultural traditions, and individual consciousnesses are explained (speculatively) by reference to material and micromechanical principles. Instead of placing "nature" (represented, for example, by cognitive science and sociobiological models) at the center of an explanatory system, ANT deploys a vocabulary of actions, actors, and agencies, to encompass "natural" as well as "social" relations. ANT has had broad influence on STS research, but many researchers who borrow from ANT fail to animate the nonhumans and, instead, focus selectively on the machinations of the human actors held responsible for a successful or failed innovation.

CONSTRUCTIONISM

Starting with the publication of Latour and Woolgar's ethnography, social studies of science became identified with the theme of the social construction (or simply construction) of scientific facts, objective representations, and other research products. Social-historical case studies and ethnographies (some of which went into considerable length to describe specific experimental practices and scientific discourse) began to speak of the "construction" of phenomena such as physical subparticles and organic molecules. The term *social construction* was first used by Peter Berger and Thomas Luckmann (1966) in their sociological treatise, *The Social Construction of Reality,* and *constructionism* later became a buzzword for a confusing array of critical theories, disciplinary approaches, and empirical studies in many social science and humanities fields. The idea that established natural scientific "facts" were constructed went well beyond Berger and Luckmann's original effort to explain the distinctive way in which "social" phenomena develop and are organized. Berger and Luckmann took for granted that natural reality differs from constructed (social) reality; their aim was to address the question of how concerted social actions emerge and become reified. The idea that "natural" reality also is constructed seemed much more startling, and it touched off considerable interest and controversy. The term *construction* is remarkably protean, but when used in connection with a term such as *fact,* it seemed to imply that the phenomenon in question was somehow different, or even less real, than a fact. Moreover, the theme encouraged arguments and investigations that challenged the universality of scientific knowledge and scientific methods, thus raising the specter of relativism and begging questions about the grounds of constructionist claims (see Hacking 1999).

Consistent with social theoretical trends toward feminist epistemology, deconstructionism, postcolonialism, and so-called postmodernism, and encouraged by SSK and

ANT research and argumentation, studies proliferated in the 1980s and 1990s that politicized the idea that the very nature and contents of science were "socially constructed" (see Haraway 1991). The earlier argument that scientific representations (facts, laws, etc.) were not inevitable or determined by "nature" alone was compounded by explicit denunciations of particular scientific representations (of gendered bodies, racial characteristics, normal and pathological conditions, etc.) and of conceptions of scientific objectivity (as "male," exploitative of "female" nature, expressing cultural privilege and domination). Social construction—both the SSK version and the more politicized cultural studies version—became a target of a flurry of books, articles, conferences, and a massive number of Web postings in the 1990s. The *science wars* were epitomized by the publication in the cultural studies journal *Social Text* of a "hoax" article by physicist Alan Sokal, which argued for a conceptual affinity between poststructuralist literary theory and current theories in quantum gravity physics. Sokal's hoax was celebrated by many opponents of constructionism and related "relativist" trends in the humanities and social sciences, and for a short time it attracted unwanted media attention to the social studies of science field. During the science wars, debates about the "construction" of science were rarely argued with much care or philosophical sophistication, and by the end of the 1990s, the heated rhetoric began to be toned down (see Labinger and Collins 2001). The field of social studies of science continued to thrive, despite the highly charged polemics about it in the 1990s, and much (indeed most) research in the field consists in uncontroversial studies of (often controversial) developments in science, engineering, and medicine. Consistent with the tendency to question conceptual boundaries between science and nonscience and between science and technology, current research explores the complex way in which science has become embedded in, and inflected by, popular social movements, legal cases and regulations, economic institutions, and systems of governance.

SOCIAL WORLDS

Combining notions of culture, social structure, and collective action, *social worlds* are collections of actors with shared understandings and shared institutionalized arrangements that convene, communicate, and coordinate behaviors on the basis of some shared interest. The conceptualization originally stems from work by Tamotsu Shibutani, Anselm Strauss, and Howard Becker, with roots traceable to John Dewey.

Social worlds is a symbolic interactionist concept that distinguishes social actors as they negotiate interactions with one another. Actors negotiate conflict when their perspectives are different, since they represent different social worlds within the same *arena*. When their perspectives are shared, the actors develop and maintain a social world as they communicate with one another and coordinate their behaviors in regard to the phenomenon of interest. Whether it is a baseball game, a soap opera, an advertising campaign, or a medical treatment program, a social world emerges as those with shared perspectives on the phenomenon interact with one another about that phenomenon. In contrast, as those with different perspectives experience conflict over it, different social worlds within a single arena can be identified.

As an interactionist concept, social worlds can be applied at micro-, meso-, or macro-levels of interaction. However, most research using the social worlds concept has been either at the micro-level, such as research on "serious leisure"—including studies on role-playing computer games, bridge playing, and bass tournament fishing—or at the meso-level in science and technology studies (STS). While the former body of research has tended to focus on how social worlds are developed and maintained, the latter STS research has tended to describe how conflicts between social worlds are negotiated at the organizational and institutional levels.

The social worlds analysis in STS is most attributable to Strauss, who thought of social worlds as the unit of interaction in society. The concept allows the analyst to account for any actor involved in a contested phenomenon. Actors

can include those who are little more than observers—such as consumers, an electorate, or community members—who help form the context of the contest. As actors become increasingly involved in the contest and mobilize their resources, their social world becomes more important in determining the contest's outcome. In this way, social worlds analysis is able to account for the influence of social movements and a society's emergent awareness of social problems on how phenomena are defined and treated.

Indeed, researchers in STS using social worlds analysis see conflict as the generic social process they study; cooperation and collaboration typically have to be mandated and cannot be taken for granted. The model of scientists producing science and recruiting supporters of it on the basis of reason and evidence was first challenged by an interests model in the 1970s. That model has since been supplanted by a number of others, including that of social worlds analysis. Unlike other perspectives, social worlds analysis tends to include nonscientific actors in its models.

Social worlds analysis raises the issue of how social worlds are distinguished. To address this issue, Adele Clarke developed the concept of *boundary objects:* things about which there is disagreement among members of different social worlds interacting in the same arena. Debate over the meaning of those boundary objects can reveal the conflicting nature of the different perspectives delineating the social worlds. For example, religious texts, government documents, and organizational policies can all constitute boundary objects; they serve as referents for common identity and consensus at a general level but can also be interpreted specifically and quite differently at local levels. The emergent conflicts over the meaning of boundary objects can thus reveal the varied perspectives constituting the different social worlds of the parties involved. Using such concepts, social worlds analyses often uncover the conflict beneath what is supposedly harmonious. These analysts have, for example, found that seeming congruous collaborations brought together by funding opportunities for democratic and community-oriented appearances are often characterized by mistrust and misunderstandings.

While social worlds analysis focuses on the mesolevel in STS, examining strategies and tactics used in conflicts between worlds, social worlds theory, used more often at the microlevel of interaction, concentrates more on the causes and consequences of an individual's involvement in a given social world, the patterns of functioning of social worlds in general. Among the questions addressed in such research are how social worlds are developed and maintained, what kinds of systems of power and hierarchy exist within them, and how personal identity and commitment to social worlds emerge.

Personal involvement is critical to social worlds. Among the findings to have emerged from this research are categorizations of involvement. Unruh describes four types of social world members: strangers, tourists, regulars, and insiders. Strangers participate little, tourists occasionally, and regulars routinely, but insiders perform the tasks critical to the creation and maintenance of the social world. Insiders tend to have the most time, experience, and resources invested in the social world and are the most committed to its existence.

An additional use of the phrase "social worlds" is a psychologically subjective use, referring to constellations of actors held in an individual's imagination. "Imaginary social worlds" has been a concept central to some dream research, which has found such worlds to reflect individuals' culture and social surroundings. For example, Caughey (1984) found that nearly 11 percent of his sample of subjects had media figures in their dreams. He also points out that all our social worlds (in the individually subjective sense) must be imaginary to some degree, in that we are all expected to know people in our society whom we have never met. Last, social worlds have also been used in reference to the social development of children. Scholars have described how in the course of developing identity, displaying mastery, and gaining a sense of agency, children's social worlds tend to coalesce around characteristics they hold in common, such as age, gender, ethnicity, religion, and skill.

SOCIALISM

Socialism is the theory and practice directed toward shared ownership and collective property holding of social

goods and services. Socialism has been enormously influential in sociology and social theory, because it shares the root concern with the social. Socialism is often identified with Marxism, but this is misleading. Socialism precedes Marxism by 50 years. The word *socialism* came into use in the 1820s. It is also larger and more varied than Marxism, for its usages refer to a wider range of places than Western Europe, where classical Marxism emanates from Germany, and to a broader set of claims and practices than the idea of scientific socialism.

In its earliest usages, the term socialism was reactive, but less against the idea of capitalism than against the idea of individualism. Socialism in its earliest phases was understood less as an alternative social system to capitalism and more as an antidote to the corrosive effects of laissez-faire and its individualism. By the twentieth century, the success of the Russian Revolution saw the installation of orthodox Marxism as the most influential type of socialism, as movement and as theory. Alongside Marxism, there were always practical reforming socialisms of different kinds, best represented emblematically by Fabianism in England and progressivism in the United States. Wherever capitalism emerged, socialists responded, often in local and pragmatic terms rather than in those of Marxism as a social theory. Socialisms are thus characterised by diversity and often by internal conflict and contradiction. In some cases, as in England and Australia, socialisms could be characterised as the confluence of middle-class ideas and their intellectual bearers with working-class strategies and their bearers in union-based social involvements. There have always been middle-class and working-class socialisms, and there have always been socialist theories and movements that do not always meld. There have always been modernist and antimodernist streams within socialism, some expressing the utopian need or desire to return to precapitalist days, others arguing to the contrary that it was necessary to have more factories but no capitalists. There have always been substantial tensions between socialist arguments for efficiency in material provision and other claims for democracy and freedom. There have often been tensions between the idea that small cooperative organization is beautiful, and the increasingly influential twentieth-century demand that the state should run society. Often these contradictions or tensions are evident within the same thinkers, as evidenced in the work of Marx or Gramsci or G. D. H. Cole, or else they emerge across the historical paths of development of their thought.

The earliest uses of the word socialism in the English language occur in England, in connection with the emerging cooperative movement. *Cooperation* is a leading example of a kind of practical, rather than theoretical, socialism. Cooperation spread across the nineteenth century in two forms, as cooperatives of consumption and production. In the first case, working people would pool their resources, buy consumer goods collectively, distribute them socially and share profits as dividends. Such practices were directed against the so-called truck system or closed economies of company towns, where wages might be paid in kind, where wage-labour relations were not formally free, and consequently where workers were even more oppressed than elsewhere, having no alternative but to buy or receive adulterated or substandard goods in lieu of wages. The history of producers' cooperatives is more complicated, as producers' co-ops are often formed in moments of crisis—for example, as an alternative to the closure of firms, where workers buy their capitalists out and introduce the strategy of self-management. Both types of cooperation are open to the Marxist criticism that they seek capitalism without capitalists. They have nevertheless been viewed as exemplary by radicals, as they demonstrate the redundancy of capitalist domination. The knowledge and skill of production belong to the workers, not their bosses. The secondary issue, that capitalists often know how to trade even if they do not know how to produce, is lost in the equation. Both types of cooperation facilitate some degree of worker self-management, a theme that resurfaces into the 1960s, where workers take over the functions of capital and seek to run firms democratically. Here, the telling criticism comes rather from the syndicalists, for whom it is bad enough that workers have to work in factories—now you expect us to run them, as well?

Cooperation remains a powerful subordinate theme in socialism, not least because it plays on the social theme in socialist argument: Shared problems warrant shared solutions. Even capital is a social product, not an individual entitlement. The dominant socialist argument in England and Australia, however, is *labourism,* a tradition that becomes more fully reconciled to the state rather than the local level as the appropriate realm of action. Labourism refers to the socialism of the organised labour movement, where the object is the defense of the interests of workers and their families, represented by unions and labour parties. Labourism is associated with the social security measures "from the cradle to the grave" of the welfare state, though welfare states were generally engineered by middle-class liberals like Keynes and Beveridge (in America, Franklin Roosevelt) rather than by labour's intellectuals. Labourism involves incremental reforms generated through "parliamentary socialism." In this, it coincides with, and is often driven on by, Fabianism. *Fabianism* is the British intellectual tradition of middle-class reform that is often associated with British sociology and social administration; by virtue of the Empire, it is also the dominant reforming ideology in Australia. Its primary educative institution was the London School of Economics, established by the Fabians in 1895. Originally an alternative life group, the Fabians became the first think tank; intellectual reformers prepared to work with any political leaders if the connection would further

their ends. This was an approach identified with Sidney and Beatrice Webb (nee Potter), but pioneered by Beatrice Potter in her apprenticeship with Charles Booth's survey of poverty in London. Its middle-class roots ran in tandem with the Christian Settlement tradition of Toynbee Hall, where young men and women like Potter would do good work with the poor; the parallel American experience is that associated with Jane Addams and Hull House in Chicago. Systematic social research should lead to publicity and then to reform. In this way, health, housing, education, transport, and so on, could incrementally but systematically be reformed, and the end result of this process would be socialism. This is the kind of socialism that the Polish revolutionary Marxist Rosa Luxemburg would ridicule as socialism by the instalment plan. Not all English socialists were Fabians, however. The romantic revolutionary William Morris called for revolution, although like his Boston reformist opponent Edward Bellamy, was coy as to how precisely socialism might come about.

Other English ethical socialists such as Richard Tawney rejected revolution but insisted that while you could peel an onion layer by layer, you could less easily peel the tiger of capitalism claw by claw. Socialists like Tawney saw inequality, rather than wage-labour, as the major problem. Social service was the solution to aristocratic parasitism. Others like G. D. H. Cole, who travelled from guild socialism to Fabianism, insisted that the problem with most socialists was that, asked to identify the central issue, they would say poverty, whereas it was really slavery (here, wage-slavery) that was at fault. The *guild socialists,* as the name indicates, wanted really to go back, to the medieval guilds, or forward to some modified modern version of guildism, where the scale of social organization was small, and work depended on the transferred traditions of skill between masters and apprentices. Later British socialists like Harold Laski followed Cole in arguing that power needed best to be dispersed: pluralism, not medievalism, was the appropriate response. Other Catholic radicals such as Hilaire Belloc argued for what they called "distributism," the breaking up of modern monopoly and state concentration and the reconstruction of a rural smallholding society. Antimodernists like these saw cities as a major problem and eulogized the image of England's green and pleasant land as a lost social alternative. A different socialist or reforming current can be traced to the influence of John Stuart Mill. Later in life, Mill offered a theoretical dispensation to the socialist idea and to the fact of cooperation. The most influential liberal of the twentieth century, John Maynard Keynes, followed Mill's agnosticism regarding the perpetuity of capitalist civilization. At the very least, Keynes seemed to be arguing, capitalism itself needed civilizing (and this is, by default, the logic of most non-Marxist socialism—the advocacy of the mixed economy, where the state fills the gaps in market activity and underwrites

social development through the welfare state). This was a less muscular socialism than the Fabians had in mind, though by the mid-twentieth century, there is some merging of horizons as Fabianism becomes the defacto theory of labourism and aristocratic liberals such as Keynes and Beveridge supply the practical blueprint for a civilized capitalism.

While the English tradition developed cooperation, the French tradition pioneered utopian socialism. Comte is usually credited with coining the idea and one version of the project of sociology; Saint-Simon and then Fourier developed ideas and schemes for utopia, ranging from urban meritocracy to the permanent rural retreat. As elsewhere, socialism in France was to rest on this central conflict between antimodernism and modernization. The greatest socialist modernizer of reform was Durkheim. Through the nineteenth century, antimodern arguments were to dominate. Georges Sorel developed the argument for the myth of revolution. Paul Lafargue, Marx's son-in-law, sought to introduce Marxism into the Latin socialist tradition, but his major contribution was an antimodern tract criticizing not only capitalism but civilization in general. It was called *The Right to Be Lazy.* With the Russian Revolution and the Bolshevization of the Socialist parties, communism came to dominate the Left in a way without parallel, save, in Britain, where labourism ruled. Communism and the French Communist Party became something of a compulsory haven or benchmark for French intellectuals, from Jean-Paul Sartre to Maurice Merleau-Ponty. The most interesting of French Marxists remained those who developed out of surrealism and existentialism into urban studies, like Lefebvre, or maverick postwar Trotskyists such as Castoriadis and Lefort, who developed major alternative social and political theories. Into the 1960s, the new wave of structuralism saw Louis Althusser displace this humanist legacy. Although Marxism came to exert a greater influence here than in any other parallel experience except Italy, it remains the case that Durkheim's influence persists across the whole period from 1890.

Durkheim argued in a series of texts from *The Division of Labor in Society* to his lectures on socialism and Saint-Simon that communism was passé. Communism was a philosophy of simplicity, austerity, and stasis, reaching back to Plato. Socialism, in comparison, was modern and modernizing, especially if it was harnessed to the new science of sociology. Contrary to the romantics, the division of labour would be used to civilize society and to cultivate interdependence, not least through the encouragement of professional associations that might fulfill some of the old integrative functions of the guilds. The parallels with English guild socialism are striking, except that Durkheim was no medievalist. Like Tawney, he believed that individuals still should serve society and each other, and he viewed unions or work-based associations as the means that might mediate between society or state and individual. Contrary

to Marx, labour here is viewed not as alienated but as potentially integrative; anomic social forms may occur, but as in the Fabians, social problems are viewed as open to analysis, research, and publicity, thence to legislative resolution. Unlike Lafargue and the romantic tradition, Durkheim offers a model of society as the working institution, where identity and purpose and social cohesion are all work generated. Work is the great social integrator. Socialism in the United States follows a broadly similar pattern, where the romanticism or communalism of the nineteenth century gives way to progressivism by the twentieth. Utopian or communal socialism thrived in the earlier parts of the nineteenth century in America, perhaps more than in any other case. It was in America, in the New World, that enthusiasts often set out to apply communal plans developed elsewhere, on the continent by the French, in Britain by Robert Owen or John Ruskin (Owen's model factories in Scotland remained exemplary of nonagrarian social experiments).

By the end of the nineteenth century, the closing of the American frontier and the emergence of crisis in the cities saw a hesitant shift to a modernizing socialism, best exemplified in the extraordinarily influential work of Edward Bellamy, *Looking Backward.* Bellamy clubs arose to propagate the cause of an industrial army-based utopia spread across the United States and as far afield as Australia. Bellamy's social model resembled Durkheim's, at least cosmetically, for both saw the construction of new forms of industrial solidarity as the challenge. By some of Durkheim's criteria, however, Bellamy's utopia remained uncomfortably close to communism in its premodern predilections. Bellamy aspired to complete equality, whereas Durkheim's image of society was closer to that of civilizing rather than negating capitalism. Bellamy, for his part, largely eschewed the language of socialism because of fear of red ragging; earlier, he called his utopia nationalist, later referring to it as a kind of public capitalism. The impulse of the Bellamy clubs was dispersed into the twentieth century. It informed the progressivist case that found its way into Roosevelt's New Deal, alongside the Keynes-Beveridge welfare state in the United Kingdom. Bellamy's socialism was a transitional phenomenon, responding to the Gilded Age, seeking to bridge country and city through the small-town tradition so central to American political culture. As the cities came to dominate American social and political life, so did socialist thinking become more urban and modernizing. In Detroit and Chicago and across the Midwest, a different transitional movement flourished briefly before the First World War. Generically called *syndicalism,* and with strong French and Italian precedents connected to anarchism, its leading movement was the Wobblies, or Industrial Workers of the World. Here unions or syndicates, rather than guilds, were the model of the new society. The transitional nature of the movement is indicated in the fact that many of the members were rural workers, itinerants, residuals of the old way of life rather than bearers of the new world of Fordism.

The success of the Russian Revolution again saw the emergence of American communism and Trotskyism in response. But the peculiar character of American socialism in the cities—in New York, Chicago, and Milwaukee—was its Germanic influence. Thanks to its immigrants from Central Europe, the Marxism of the German Social Democrats, which in turn influenced Poles, Russians, and Ukrainians, became the substance of American socialism over the turn of the century. As participant critics such as Daniel Bell then argued, Marxism discredited itself in America by failing to Americanize. This was the socialism of the ghetto, of the old country rather than the New World. American Marxism, on this account, was not of this world. As the subsequent paths of American Marxists such as Max Eastman and Sidney Hook show, Marxism seeks to renegotiate local tradition through American pragmatism, right through to the contemporary work of Richard Rorty, while others, such as Cornell West, were to claim not a new Marxism but a new progressivism as the American radical politics for the twenty-first century. Having been outflanked by the Bolsheviks and then crushed by the Nazis, the German Social Democrats led the way into the postwar period with a managerial version of civilized capitalism. The Keynesian consensus ruled, until its defeat into the 1970s and 1980s by neoliberalism. The social infrastructure facilitated by state intervention and cooperation remain a subordinate note in most industrial countries, with the qualified exception of the United States.

SOCIALIZATION

Socialization is a process by which the larger societal and cultural norms and values are transmitted to the individual. Successful socialization also involves an internalization of

the larger norms and values into the consciousness of the individual actor. This process usually takes place when adults teach small children "right" from "wrong." Children learn what is expected of them from the social system as well as what to expect from the social system and are simultaneously bound to the system by those expectations. Childhood socialization equips the individual with only a very general sense of how to respond to social situations, and a continued lifelong socialization process is necessary to prepare individuals with how to deal with more specific situations.

The first sociologist to truly grapple with the topic of socialization was Émile Durkheim. Durkheim held the view that human beings are riddled with innate human passions that at every moment threaten to overtake them and society at large. The only way to restrain these passions is through a collective morality, or a collective conscience. These ideas led Durkheim to an interest in how social morals are internalized through education and socialization.

Durkheim defined education and socialization as the processes through which a given group or society transmits its ways to its members. It is a means by which the actor is able to learn the necessary physical, mental, and most important to Durkheim, moral tools he or she will need to function properly in a given group or society.

Durkheim believed that moral education and socialization more generally had three important goals. First, their goal is to teach the individuals the necessary discipline they will need in order to control their passions. It is only by limiting these passions that individuals can ever achieve a sense of happiness and good moral health. Second, these processes provide individuals with a sense of autonomy. This is not a traditional sense of autonomy, however, because it does not imply free will but, rather, an understanding of why the larger social norms and values should be desired of one's own free will. Third, socialization and moral education seek to instill within the individual a strong sense of devotion to the larger society and its moral system.

Another sociologist who dealt heavily with the topic of socialization was the structural-functionalist, Talcott Parsons. Parsons believed that socialization was a means whereby the normative order was able to control the behavioral order. He assumed that actors were passive recipients of the norms, values, and morals taught to them by means of socialization and that they would largely successfully internalize these standards of the larger social system. This would ensure that even when actors were pursuing what they believed to be their own best interests, they would also, in fact, be pursuing the best interests of the social system as a whole.

There are instances, however, when individuals seem to be not in line with what is expected of them by the larger social system. These "deviants" can pose a threat to the social order, and the use of what Parsons called "social controls" might be in order. He believed that these social controls should be used sparingly, however, because a flexible social system is stronger than a rigid one. In this way, socialization in combination with social control helps keep the social system in balance.

In contrast to the view of socialization taken by Parsons, many ethnomethodologists argue that socialization is not a one-way process of internalization. For example, Speier (1970) argues that "socialization is the acquisition of interactional competencies" (p. 189). Thus, many ethnomethodologists support the view of socialization as a two-way process involving the interaction of both instructor and recipient. Robert W. Mackay has used the example of childhood socialization as an exemplar of the differences between normative sociology and ethnomethodology. He argues that whereas normative sociology sees socialization as a series of stages whereby "incomplete" children are taught by "complete" adults, ethnomethodologists see socialization as an interactive process in which children are active participants in the construction of the social order.

SOCIOLOGIES OF EVERYDAY LIFE

Sociologies of everyday life are qualitative sociologies that examine small-group interaction and place a primacy on understanding and reporting the lives of the members of everyday life as they see it or as close as possible to it. They all share a common concern with the members' perspective about society and a qualitative methodological approach to the study of human interaction. Sociologies of everyday life encompass a variety of sociologies, most of which never refer to or associate themselves with the name *sociologies of everyday life.* The term itself comes from a book by Jack Douglas and some of his graduate students (Douglas et al. 1980).

The origins of the sociologies of everyday life are diverse. Douglas attributes its origin to the nineteenth-century Scottish moral philosophers. Perhaps more direct is the derivation from the two philosophical currents known as pragmatism and phenomenology. Pragmatism, especially in the works of George H. Mead, Charles Horton Cooley, and John Dewey, is the recognized foundation of some sociologies of everyday life. The stress on the study of small-group interaction and the symbols used by the members of society in communication are paramount features of the sociologies of everyday life, as informed by the pragmatist philosophies.

Phenomenology, similarly, focuses on the study of society based on the meaning attributed to it by its members. Stemming loosely from the philosophy of Edmund Husserl with its centrality on understanding the phenomena of the world, phenomenology was applied to sociology primarily by Alfred Schütz (1962), whose work shares fundamental social principles with the pragmatists, especially Mead, and informs some of the sociologies of everyday life. Schütz and Mead both focused on the socialization process (common stock of knowledge) of the members of society, their ability to interact (reciprocity of perspective), and the relevance of understanding the meaning they attributed to everyday life.

Other phenomenologists stressed the incarnate nature of humans, collapsing the dichotomy of self as established by René Descartes. Martin Heidegger refers to it as *dasein* (being-in-the-world). Maurice Merleau-Ponty also places emphasis on being in the world (*étre-au-monde*). Phenomenologists (along with others) reject human attributes that can be grasped outside of the realm of everyday life. We (*qua* humans) are irremediably embedded in this world through the carnality of our bodies—we are our bodies. Thus, the sociologies of everyday life embed the members of society in the world of everyday life while focusing on the negotiated meaning of their interactions.

The sociologies generally considered to be "of everyday life" are the following: *symbolic interactionism, dramaturgy, labeling theory, ethnomethodology, existential sociology,* and *postmodern sociology.* They all share some common ideas, which has led to their grouping together, yet at times, they have marked differences.

The first concept shared by the sociologies of everyday life is the concern with maintaining the integrity of phenomena. Researchers must spend time with the members of the group studied to gain an understanding of how the group views and describes the social world, as well as the members' daily concerns. Researchers must not superimpose any theoretical preconception on the study but must, instead, derive their notions as they stem from the accounts of the members themselves. Thus, all the sociologies of everyday life would rely on the methods of participant observation, in-depth-interviewing, or both and on inductive reasoning to reach a better understanding and minimize distortions of the phenomena studied.

The second concept shared is with understanding the symbols used by the members of society in interacting with each other. Since symbols can vary and mean different things for different cultures or subcultures the researchers must become familiar with the group studied and their use and interpretation of symbols. The emphasis would be different for different sociologies. For instance, symbolic interactionism and labeling theory would focus on the symbols used in interaction, dramaturgy would look at the symbols used by the actors in their presentation of self, ethnomethodology would ponder why some symbols are used rather than others, existential sociology would emphasize the emotional component of symbols, and postmodern sociology would observe the interplay between everyday life and media-presented symbols.

The third concept shared concerns the methods used by the members of society to create and sustain their reality (Gubrium and Holstein 1997). The focus here is not so much on what the events are but on how the members of everyday life create and describe their lives. The sociologies of everyday life and especially ethnomethodology would reflexively study the accounts of the members of society—what stories do they tell about themselves and how do they tell them to gain certain effects?

There are marked differences among various sociologies of everyday life. Symbolic interactionism, dramaturgy, labeling theory, and ethnomethodology continue in the tradition of mainstream sociology and wish to conduct research in an objective and neutral fashion. Existential sociology and postmodern sociology reject the assumption of objectivity and instead advocate partisanship and cooperation with the group under study (often an oppressed or disadvantaged group).

Another difference is in the emphasis of rational behavior versus the role played by feeling and emotions in decision making by the members of society. Existential sociology and postmodern sociology emphasize feelings rather than rational elements in trying to understand what makes people act in certain ways.

A final difference among the various sociologies of everyday life is in the reporting procedures used to describe research studies. Most of the sociologies of everyday life continue to use the sparse language of science and traditional methods of reporting, while existential sociology (Kotarba and Johnson 2002) and postmodern sociology (Fontana 2003) experiment with new modes of reporting. Thus, rather than taking the form of conventional journal articles, postmodern modes use the short-story format or make use of performances or even poetry.

SOMBART, WERNER

Werner Sombart (1863–1941) was a German economist and founding figure of sociology. While he was very well known during his lifetime, he was largely forgotten after his death. Outside Germany, Sombart is perhaps best known for his essay *Why Is There No Socialism in the United States?* first published in 1906 (Sombart 1976). To this day, political scientists, historians, and labor specialists refer to the "Sombart question" when addressing the exceptional character of the American labor movement.

Sombart came from a liberal bourgeois family. He obtained his doctoral degree under Gustav Schmoller in Berlin in 1888 with a dissertation on the Roman Campagna. At the recommendation of Schmoller, but against the opposition of the faculty, two years later he was appointed associate professor at Breslau. It was not until the end of the First World War that Sombart became full professor in Berlin, where he succeeded one of his teachers, Adolph Wagner. Before that, Max Weber tried twice, unsuccessfully, to get him appointed as his successor, first in Freiburg, later in Heidelberg. In 1904, Sombart became one of the editors of the *Archiv für Sozialwissenschaft und Sozialpolitik* (Archive of Social Science and Social Policy) along with Max Weber and Edgar Jaffé. The *Archiv* was the most influential German social science journal of the time until its closure in 1933.

His main work is *Moderner Kapitalismus* (Modern Capitalism), first published in two volumes in 1902 and reissued in a much-enlarged second edition from 1916 to 1928, albeit never translated entirely into English. While Sombart was not the first to use the term *capitalism* (Louis Blanc is considered to have coined the term in the 1850s), the title of this work puts the term capitalism in a prominent position. Marx had never used the noun but spoke of the "capitalist mode of production." The book offers in the eyes of many contemporary social scientists a classical analysis of the origins and the nature of capitalism. He also develops a kind of methodological and epistemological manifesto for a modern social science. In contrast to the "historical school" in economics from which he started (being a pupil of Gustav Schmoller), he started to aim for explanations based on ultimate causes. For Sombart, historical appearances build up to a social system that can be grasped by theory (and here he mentions explicitly the theory of Marx). However, he still considers himself a member of the historical school. Sombart did not follow the intellectual agenda of Marx's base-superstructure theorem in which productive forces are the most basic layer in society, on which relations of production are erected and are, in turn, overlaid with an ideological sphere. In Marx, the primacy is with the former two, in Sombart, with the latter—he gives definite priority to the spiritual sphere of society. Sombart thus was not a Marxist in the strict sense, but he was sympathetic to the socialist cause (Lenger 1994).

Among the recurring themes in Sombart's works are race, Judaism, Germanness, capitalism and technology, Marxism, fashion, consumption and leisure, and methodological issues. The first three are somewhat odd for a sociologist; nevertheless, they were of central importance to him. He also advocated a new program for sociology, which he called "Noo-sociology" and which attracted hardly any followers. A noological sociology is based on the premise that all society is spirit (*Geist*) and all spirit, society. Its fields of investigation are forms and cycles of civilization. Its methods, therefore, cannot be those of the natural sciences. It is committed to emergent social phenomena that must be understood and placed in restrictive sociohistorical and institutional contexts—for example, religion, the state, the church, or the economy. It is worth noting that Sombart calls the scientific approach "Western" and the noological approach, "German" sociology.

If one were to summarize Sombart's intellectual development, one could say that he radically changed his mind about two crucial issues: Marxism and Germany. He started out as an ardent fighter for the cause of the socialist movement. This earned him the recognition of Friedrich Engels. In this period, Sombart did not try to reject or transcend Marx. Instead, he attempted to complete the Marxian perspective by adding a sociopsychological and sociocultural dimension to the analysis of the genesis and the nature of capitalism.

After the turn of the century, Sombart became a fervent anti-Marxist, with some anti-Semitic overtones. His relation to Germany was marked by an equal shift of valuation: In his early writings, Sombart had many reservations about his country, but around 1910, he turned into a strident nationalist. His intellectual development can also be followed through different editions of the same book, *Sozialismus und Soziale Bewegung* (Socialism and the Social Movement), which first appeared in 1896. While the first nine editions were sympathetic to the socialist movement, the 10th edition (1924) revealed Sombart as a critic of Marx and socialism. This edition had the title *Proletarischer Sozialismus (Marxismus).* In 1934, when the final edition of the book appeared, it was called *Deutscher Sozialismus* and supported the Nazi rulers. Princeton University Press published an English translation of this book under the title *A New Social Philosophy* in 1937.

Sombart and Weber both attempted to explain the origins of capitalism by invoking the importance of religion. While Weber saw the Protestant ethic as root cause for the emergence of capitalism, Sombart awarded this role to the Jewish religion. While Weber and Sombart largely agreed about the role of the Jews in economic history as being traders and moneylenders, they disagreed about the Jews' role in the development of capitalism and about the role of race. While Sombart was beset with issues of race, Weber was not. Most important, Sombart mixed these contested issues with ethical and moral aspects. His analysis of causes of capitalism is coupled to a discussion about an attribution of blame. Since he abhorred capitalism and free markets, he did not stop at analytical statements about the sociohistorical role of the Jews (no matter how contested such observations may be) but linked these observations to moral judgments. Likewise, his discussion about the course of civilization is interspersed with arguments about "superior" and "inferior," "mixed" and "pure" races. He states, for example, "One can be sure that the Jews have had a significant share in the genesis of capitalism. This follows from, among other things, their racial disposition" (Sombart 1902:390). Sombart emphasizes the dominance of willpower, egotism, and abstract mentality in the "Jewish race."

In another context, he identified two "worldviews" contesting each other during World War I. On one side were the nations of shopkeepers and merchants; on the other was the land of heroes, philosophers, and soldiers, prepared to sacrifice themselves for higher ideals. For Sombart, England represented the former set of worldviews, and Germany, the latter. In this instance too, he changed his views in the course of his life quite fundamentally.

In Sombart's book *Die deutsche Volkswirtschaft im Neunzehnten Jahrhundert* (The German Economy in the 19th Century, published in 1903), he points to a manifest link between the national character of the German people and the spirit of capitalism. While retaining his hostility toward capitalism, he would, however, slowly develop a "strategy" of reconciliation with "*Deutschtum.*" (Germanness). The distinction between two types of capitalists—entrepreneurs and traders—became crucial. While the entrepreneur is quick in comprehension, true in judgment, and clear in thought, with a sure eye for the needful and a good memory, the trader's "intellectual and emotional world is directed to the money value of conditions and dealings, who therefore calculates everything in terms of money" (Sombart [1913]2001:39–40). Sombart was to identify this role as occupied by the "Jewish species." The peoples less inclined to capitalism were the Celts and a few of the Germanic tribes, the Goths in particular. Wherever the Celtic element predominated, capitalism made little headway.

Sombart persistently dwelled on the topic of racial categories. It cannot come as a surprise therefore that he welcomed the Nazis' rise to power, whose chief ideologue he imagined himself to be—a feeling that was not reciprocated. And he was quite naive at that, given that even in his most nazified book (Sombart 1937), he time and again mentions Marx as an intellectual authority.

It should also be noted that Sombart is held in high esteem by some Jewish scholars, who are followers of the capitalist economic order and therefore applaud his attempt to establish their beneficial role in the emergence and development of capitalism. For example, Werner Mosse (1987) concludes his book with a quote from Sombart that emphasizes the beneficial consequences of the Jews for the German economic development.

Sombart's work on culture, consumption, and luxury is still regarded as "classic." This field had been left almost exclusively to economists who treat consumer behavior in an ahistorical framework of assumptions and consider it to be basically the same for all peoples at all times.

Sombart suggested a close connection between the insatiable patterns of consumption in early modern court life and the growth of capitalist production. The demand for luxury was not so much connected to a pursuit of comfort as to social ambition and mobility, a point also made by Norbert Elias who argued that the highly complex and expensive culture of consumption within the court was not only there to distract a bored aristocracy but was a central means by which Louis XIV controlled the French aristocracy. Aristocrats became especially passionate about assembling rare objects from around the world. The display of these objects, plants, and animals prefigures Veblen's conspicuous consumption. Where Veblen would stress the point that this was wasteful consumption, Sombart sees it as a way to mark ranks where social stratification was unclear. Others have pointed out that a materialist consumer culture oriented around products and goods from all over the world was the "prerequisite for the technological

revolution of industrial capitalism" (Appadurai 1986:37) not its result.

SOROKIN, PITIRIM

Pitirim Alexandrovich Sorokin was born in Russia in 1889. During the Russian revolution, he was a member of the Social Revolutionary Party. He was active in opposing both the Czarist government and the Communists, being arrested and imprisoned by both regimes. Sorokin served in the cabinet of the post-Czarist Kerensky government in 1917. After his second arrest by the Communists, his death sentence was revoked, and he was allowed to return to graduate work at the University of St. Petersburg, where he was awarded his doctorate in 1922. Later that year, he was exiled from Russia by the Communists. After coming to the United States, he taught at the University of Minnesota. In 1930, he became the first chairperson of the Sociology Department at Harvard University. Sorokin later founded the Harvard Research Center in Creative Altruism. He was elected president of the American Sociological Association in 1965. Sorokin died in 1968.

Sorokin is the most published and translated writer in the history of sociology. During his career, he wrote 37 books and more than 400 articles. His contributions to sociology are original, fundamental, and comprehensive. Sorokin's most important writings are in the areas of cultural structure and change, social differentiation, social stratification, social conflict, and the causes and effects of altruistic love. He also made major contributions in the classification and critical analysis of theories, epistemology, methodology, the analysis of social space and time, the sociology of revolution, and the sociology of crisis.

His work taken as a whole constitutes a comprehensive general system of sociology that integrates the scientific, reformist, and practical traditions of the discipline. Following this cosmopolitan character of his system of thought, Sorokin's writings range from complex and insightful scientific formulations to writings intended to inform the general public on problematic conditions and provide suggestions for their resolution.

Sorokin was the first theorist to explicitly identify culture, society, and personality as the basic frame of reference of sociology. This perspective on the subject matter of sociology pervades his work.

CULTURAL STRUCTURE AND DYNAMICS

Cultural Integration

Sorokin is best known for his theory of cultural organization and change. His work in historical sociology is a major effort in applying both quantitative and qualitative methods to cultural and social trends over a 2,500-year period, primarily in Western civilization. Collaborating scholars who were not aware of the overall purpose classified data representing a time period typically ranging from 600 B.C. to 1925 A.D. This data is tabulated by varying intervals of time ranging from 20 to 100 years. In some instances, correlation methods are also employed. Sorokin's culture types and his analysis of cultural and social change are thus based on a massive compilation and analysis of empirical data.

The meaningful aspect of culture is considered foundational. Behavior and material products objectify these ideological aspects of culture. Cultures vary in their degree of integration. A culture is integrated to the degree that its components are logically consistent, interrelated, and interdependent. The basis of integration is the predominant cultural definitions pertaining to four major premises: the nature of reality, the needs and ends to be satisfied, the extent of their satisfaction, and the methods of their satisfaction.

On the basis of contrasting definitions of these universal questions, two polar types of integrated culture can be considered—the ideational and the sensate. All existing

cultures fall somewhere on the continuum between these two ideal types. In an ideational culture, the nature of reality is regarded as supersensory and superrational, organized in reference to some idea of God or the Ultimate Reality. The needs and ends are thus primarily spiritual and otherworldly, their satisfaction is maximum, and the primary method of satisfaction is modification of the self to conform to transcendental standards. In a sensate culture, the nature of reality is viewed as limited to that which is physical and material. Needs and ends are thus of this nature, and their satisfaction is to the maximum. The primary method of satisfaction is engagement with the external environment to take from it or change it in some manner to satisfy needs. A third type of integrated culture, the idealistic, later called the integral, represents a harmonious synthesis of these two polar types, with the ideational content of basic premises being foundational.

Variations in the content of these basic premises are reflected in differences in what Sorokin termed the compartments of culture. For example, in an ideational culture the system of truth and knowledge is based primarily on the truth of faith, which is considered as the revealed truth of God. In direct contrast, in a sensate culture, induction and empiricism are the sources of truth. In an idealistic culture, reason is used to combine these contrasting ontologies and epistemologies into a harmonious system of truth and knowledge. In ethics, ideational ethics consists of absolute principles derived from transcendental sources and intended to guide the lives of individuals according to ultimate values. In contrast, sensate ethics consists of relative and changeable rules made by humans to maximize human happiness. Idealistic ethics combines these contrasting types into an integrated system in which the absolute principles of ideationalism are fundamental. Basic differences between ideational and sensate cultures can be observed in other compartments of culture such as philosophy, law, and art of various types.

Cultural Change

Change is immanent, in the sense that its source is the properties and processes of the system itself. Sociocultural systems change because they are composed of individuals, ideas, and material vehicles, all of which are constantly changing. However, the range of this change is limited. This is because almost all basic sociocultural systems and processes can assume a relatively small number of distinctive forms. The principles of immanence and of limits explain the recurrence of sociocultural phenomena over time.

These principles of change are the basis of understanding the recurrence of ideational, idealistic, and sensate culture forms in Western civilization. Further understanding of this change in culture types rests on the idea that the true reality contains empirical-sensory, rational-mindful,

and superrational-supersensory aspects. When a culture approaches too close to the polar type of either ideational or sensate, it moves further from the nature of true reality and thus becomes increasingly false. Since culture provides the framework through which individuals and groups adapt to reality, if the false parts of culture are too great, both individual and social life are impoverished. Basic human needs are not met and social life becomes unnecessarily limited and problematic. Because of these conditions, increasing numbers of individuals question established definitions of reality and search for alternatives. A fundamentally opposite culture begins to emerge and eventually becomes dominant. This explains the fluctuation from ideational to sensate culture types. The explanation of change is somewhat different for the idealistic culture that combines sensate and ideational in a harmonious system. This type of culture is considered to be relatively short-lived because of the difficulty of maintaining a balance of components that are essentially opposite. Historically, it has been transitional between ideational and sensate.

SOCIAL STRUCTURE AND DYNAMICS

Sorokin's writings contain conceptual and theoretical formulations in a number of major areas in the study of social structure and dynamics. His major ideas can be organized by three general topics: social differentiation, social stratification, and social conflict.

The analysis of society is based on the assumption that meaningful interaction is the most basic sociocultural phenomenon. It has three components: two or more thinking and acting individuals; meanings, values, and norms that are exchanged and realized in interaction; and behavior and material vehicles that objectify and socialize the ideas involved in interaction. A second basic assumption is that there are three inseparable components of all sociocultural phenomena: culture, society, and personality.

Social Differentiation

There are three universal types of social relationship: familistic, contractual, and compulsory. Almost all social groups are a combination of these pure types. In the familistic type, solidarity is high, interaction is extensive, typically of long duration, and includes the important values of the interacting parties. Contractual relationships are typically limited in extensity and duration and are based on the interacting parties' mutually fulfilling obligations and gaining from the relationship. Compulsory social relations are antagonistic. In these relations, one party imposes conduct on the other party contrary to the second party's desires or benefit.

Social relationships in major institutional groupings from the eighth to the twentieth century in Europe are analyzed with this typology. Ideational culture tends toward

familistic social relationships, while sensate is conducive to both contractual and compulsory relationships.

Groups are classified according to the number and nature of the meanings, norms, and values in terms of which the group is organized. Unibonded groups are organized around one set of meanings, norms, and values, multibonded groups around two or more. Some unibonded groups are organized around the meanings associated with a biosocial characteristic, such as sex or race, others around sociocultural characteristics such as occupational or political groupings. Important multibonded groups include the family, social class, and nation.

Social Stratification

The essence of social stratification is the unequal distribution of power, influence, privileges, privations, and responsibilities. Stratification involves the hierarchial arrangement of groups into upper and lower strata. Stratification is pervasive and universal, although its forms can vary considerably. All organized groups are stratified internally and in relation to other groups. In some instances, strata are formally organized and have the characteristics of organized groups. In other instances, such as that of social class, the organization is less developed.

As with groups, stratification can be unibonded or multibonded. Race, sex, and age are examples of unibonded stratification. In multibonded stratification, strata are superior or inferior on a number of criteria. Castes, orders, and classes are examples of this type of stratification. When multibonded stratification involves disparate positions, such as low state position but high wealth or vice versa, it can create pressures for change.

Social mobility is universal, although it may vary considerably in degree. It involves the movement of individuals or groups upward or downward in a system of stratification. Mobility takes place through the channels of circulation provided by major social institutions, such as the political, military, or educational. Within these channels, mobility is regulated by testing mechanisms, the criteria that determine what types of individuals may move up or be prevented from doing so.

Mobility into elite groups becomes a crucial problem in the modern era because of the concentration of power. Considerable historical data indicates frequent dualism in morality and intelligence of rulers and other elites. In general, these groups are found to be more criminal than the general population, although this criminality decreases when the power of elite groups is limited.

Social Conflict

Sorokin's theory of war and of internal disturbances is based on extensive historical research. For example, various quantitative indicators are used to study 967 wars in Greece, Rome, and Europe from 500 B.C. to 1925 A.D. A total of 1,622 internal disturbances are ranked according to magnitude by a multiple-factor index. Fluctuations over time in both types of conflict are studied.

Culture is an important factor in both kinds of conflict. The basis of international peace is compatibility of the basic values of nations that are in contact rather than similarity or difference of values in itself. The occurrence of war is greatest in periods when basic values are in transformation. Internal peace is also based on the compatibility of values of the various factions within a nation. Civil wars and other major internal disturbances are most likely to occur when there is a basic and rapid change in the values of one segment of a society.

Revolutionary change is an internal disturbance of high magnitude aimed at extensive changes in values and institutions. It is typically rapid and involves the use of force. Revolutions involve a destructive phase in which values and institutions are destroyed. During this phase, ethical polarization occurs, with the negative predominating over the positive. Thus, antisocial behavior increases, as does mental illness and mob psychology. The destructive phase is followed by a declining phase in which some values and institutions are restored and the society returns to a higher degree of stability and solidarity.

Sorokin also developed a general theory of solidarity and antagonism. Such a theory is considered important because if we knew how to increase solidarity and decrease antagonism, and were able to apply the knowledge effectively, social tragedies such as war and coercion could be reduced or eliminated. The most important factor in the relative incidence of solidarity and antagonism in both interpersonal and intergroup interaction is the character of cultural values and norms. Values and norms that stress mutual aid and sympathy will increase solidarity interaction. Conversely, values and norms that stress egoism and competition for limited resources will generate antagonistic interaction. A second factor in the relative predominance of solidarity or antagonism in interaction and intergroup relations is the concordance or discordance of values and norms of the interacting parties. Concordance increases solidarity, while discordance increases antagonism. This is particularly so if the discordant values and norms themselves encourage antagonism. These effects of culture are increased to the degree that the predominant values and norms are manifested in behavior.

PERSONALITY

There are four levels of personality. Most fundamental is the biological unconscious, which consists of various biological energies. Next are conscious biological egos, such as sex or age. The third level is the multiple conscious

sociocultural egos. Each ego reflects the influence of one of the various groups to which the individual has belonged. Much of the individual's mentality is derived from these group affiliations. The fourth level is the supraconscious, or soul. It operates through intuition and is important in creativity, spirituality, and in basic conceptions of truth, beauty, and goodness.

CRITICAL SOCIOLOGY AND THE CALL FOR REFORM

On the basis of his historical and comparative research and analysis, Sorokin formulated a critique of contemporary culture and society and issued a call for reform. The focal point of his critique was the inadequacy of the declining sensate culture. Its false parts have become greater than the true; hence, it does not provide for orderly relations between groups or the meeting of basic human needs. The profound crisis engendered by the decline of sensate culture is the most important and fundamental event of the historical era that began with the twentieth century. The locus of this event is primarily Western civilization. However, its effects are worldwide due to the decreasing separation of East and West because of factors such as communication, transportation, technology, and cultural diffusion.

The loss of vitality and creativity in sensate culture is evident in all its compartments. The system of truth is characterized by skepticism, relativism, and the separation of scientific endeavor from any criteria of the good. The ethical compartment of culture emphasizes expediency, relativism, hedonism, and subjectivism. Without universal standards, the ethical system cannot provide positive motivation or control behavior. Art is focused on giving pleasure and enjoyment and is often antisocial and amoral. Sensate ideas of freedom multiply desires without instilling restraint.

This cultural system contributes to the decline of familistic relationships, the breakdown of equity in contractual relationships, and the rise of the compulsory. Great power is held by a limited number, and its use is not adequately controlled. Because of the lack of universal standards and the proliferation of wants generic to sensate culture, an anomic situation is created in which interpersonal and intergroup conflicts, including war, are frequent, often intense, and inevitable.

PRACTICAL SOCIOLOGY AND RECONSTRUCTION

Sorokin believed that an increase in altruistic love represents the best practical solution to the problems of this historical era. Altruistic love, love that is unselfish, disinterested, and sacrificial, is one of the greatest powers in the universe. Evidence is presented to show that it has numerous positive effects on individuals and on society. Love of

this nature contributes to mental and physical health, longevity, and the most beneficial development of personality. At some minimal level, altruistic love is necessary for social solidarity. This love provides for the cooperation, mutual aid, and justice that make creativity and social harmony possible.

In Sorokin's view, any practical solution to the human and social problems of this era depends on the recognition that culture, society, and individual personality must all be changed. Society and culture are ultimately the creation of the actions of individuals. Therefore, reconstruction must begin with the conscious and deliberate efforts of individuals to increase their own capacity and practice of altruistic love. A planned reconstruction of culture in all its compartments and of social relations rests on this foundation.

Social science can help provide the knowledge and understanding of how love can be increased. Altruistic love has five dimensions: intensity, extensity, duration, purity, and adequacy. The relationships between these dimensions are considered. On this foundation, the techniques of altruistic transformation are described and illustrated with case study examples on both the individual and group level.

The necessary reconstruction of society and culture can be effected on the foundation of the altruistic transformation of individuals. The basic premise pertaining to the nature of reality is the foundation of cultural integration. Therefore, Sorokin believed that changing this premise to an integral one in which sensory, rational, and superrational aspects of reality are recognized is the most effective way to transform the culture. This will shift the system of values from egoism toward the impersonal, inexhaustible, and universal values of truth, beauty, and goodness. Within this cultural context, the power of elites can be effectively limited and a social order in which familistic relationships will predominate can be created. Different cultures will become more compatible with the infusing of spiritual principles and values. As a result, interpersonal and intergroup conflict can be reduced.

INTEGRALISM AND THE SOCIAL SCIENCES

The foundational idea in much of Sorokin's system of thought is integralism. It is expressed in his analysis of cultural organization and change and represents the basis of his vision of personal, social, and cultural reconstruction. Integralism is also the guiding principle in the ontology and epistemology of his system of sociology.

Sorokin considered the adoption of an integral perspective a necessary condition for vitality and creativity in the social sciences. The basic assumption of integralism is that reality contains empirical-sensory, rational-mindful, and superrational-sensory components. It thus requires a different ontology and epistemology from that of contemporary social science.

An integral system of truth would incorporate empirical, rational, and supersensory modes of cognition. The last of these sources of truth would involve intuition, including the revelation and mystical intuition of religious conceptions of sources of truth. Each method of cognition is fallible by itself. When combined into a harmonious integral system, they can cross-validate each other, thus providing a more powerful epistemology. Integralism would unite science, philosophy, and religion in the common endeavor of providing knowledge and understanding of how personal, social, and cultural reconstruction can be achieved and maintained. In this context, the practice of science would be directed toward the realization of greater altruistic love, the ethical principles of the major world religions, and the universal values of truth, beauty, and goodness.

The integralism advocated by Sorokin is a complete system of sociology incorporating the scientific, reform, and practical traditions of the discipline. It involves rigorous scientific research, an explicit commitment to reform that engages social science in public debate of desirable ends, and a scientifically based program of means to achieve personal, social, and cultural reconstruction.

SPENCER, HERBERT

Herbert Spencer (1820–1903) was one of the most influential thinkers of his time. To understand why, one must read Spencer as an evolutionary theorist. This is how he saw himself and how his contemporaries responded to him and his work. It is what marked his place in the history of sociology and what accounts for his influence far beyond the confines of the discipline he helped to found.

Who is Spencer? Spencer was born on April 27, 1820, at Derby, England, the only surviving child of William George Spencer and Harriet Holmes. In his autobiographical writings, Spencer offers a brief intellectual history of himself, identifying how key aspects of his life were linked to the origins and transformations of his evolutionary ideas. Not surprisingly, he begins with the nonconformist upbringing he received at the hands of the Spencer family and the family of his mother. To this upbringing and, in particular, his father, he attributes the early development of emotional and intellectual traits that were to operate throughout his life: a willingness to resist arbitrary authority no matter the source (church or state) or the cost (financial or health); the mental habits of seeking natural causes, analyzing, and synthesizing; and a love of completeness that would reach its fullest expression in a 10-volume *Synthetic Philosophy* that covered religion, philosophy of science, biology, psychology, sociology, and ethics. George Spencer was a teacher, but poor health prevented him from educating his son. Spencer thus went to a day school until 1830 when his uncle William Spencer resumed teaching at the school that he had inherited from his father. Spencer remained there as one of a select number of pupils until 1833 when he moved to Hinton to attend a school run by another uncle, Thomas Spencer, who, like his brothers, emphasized science and mathematics at the expense of the classics. This education prepared Spencer for the career as a civil engineer he began with the London and Birmingham Railway at the age of 17. Lasting off and on until 1846, this career in civil engineering provided opportunities to exercise mental habits developed in childhood and boyhood and resulted in several of the inventions that Spencer would make during his lifetime. It also rekindled a boyhood interest in collecting fossils, prompting Spencer to read Charles Lyell's *Principles of Geology* (1831–1833). During this period, his uncle Thomas encouraged him to write the series of 12 letters on the proper sphere of government that were published in *The Nonconfomist*—a newspaper established by and for the advanced dissenters. But it was not until he became the subeditor of *The Economist* in 1848 that he began the literary career that, despite major ups (e.g., the legacies from his uncles Thomas and William, endorsements of the *Synthetic Philosophy* by the chief men of science, leading men of letters and statesmen) and downs (e.g., persistent health problems, financial difficulties) was to occupy him for the rest of his life.

Spencer was a prolific writer. In addition to the *Synthetic Philosophy,* he published *Social Statics* (1855), *Education* (1861), *The Study of Sociology* (1873), *The Man versus the State* (1884), three series of *Essays* (1857, 1863, 1874),

Various Fragments (1897), *Facts and Comments* (1902), *Descriptive Sociology* (1873–1881), *An Autobiography* (1904), and "The Filiation of Ideas," a natural history of his evolutionary theory that was completed in March of 1899 and included in David Duncan's biography, *Life and Letters of Herbert Spencer* (1908). Throughout his life, Spencer was a regular contributor to the major general periodicals and specialty journals both as an author and as a reviewer. He was a member of the famous X Club, nine leading men of science who successfully challenged the cultural authority of the clergy by advocating scientific, naturalistic explanations of world. His election to the Athenaeum Club in 1867 by the committee under Rule 2 (a rule allowing the committee to select chief representatives of science, literature, and art) solidified his place in the elite intellectual circles of his day. By also publishing widely in magazines and newspapers, he established himself not just as a prominent member of the scientific community but also as a popularizer of science and, in particular, evolutionary theory.

What does it mean to say that Spencer is an evolutionary theorist? To answer this question, it is necessary to distinguish between the ways in which "evolution" and "evolutionary theory" are used in sociology and biology. Sociologists routinely use evolution and development as synonyms to denote unfolding models of change. In biology, evolution and development are universally recognized as distinct and fundamentally different processes. Development is an unfolding of preexisting potentials inherent in an organism at the time it begins life. Because this is a process of immanent change, environmental factors can only speed up, slow down, or stop the process of unfolding; they cannot create new potentials. Evolution, in contrast, depends on organism-environment interactions. There are no predetermined paths or preset goals. Environmental contingency, historical specificity, and probabilism are hallmarks of evolutionary theories.

Spencer's social theory is evolutionary in the modern biological sense of the term *evolution*. What are its central ideas and arguments? How did Spencer arrive at it? How was it received by his contemporaries? What was its subsequent fate? Answering these questions requires a historically contextualizing evaluation of Spencer that captures how his theory of organic evolution, his reconciliation of religion and science, and his philosophy of science helped shape the content, development, and reception of his evolutionary social theory.

SPENCER'S THEORY OF ORGANIC EVOLUTION

Spencer developed his theory of social evolution by participating in the nineteenth-century debates about the fact and mechanism of organic evolution. To establish the fact of evolution, the first evolutionists had to successfully challenge the special creation solution to the organic origins problem. In his biological works, Spencer used standard nineteenth-century arguments from classification, embryology, morphology, and distribution to challenge the hypothesis of special creation. By demonstrating that the hypothesis of evolution can explain facts that anti-evolutionists claimed could be explained only by special creation and facts that special creation cannot explain, these works help to establish the fact of evolution.

To explain the fact of evolution, Spencer turned to use inheritance, arguing that structures that organisms acquire during their lives through use or disuse of organs in response to environmental influences (e.g., the stronger legs [use] and weaker wings [disuse] of domestic fowl) can be passed on to their offspring. Spencer discovered the Lamarckian formulation of use inheritance in 1840 when he read Lyell's *Principles of Geology*. Most of the scientific community agreed with Lyell's conclusion that this explanation of organic evolution was unscientific—but not Spencer. In use inheritance, he found the evolutionary explanation of organic change that would remain one of the cornerstones of his theory of organic evolution. The introduction of its other cornerstone, Karl Ernst von Baer's law of individual development, in 1857 left the Lamarckian foundation of his theory unchanged. Spencer used this law of individual development to specify the course of organic change as a movement from homogeneity of structure to heterogeneity of structure through a process of successive differentiations and integrations. Explained by use inheritance, the transition from homogeneity to heterogeneity is contingent on favorable environmental conditions. A more heterogeneous structure will develop only if the environment demands more complex habits. Otherwise, there will be stasis or retrogression.

In his early biological works, Spencer used evolution and use inheritance as synonyms. Then in 1859, Charles Darwin published his alternative explanation of organic evolution, natural selection, in *On the Origin of Species*. Unlike most of his contemporaries, Spencer immediately adopted the environmental selection of random variation as a cause of evolutionary change. In *The Principles of Biology*, in his other post-1859 works, and in post-1859 editions of earlier works, Spencer followed Darwin and argued that neither use inheritance nor natural selection was a sufficient cause of organic evolution. But where Darwin argued that natural selection was the principal mechanism of organic evolution in all times and all places, Spencer concluded that natural selection was the principal cause of organic change only for inferior plants and animals and for the early evolutionary stages of superior plants and animals. In higher life forms, including humans, use inheritance is the primary mechanism of organic evolution. And where Darwin stressed that he was concerned only with organic evolution, Spencer made the concept of evolution the linchpin of a synthetic philosophy that included not just his

Principles of Biology but also his *Principles of Sociology,* his *Principles of Psychology,* and his *Principles of Ethics.* Together, these works explored the implications of Spencer's understanding of the course and mechanism of organic evolution for society, mind, and morals.

By the time Spencer began work on the synthetic philosophy in the spring of 1860, the debate about implications of evolutionary theorizing for connections among science, religion, and theology had intensified. Natural theologians had little difficulty accommodating the fact of evolution. They simply interpreted apparent design in nature (e.g., eyes, wings of birds, economy of nature) as empirical evidence for the existence of God. Evolutionary explanations of organic evolution were another matter altogether because they eliminated both design and designer from nature. Nowhere were the repercussions of doing this more evident than in the response to Darwin's theory of evolution by means of natural selection. This theory was attacked on religious and scientific grounds by some of the most influential philosophers, theologians, and scientists of the day. Spencer realized that if he hoped to convince the scientific community of the validity of his own evolutionary explanations of the natural and social worlds, he had to confront these attacks head on. The reconciliation of religion and science set out in Part I of *First Principles,* the first volume of his synthetic philosophy, and the philosophy of science that followed in Part II were intended to do just this.

SPENCER'S RECONCILIATION OF RELIGION AND SCIENCE

Spencer's reconciliation of religion and science started from the widely held view that the key to reconciling religion and science was facing the limits of each. For Spencer, the domain of religion was matters of faith and belief or what he called "The Unknowable." The domain of science, in contrast, was made up of matters of fact or knowledge. By making the domain of science coterminous with "The Knowable," Spencer could claim for science not just nature but man, mind, and morality.

Spencer deduced this view of the domains of religion and science from arguments about the nature of the human mind and how it obtains knowledge. If, as he had argued in his psychological writings, the human mind is incapable of knowing anything but phenomena that can be apprehended by the senses, and if "thinking is relationing," then all knowledge is relative, and that which is infinite, absolute, and unconditioned (i.e., God) cannot be grasped by the human mind. But because we can believe in what we cannot know, recognizing that God transcends the reach of human intelligence and the limits of knowledge in no way implies that God does not exist.

This defense of the limits of religion and science was not original to Spencer. Nor was the use of The Unknowable

and The Knowable to demarcate the domains of religion and science. Spencer took them from the Scottish philosopher Sir William Hamilton and the theologian Reverend Henry Longueville Mansel, author of the much-debated Bampton Lectures on the limits of religious thought. The originality of Spencer's reconciliation of religion and science became clear when he turned to the question, "What must we say concerning that which transcends knowledge?" (1862/1911:64). Where Hamilton and Mansel concluded that the absolute or infinite could be apprehended only negatively (i.e., from the consciousness not of what is but of what is not), Spencer countered that the same laws of thought that preclude knowledge of an infinite, absolute God affirm that there is a God. The necessity of thinking in relations makes it impossible for humans to rid themselves of the consciousness of an actuality lying behind appearance. From a scientific point of view, then, the conclusion that there is a nonrelative that passes the sphere of the intellect is unavoidable. Because this indestructible belief in the existence of a mystery absolutely beyond comprehension is the fundamental truth that religion asserts in the absence of science, this is the common ground that reconciles science and religion.

Spencer was prepared to take full credit for arriving at what he presented as the only possible reconciliation of religion and science. But as he points out in his autobiographical writings, what really mattered to him was what this reconciliation of religion and science said about his own evolutionary theory: First, his evolutionary theory could and, indeed, did contest theological explanations of the natural and social worlds. Special creation, miracles, and design (and designer) in nature are legitimate targets of evolutionary science. Second, his evolutionary theory did not and, indeed, could not contest religion "properly understood," and therefore, it could not be dismissed as irreligious, purely materialistic, or inherently atheistic. By allowing Spencer to attack theology without undermining faith, this reconciliation helped to undermine the authority of the clergy in matters of fact. Third, his evolutionary theory had no place for metaphysical principles where metaphysics is understood as the study of the absolute. Against this backdrop, Spencer could ask readers to set aside disagreements about religious and metaphysical beliefs when considering the essential part of *First Principles*—the philosophy of science set out in Part II, "The Knowable."

SPENCER'S PHILOSOPHY OF SCIENCE

The 1830s and 1840s were the most important period in the development of philosophy of science in Britain. Like his contemporaries, Spencer accepted that John F. W. Herschel, William Whewell, and John Stuart Mill had identified the kind of theory and the kind of evidence that

were necessary for good science. By first combining the methodological principles they shared in his own philosophy of science and then using this philosophy of science to ground his synthetic philosophy, Spencer hoped to convince the scientific community that his evolutionary biology, sociology, psychology, and ethics conformed to this canonical standard for science.

The law of evolution and the persistence of force are the central ideas of Spencer's philosophy of science. As philosophical truths, they are defined by their relationship to scientific truths: Standing in the same relation to the highest scientific truths as these truths do to lower scientific truths, they integrate scientific knowledge by grouping laws of coexistence and sequence of phenomena into higher, more extended generalizations. For Spencer, the only thing that sets philosophy apart from science is its higher degree of generality. Philosophy is the science of the sciences.

Spencer organized his philosophy of science around the two kinds of laws that Whewell, Herschel, and Mill had argued were necessary for good science: Phenomenal laws describe empirical regularities in the succession and coexistence of phenomena (e.g., the planets move in ellipses around the sun). Fundamental laws (e.g., gravitation) explain why observed regularities occur. Spencer's law of evolution describes the course of change throughout all classes of phenomena (inorganic, organic, and superorganic) as an integration of matter and concomitant dissipation of motion; during which the matter passes from a relatively indefinite, incoherent homogeneity to a relatively definite, coherent heterogeneity, and during which the retained motion undergoes a parallel transformation (1862/1911:321). His use of matter and motion to frame this phenomenal law follows logically from his claim that to consolidate the widest generalizations of science, philosophy must use the most general phenomena we can know. This claim also underpins his use of force to frame the fundamental law that explains these experiences of matter and motion. The persistence of force—Spencer's restatement of the law of conservation of energy—occupies a special place in his philosophy of science. As its most general and simple proposition, it cannot be merged into nor derived from any other truth. All other truths are proved by derivation from it. Thus, in the same way that laws of planetary motion can be interpreted as necessary consequences of the law of gravitation, the experiences of matter and motion described by the law of evolution can be interpreted as necessary consequences of the principle that force can neither be created nor destroyed. The greater certainty accorded to this deductive proof does not follow from the process of deductive reasoning *per se* but rather from the confidence that results from the fit between its results and *a posteriori* observations.

The methodology for sociology set out in *The Study of Sociology* and *Principles of Sociology* must be read against the backdrop of this philosophy of science. Because the natural sciences and the social sciences share a common canonical standard, there can be no radical break between them. Sociology has the same logical structure as the natural sciences and extends their concern with control through prediction to the social environment. Its goal, like the goal of all science, is causal explanation.

This emphasis on causal explanation led Spencer to another shared premise of Whewell, Herschel, and Mill: the premise that good scientific systems are hypothetico-deductive systems that use observations to confirm or disprove hypotheses. Where and how scientists obtain these hypotheses does not matter. What matters is that these hypotheses are subjected to observational or experimental tests. Spencer's naturalistic conception of sociology follows logically from this view of how science ought to be done. So does his argument that lawful relations can be discovered only through the systematic study of empirically observable phenomena and his strategy of eliminating competing hypotheses on the basis of lack of agreement with observations.

Spencer's argument for the unity of science did not blind him to three sets of "difficulties" that set sociology apart from other sciences. The first set identifies sources of error in the data of sociology that follow from the fact that sociological phenomena are not directly perceptible and thus cannot be studied with measurement instruments analogous to thermometers or microscopes. Sociologists must rely on the observational-comparative method to study social structures and functions in terms of their origins, development, and transformation. The second set identifies difficulties that arise from the intellectual and emotional faculties of the social scientists who analyze and interpret these comparative data (i.e., faculties that are neither complex enough nor flexible enough and feelings of impatience, sympathy, and antipathy). The final set points to distortions that result from the participation of observers in the social arrangements they study: the bias of education, the bias of patriotism, the class bias, the political bias, and the theological bias. Spencer's rules of sociological method are designed to eliminate these preconceptions and biases or to make allowances for the errors they introduce.

Recognizing the differences between sociology and the other sciences and the importance of the comparative method is necessary but not sufficient for the development of a science of sociology. For Spencer, the Lamarckian, "preliminary studies" are also necessary, not to provide requisite data but to evolve a habit of thought which is appropriate for the scientific study of evolution in its most complex form. To prepare sociologists for studying the complex causal chains that connect social phenomena, the analytical habit of mind, the synthetical habit of mind, and consciousness of causation must all be exercised—preferably by preparation in biology and psychology. Because these are the very traits Spencer believed he had

inherited from his father and then developed further by writing his biological and psychological works, he could claim to be uniquely positioned to undertake the successful study of sociology.

SPENCER'S EVOLUTIONARY SOCIAL THEORY

Sociology, for Spencer, is the study of social evolution. Like any theory of social change at the historical scale, Spencer's evolutionary theory must answer three questions: What is changing? What is the course of change? What is the mechanism of change? Spencer did not make the modern distinction between organic evolution (information that is transmitted through genetic mechanisms) and cultural evolution (information that is transmitted through nongenetic mechanisms like learning). He could thus argue that organic evolution and social evolution do not just have the same courses; they also have the same mechanism. Social change is a response to environmentally induced changes in the physical, emotional, and intellectual traits of individuals. In more explicitly Lamarckian terms, environmental changes create new needs; new needs require new habits, which, in turn, require changes in the physical, emotional, and intellectual traits of individuals. These changed individuals then mold societies into corresponding forms. Because the environmental changes that trigger this process can originate in the social relations that make up a society and in the relations among societies (Spencer's superorganic environment), the individual-society relationship is reciprocal, with societies and people modifying each other through successive generations. Spencer's answer to the question "What is changing" is society, where societies are conditions and consequences of the actions and interactions of their members. "Be it rudimentary or be it advanced, every society displays phenomena that are ascribable to the characters of its units and to the conditions under which they exist" (Spencer 1896:8–9).

This argument for the social environment as the major source of adaptational variation in social evolution also grounds Spencer's use of the militant-industrial distinction to classify societies. The distinction was not original to Spencer, but the way in which he used it was. Whether the organization for offense and defense or the sustaining organization is more developed depends on the nature of the interactions that occur between a society and its neighboring societies in the struggle for existence. If these interactions are hostile, then militancy evolves; if peaceful, then industrialism is adaptive. For Spencer, then, the transition from the militant to the industrial type of social organization is not inevitable; it is contingent on favorable environmental conditions. The argument for environmental specificity also holds where societies are classified by degree of composition as simple, compound, doubly compound, or trebly compound. In social organisms, as in biological organisms,

structural change occurs in response to environmental pressures. More heterogeneous structures develop only if the environment demands more complex habits. In other environments, there will be stasis or retrogression.

Spencer's hypotheses about the course and mechanism of social evolution, his theory of micro-macro linkage, and his evolutionary systems for classifying societies are all framed at the societal level. The institutional analysis that makes up the bulk of *Principles of Sociology* uses the data on societies that exist and have existed compiled in the *Descriptive Sociology* to extend this analysis of superorganic complexity and diversity to the institutional level. These levels are linked through the definition of society as a cluster of social institutions that Spencer used to divide the field of sociology into domestic institutions, ceremonial institutions, political institutions, ecclesiastical institutions, professional institutions, and industrial institutions.

Spencer's institutional analysis can be read as an empirical demonstration of the explanatory power of his evolutionary approach to the study of social phenomena. Reading it in this way highlights the methodological suppositions, approach to the micro-macro link, and explanatory form of the evolutionary social theory it builds on and elaborates. Spencer's rules of sociological method are reflected in his strategies for eliminating preconceptions and biases and in his use of the comparative method to establish inductive generalizations and test hypotheses. His theory of micro-macro linkage underpins his relational conception of social institution. The use of Lamarckism as the mechanism that links micro- and macro-levels also explains why the militant-industrial system of classification dominates this comparative institutional analysis.

Spencer's analysis of marital relations provides compelling evidence that domestic institutions depend on variations in the biophysical and social environments. Polyandry is adaptive in environments with small carrying capacities. Here, the low birth rate that results from the marriage of one woman to more than one man helps to prevent overpopulation and to ensure the needs of children. In environments where food supply is not a limiting factor and where intersocietal hostility is chronic, polyandry is maladaptive. The high death rate of men and surplus of women produced by chronic warfare mean that the rapid replacement of members necessary for offense and defense can occur only through the marriage of one man to more than one woman. In this environment polygyny is adaptive.

Domestic institutions guide, direct, and regulate the private conduct of individuals. Their public conduct is the domain of the ceremonial, political, and ecclesiastical institutions that make up the regulating system. Spencer's comparative analysis of ceremonial institutions showed that as expressions of subordination and deference, marks of superordination (e.g., titles) and subordination (e.g., mutilations) are concomitants of militancy. His findings for political

institutions provide a particularly clear demonstration of how social institutions depend on the nature of their environments and the physical, emotional, and intellectual traits of their members. This analysis refined the militant-industrial classification to specify two radically different types of political organization. The militant type of society specifies the nature of political organization that accompanies chronic militancy. In this environment, the society as a whole must survive if any individual is to survive. Cooperation is therefore compulsory. Where intersocietal conflict is rare or absent altogether, joint action for offense and defense is unnecessary. Here, voluntary cooperation confers survival advantages in the struggle for existence, and the industrial type of society is adaptive. If individuals and societies reciprocally determine each other, then the physical, intellectual, and emotional traits of members of industrial societies should differ from those of their militant counterparts. This is exactly what Spencer found. In industrial societies, sentiments like loyalty, faith in government, and patriotism are rarely exercised, while humane sentiments like honesty, truthfulness, forgiveness, and kindness evolve because of high levels of use.

Spencer also found that individuals in militant societies deal with fellow members and supernatural beings in the same way. Because coercive, centralized civil rule and coercive, centralized religious rule go hand in hand, Spencer concluded that ecclesiastical institutions evolve in response to pressures from the environment. The industrial institutions that make up the sustaining system of a society are also environment specific. Slavery, serfdom, and guilds are found in societies that exist in environments where militant activities predominate. Forms of industrial regulation that do not demand compulsory cooperation (e.g., free labor, contract) become increasingly important as the superorganic environment becomes more industrial.

These empirically verified statements of the causes and conditions under which different kinds of institutions and the societies they constitute originate, persist, or change are framed at the level of what Spencer called proximate causation. Produced by inductive inference and the testing of hypotheses against facts about societies that exist and have existed, these explanations are distinctly sociological. But like other scientists of his day who accepted the Whewell-Herschel-Mill view of how science ought to be done, Spencer felt compelled to interpret these findings in terms of matter, motion, and force. Only ultimate causal explanations can do this, where ultimate is used in the Herschellian sense of incapable of further analysis. Induction and hypothetico-deduction must be joined with deduction, where this deduction is used in Mill's sense of the verification of special laws by their deduction from simpler and more general laws. Because the principles of sociology are the most general laws of the science of sociology, they can be deductively interpreted only by documenting their affiliation on the law of evolution. Spencer thus verified these proximate causal explanations by showing that the evolution of domestic institutions, ceremonial institutions, political institutions, ecclesiastical institutions, professional institutions, and industrial institutions conformed to the law of evolution. This strategy is practicable only because the law of evolution and the persistence of force that explains why this is the course of transformation satisfy the Whewell-Herschel-Mill canons of good science.

THE FATE OF SPENCER'S EVOLUTIONARY SOCIAL THEORY

It would be hard to overstate the importance of use inheritance to Spencer's evolutionary theorizing. It is no surprise, then, that Spencer took a leading role in the controversy that surrounded the claim by the "neo-Darwinian" August Weismann that natural selection was the sole cause of organic change. By this time in his life (his 70s) Spencer was no stranger to controversy. But persistent health problems had long before forced him to ignore most attacks on his ideas. What was it about this controversy that led him to abandon this strategy? Simply this: Spencer believed that the inheritance of acquired characters was the primary mechanism of evolution and, therefore, that the outcome of this debate would profoundly affect views of life, mind, morals, and politics. Played out in major general and speciality journals, the controversy ended with Spencer and Weismann agreeing to disagree. The neo-Darwinian threat to Spencer's evolutionary theory and the synthetic philosophy that it unified was thus avoided. At the time of his death, Spencer could be eulogized as a member of the British scientific elite and as one of Britain's greatest philosophers. The former focused attention on his evolutionary theories of organic and social change; the latter on his contribution of his synthetic philosophy.

Spencer's contemporaries believed that his synthetic philosophy offered the most complete synthesis and generalization of knowledge of the time he wrote and that this accomplishment alone would ensure his place in the history of thought. Where they speculated on how he would be received by later thinkers, they offered two prescient observations: First, these thinkers would feel compelled to engage his ideas, whether or not they agreed with him. Second, advances in science would undermine at least some of Spencer's ideas—an outcome that Spencer himself would have accepted just as he accepted successful challenges during his lifetime. What they did not anticipate was the extent to which these advances would influence the rules for engaging Spencer and his ideas.

When the Spencer-Weismann debate ended, the verdict was still not in on use inheritance. But since the development of the modern evolutionary synthesis in the 1940s, biologists have accepted natural selection as the sole mechanism of

organic evolution. Once it was established that acquired characters cannot be inherited, Spencer's reliance on this mechanism rendered his theory of organic evolution obsolete. In biology today, Spencer is almost forgotten. Some evolutionary sociologists today also distance themselves from Spencer for this reason. Those who regard Spencer as the leading proponent of Social Darwinism use the unrelenting attack on this application of evolutionary theory to human society. Others take a very different tack. They join forces with critics of evolutionary theorizing in sociology to justify the neglect of Spencer in sociology. They argue that Spencer's evolutionary theory is a form of developmentalism (i.e., immanent causation), that developmentalism cannot account adequately for social change, and therefore, that Spencer is dead. They defend this developmental interpretation of Spencer's theory on the grounds that (1) it confounds evolutionary and developmental models of change, (2) its mechanism is the Lamarckian law of progressive development, or (3) its mechanism is a metaphysical principle, the persistence of force. The first argument acknowledges Spencer's debt to von Baer but misrepresents his law of individual development as a source analogy for Spencer's specification of the mechanism of organic evolution and social evolution. It only specified the course of organic and social change. The second argument assigns Lamarckism its proper role but is marred by the fundamental misunderstanding that, for Spencer, Lamarckism meant an inherent tendency toward progress or perfection. For Spencer, Lamarckism meant use inheritance. The third argument misconstrues the logical status of the persistence of force and its role in Spencer's sociology. The persistence of force is a fundamental law. By tying together facts from biology and sociology, it points to a fundamental unity that underlies their apparent diversity—exactly what the Whewell-Herschel-Mill canons of good science prescribed.

The developmental reconstruction does not adequately represent Spencer's social theory. Its prominence in the scholarship on Spencer has nonetheless proven particularly damaging to his current reputational standing. The developmental reconstruction of Spencer's social theory has also made it almost impossible for sociologists today to grasp why Spencer's contemporaries took him so seriously. How Spencer was a product of his time and how he transcended it by offering ideas and arguments that can be exploited in debates of contemporary theoretical consequence become clear only when he is read as an evolutionary theorist.

SPORT

Sport—loosely defined as the regulated manifestation of competitively based physical activity—is a complex phenomenon that operates simultaneously within numerous social realms (i.e., physical, commercial, media, and political) and can be experienced in a number of different ways (i.e., as participant, spectator, viewer, owner, investor, and worker). Adding to its complexity, sport is also a fluid category whose precise constitution is bound to the specificities of the context in question. Despite this historical and cultural contingency, sport can still be considered a universal practice. Virtually all societies exhibit some form of sporting activity, which, to varying degrees and in varying ways, provides a vehicle for the embodied expression of local identity and difference. Therefore, in deriving from, and contributing toward, the structural, institutional, processional, and behavioral dimensions of social life, sport represents a potentially illuminating field of sociological inquiry; something fully recognized by those within the sociology of sport. Indeed, the approximately four-decade evolution of the sociology of sport subdiscipline has

generated an empirically rich, politically prescient, and both theoretically sophisticated and diverse body of work.

Propelled by a growing band of scholars located in, among other places, Australia, Canada, Finland, France, Holland, Japan, New Zealand, Norway, South Africa, South Korea, the United Kingdom, and the United States, the sociology of sport can be considered a truly global academic community. As well as an expanding array of sport-focused books and book series, the primary vehicle for the dissemination of sociology of sport research has been through the field's major academic journals: *Sport in Society; International Review for the Sociology of Sport; Journal of Sport and Social Issues;* and the *Sociology of Sport Journal.* The accumulated body of work represented within these various publication outlets demonstrates an understandable lack of uniformity with regard to the manner in which sport is addressed as a sociological problem. Sport's multidimensional character means there is no, nor has there ever been, an empirical, methodological, or theoretical orthodoxy within the sociology of sport. With regard to social theory, it is possible to discern exponents of virtually every major strand—from structural functionalism to postmodernism—among sociologically informed sport scholars. To illustrate the breadth of this theoretical diversity, the remainder of this brief overview will concentrate on the five major social theorists whose influence is most evident within contemporary sociology of sport research.

As in other subdisciplines within the social sciences, Karl Marx's impact on the sociology of sport has been extensive yet varied. He may have referred to sport only once in his voluminous writings; nevertheless, there are a number of insightful analyses of the political economy of contemporary sport from a Marxist perspective. Shifting from the economy to culture as the locus of critical engagement, Marx's influence is also apparent within an array of Gramscian-inflected sport studies that, from various different vantage points (be they ethnic, race, gender, sexuality, or nation oriented), approach sport as a cultural terrain on which everyday identities and experiences are immersed in a process of continual contestation.

While perhaps not as prevalent as Marxist-oriented scholarship, Max Weber's theorizing has also been a consistent feature of sociologically based sport studies. His concept of rationalization, and more specifically, the notion of instrumental rationality, has proved particularly useful for those interested in theorizing the increasingly commercialized and bureaucratized nature of sport organizations.

Of all social theories Elias's figurational approach has made the most direct contribution to the sociological understanding of sport. Elias identified the processes responsible for the emergence of modern sport forms as being illustrative of his core theory of the civilizing process. According to Elias, the development of modern societies, and sports, was attributed to the formation of increasingly complex and extensive social figurations (chains of interdependence between individuals) that increased pressures on individuals to control their expressive impulses—hence, the emergence of modern sport forms as regulated and codified expressions of physical culture. In addition to accounting for the modernization of sport in general, and that of specific sports in particular, the figurational approach has also been used to study issues pertaining to sport crowd behavior, sport and globalization, race and sport, gender and sport, and drugs and sport.

As with Elias, although not to the same extent, Bourdieu's work discussed sport's importance as a social phenomenon. In addition, each of these theorists focused on sport's fundamentally expressive relationship with the body—for both, sport being the bodily incorporation and practice of socially constructed conventions. Bourdieu identified the sporting body as a vehicle for materializing the status differences, in terms of particular lifestyle choices, through which class-based hierarchies are enacted. This observation has been engaged within numerous studies focused on various aspects of the relationship between sport, physical activity, and social status, and using sporting practices as diverse as basketball, boxing, extreme sports, football, rugby, and wrestling, as the vehicle of empirical analysis.

Last, but certainly not least in terms of its influence on the sociology of sport, Michel Foucault's theory of modern disciplinary power has generated a substantial body of work focused on the relationship between sport, power, and the body. Like Foucault's project itself, this sport-related research can be broadly characterized into two related strands. First, those studies focusing on sport as a disciplinary institution that contributes to the discursive normalization of the modern subject. Second, those studies concerned with the micropolitics of discursive power and more discrete examinations of technologies of the sporting self.

STANDPOINT THEORY

The idea of a standpoint theory is most widely used in feminist theory and most strongly rooted in a broader sense of multicultural theory. Most generally, a standpoint theory is one that gives light to the specific circumstances and insider knowledge available only to members of a certain collective standpoint. This collective need not be a group in the strictest sense of the word but rather a shared location identified by some heterogeneous commonality. In other words, the idea of a collective standpoint does not imply an essential overarching characteristic but rather a sense of belonging to a group bounded by a shared experience.

The idea of a standpoint theory is a group-based ideology. An individual can be a member of several standpoints (black, woman, Jew, or black female Jew) at once, although the ways in which various forms of oppression intersect will have the strongest impact on the standpoint theory of the individual.

Standpoint theorists rally around the idea of social justice and support protesting, organizing, and testifying to one's unique social location as a means of raising awareness of, and giving validity to, all lived social experiences. There is a goal of empowering those who lack power and to diminish the line between traditional theory and other narratives. Standpoint theories are value laden and seek to disrupt the intellectual and social world but only as a means of opening them up to diversity. There is an edge to standpoint theory that is both self-critical as well as critical of other theories and the social world more broadly. Most important, standpoint theories recognize their own limitations by virtue of their unique historical, social, and cultural locations and seek to open the social stage to all members of society.

STATE

The state is a set of institutions and agencies that has the authority to define and enforce collectively binding decisions on members of a society in the name of their common interest or general will. As noted by Max Weber, the state is distinct from other political entities by its system of legitimate domination based on rational-legal authority. The state possesses distinctive capacities that include, for example, the ability to raise taxes and the right to make decisions and laws that regulate the conduct of individuals and groups in society. The state can also be characterized by its distinctive political logic or governmentality that includes the maintenance of territorial sovereignty and the promotion of social solidarity and a national identity. Hence, the state includes a system of legal rules that bind individuals to the society, civil service bureaucracy, elected representatives, and coercive institutions such as the police and armed forces. Thus, the state is not a unified entity, nor does it have fixed institutional boundaries. It is, rather, an ensemble of multifunctional institutions and organizations. The state has no unitary interest but, rather, contains many competing interests in different parts of the state. These interests develop through negotiation, bargaining, and compromise among different groups in society, among different state actors, and between state actors and societal groups.

It is difficult to specify the relationship between the state with other institutional orders and society. Early political thinkers such as Aristotle, Augustine, and Georg Hegel believed that the state was a political abstraction standing over and above society. Karl Marx believed that the state arises with the development of modern capitalism. For Marx, the appearance of the state coincides with the development of *civil society,* which protects private property, promotes individual pursuit of private interest, and fosters the illusion that competitive market relations can create democratic and egalitarian societies. Later Marxists, including Antonio Gramsci and Louis Althusser, questioned the distinction between the state and civil society. Althusser maintained that civil organizations such as political parties, the church, and schools are part of the *ideological state apparatus.* Some aspects of civil society have a close relationship to the state and play an important role in developing public policy. The state also regulates parts of civil society by providing laws, charters, regulations, and financial support that influence the actions and decisions of organizations. Moreover, the institutional boundaries of the state are not static. They are always changing through devolution (transferring responsibilities from the national government to subnational governments), privatization (transferring responsibilities from the government to the private sector), and deregulating public policy or creating new regulatory agencies. Often, the establishment of quasi public-private organizations blurs the boundaries between the state and civil society. As the articulation of the state and civil society changes, the state becomes both a site and an object of political struggle among different groups.

The role of the state is complex and multidimensional. Five major themes are addressed: conceptualizations of the

state and state power, which groups control the state policy, the development of middle-range state theory, the question of *governance,* and relationship between globalization and the state.

CONCEPTUALIZATIONS OF THE STATE AND STATE POWER

No single usage of the concept of the "state" is self-evidently correct, nor does one definition necessarily exclude other definitions in different contexts. While the state is a contested concept, empirical research and generalizations about the state and state power vary according to the theoretical orientation and level of analysis. In the *Manifesto of the Communist Party,* Marx and Engels treated the state as a committee for managing the common affairs of the bourgeois. For Max Weber, the state claims a monopoly on the legitimate use of physical force within a specific territory. Following Weber, Anthony Giddens (1987) defines the state as a "bordered power container." The boundaries of the state are not merely administrative divisions but potentially, at least, lines along which violence may erupt. The mechanisms of state power include the state's capacity for making war, its capacity to extract resources to fund its operations, the expansion of surveillance capabilities and the policing of deviance, and the active construction and maintenance of consensus and legitimacy.

For Marxian scholars, however, the role of the modern state is to reproduce the social conditions necessary for capital accumulation. Early work conceptualized the state in several different ways—for example, as an instrument of class rule, a factor of cohesion, or an institutional ensemble that mediates class conflict. Later accounts highlighted the conflicts the state faces in managing social antagonisms and crisis tendencies within capitalism. On one hand, the state must sustain the process of capital accumulation, since its own survival depends on a continuous flow of revenue; on the other hand, the state must preserve the belief in itself as a neutral arbiter of divergent societal interests to legitimate its power. For James O'Connor and Claus Offe, the state cannot effectively secure the market conditions necessary for capitalist accumulation unless it can conceal its class bias behind the cloak of democratic legitimacy. In so far as the state is increasingly called on to compensate for the failures of market mechanisms without infringing on the primacy of private production, the state will be faced with a fiscal crisis or a crisis of legitimacy. This means that crisis management will assume the form of trial-and-error responses, the content of which is determined by the changing balance of class forces.

Feminist scholars have conceptualized the state and state power in several different ways. Early work focused on the state's role in reproducing patriarchal social relations by institutionalizing male dominance over women in social policy and law. More recently, feminist scholars have focused empirical attention on how different aspects of state power, policy, and action shape, and are shaped by, gender relations. Based on studies covering welfare policy, law, and crime, feminist theorists have developed a conception of the state as a differentiated entity, composed of multiple and conflicting gender arrangements. The result has been a proliferation and diversification of feminist analyses of the state. Much of this new feminist scholarship proceeds analytically, focusing on particular state apparatuses rather than on the state as whole. In her examination of the *politics of need interpretation,* Nancy Fraser (1989) argued that state actions and practices—the *juridical-administrative-therapeutic state apparatus* (JAT)—construct women and women's needs according to certain specific but contestable interpretations, such as *caregiving, homemaker-mothers, deserving* and *undeserving* poor, among others. Other feminist work has looked at the discourse underlying state policy, examining how meanings and interpretations of femininity, masculinity, and other gender stereotypes derive in part from the shape and administration of state programs. Over the last decade, feminist theory has shifted away from discussions of how or why the state oppresses women to analyses that identify the different *gendered regimes* that women and men encounter in different parts of the state apparatus (Haney 2000).

Sociologists of race focus on the racial bases of state power, the racial biases of state actors, and the discriminatory effects of state policy. Most accounts focus on the socially constructed nature of *race* and racism and reject the notion that the state is inherently *racist* or that it is necessary or inevitable that the state policies will always reproduce racial divisions and inequality. Rather, race must be understood as occupying different degrees of importance in different state institutions at different historical moments. Such an approach sensitizes us to the inherent improbability of a unified state and the need to examine the economic, political, and cultural factors that contribute to the racialization of state policy. Thus, some state agencies may challenge racial divisions, others may be neutral, and still others may reinforce racial divisions through policies and institutional practices that are explicitly or implicitly racial (e.g., education programs, family law, and procedures for punishment, treatment, and surveillance of the criminal, deviant, and mentally ill). Examples include the use of racial criteria to assign unequal political rights to different races, different punishments for equivalent crimes according to the race of criminals and victims, the segregation of schoolchildren according to race, and other policies that discriminate on the basis of race. In short, the racial intents and effects of state policy cannot be established a priori, but only through a historical examination of specific state agencies, political processes, and historical contingencies that shape the formulation and implementation of particular policies, and exclude other policy options (Gotham 2000).

THE STATE AND SOCIAL POLICY

A second major topic concerns which groups control the policy formulation process, who supports and opposes policy proposals, and which groups benefit and suffer once the state enacts and implements certain social policies. Pluralists view the state as containing different spheres of power and influence that mediate social conflict. State actions are responses to different group pressures. For some pluralists, power is broadly shared among different political and economic interests with no one group dominating. Decision making in the political arena involves a division of labor among top decision makers. Interest groups all compete more or less equally within the political system to influence political decisions. Important policy decisions are not made by a small number of powerful individuals or groups. While large corporations might influence decisions by contributing to political candidates, for example, labor unions also contribute to their candidates. Over the long run, different interest groups share equally in the decisions made by elected officials. Control of the state by any one interest group over the long term is not possible.

Marxian theories focus on the degree to which state is subject to influence and control by the capitalist class. In his famous book, the *State in Capitalist Society*, Ralph Miliband (1969) argued that the "ruling class of capitalist society" which "owns and controls the means of production" is able "to use the state as its instrument for the domination of society" (p. 32). In a debate with Miliband, Nicos Poulantzas (1976) argued that the direct participation of members of the capitalist class in the state apparatus is not important since there are structural factors that make the state serve capitalist ends regardless of whether capitalists intervene directly, indirectly, or not at all. Whereas Miliband analyzed the state in terms of the individual human subjects who control it, Poulantzas conceptualized the state in relation to its structurally determined role in capitalist society.

The famous Miliband-Poulantzas debate helped launch a three-way debate between *class dominance theory, state-centered theory,* and *Marxian structuralism* during the 1980s and 1990s. Class dominance theorists argue that state policy is intentionally dictated by corporate interests whose representatives have captured or control the state. Some proponents maintain that corporate leaders are *overrepresented* in high decision-making positions and therefore dominate the policy-making process. Others argue that classwide rationality is articulated by representatives of the capitalist class who sit on multiple corporate boards. These representatives influence policy by acting on the basis of what is best for business as a whole. In short, class dominance theorists emphasize the class basis of state power; interactions among corporate elites, especially the largest corporations and financial institutions; and the specific political, economic, and organizational resources that allow corporate leaders to dominate the policy-making process in the face of resistance.

State-centered theory views the formulation and enactment of social policy as contingent on previous policy precedents, the *autonomous* power of state managers, and the capacities of state structures. State institutions and party organizations can be *independent* determinants of political conflicts and outcomes because officials within the state may have interests fundamentally opposed to interests in society. Once instituted, social policies reshape the organization of the state itself and affect the goals and alliances of social groups involved in ongoing political struggle. Business unity, division, and influence are only tangentially related to state economic policy since it is state managers, and not individual capitalists, who implement state policy.

Marxian structuralists focus on the structural foundations of capitalism and the process of capital accumulation as salient factors in the formulation of social policies. Influenced by Poulantzas's (1980) work, structuralists do not deny that business leaders play a central role in the policy formulation process, but they view this role as symptomatic of the structural forces of capitalism, not an ultimate cause. State policy and state structures constitute a relatively autonomous political arena that groups of capitalists use to organize political coalitions that compete for political dominance. Those coalitions that overcome opposition become the dominant power bloc. However, these political coalitions and actors cannot formulate policies at their behest but operate within a capitalist context that defines the major contending interests and sets limits on the range of likely solutions. This perspective suggests that states can be *relatively autonomous* from the capitalist class only because both are part of the mode of production.

THE DEVELOPMENT OF MIDDLE-RANGE STATE THEORY

The 1990s witnessed a third development in state theory—the development of middle-range approaches to show the complementary nature of state theories when examining state policy at different levels of analysis. Proponents of *middle-range state theory* attempt to identify the conditions under which the policy formulation mechanisms specified by the different theories—variants of Marxism, state-centric, class dominance theory, and so on—augment each other. Current research does not assume that the state, the capitalist class, or selected class factions are unified at all times. Capitalist class unity is affected by accumulation opportunities and constraints of particular class factions. Whether the needs and interests of factions of capital are contradictory or whether unity exists within the capitalist class are historically contingent questions. According to Harland Prechel (2001), the

key issue to understand when considering capital-state relations is not whether class segments are united or divided, but rather the conditions under which the capitalist class is more or less divided. Similarly, the issue is not whether states are autonomous from the capitalist class or class segments, but rather the conditions under which the state is more or less autonomous. (p. 152)

Middle-range adaptations of state theories do not preclude the possibility for making general statements about the state. They do, however, challenge scholars to clearly identify the social conditions (e.g., war, depression, mass protest, and disorder) that facilitate or constrain policy choices. Gregory Hooks's (1993:40–41) analysis of World War II and postwar investment processes in the United States synthesizes three state theories—that is, class dominance, structural Marxism, and state-centered theory—to demonstrate how the U.S. federal government participated in the post-World War II industrial mobilization. At particular historical moments, state agencies and legislative committees are heavily influenced by business and business elites. Other agencies are insulated from the direct influence of business elites and may promote policies that harm certain capitalist groups. Still other agencies pursue an agenda that suits the state's administrative goals despite the resistance of business elites. Thus, state theories can complement one another: The challenge is to analyze the institutional context in which the state conceives and implements certain policies. In short, middle-range positions compel the analysis to situate historical analyses of state agencies in relation to other processes and actors (e.g., class segments, business elites) to specify the conditions that produce the outcomes asserted by each theory.

THE QUESTION OF GOVERNANCE OF THE ECONOMY

A fourth topic in state research concerns the question of *governance.* A burgeoning literature on the relationships between states and markets focuses on how market creation and regulation takes place through states. States provide an array of governance structures or mechanisms (e.g., property rights, laws, regulations, rules of exchange, etc.) that define relations of competition and enable actors in markets to organize themselves. The development of capitalist economies, including the establishment of stable and reliable conditions under which economic actors organize, compete, cooperate, and exchange is part of the core of state building. One of the central tenets of institutional theory, as it applies to the link between political actors and the state, is that the development of markets is causally related to the emergence and consolidation of specific symbiotic relationships that form between economic actors, state structures, and rules of exchange. The state's enforcement of laws, property rights, and rules of exchange affect what conceptions of control produce stable markets, disrupt some kinds of economic activity, and create new markets. Changes in property rights, rules of exchange, and legal regulations promote changes in market institutions and state-firm relations.

All forms of economic activity are embedded in social relations, and states create the institutional conditions for markets to be stable. As economic crises and new circumstances arise, powerful organized interests and market actors will attempt to influence government organizations, including legislators and the courts, to destabilize old markets and create new rules and legal opportunities to establish and expand markets. As governance structures and institutions develop, they tend to *feed back* onto economic activity. Through such feedback loops, new market networks and relationships develop symbiotically into specific state structures and regulatory frameworks that gradually embed actors' orientations and understandings of existing arrangements. This process is not static but dynamic. It means that economic actors and networks of actors exist in a competitive political climate where they must constantly struggle to influence state officials to create new rules and adapt existing rules to changing circumstances. The basic insight is that the state provides the political and legal framework that permanently shapes the economy.

GLOBALIZATION AND THE STATE

A fifth and final concern is the relationship between globalization and the state. The recent focus on globalization in state theory directs attention to the ways in which global-level forces are transforming social relations and influencing the activities and operations of states. Globalization recasts the state debate in terms of the relationship between the state and transnational processes and struggles. So-called *hyperglobalist* perspectives stress the omnipresence of globalization, maintaining that globalization imposes a financial discipline on governments, leading to a decline in the ability of states to regulate economic and social activities within their borders. In this respect, many scholars believe that the emergence of new institutions of global financial regulation (e.g., the World Bank and the International Monetary Fund) and increasing cross-border capital flows are evidence of a new global economy that prefigures the erosion or disempowering of the state (Jessop 2002). So-called *statist* perspectives emphasize the continuing significance of state institutions and national policy in organizing global economic flows and constituting the global economy. While globalization may have pushed forward a new geographic extension of state authority or a transformation of state capacities, the modern state remains a vehicle of globalization. In this conception, globalization is not a novel socioeconomic condition, nor does

it undermine the power of national governments or state sovereignty. Globalization may affect the attributes of states, but it does not change their basic identity or disrupt their capacity to act.

It is not the state that is pressured by globalization or that generates globalization. Some parts of the state are actively involved in promoting some kinds of globalization, other parts of the state may be harmed by these state actions, other parts of the state may see their capacities strengthen or weaken as a result of global pressures, and other parts of the state may actively resist globalization. Even as some parts of the state may disengage from the market economy (e.g., through privatization, deregulation, and trade liberalization), they may intervene in other extra-market sectors and attempt to create the social conditions for marketization, commodification, and valorization. In doing so, they may favor some factions, classes, and social forces over others; they may prompt struggles to reorganize state capacities; they may constrain the actions of firms and alter networks; and they may aggravate economic contradictions and crisis tendencies.

STATICS AND DYNAMICS

Contemporary usage of the terms *statics* and *dynamics* has its roots in the work of Auguste Comte (1798–1857). Comte developed social physics, or what he eventually referred to as *sociology* (Comte was the first to use this term), during the 1830s in France. He believed that sociology should be strongly modeled after the hard sciences, particularly biology. He saw society as a social organism and was interested in studying how various components, or subsystems, contributed to the social system as a whole. Comte was relatively unconcerned with the domain of the individual (although his thinking was shaped by basic assumptions about individuals) but, rather, was concerned with the social groupings of individuals, collective existence, and macrolevel phenomena (especially the family). Furthermore, Comte gave priority to theory over empirical research.

Statics and dynamics are cornerstones of Comtean theory. Comte argued that sociology should be concerned with both existing social structures, or social statics, and social change, or social dynamics. Comte's study of social statics is a forerunner to much contemporary work in sociology in general, and sociological theory in particular, especially structural-functionalism. He was interested in the ways in which the various parts of the society functioned and, more important, with their relationship to the social whole. He saw the parts of society and the whole in a state of harmony (what would later be called equilibrium) and privileged starting from the social whole and proceeding to the parts. Social statics, as the name implies, also meant freezing time to get a look at society as it existed at a particular historical moment.

In contrast to social statics, social dynamics involves looking at the ways in which society changes over time. Time is a necessary element for the study of social dynamics since it is inherent in what Comte saw to be the natural evolution of society toward a final harmonious state. Comte ([1830–42]1855) even refers to social dynamics as the "theory of Natural Progress of Human Society" (p. 515). He believed that society was continually improving and that the same law of progressive development applied universally to all societies. Thus, although the speed of social evolution may vary from one society to another, or from one time period to another within a given society, there is a continual progression toward the goal of a more harmonious society.

Although Comte felt that studying both social statics and social dynamics were important for understanding society, he placed a greater emphasis on social dynamics. This relates to Comte's view that society did not need a revolution in order to make things better (he was largely critical of the French Revolution and its effects on society) because the natural progress of things would eventually deal with the ills that were plaguing the social world. Therefore, he

advocated reforms, but only as a means of helping along the natural evolution of society. Since society was constantly evolving, and such evolution brought with it continual improvement, the study of social dynamics was privileged over the study of social statics.

Comte's work on statics and dynamics influenced many future sociologists. Émile Durkheim was particularly influenced by his ideas on macrosociology and the social body as an organism (especially in his thinking on material and nonmaterial social facts), evolution (Durkheim focused on the change from mechanical to organic solidarity), and the promotion of reforms to cure the pathologies of society.

Herbert Spencer was also heavily influenced by Comte and his thinking on social statics and dynamics. Spencer, however, did not want to be seen as a disciple of Comte but rather as one of his antagonists. Thus, although he held Comte in the highest esteem, he believed that his ideas were of a very different nature. Ironically, Spencer's first book was titled *Social Statics* ([1850]1954). He claimed that at the time of its publication he had knowledge of Comte only insofar as that he knew he was a French philosopher and not at all his body of work. Thus, Spencer ([1850] 1954) gives quite different meanings to the terms *statics* and *dynamics* in his work. He takes social statics to mean "the equilibrium of a perfect society" and social dynamics to mean "the forces by which society is advanced toward perfection" (p. 367).

Structural functionalists in general, as well as their leading figure Talcott Parsons, were another group of social thinkers influenced by Comte's (as well as Spencer's) emphasis on social statics in their focus on social structures and social institutions. Furthermore, later in his career, Parsons developed an evolutionary theory that bore at least some resemblance to Comte's.

The entire field of sociology owes a great deal to Comte. His emphasis on social statics and dynamics continues to be of importance to many in sociology today in the often-made distinction between social structure and social change.

STATUS RELATIONS

Status generally refers to an individual's position or rank, along a standard of honor or respect, within a group or social hierarchy. As such, *status relations* are defined as observable rank-ordered pairings of individuals in some social situation. For instance, when male presidential advisors are more influential than females, when senior partners in a legal firm are given access to the beach home but junior partners are excluded, or when attractive children dominate the best playground equipment, relations are affected by status. In each case, a characteristic (i.e., gender, seniority, or beauty) produces advantages wherein some individuals are ranked more highly than others. What follows is a brief examination of historical accounts of status relations, their causes and consequences in group interaction, and prevailing theories of this phenomenon. We conclude by surveying contemporary directions in status research.

BACKGROUND

Interest in status relations is as varied and diverse as sociology itself. The first systematic writings can be traced to Aristotle, who claimed that status, merit, or excellence is one basis for the allocation of social rewards. Max Weber applied the concept of status more broadly, noting that status groups (i.e., white-collar workers vs. blue-collar workers) share common lifestyles as indicated by housing, dress, and leisure time activities. For Weber, status is an important dimension of social stratification. Thorstein Veblen linked status and economic behaviors, noting that people express status through the conspicuous consumption of material wealth. Modern theorists tend to use the term *status* more uniformly, in reference to the honor or prestige one is granted in a social situation.

That status relations have captured the attention of social theorists probably stems from the numerous interesting properties such relations exhibit. Status relations are seemingly universal, quite robust, and often paradoxical. First, status relations are universal in that they emerge among turkeys eating bugs, macaques living in captivity, and humans deliberating on a jury. That humans and animals order themselves along a standard of respect or deference is a phenomenon that spans the phylogenetic scale. Second, status relations are fairly robust in that they emerge quickly and are mostly stable. In human groups, status ordering typically emerges within the first few minutes of interaction and tends to change very little over time. Finally, perhaps the most compelling and bothersome property is that status relations frequently pose a paradox. That is, status ordering frequently exists even when the most competent or capable individuals are not those with the most input or influence in the group. The combination of these three factors may

account for the widespread interest in status and status relations. Some of the ways that status affects social relationships are considered next.

EFFECTS OF STATUS

Over five decades of research has been aimed at understanding how status affects behavior, cognition, and emotion. In terms of behavior, early studies found that high status tends to produce social influence. For instance, in a classic military study of three-person decision-making teams, it was found that pilots were more influential than navigators, and navigators were more influential than gunners. In essence, the participants act as if those with more prestigious occupations (i.e., pilots) have better ideas than those with lower occupational prestige (i.e., gunners) even when the task is not related to occupation. Such early studies set the stage for more detailed inquiry and the discovery that status relations tend to produce a complex web of interrelated behaviors, perceptions, and emotions. The most significant program in this regard was initiated by Robert Freed Bales.

Bales studied relatively small groups of individuals (2 to 20) working together on a common task. A graduate student of Bales, Joseph Berger, noticed that within a relatively short period of time, a structure of inequality emerged wherein some individuals dominate the interaction more than others. For instance, some people in the group (1) receive more opportunities to perform, (2) perform more often, (3) are evaluated more positively for their performance, and (4) have more influence over the group decisions. Berger noted that such measures tend to be highly correlated, such that individuals high on one dimension tended to be high on all dimensions. He conceived of these interrelated measures as reflecting a single *observable power and prestige order.* Today, we know that the primary effect of status is that it leads to an observable power and prestige order wherein some individuals are advantaged over others.

Status not only affects overt behavior but also influences perceptions, cognitions, and emotional reactions. For instance, high-status individuals are perceived to be generally more competent at a range of tasks, viewed as better group leaders, and largely regarded as more socially important than lower-status individuals. Martha Foschi and associates have shown that status beliefs often result in a "double standard," wherein the same activity by high- and low-status people (i.e., scoring 82 on a math test) is treated as differentially reflecting math ability. Another line of research tracks how status alters emotions and sentiments. Here, it has been shown that high status is associated with positive emotions while low status tends to produce negative emotions. High-status people tend to experience pride, satisfaction, and happiness from interaction, while low-status

individuals often report feelings of fear, resentment, and anger. Not only does status affect how one feels, it also affects what one can express. Some research shows that high-status members are normatively free to publicly express their emotions more so than low-status members.

CAUSES OF STATUS

In general, status is a result of the traits people possess, the resources they control, and their actions in group situations. The lion's share of research to date has focused on how observable traits, either achieved or ascribed, lead to status. Achieved status occurs when a person earns some level of honor or respect by way of individual merit or achievement. For example, Bill Gates, founder of Microsoft, may be said to have achieved his high status as a result of his entrepreneurial ability and business savvy. Ascribed status, on the other hand, occurs when a person attains status based on inherent characteristics or family lineage. For instance, George W. Bush, the 43rd president of the United States, may be said to have ascribed status based on his membership in a wealthy and politically powerful family. Also notable is that he possesses other significant characteristics, such as race and gender, that tend to carry social advantages. For instance, studies generally find that men are allocated higher status than women when the two interact, and whites are allocated higher status than African Americans.

More broadly, any trait that systematically produces advantages and disadvantages in a given culture is known as a *status characteristic.* The theory of status characteristics and expectation states, developed by Berger and associates, conceptualizes two kinds of status characteristics. *Specific status characteristics* exist when (1) there are two or more states that are differentially evaluated, and (2) each state is associated with specific performance expectations. For example, algebra skill is a specific status characteristic when being good at algebra is preferable to being bad at algebra and when one expects an algebra expert to be competent at a range of other math-related tasks. Specific status characteristics generate status for a relatively narrow range of tasks.

Diffuse status characteristics are broader in their effect. The defining characteristic of a diffuse status characteristic is that, in addition to having two or more states that are differentially valued, and carrying specific performance expectations, such traits also produce a wide range of general performance expectations. For example, gender is a diffuse status characteristic when one state (e.g., male) is more highly valued than the other state (e.g., female), when men are expected to be more competent than women at specific tasks such as sports, and when men are generally expected to be more logical, intelligent, and capable at a wide range of tasks. Studies in the United States show that race, gender, age, physical attractiveness, education, and occupation are diffuse status characteristics that affect

social interaction. In each case, individuals who possess the positive state (i.e., white, male, older, attractive, educated) are treated as if they are more competent than those who possess the negative state (i.e., African American, female, younger, unattractive, uneducated).

Although it is easy to understand why status might be granted to a person with a specific skill (i.e., knowledge of algebra) related to a group task (i.e., completing a math assignment), it is more difficult to understand how status comes to be associated with inherent traits such as gender, race, and physical attractiveness. Why would whites/men/attractive people be viewed as more competent? From where do such beliefs arise in the first place, and how are they perpetuated? Cecilia Ridgeway's *Status Construction Theory* offers one explanation. The theory asserts that traits become status characteristics when they are systematically linked to another valued characteristic. Thus, imagine a group whose members contain different levels of some social reward (i.e., call them rich vs. poor) and some other distinguishing attribute that has no status significance (i.e., dark vs. fair hair). Now, if for some reason people observe that more dark-haired individuals are resource rich, and more fair-haired individuals are resource poor, then those people may come to view dark hair as indicating higher status or worthiness. It is as if people presume that dark-haired individuals are resource rich because they are more deserving. Ridgeway and associates have shown that once such beliefs emerge, people act on the beliefs in social interaction and can even spread them to others. In this manner, a particular status belief may eventually become consensual within a society, and part of the overall cultural framework.

To illustrate, consider a basketball team that has bearded and nonbearded players (i.e., a nominal difference with no status value). Now imagine that the bearded players happen to perform better than the nonbearded players during the very first game. Even if there is no "real" difference in the players' abilities, the members of the team are likely to walk away from the game (mis)attributing greater competence to the bearded players. In addition, they will carry that expectation with them to other games and other social situations. Moreover, since the players, both bearded and nonbearded, expect the bearded players to perform better, chances are they will be given more opportunities to do so (i.e., more opportunities to shoot and more influence over team strategy). This results in a sort of self-fulfilling prophecy that bolsters and reinforces the initial status belief. Over time, we can imagine that the "bearded is better" idea will be spread throughout the league and become normatively accepted.

THEORIES CONNECTING CAUSE AND EFFECT

Perhaps the most influential theory, in terms of spawning a proliferation of other theories, was developed by Joseph Berger and associates in the 1960s. Berger's *expectation states theory* proposes the notion of a performance expectation to explain status in groups. A *performance expectation* is a belief about an actor's future task performance. Performance expectations are not generally conscious; rather, they are hunches, of which one is unaware, about whose suggestions are likely to be better. The theory claims that through social interaction, individuals develop performance expectations for themselves and others regarding task competency. Because performance expectations are formed on the basis of observable acts and shared understandings of the world, these beliefs are generally consensual across members of a group. Those perceived to be more competent are higher in the ordering of expectations; those perceived to be less competent are lower. In turn, performance expectations are postulated to be the key theoretical construct that shapes differentiation along an observable order of power and prestige. Later elaborations of expectation states theory give critical insights into the traits and behaviors that yield expectations and status in groups.

Status characteristics theory is a related branch of the larger expectation states program that emerged in the 1970s to connect culturally specific beliefs and performance expectations. Briefly, status characteristics theory consists of five interrelated assumptions that explain how status characteristics translate into behavioral outcomes. First, status characteristics become salient if they differentiate members of a task group or are directly relevant to the task at hand. Second, salient status characteristics are assumed to be task relevant unless they are explicitly shown to be irrelevant. Third, status information is incorporated and maintained, according to the principles described in the first two assumptions above, as individuals enter or leave the group. Fourth, all salient status information is combined to form an aggregated performance expectation associated with each member. Finally, aggregated performance expectations give rise to observable differences in social interaction. Those with relatively higher performance expectations are predicted to receive more opportunities to perform, perform more often, be evaluated more positively, and have greater social influence over the group's decisions. Tests have generally supported the basic claims of the theory.

Another branch of the expectation states program focuses on the relation between rewards and performance expectations. The principle idea undergirding *reward expectations theory* is that levels of reward can induce performance expectations and, subsequently, status. In one study, Karen Cook (1975) showed that when experimental subjects received high versus low levels of payment, those subjects used their payment level to infer they had greater or lesser task ability. Studies find that individuals receiving higher levels of rewards are presumed to be more competent, or somehow better, than those receiving lower levels of reward. Imagine choosing between two doctors, knowing

only that Dr. Jones makes $100,000 while Dr. Smith makes $40,000. It is easy to attribute a causal link between pay and skill, as in "Dr. Jones would not be so highly paid if he were not a great doctor." This illustrates how performance expectations can be inferred from associated rewards.

Finally, other theoretical research shows that overt behaviors can produce status in groups. Actions such as taking the head seat at a table, talking in a confident and firm manner, maintaining an upright posture, making direct eye contact, and various other actions are seen as indicators of competence and can thereby produce status. Berger and colleagues refer to such factors as *task cues,* because they tend to signal who is most comfortable and competent at completing the group task. A more complex kind of behavioral sequence, in which behavioral cycles between two or more actors come to reinforce the status order, is called a *behavior interchange pattern.* For example, a repetitive pattern of one individual asserting, "I think that we should do X" while a second individual agrees, "I think this is a good idea," serves to reinforce the higher status of the first person relative to the second. M. Hamit Fisek and associates have recently developed a theory that explains how behavior interchange patterns interact with status cues to produce participation rates in groups.

CURRENT TRENDS

The majority of research to date has aimed to understand the cause and effect of status in isolation of other social processes—status neat, as it were. With a basic understanding of status now in place, investigators recently have examined how status interacts with other social forces such as legitimacy, power, identity, and organizational structure. For instance, Henry Walker and Morris Zelditch (1993) have sought to understand how status inequalities come to be accepted, or treated as normatively appropriate, in groups. Their studies document a range of conditions under which status inequalities are legitimated and come to persist over time.

Although the two are distinct, status also is linked to social power, defined as a structural ability to extract valued resources from another person. For instance, Shane Thye (2000) has demonstrated that resources controlled by high-status actors are seen as more valuable than resources controlled by lower-status actors. This provides high-status individuals with an advantage when they negotiate with lower-status partners. This phenomenon has also been documented in the field, where studies find that African American women are sharply disadvantaged in car negotiations. Interestingly, although status produces power, the converse is not necessarily true. That is, having high power does not necessarily lead to high status. High-power actors who exercise their power (i.e., a dictator exercising political power) can often stir negative emotions within those whom power is used against. Michael Lovaglia and Jeffrey Houser have shown that high power yields high status only when negative emotions are blocked.

Perhaps the latest trend in status research is to combine status, social identity, and organizational structure. A recent series of tests by William Kalkhoff and Chris Barnum have determined that status and social identity have comparable effects in producing influence. That is, given a disagreement with another person, subjects were about as influenced by higher-status partners as they were by in-group members. In addition, Ridgeway and associates have argued that status-organizing processes are also affected by organizational structure. That is, imagine an all-female group in an otherwise male-dominated organization. It is not difficult to imagine that, in such a context, gender status will become salient for those women in the group and affect their performance. Research in this domain will inevitably shed light on gender-based inequalities found in the modern organization and promises to be an important avenue for investigation as future research unfolds.

STRATIFICATION

Stratification describes the differential arrangement of persons or positions within a society. The term can also be used to refer to the hierarchical ordering of societies or other macrolevel entities.

Many of the founding fathers of sociology were interested in issues of stratification. Karl Marx was most interested in economic stratification and how it spelled itself out in the capitalist system. He saw two broad layers (although an argument can be made that he actually saw more) in society—capitalists at the top and proletariat at the bottom. His means for determining the social strata were purely economic and based on the ownership of the means of production.

Max Weber took Marx's theory of stratification one step further to also include dimensions of status and power as well as economics. Weber's ideas about economic stratification are found in what he termed *class.* The concept of a class does not refer to a community of actors but rather to any group of actors whose shared class location is, or at least could be, the basis of some form of action. Status, on the other hand, does represent a shared community. While class refers to economic production, class refers largely to consumption. Hence, status is based on one's lifestyle. A third dimension of stratification, the concept of a party, is oriented solely toward the attainment of power. This is the most highly organized of the three and is found in the political realm.

Kingsley Davis and Wilbert Moore (1945) wrote what is perhaps the best-known piece of structural-functional literature on the topic of stratification. They argued that social stratification is both functional and necessary for a society to continue and be healthy. They argued that no society had ever been totally classless because all societies need a system of stratification, and this need brings such a system into existence. This is not to imply that the creation of a stratified system is a conscious undertaking of the society but rather that it is an "unconsciously evolved device." Their theoretical orientation of structural-functionalism also led them to view society not in terms of actors but in terms of positions. Consequently, their main interest was in how certain positions come to be ranked higher or lower in the system, not how certain people come to fill those particular positions.

Davis and Moore believed that one of the major problems in society was how to get the right people into the right positions and after they are there, how to keep them there. This was a problem because some positions are more pleasant to occupy than others, some are more important to the continuity of society, and different positions require different skills. They argued that those positions that are deemed higher up in society (e.g., doctors, lawyers, politicians) were less pleasant to occupy, more important to the overall society, and required the greatest level of ability. Hence, these positions had to be rewarded with the highest levels of prestige, money, and leisure.

The structural-functional approach to stratification has been criticized on many levels. First, it is seen as simply perpetuating the privilege of those who already enjoy it. Second, it assumes that simply because stratification has existed in the past, it must continue in the future. Third, it is difficult to support that there are positions in society that are more or less important than others. Are nurses any less important than the doctor's they assist? Fourth, any shortage of people willing to occupy higher positions in that stratified system is caused primarily by the stratified system itself through differential access to means such as education and training. Finally, it negates the possibility of one's being motivated to accept a higher position solely, or even in part, for its intrinsic rewards.

A more contemporary theory of stratification was put forth by Randall Collins (1975, 1990). Unlike Marx, Weber, or Davis and Moore, Collins focused on the microlevel effects of stratification. He studied stratification because he sees this phenomenon affecting nearly ever aspect of people's daily lives. He was especially interested in showing that "stratification and organization are grounded in the interactions of everyday life" (Collins 1990:72). For this reason, although he drew from Marx and Weber's theories, he drew most heavily from ethnomethodology and phenomenology.

Collins's theory begins with the assumption that people are inherently social but that they are also self-interested and hence conflict prone as they seek to outdo others. Three basic tenets outline his conflict approach: (1) People live in self-constructed subjective worlds, (2) people other than the individual actor may have the power to affect that actor's subjective experience, and (3) these outside people often try to control the actor's experience, which leads to a conflict. These tenets led Collins to his five basic principles of conflict analysis in social stratification: (1) There should be a focus on real-life experiences rather than abstract ideologies, (2) an examination should be made into how each actor is able to manipulate or is restricted by possession of material factors or lack thereof, (3) there is a conscious or unconscious exploitation of those with fewer resources by those with greater access to resources, (4) beliefs and idea systems should be analyzed with consideration to interests,

resources, and power, and (5) the study of stratification should be undertaken in a scientific way, using hypothesis testing, empirical research, and whenever possible, causal explanations.

The study of stratification is also undertaken within feminist theory. For example, Janet Chafetz (1984, 1990) uses analytic conflict theory to focus on gender inequality, or what she calls sex stratification. She seeks to understand the structural conditions that lead to sex stratification across time and cultures. She explores the conditions that affect its intensity, including fertility patterns, economic surplus, and patriarchal ideologies among others. These variables are considered important because they are the framework of the home and the economic marketplace and how women are able to move between these two locations. Chafetz asserts that women will experience the least disadvantage when they are able to find an equilibrium between the responsibilities in the home environment and an autonomous role in the economic marketplace. She also outlines what she perceives as important locations in the structure where gender equity might be achieved by improving women's conditions.

STRAUSS, ANSELM

Anselm L. Strauss (1916–1996) was an American symbolic interactionist and cofounder of the grounded theory method. Strauss advocated developing middle-range

theories from systematic analysis of qualitative data. His noted works span his career from his major coauthored textbook with Alfred Lindesmith, *Social Psychology,* in 1949 to his culminating volume, *Continuous Permutations of Actions* in 1993. Among Strauss's principal contributions are his coauthored works, *Awareness of Dying* (1965) and *The Discovery of Grounded Theory* (1967) as well as numerous theoretical analyses of empirical research that reconceptualized ideas in their respective substantive fields. Strauss received his baccalaureate degree from the University of Virginia, where the writings of Robert Park awakened his sociological consciousness. He received his doctorate from the University of Chicago. While at Chicago, the works of pragmatists George Herbert Mead, John Dewey, and Charles Peirce influenced him, and numerous conversations with Herbert Blumer inspired his quest to integrate theory and research. His involvement in the vibrant intellectual climate at Chicago among faculty and graduate students made Strauss a vital part of the "second Chicago school" (Fine 1995).

Strauss brought the freshness and fluidity of pragmatist thought to his studies and integrated pragmatist concerns with action throughout his lengthy career. Agency and acts—and their meanings to the actors themselves—were fundamental to Strauss's sociological research and theorizing. This stance distinguished his work from midcentury structural-functionalists who discounted firsthand studies of research participants' views, endeavors, and accounts and distrusted theorizing that began with them. Strauss's work provided a major source of continuity and development of Chicago school sociology during the latter half of the twentieth century. He began theorizing by challenging deterministic views with a social psychology that was open-ended, emergent, and thus, somewhat indeterminate. The originality of his thought is evident in his early essay, *Mirrors and Masks: The Search for Identity* (1959) in which he treats identity as a way to organize ideas and to permit new theoretical insights to emerge that take into account social processes and their symbolic underpinnings. Strauss argues that language plays a crucial role in human behavior and in the complex weaving of subjective and social identities. Through naming, individuals locate, evaluate, and understand self and others as well as objects and events and subsequently direct their actions.

Although first known as a social psychologist, Strauss developed the concept of *negotiated order* in his 1978 publication of *Negotiations: Varieties, Processes, Contexts, and Social Order.* This treatise brought symbolic interactionism to the mesolevel of analysis and recast conceptualizations of how organizations work. By looking at the mesolevel, Strauss addressed the collective life of social worlds and organizations that lie between micro-interactions and macrosocietal structure. Rather than assuming order as a given in social life, Strauss showed that people negotiated

and renegotiated order as they interacted individually and collectively. However, Strauss's explicit constructionist statement did not deny the existence of social structural constraints. Instead, it fostered seeing how interacting individuals acted toward, contested, or reproduced them through taken-for-granted understandings and routines.

Consistent with Strauss's interest in action and organization, his coauthored study with Barney G. Glaser, *Awareness of Dying* (1965), provided a theoretical explication of the organization of information about the dying patient's status, including who knew the patient was dying, when they knew, and what, if anything, they said or did about it. The temporal features of the patient's dying also intersect with work, careers, and earlier predictions—all of which affect information control. Glaser and Strauss's types of *awareness contexts* had wide applicability in situations in which vital information is withheld from certain central participants.

Glaser and Strauss attempted to delineate their methods of conceptual development in their study of dying in *The Discovery of Grounded Theory* (1967). This book advanced both theory construction and methodological rigor by offering a flexible set of systematic guidelines to develop inductive middle-range theories from empirical data that, in turn, explain those data. The authors combined the Chicago school emphases on symbolic interactionism and qualitative research with codified methods of theory construction. Glaser and Strauss's book challenged the theoretical and methodological hegemony of the day, legitimated conducting qualitative research in its own right, and ultimately advanced theory development in many substantive fields, disciplines, and professions.

Grounded theory involves simultaneous data collection and analytic procedures in which the emerging analysis shapes further data collection. Coding is aimed to identify processes and their categories and to define the properties of categories theoretically. Grounded theory is an inherently comparative method. Grounded theorists compare data with data, data with category, and category to category. They use each level of comparison to illuminate properties and to specify conditions under which their categories are germane. As grounded theorists' categories become more conceptual, they engage in *theoretical sampling*. This type of sampling means seeking data to fill out, refine, and test their theoretical categories. Grounded theorists work across substantive fields to develop generic theoretical categories with broad explanatory power. The resulting grounded theories fit the data they explain, provide useful, dense, and integrated explanations, offer insights to research participants, and are modifiable through further research.

The *Discovery* book laid out the logic and justifications for building middle-range theory from qualitative research. Strauss developed his position and explicated how to construct grounded theories in two important qualitative analysis textbooks, *Qualitative Analysis for Social Scientists* (1987) and *Basics of Qualitative Research* (1998), coauthored with Juliet Corbin. In these books, he moved toward technical advancement of grounded theory methodology and verification, although he maintained the earlier emphasis on comparative methods and theoretical sampling.

Strauss's contributions cut across several substantive areas. He gave a new depth to urban sociology through studying symbolic imagery in *Images of the American City,* published in 1961. The images that people hold of cities influence their actions and moral stance toward them. Strauss brought a processural view to occupations and professions by looking at differentiation and interaction between sectors of professions and how they advanced their positions. His work made conceptual advances in medical sociology that informed the entire discipline when this subfield might have otherwise developed only as an applied area. Strauss's numerous studies in medical sociology move from managing information and illness to larger theoretical questions of body and identity and biographical disruption. In addition, his interest in the organization of medical work sparked generic organizational concepts. Strauss proposed a concept of *social worlds* as a new unit of theoretical analysis in organizational studies. The concept assumes permeable group boundaries, individual and collective commitments, the temporality of social structures, and viewed process and change as routine. This perspective takes how people organize themselves into account—despite structural constraints and actual or potential conflict.

The concerns with which Strauss began his career resound in his final theoretical statement, *Continual Permutations of Action* (1993): the theoretical significance of meaning and action, dynamic—and open-ended—relations between individuals and social structures, the integration of social psychology and social organization, tensions between negotiated orders and habitual routines, and the explication of a pragmatist theory of action. Strauss (1) articulates anew the significance of language, fluidity of complex relations, the emergence of contingencies, and the blurred collective boundaries that he implied decades before in *Mirrors and Masks;* (2) extends his theoretical insights about relations between body, self, time, and symbols that informed his medical sociology; (3) argues against the presumed objective consequences of status variables; and (4) develops his statement of action as interactions between and among group members. In the introduction to the book, Strauss describes himself as someone who has devoted himself to working out the sociological implications of the pragmatist/interactionist traditions. His opus stands as testimony to the significance of this effort.

STRENGTH OF WEAK TIES

The concept of the "strength of weak ties" was first proposed and developed by Mark Granovetter in a 1973 article of the same title. The argument is that while one might think strong interpersonal ties are more significant than weak for most purposes, this may not be so when what people need is information. Because our close friends tend to move in the same circles that we do, the information they receive overlaps considerably with what we already know. Acquaintances, by contrast, know people that we do not, and thus receive more novel information. This is in part because acquaintances are typically less similar to one another than close friends and in part because they spend less time together. Moving in different circles from ours, they connect us to a wider world. They may therefore be better sources when we need to go beyond what our own group knows, as in finding a new job or obtaining a scarce service. This is so even though close friends may be more interested than acquaintances in helping us; social structure dominates motivation.

This argument also has macrolevel implications. If each person's close friends know one another, they form a close-knit clique. This suggests that individuals are connected to other cliques through their weak ties and not their strong ones. Thus, from an "aerial" view of social networks, cliques are connected to one another, if at all, mainly by weak ties. It is, then, weak ties that determine the extent of information diffusion in large-scale social structures (playing, in this regard, a role similar to that of hydrogen bonds in chemical reactions). One outcome of this is that in scientific fields, new information and ideas are more efficiently diffused through weak ties (see Granovetter 1983). Another application is to community organization. Granovetter (1973) argued that communities lacking in weak ties may be fragmented into discrete cliques that have great difficulty organizing across these to confront a common threat. See,

for example, his comments on the inability of some communities to resist destruction brought by "urban renewal" (pp. 1373–76) and his exchange with Herbert Gans (Granovetter 1974) who had proposed a more cultural argument to explain the same phenomenon.

Though Granovetter was the first to develop the sociological implications of this argument in detail, he drew on earlier research that strongly suggested this effect. For example, Rapoport and Horvath (1961) had shown that if you ask junior high school students to name their eight best friends in order, best, next best, and so on, and you then trace out networks of all those reached from randomly chosen starting points, considerably more people can be reached through seventh and eighth best friends than through first and second best. They attributed this to the greater overlap of networks among closer friends.

Later work has extended these arguments. Granovetter (1983) reviewed a series of studies that used or assessed the validity of the weak ties idea. Marsden and Campbell (1984) made the first serious attempt to assess the validity of different measures of tie strength, concluding that "closeness" or "emotional intensity" was a better indicator than three others Granovetter had mentioned in his original article—amount of time spent together, reciprocal services, and mutual confiding. Burt (1992) extended the weak ties argument by emphasizing the importance of "structural holes" in social networks. His approach emphasizes the importance of whether ties bridge separate parts of social networks and the strategic advantage for those who can operate through those bridging ties and thus control the only route for important information or resources to flow from one segment to another. Beginning in the late 1990s, the idea of weak ties became one part of a new interdisciplinary literature on complex networks, which developed more sophisticated arguments than before on flows, connectivity, and the robustness or fragility of large networks, including metabolic reactions in biochemistry, systems of electric power distribution, and the World Wide Web (see Barabasi 2002; Buchanan 2002; Watts 2003).

STRUCTURAL FUNCTIONALISM

Although it was once the dominant sociological theory, structural functionalism is now more of a relic. Recent decades have seen this theoretical orientation slip into the background as more contemporary theories (including neofunctionalism) have taken its place.

Structural functionalism is one type of consensus theory— it posits that society is based on mutual agreements, sees the creation and maintenance of shared values and norms as crucial to society, and views social change as a slow, orderly process. Examples of prominent consensus theorists include Auguste Comte, Émile Durkheim, Talcott Parsons, and Robert Merton. These theories stand in contrast to conflict theories, such as those of Karl Marx, that view the world as based on a system of oppressive hierarchies, social order at the whim of dominant groups, and social change as rapid and disorderly resulting from struggles between groups.

The term *structural functionalism* can be broken down into its constituent parts. An analysis can be made of structures without reference to functions, and conversely, an analysis can be made of functions without reference to structures. Generally, however, these two are used in conjunction with one another. Furthermore, most theorists in this field were particularly interested in societal functionalism, or the specific structures and functions of society as a whole.

Parsons (1937, 1970) was the founder of, and perhaps the most prominent contributor to, structural functionalism. He was concerned with the question of how society was able to maintain order and not fall into utter chaos. He answered this question from the viewpoint of structural functionalism and outlined what he believed are its major tenets: (1) Systems are ordered and their parts are all interdependent; (2) systems tend toward a goal of equilibrium or self-maintenance; (3) systems may be either inert or change in an ordered manner; (4) each part of the system has an effect on the forms the other parts can take; (5) systems create and maintain boundaries separating them from their environments; (6) allocation and integration are necessary for a system to reach a certain state of equilibrium;

and (7) systems will tend toward self-maintenance by maintaining their boundaries, the interdependent relationship among parts, and the relationship between parts and the whole; by controlling variations in the environment; and by controlling tendencies of the system to change from within.

In addition to structures, Parsons was also concerned with functions. Parsons saw functions as those activities that had the goal of fulfilling a need of the system. He believed that there were four necessary functional imperatives of all systems: [A] adaptation (how a system copes with its outside environment by both adapting to it and by adapting the environment to meet the needs of the system), [G] goal attainment (the definition and achievement of the primary goals of the system), [I] integration (how the system regulates the relationship of its various parts as well as the relationship among the other three functional imperatives), and [L] latency, or pattern maintenance (how the system provides, maintains, and rejuvenates the motivation of individuals and the cultural patterns that stimulate and maintain that motivation). These functional imperatives are known as Parsons's AGIL scheme.

Functions become integrated with systems in Parsons's theory as each component of the AGIL scheme is handled by a different system. Most generally, adaptation is handled by the behavioral organism that adjusts to and transforms the outside world. Goal attainment is handled by the personality system that defines the goals of the system and mobilizes the necessary resources to reach outlined goals. Integration is done by the social system that controls the various components of the system. Latency is performed by the cultural system that provides individuals with norms and values to motivate them to action.

Merton (1968), a student of Parsons, continued and enriched the tradition of structural functionalism. He argued that traditional postulates in functionalism, as outlined mainly by anthropologists such as Malinowski, were grounded too heavily in abstract theory and lacked the empirical evidence needed to give them credence. He believed that to conduct proper functional analyses, theory must be coupled with empirical research. Merton helped define his viewpoint by criticizing several postulates of functional analysis. First, he criticized the postulate of functional unity by arguing that in complex societies not all components had to be integrated to a high degree. Second, he criticized the postulate of universal functionalism by contending that not all forms and structures in society have positive consequences or functions. Finally, he criticized the postulate of indispensability and rejected the idea that every aspect of society served a necessary and vital purpose; there are components that the society could function without.

Merton defined functions as those consequences that lead to the adjustment or adaptation of a system. In addition, he argued that not all functions had positive consequences and that some, in fact, were better described as dysfunctions. In

addition, nonfunctions are those consequences that have no effect at all on the system.

The development of dysfunctions and nonfunctions to complement the existing theory of functions led Merton to develop the idea of a net balance. A net balance is an understanding of the relative weight of functions and dysfunctions in a given system. It is more of a theoretical orientation then an empirical tool because the magnitude and evaluation of what constitutes functions and dysfunctions are highly subjective.

The issue of how to study a net balance led Merton to the idea of levels of functional analysis. He argued that society did not have to be studied as a whole but that organizations, groups, and other subcomponents of society were also valid as research topics. Merton, in fact, was a proponent of "middle-range" theories. Thus, what is the net balance of those functions, and dysfunctions, at one level may well be different at another level.

Another valuable contribution of Merton to the field of structural functionalism was the idea of manifest and latent functions. Manifest functions are those that are intended, whereas latent functions are those that are unintended yet still functional for the system. Closely related to the idea of latent functions is that of unanticipated consequences, although this term encompasses not only those unintended consequences that are functional for the system but also those that are dysfunctional and nonfunctional as well.

Merton defined culture as a system of norms and values that is present in society and is common to, and governs the behavior of, its members. He defined social structure as the ordered system of social interactions in which the members of a given society are occupied. In addition, Merton was interested in the relationship between culturally defined ends and the structurally possible means of achieving those ends. *Anomie*, or a state of normlessness, occurs when the available means make it difficult, if not impossible, for members of a society to achieve the culturally defined goals. The reaction of individuals to this discrepancy can involve deviant behavior because they are forced to attempt alternate (sometimes illegal) means to achieve their desired (as prescribed by society) ends. Anomie, for Merton, represents the disjuncture between social structures and cultural goals and hence can be dysfunctional for society.

Kingsley Davis and Wilbert Moore (1945) wrote what is perhaps the best-known piece of structural functional literature on the topic of social stratification. They argued that a system of stratification is not only functional but also necessary for societies to persist and remain healthy. This idea led them to argue that a classless society had never existed because the need for a system of stratification had always created such a system. They did not, however, believe that the creation of such a stratified system was always a conscious undertaking on the part of society but, rather, that it could be, and often was, an "unconsciously evolved device."

Following their structural functional orientation, Davis and Moore saw stratification in society not in terms of people but in terms of positions. This meant that they were primarily interested in how certain positions came to be ranked higher or lower than other positions, not in how certain individuals came to fill those ranked positions. They did believe, however, that one of the biggest problems faced by society was how to get the right people to fill the right positions and then, more important, how to keep them there.

Their argument was that some positions in society are more pleasant to occupy, some are more crucial for the health and continuity of the society as a whole, and different types of positions require different types of knowledge and skills. Those positions that are generally attributed with a higher social ranking (e.g., politicians, bankers, lawyers) are not as pleasant to occupy, are more important to the overall health of society, and require the highest level of skill and education. Consequently, it is these positions that must also carry the highest level of social prestige, monetary compensation, and available leisure time.

Davis and Moore's structural functional explanation of stratification has been criticized by many for a number of reasons. First, it assumes that a system of stratification has always existed in every society and that such a system will exist in all societies in the future. Second, it provides a theoretical rationale for perpetuating the privileges of the elite. Third, many find it difficult to accept that any position in society is more or less important than any other position. Garbage collectors, for example, are arguably as important as politicians. Fourth, the stratified system makes it difficult for those in lower rankings to obtain the education and training necessary to achieve a higher ranking. Finally, there is no consideration of individuals being motivated to accept a higher (or lower) position based solely on intrinsic rewards.

Given that it was the dominant theory in sociology for such a long time, structural functionalism has also been critiqued by many in the field. A number of the more noteworthy critiques include (1) that it is ahistorical (it did in fact develop in reaction to the historical evolutionary approach of many anthropologists at that time); (2) it is unable to deal with contemporary processes of social change; (3) it cannot adequately deal with conflict (it is generally viewed as a consensus theory and hence in contradiction to conflict theory); (4) it has a conservative bias that maintains the status quo and the dominating power of the elite class; (5) it is generally too abstract, vague, and ambiguous to bear much relationship to the real world; (6) the theories are too grand and ambitious when more historically and situation relevant theories might be more appropriate; (7) there are inadequate methods to research the questions of interest; and (8) comparative analysis is virtually impossible.

Turner and Maryanski (1979) also saw the problems of teleology and tautology plaguing structural functionalism.

More specifically, they saw illegitimate teleology as a problem. It is legitimate to assume that society has certain goals and that it brings certain structures and functions into creation to achieve these goals. What many structural functionalists do, however, that is illegitimate is to assume that the current structures and functions in society are the only ones that could have been created to achieve these goals. In addition, tautology is a problem because both the whole and its parts are defined in terms of the other. The whole is defined in terms of its parts and the various parts are then defined in terms of the whole. Hence, neither is truly defined at all.

At the barrage of such critiques as those outlined above, structural functionalism eventually fell out of the limelight of sociology. Jeffrey Alexander and Paul Colomy (1985), however, made an attempt to revive interest in the topic by developing neofunctionalism in the mid-1980s. The term itself, *neofunctionalism*, implies both a strong relationship to "functionalism" as well as the implications of a new, "neo," direction. This is exactly what Alexander and Colomy had in mind; they saw neofunctionalism as broader and more integrative than traditional structural functionalism.

Although neofunctionalism is not considered so much a fully developed theory as a "tendency," Alexander (1985) has outlined some of its basic tenets: (1) It sees society as composed of interacting elements (that are not controlled by an overarching force) that form a pattern that allows it to be differentiated from the outside environment; (2) approximately equal attention is given to action and order; (3) integration is seen as a possibility rather than an accomplishment; (4) there is still an emphasis on personality, culture, and social systems, although the tension between these systems is seen as a source of control as well as change; (5) there is a focus on social change found in the differentiation within the personality, culture, and social systems; and (6) it implies a promise to the autonomy of conceptualization and theorizing from additional levels of sociological investigation.

Although it did succeed in its goal of reviving interest in the work of structural functionalists, and particularly Parsons, neofunctionalism seems to have gone the way of its predecessor and fallen out of style. This is even acknowledged by Alexander (1998) who has abandoned this orientation in lieu of pursuing what he believes will be a new wave in the creation of theory that is able to go beyond even the advances made by neofunctionalism.

STRUCTURALISM

It is important to understand structuralism not only in and for itself but also as a precursor to poststructuralism and ultimately to postmodern social theory. Structuralism came to be most highly developed in France (and hence is often called French structuralism). Its greatest flowering involved, at least in part, a backlash against the humanism, and especially the existentialism (Sartre was the major exponent of this perspective), that was so pervasive in post-World War II France. Humanists such as Sartre gave considerable attention to individuals and afforded them a great deal of autonomy and agency. Structuralists turned this perspective on its head by focusing on the structures that they saw as the true base of the social world. Instead of having autonomy and agency, people were seen as being impelled, if not determined, by structures.

The roots of structuralism are not in sociology but, rather, are traceable to various disciplines.

Many structuralists focus on what they believe are the deep underlying structures of society. For example, Karl Marx focuses on the underlying economic structures of society that he sees structuring not only the economy but much of society. For the economy and the larger society to change, these structures need to be uncovered, understood, and transformed. Later structural Marxists (Althusser, Poulantzas) came to see Marx as a structuralist as evidenced by his concern with the largely invisible economic structure of a capitalist society. It is this concern with underlying invisible economic structures and a rejection of empirical analysis that makes structural Marxism a form of structuralism.

Other thinkers focus on the underlying structures of the mind, especially those found in the unconscious. Sigmund Freud was a leading exponent of this idea and thought it was important not only to understand these underlying

structures but also to uncover them and their operations in order to allow people to deal better with the impact of these structures on their thoughts and actions. Jacques Lacan was a French psychoanalyst who took the ideas of Freud and combined them with those of Saussure to develop the idea that the unconscious is structured in the same way as language. This position sees language as pivotal in the formation of the individual and also as central to the way in which the unconscious mind is structured.

Still others define structures as the models they build of social reality. One example of this is Pierre Bourdieu. Although generally considered a poststructuralist, Bourdieu exhibited elements of structuralism in his theory on habitus and field by asserting that structures can exist in the social world itself independent of language and culture.

Finally, a fourth group, such as anthropologist Claude Lévi-Strauss (often referred to as "the father of structuralism" [Kurzweil 1980:13]), can be seen as being concerned with the dialectical relationship between structures of the mind and the structures found in society.

Although it arose in a number of different disciplines (Marx [as well as the structural Marxists] in political economy, Freud in psychiatry, and Lévi-Strauss in anthropology, among many others), the greatest interest in and development of structuralism is to be found in linguistics, especially the work of Ferdinand de Saussure (1857–1913). However, the field of linguistics in general, and Saussure in particular, has had a profound impact outside the field of linguistics. They helped give rise to the linguistic turn, or a shift in focal concern from social to linguistic structures, that has altered many of the social sciences.

Saussure was interested in the differences between *langue,* or the universal structure underlying all language, and *parole,* or the way speakers actually use the langue. *Langue,* however, was the more important of the two to Saussure; he believed it was most relevant to look at the formal system of language rather than the ways in which individuals made use of this structure. *Langue* can be seen as a system of signs where each sign depends on the other signs in the system for meaning. This is clearest in the case of binary oppositions. For example, the word *high* does not convey a sense of elevated positioning without at least an implied reference to its binary opposite low. The structure of *langue* is not one that is shaped by individuals but, rather, one that shapes the meanings of words, the mind, and ultimately the social structure. Lévi-Strauss took the work of Saussure on linguistic structuralism and applied it to anthropology. He reconceptualized a number of social phenomena (most notably kinship systems) as communication systems in order to subject them to a structural analysis.

Eventually, the concern for an underlying structure and the system of signs grew into a discipline in its own right. *Semiotics* is the field of study concerned with structure of sign systems. Semiotics is concerned not only with language but with all sign and symbol systems, in other words, with all forms (verbal and nonverbal) of communication.

STRUCTURALIST MARXISM

Marxism that came under the influence of structuralism—with its emphasis on meaning as deriving from a system of differences—criticised Marxist humanism, as found, for example, in the work of Jean-Paul Sartre (1905–1980) and Herbert Marcuse (1898–1979). Humanist Marxism placed the epistemological figure of "man" at the heart in its framework of the analysis of society, without always seeing that this was an epistemological stance, preferring instead to believe in the intentions and the will of "actual" human beings.

At its height in the decade 1965 to 1975, structuralist Marxism, was no doubt strongest in France, possibly, in part, because of that nation's rationalist tradition. The specification of such clear chronological markers, however, implies that such a Marxism's day has passed. But as will be noted later, it lives on in aspects of the epistemological stance of sociologists, such as Pierre Bourdieu (1930–2002), influenced by the epistemological school inspired by the work of Gaston Bachelard (1884–1962).

Structuralist Marxism has several strands, including the philosophical, and "scientific" Marxism promoted by Louis Althusser (1918–1990) in France; the genetic Marxism of Lucien Goldman (1913–1970), again in France; and Galvano della Volpe (1895–1968) and Lucio Colletti (1924–2001) in Italy. Structuralist Marxism consisted, first, of a method: The key achievement here was a "return to Marx," which opened up Marx's work to a critical and "symptomatic" reading (in the manner of Freud's interpretation of dreams). This reoriented political Marxism away from a crude, humanist, "battle of ideologies" approach, derived from Marx's early works, toward an understanding

of the implicit structure of the relations of production in political economy. Second, Structuralist Marxism, as with the movement of structuralism in general, de-centered the subject, so that history ceased to be seen as the expression of a subjective human essence. Third, history becomes discontinuous because it is not the history of a subject (whether this be man or nature or the state) but, rather, is the autonomous evolution of time in which numerous forces are at work.

Of course, no explanation of structuralism—whether or not of the Marxist variety—can avoid considering the innovation brought to the understanding of language by Ferdinand de Saussure (1857–1913); nor can it avoid noting the importance attributed to language in the social sciences influenced by a structuralist approach. The work of Claude Lévi-Strauss in anthropology is a case in point. The structure of language becomes the methodological point of departure par excellence*;* the social world itself is like a language, based on relations, not on essential attributes.

For the structuralist view, then, language is a system of relations, not a collection of static elements (words). Value (e.g., meaning) is established through analysing the differential relations pertaining between the elements. Value emerges only in the relation between the elements themselves. As Saussure famously said, "Language is a system without positive terms." At another, more historical, level, structuralist Marxism was also developed by thinkers (Althusser, Balibar, Rancière et al.) for whom epistemology was the point of departure for analysing economic and political phenomena. Influential in this regard is the "father" of epistemology and the history of science in France, Gaston Bachelard. Indeed, if one looks to Bachelard here, structuralist Marxism begins to fall within a program of thinking and research that would clearly include philosophers and sociologists such as Michel Foucault (1926–1984) and Pierre Bourdieu (1930–2002), even though their allegiance to Marxism was always weak.

Three aspects of Bachelard's thought endeared him to a structuralist approach. The first is his emphasis on epistemology, which implied that scientists should not be blinded by positivism but should develop a reflexive sense. In other words, knowledge of the subjective dimension is also important to the scientific project. Scientists need to grasp the real space in which they are working as well as the represented space they are studying. An appreciation of the difference between real and represented space requires recourse to theory. This is not to deny the real. For connected to Bachelard's emphasis on theory is his strongly held position that a rationalist framework (field of interpretation and reason) in science is impotent when detached from experimentation. Thus, although experiment without theory leads to naive empiricism, theory without experimentation is sterile.

Second, Bachelard proposes a nonsequential, noncausal (in the simple sense) explanation of history. Science, for example, evolves in fits and starts; it exemplifies "discontinuity" as much as, or more than, continuities. Newton's work cannot predict Einstein's, for example. In fact, this aspect of Bachelard's work was reinforced by his anti-Cartesian stance. So whereas Descartes had aimed to reduce reality to its simplest element, Bachelard argues that after the revolution brought by quantum physics, even an apparently simple element turns out to be complex. Thus, complexity (or "complex causation" as Althusser expressed it) is at the heart of things not simplicity.

Third, Bachelard made the imagination a fundamental object of analysis, a fact that opened the way to a structural view of subjectivity, even if Bachelard's own credentials as a structuralist were at best ambiguous.

In raising method to pride of place in understanding society and class struggle, structuralist Marxism focused on the relations between elements—whether in politics, or the economy—as Saussure had done in his revision of linguistics. Althusser thus argued that the nature, meaning, and importance of Marx's concepts were not given in advance in a self-evident, obvious way. Rather, they had to be produced through a symptomatic reading—particularly of *Capital*—to arrive at Marx's truly original insights, insights of which Marx himself might not have been entirely aware because the theoretical and philosophical language available to him was quite literally, pre-Marxist. More specifically, this language was anthropological and placed "man" at the center of a secular universe. To confirm this, Dostoyevsky (1821–1881), Nietzsche (1844–1900), and others proclaimed the death of God, without always recognising that if God is dead, so is man. For the anthropology in question is indebted to the same metaphysics as the religious orientation it opposes. Thus is Ludwig Feuerbach's (1804–1872) critique of Christianity reinforced by the same anthropological view of the world when he claims that things can be put to rights by substituting man for God—or rather, by saying that God is man's creation (Feuerbach [1841]1989).

Historically, a key question for Western intellectuals in the post-World War II period in light of dominance of Stalinism, concerned the true nature of Marxism. Was it necessary to accept that Stalin and the gulag were the inevitable outcome of Marx's intellectual and political legacy? For a number of key philosophers and thinkers, such as György Lukács (1885–1971), the discovery of Marx's early writings, which focused on the concept of "man," the answer was "no." Indeed, by way of these early writings, a case could be made, Lukács claimed, for saying that, within the capitalist system, the notion of alienation explained why human life had become so degraded. With the generalised commodification—and thus, objectification—resulting from the dominance of exchange-value under capitalism,

this argument said, humanity had lost touch with its natural human essence founded in community. The object had become a force over and against "man," not a force for liberation and enrichment. And it emerged that in France and elsewhere between 1945 and 1960, Marx's theoretical and metaphysical writings giving "man" pride of place in economic and political affairs came to be seen as the secret to all Marx's other works, including *Capital.*

When Jean-Paul Sartre called Marxism the "unsurpassable philosophy of the modern era," he meant by this that Marx had alerted the world to the necessity of an essentially humanist critique of capitalism, a critique that would reveal the importance of human subjectivity—thus, morality—in political matters and that, furthermore, would see history as the reflection of human consciousness caught at a given moment of time. To write history thus meant giving a phenomenological description of human consciousness. Through such a strategy, the determinist approach of economistic Marxism, inherited from the Second International, could be avoided.

Humanist Marxism had another feature, however, one that was more problematic. This is highlighted by Claude Lévi-Strauss's critique of Sartre's theory of history. Briefly, Lévi-Strauss argued that it is a mistake to raise the "I" to the power of "we," as Sartre's Cartesian notion of the subject had led him to do. In other words, it is inadequate to project qualities of the individual onto the collectivity. Sartre's approach entailed deducing the nature of collective entities, such as "the people," "the state," "the party," "the species" (man), from the nature of individual consciousness and inserting the result into a historical narrative hailing the triumph of the collectivity, whatever name one gave to it. By the 1960s, a number of intellectuals realised that Stalinism and totalitarian Marxism could be understood as regimes that precisely forced subservience to such collective entities. In this sense, Stalinism, rather than being the antithesis of Marxist humanism, could be seen as its continuation.

Moreover, if Marxism was a humanism because it focused on the relation between man and nature and between self and other, it would, from an epistemological and metaphysical perspective, be little different from a host of nineteenth-century philosophies of man that inherited the Enlightenment push for the secularisation of society, a principle underlying the French Revolution. It was necessary, then, to discover the truly unique qualities of Marx's thought, and it was this that raised questions of method. Marx cannot be inserted into the Enlightenment secular heritage so easily if the originality of his thought is to be preserved. Moreover, it is the humanist approach to Marxism that made a reconciliation possible between Marxism and certain strands of Catholicism, especially in France.

Consequently, through Althusser, structuralist Marxism argued for an "epistemological break" between Marx and Hegel and between Marx and Feuerbach, and it rejected the idea of a quiet and continuous evolution between the essential qualities of Marx's thought and what had gone before. "Epistemological break" implies that there is not even a continuity between Marx's method and concepts and those invoked by humanists of every stripe. Structuralist Marxism famously became a "theoretical anti-humanism," which opponents claimed was equivalent to its being Stalinist (cf. C. P. Thompson). Certainly, it was abstract rather than concrete or empirical, but whether it was inhuman in a moral sense is another matter. For, in fact, the whole field of moral and ethical action raises key questions that could be addressed only through the idea, developed in the theory of the French psychoanalyst, Jacques Lacan (1901–1980), of the unconscious understood structurally as a specific kind of discourse. For Lacan, the subject is the subject in language, the subject as formed in and through the symbolic order oriented around the relationship between signifier and signified. Here, it is not that ethical action is impossible but, rather, that it is never the spontaneous process that the conscious ego often believes it to be. Here, there is no subject independent of the signifier. There is, in other words, no original human nature (or natural sexuality), giving rise to a subject identical with itself (where the subject is the self-conscious subject, entirely present to itself). The structural unconscious decenters the subject, and this is the view that structuralist Marxism also took before it—in the work of Althusser, in particular.

For its part, genetic structuralism, derived largely from two moments: The first was the debate around the historical relationship between Hegel and Marx, inaugurated by Jean Hyppolite (1969), where the key question centered on the extent to which Marx was, or was not, the inheritor of Hegel's system. The second moment came from psychology, where its chief instigator was Jean Piaget (1896–1980). The chief claim of genetic structuralism and its Marxist variant, as articulated in the work of Goldman, was that it soft-pedalled discontinuity in favour of a historical and evolutionist approach to the study of art and society. In effect, it sought to balance the overemphasis on "synchrony" (the same time: a static moment favoured by those influenced by Saussure) with diachrony (time as movement and evolution).

ECONOMIC DETERMINISM

Marxism of the Second International, which collapsed in 1914, espoused an "official" Marxism that gave primacy to economic activity in the evolutionary transformation of society: The economic laws governing society would inevitably bring about a socialist, and then communist, society. Culture, by contrast, was seen to be "superstructural": the level of ideas and idealism, if not of false consciousness. Here we have an abiding issue in theoretical Marxism: The nature of the separation of the ideological superstructure

from the economic—therefore material—infrastructure. For the economistic view, the laws of the formation of the infrastructure determine the superstructure. Such was confirmed by the Comintern founded by Stalin in 1938. In other words, living, real communism promoted a blatant economic determinism.

It was precisely this simple determinism—implying that the economy was a totality that *expressed* underlying forces of production—that structuralist Marxism set out to contest. Instead, it offered a nuanced philosophical view of the relation between the economic and cultural spheres by saying that the economic never appears simply in its own right for all to see but, rather, appears in a displaced form in a wide range of activities, from art production and education to politics and religion. For this approach, it is not a matter of the economic sphere on one side and the superstructural dimension on the other. There is, rather, a fundamental imbrication of the two, to the point that it has to be admitted that a knowledge of material life can be gained only through the prism of ideas emerging in the superstructure. The argument is not unlike Freud's when he talks about the relationship between primary and secondary (or symbolic) psychical processes. The latter constitute the prism through which knowledge of the displaced actions of the primary processes becomes possible.

Or again we could point to a nondeterminist way of understanding technology—technology being fundamental to economic development, even for Marx. Thus, instead of technology determining social relations, it becomes a feature of, and is implicated in, the cultural field itself. Had not Marcel Mauss, the anthropologist most influential for structuralism before Lévi-Strauss, said that techniques of the body (even spitting) imply that, through techniques, technology crosses over into the psychical and social domains instead of being separate from them? It is not essentially, in the words of Marx, a "mode of production," found uniquely in the economy understood as the accumulation of goods. Or we could say that the economy is more than the quantitative version of it. The economic, as exchange—as giving and receiving—and as the search for equilibrium, as the principle of "zero-sum," and, above all, as the principle of differential relations between elements in the productive process, penetrates all the hitherto superstructural domains of society.

More specifically, Althusser and Etienne Balibar argue, in *Reading Capital* (1970), that Marx shows that it is the capitalist system itself that valorises a narrow view of the economy as determining the nature of social and cultural forms. Within the capitalist system, the economy appears only in the version in which consumers adopt a fetishistic attitude to commodities, meaning that goods are desired for their own sake rather than for the deeper insights into society at large that production provides—insights about how, for example, kinship relations might be structured by the mode of production, without being reducible to it.

The uneven development of the various levels of the socioeconomic formation mean that it is impossible to have a homogeneous whole that, mirrorlike, reflects society and the economy. Rather, it is a matter of "the effectivity of a structure on its elements" (Althusser and Balibar 1970:29). That is to say, at any given historical moment, one aspect of the whole can come into dominance. At one time, it might be the economy narrowly understood; at another time, it might be politics; at another, cultural elements. What emerges in dominance is a historical, not a theoretical question. The conditions of possibility of the historical determination, however, depend on the nature of the articulation of the socioeconomic structure, which is itself in time. Although it is not a simple whole, this structure has its laws and its order, and these are accessible only through grasping the nature of the relations between the elements themselves.

"Structuralist Marxism" is thus also a reading of *Capital* in terms of an epistemological position. The latter entails the idea that Marx founded a science, the science of history, and that this science can be found embedded in Marx's writing, if one knows how to look for it—that is, if one has a sophisticated idea of reading based on a scientific theory or if one has a rigorous method enabling a passage beyond the self-evident aspect of the text, a self-evidency that in all probability is governed by ideology.

By contrast, humanist Marxism in France was driven by Sartre's claim that existentialism is a humanism, ultimately subservient to Marxism. For Sartre, the main focus had to be on the moral status of particular acts. With the discovery of Marx's early writings in the 1930s, the members of the Frankfurt School, such as Herbert Marcuse, also claimed a humanist heritage for Marx and added that this humanism led to the conscious determination to escape the alienation implicit in the capitalist system. But where was humanist Marxism going? What would be the result if alienation were finally overcome? Is it equivalent to the end of politics?

For its part, structuralist Marxism (Althusser, Balibar, Badiou, Godelier) saw the gaining of a knowledge of the form and content of the "social formation" as the central issue. Thus, in the work of Althusser and Balibar, the idea of "economic" is broadened to include ideological and political factors that interact with the economy—an interaction that is crucial, even if the economy is still determinate "in the last instance" (which never comes: the origin is never present). Here, there is—again following the lead of Freud—an issue of "overdetermination," meaning that there is a complex and not a simple relation between cause and effect. There are contradictions between different levels of the social formation. And in any case, the economy can, at mininmum, be seen as the scene of exchanges at a structural level: exchange of goods, exchange of women.

GENETIC AND NONGENETIC MARXISM

Along with Goldman and Piaget, structure emerged in a genetic form in the work of the historians of the *Annales* school in France, for whom the "*longue durée*" (long span) is beyond the consciousness of *histoire evenmentielle* (history of discrete, everyday events). The *longue durée* is the slow centuries of time, barely perceptible and yet inexorable. It is history equivalent to the changes in climate patterns and geographic transformations. Indeed, the *longue durée* is a "spatialisation of time" as structure is in the field of nongenetic structural Marxism. The objective of the history with this very broad focus is to escape the narrowness of history as chronicle, where individual events are recounted but where a deep understanding of their logic and complexity is impossible. Events history is inherently simple, for it is always reducible to the individual events themselves.

HISTORICAL MOMENT OF STRUCTURALIST MARXISM

Although structuralist Marxism had its formal beginning with the work of Althusser in the mid-1960s, its roots were in fact more concrete. They were linked, not only to the dissatisfaction with the moral Marxism propounded by Sartre, and with the subjectivist Marxism promoted by the Frankfurt School, but also to opposition to all movements that valorised the agent of action to the exclusion of social conditions. The context of action needed attention. Back in 1947, Heidegger (1889–1976), in his "Letter on Humanism" ([1947]1993), criticised Sartre and his insistence that the human subject was its acts: that existence preceded essence. Such an approach privileged consciousness inordinately as well as the idea of moral responsibility. "Man" became responsible for what he did, despite the situation. However, Heidegger was less concerned to criticise consciousness and moral bearing and more concerned to question the privileging of beings (existence) at the expense of Being.

In keeping with the critique of agency and consciousness inaugurated by structuralist Marxism, Pierre Bourdieu articulated a structuralist sociology aiming to provide a complex theory of the individual in a given society as both constituted by and constituting the social world in which he or she is located. Forms of perception, apperception and appreciation are in large measure articulated through Bourdieu's concept of "habitus," which is also defined by the levels of cultural and economic capital specific to a given agent. Saying this implies that, through the concept of habitus, a structuralist approach "breaks" with a commonsense epistemology based on the obviousness of perception—the level of empiricism for Althusser. The complexity that habitus points to evokes the space where the scientist works and, thus, the influence of Bachelard. For Bourdieu, complexity also arises because, as Marx said,

human beings *produce* their way of life. More specifically, habitus is a kind of grammar that sets the limits to action without determining how a specific individual will act within it, just as the grammar of a natural language sets the limits to possible speech acts without determining the kind of speech that will be enacted in any contingent situation. Overall, Bourdieu's claim is that class struggle is a struggle between the habitus of the dominant and the habitus of the dominated class as much as it is a struggle between social positions based on the differential possession of economic and other forms of capital. In fact, the reproduction of the unequal distribution of economic capital cannot occur, Bourdieu argues, outside the framework of the habitus that enables the unequal distribution of economic wealth to become manifest. Even though he belongs to no Marxist school, Bourdieu, like Marx, refuses to accept the status quo, a status quo in favour, clearly, of the dominant class. Class struggle is therefore the name of the political and social game for both Marx and Bourdieu, and the reality and truth of this game can be revealed through rigorous scientific research—what Bourdieu calls a knowledge of necessity.

Where Bourdieu differs from both Marx and structuralism is in his refusal to see class in solely economic terms—however broadly *economic* is defined—and in his refusal to accept what he calls the "objectivist," or "scholastic" illusion of structuralism, an illusion that gives too little weight to "practice" or to agency. In short, actions, often couched in complex strategies, for Bourdieu, do make a difference.

Like Althusser's, Bourdieu's work is also marked by the approach to epistemological questions in science inaugurated by Gaston Bachelard, where the notion of an epistemological break is crucial. Bourdieu, however, includes in the equation, the social disposition of the researcher. The researcher can thus go through a kind of "mental transformation," or "conversion of thought," which breaks with spontaneous yet preconstructed perspectives that support the existing social system.

With his emphasis on the way privilege is reproduced—especially through education, where the next generation inherits the benefits of its forebears—Bourdieu has an affinity with genetic structuralism. For it is in the passage of inheritance that time enters the picture and the exclusively synchronic (= one time) approach of "pure" structuralism is modified if it is not entirely rejected. On this basis, too, the agent of the system can play a part in the determination of social conditions through the implementation of strategies—strategies that the idea of agents as mere supports for the structure (as in the work of Althusser) leaves out.

PLACE OF IDEOLOGY

For structuralist Marxism, ideology becomes a practice. Writing of the phenomenon of ideology, Althusser cites

Pascal who offers advice to the one without faith, the one who does not know how to pray: kneel down, move your lips and you will believe, entreats Pascal. Believing—ideology—is thus in the everyday practice, not in a prior faith worked out intellectually. Thus for Althusser, ideology is not a competing intellectual system, but a way of being and acting. Ideology interpellates—calls—individuals to come to be what the system wants them to be. Ideology is a way of using identity to create human supports for the system. In addition, according to Althusser, "ideology has no history."

Slovoj Žižek follows up this practical structuralist Marxist approach to ideology by arguing that ideology is what cannot be rationally justified: We might know that consumer behaviour is furthering the interests of capitalism, but we engage in it all the same. For ideology cannot be explained by false consciousness, which would imply that once people become enlightened, they would change their behaviour. It is rather a set of practices through which individuals constitute themselves in the social world. Only an unthought-out voluntarism could argue that it is enlightenment and education that will bring people to their senses. Such an approach cannot meet Marx's point in the theses on Feuerbach that "the educator also needs to be educated."

KINSHIP AND THE MODE OF PRODUCTION

It would be wrong to think that stucturalist Marxism attempted to analyse and explain only modern capitalist societies of the Western sort. There was, in addition, a lively debate about the status (historical, political, philosophical) of precapitalist economic formations. Could the latter be explained by a Marxist science, or would it have to be conceded that Marx still had work to do here and that therefore the notion of mode of production is limited in relation to explaining the dynamics of noncapitalist, or precapitalist societies and cultures? Certainly, it was recognised that a narrow conception of the "economic base" had little to offer in interpreting societies structured around kinship relations.

When discussing the question of the economic base versus kinship as the determining factor in the reproduction of society, a number of writers in the field made the mode of production sui generis, an entity in its own right that either dominated or did not dominate the spheres of power and social relations. This, however, is to take a very narrow view of "economic." For the latter could be defined, in keeping with Marx's early writings, as the way humanity produces its means of subsistence—that is, the economic field is the one in which humans first of all survive and then do, or do not, flourish. On this basis, the opposition to Marx is not so much that he privileges the economy, which, as structural Marxism argued, can be articulated throughout a system in a highly displaced form but that the economic thesis cannot envisage the nonsurvival, or self-destruction,

of a society. To say "economic" (and the reproductive power that accompanies this) is to say no to death—forever, if possible.

CRITICISMS OF STRUCTURALIST MARXISM

However, some societies have a destructive principle at their very heart: Only in such social formations can a noneconomic way of life not based in physical needs be envisaged. This is the sense, then, of Marx's reductionism—a reductionism that is also an essentialism, because it says that the economy is determinate, not historically, but in principle, as has been noted by several major commentators (Baudrillard 1981; Laclau and Mouffe 1985). Ultimately, therefore, as sophisticated as structuralist Marxism was in its theoretical approach, it nevertheless gave into the idea of a founding principle revealed philosophically rather than historically.

Moreover, in wishing to keep a tight reign on the role of the subject and of agency, structuralist Marxism added a further essentialist aspect to its framework. For while it is true that subjectivity and the notion of the subject can also lead to a certain essentialism when the subject is defined in a noncontingent, or analytical, way, it is also true that subjectivity can be seen as the place where action changes things. Subjectivity is action—or, the subject is always "in process" (Kristeva), an "open system," restructuring itself in light of new experiences and, reciprocally, changes a small part of social reality in the process.

Of course, the ultimate criticism of structural Marxism was, and is, that it is intellectualist. In this, it goes beyond Bachelard's call for theory to grasp the place from where the scientist works—a use of theory that accepts the synthetic, open-ended nature of reality—and becomes an end in itself, a law unto itself, unable to identify with what Pierre Bourdieu called the "logic of practice." Instead of opening things up with its theoretical boldness, structuralist Marxism closed things down; it privileged the production of a theoretical practice of analysis articulated in discourse, a discourse having the structure of language as Saussure ([1916]1983) has outlined it, therefore a discourse eminently analysable at every point. In effect, against structuralist Marxism, reality cannot be reduced to discourse. There is a nondiscursive reality. Reality, like the subject, is also difference, otherness, the event, the shock of history, the revelations of time, what cannot be easily, if at all, assimilated into a structure.

To suggest that the structuralist version of Marxism is flawed is not to say—far from it—that the opposing humanist position and its variants is superior in its explanatory power. Even if structuralist Marxism was determinist and intellectualist, there was a historical reason for its emergence, and this was to show an interpretation of Marx that privileged neither consciousness nor an essentialist

idea of "man," as was common in the nineteenth century. Moreover, if the strictures about a Marxist science, as proposed by Althusser, ultimately turned out to be dogmatic, they had the effect, at the same time, of forcing intellectuals and others to think again about what science is. And in this regard, a more rigorous approach to the study of society shows that there are aspects of social and cultural life that are simply not available to consciousness, and all the self-conscious work in the world will never give access to the crucially "hidden" structures of social life, in the same way that consciousness cannot have access to the structure of language because it is also a product of language. In Freudian terms, there is an *un*conscious dimension to life and society.

It nevertheless remains true that if the "truth" of politics and society resides in the unconscious social structures, it would seem necessary for intellectuals to take on the responsibility of revealing these to the public at large. There is, then, the easy accusation against structuralism that, for it, society has to be run by elites as the keepers of truth. Such an issue opens up the question Nietzsche raises of the *ressentiment* of those who perceive that they are in the position of slave and not of master. For while a claim to science is problematic in the domain of politics, the claim that scientific knowledge cannot be directly available to all surely goes without saying.

Such questions, which cannot be answered fully here, serve to show that, for all its faults, structuralist Marxism raised serious and fundamental questions about how scientific and intellectual work is carried out in supposedly liberal democracies.

STRUCTURATION

Structuration theory is a broad-ranging sociological ontology in which social practices are postulated as the basic constituents of the social world. Sociological ontologies differ from ontologies in the philosophical sense of the term. Whereas philosophical ontologies derive from primordial metaphysical questions such as what is the ultimate nature of being and existence, sociological ontologies begin more modestly by asking questions about the generic (i.e., transcultural and transhistoric) properties of social life subject to sociological inquiry. Prior to structuration theory, two antithetical positions dominated ontological thinking in sociology. On the one hand, individualism maintained that the social world is constituted by actors impelled to behave in certain ways by their own interests or motives or by their interpretations of their situations. On the other hand, collectivism maintained that the social world is constituted through the effects of social groups that shape, channel, and constrain social action. Structuration theory develops a third approach to sociological ontology that is neither individualistic nor collectivist, although it incorporates key insights from each.

Structuration theory maintains that social praxis is the most basic property of all phenomena of sociological interest. Social praxis is simply the generic term for practices of all kinds in the same sense that the individual is a generic term for actors of all kinds. Structuration theory's emphasis on praxis begins from the intuitively appealing insight that whatever types of social events or forms of structured collectivities may arise or change in a given culture or historical era, these types of events or forms of collectivities are generated in the course of social conduct and through the consequences of this conduct. Long-lasting forms of events and enduring collectivities that maintain their structural features for extended periods of time result from the reproduction of broadly similar forms of praxis. Conversely,

when new forms of events or features of collectivities arise, we can be sure that these changes are driven by widespread transformations in social praxis. For example, when capitalism supplanted the political economy of feudalism as the prevailing mode of European production and exchange, the transformation pivoted on newly devised practices of labor, trade, investment, and consumption. Similarly, the new form of political culture that developed in the late eighteenth century in the United States was generated by numerous shifts in praxis, including new forms of political gatherings, political language, and even new forms of public interaction that generated what we now term civil society. It is true, of course, that individuals and collectivities also changed during these transformative periods. However, from a structurational standpoint, without the changes in praxis, these other changes would not have come about.

Structuration theory originated in the writings of the British social theorist Anthony Giddens during the period from 1976 to 1991 when Giddens was on the faculty at the University of Cambridge. Giddens had become interested in sociologies of praxis during several trips to North America in the early 1970s. In his first book on structuration theory, Giddens (1976) began to synthesize points of emphasis from American theories of praxis, including ethnomethodology, social phenomenology, and Erving Goffman's accounts of the interaction order. Continuing his synthetic approach, Giddens found that these American theories shared common ground with British and Continental conceptions of praxis, including works inspired by the later philosophy of Ludwig Wittgenstein, the hermeneutic philosophy of Hans-Georg Gadamer, and Jürgen Habermas's early writings on critical theory.

While Giddens was heavily influenced by these theories of praxis, he was dissatisfied with their neglect of the collective dimensions of social life. Conversely, Giddens was also highly critical of collectivist theories for their neglect of social praxis. Among collectivist theorists Giddens paid close attention to Marx, Durkheim, Merton, and Parsons, as well as French structuralists including Levi-Strauss, Althusser, and Derrida. In addition, Giddens imported significant insights into his writings on collectivities from the new field of time geography. In Giddens's most widely cited writings on structuration theory (1979, 1984; see also Cohen 1989), he synthesized key insights from his sources to open theories of praxis to issues regarding social collectivities and, conversely, to open theories of collectivities to issues in the production and reproduction of everyday social life.

The integration of social praxis with the collective dimensions of social life in structuration theory is sometimes referred to as a solution to the problem of structure and agency. However, this catchphrase actually condenses a number of different problems, particularly on the collectivist

side. Indeed, the notion of structure is one of three different dimensions of collectivities interwoven in the structurationist ontology. In addition to structure, Giddens also takes into account recurring patterns of social relations such as networks and systems, as well as the nature of domination and relations of power in social life.

A singularly important step in reconciling praxis and collectivities is to methodologically suspend the ever-present possibility of innovations in social praxis. The justification for this move is as follows: While it is true that on any given occasion actors may do something new, or make a mistake, or simply refuse to do what others expect or demand, it is also true that, except in periods of great social transformation such as wars, revolutions, or disasters, most social practices are routinely performed. For example, in modern societies, people coordinate their affairs according to clocks and watches innumerable times each day. They also ride in autos, speak a common language, prepare and eat familiar foods, and use commonly practiced interaction rituals for greetings, departures, and other conventional moves in personal encounters. All sorts of organizations from schools to business firms to armies to hospitals operate according to scheduled routines. Family life and personal life operate according to repetitive everyday routines as well. Overall, not only each day, but each week, each year, and for periods that may span several generations, commonplace social routines maintain the continuity and order in social life. No two instances of any given practice may be precisely the same in every respect, but the similarities are sufficient to generate a world in which participants know their way around. This is a world structured through the reproduction of common practices. Or in Giddens's terms, this is a world that is structured through structuration.

One of Giddens's central concepts, the duality of structure, provides an abstract image of how processes of structuration occur. In structuration theory, the reproduction of routines is a reflexive process. Unlike those who make fine-grained investigations of everyday life that ignore the preconditions of praxis in local settings, Giddens emphasizes that social actors bring a large repertoire of previously acquired competencies with them as they enter a new social scene. The reflexivity at the center of the duality of structure arises because, in appropriate circumstances, actors draw on these competencies to reproduce familiar practices and social contexts in a new social moment. Thus, as I write these words, I reproduce familiar elements of everything from English grammar and syntax to a narrative voice and expository form appropriate for an entry in a reference work. In these practices, I draw on preestablished competencies to reproduce a new instance of a familiar form. I thereby regenerate a small, structured feature of the academic world. Any commonly reproduced practice may be understood the same way.

But it is not practices performed one at a time that gives the duality of structure its expansive significance. Rather, it is the manifold reproduction of the same practice in a multitude of situations. For example, although one simple act of preparing a meal may not structure the dietary practices of an entire culture, the fact that on any given day a multitude of meals are prepared in the same way does indeed provide structure to the diet within that culture. The duality of structure refers to this recurrent process of reproducing familiar practices to structure the present as it was structured in the past. Of course, once we withdraw the methodological brackets, the duality of structure works just as well to account for change as for reproduction. Thus, cooks may systematically alter old culinary practices or combine several old practices in new ways. If these innovations are disseminated and appropriated by a given population, the diet of an entire culture may be restructured as a result. But whether reproduction or social change is at issue, the reflexivity in the duality of structure continues to operate so long as people use competencies for structuration acquired in the past to structure situations in the present.

The duality of structure provides the means to understand how the social world can be a world of constant praxis and yet a world that remains much the same from one day to the next. But the idea of a structured social world on this everyday scale may seem a long way from the structuration of large-scale cultures, societies, or historical eras. And it is after all the structured properties of large collectivities that have been the focus of a great deal of social theory beginning with the foundational writings of Marx and Durkheim. There is nothing in structuration theory that approaches the conceptual specificity of Marx's concept of the mode of production or Durkheim's concept of the *conscience collective.* However, Giddens does provide a set of conceptual tools for structural analysis that permit a similarly expansive view. One advantage of these conceptual tools is that they permit Giddens to sidestep the intractable theoretical debates over the primacy of materialist or idealist factors in the constitution of large collectivities as well as in historical stasis and change. Along with an increasing number of contemporary theorists, Giddens believes that history offers too many different cultures and civilizations with diverse historical trajectories to postulate the primacy of one set of structural factors over all others. Therefore, he simply offers four categories for the analysis of structural properties that are ultimately no more than conceptual tools for structural analysis. The four forms are (1) *performative rules* that analytically refer to the enactment of routines, (2) *normative rules* that refer to the appropriate circumstances and manner in which routines are performed, (3) *authoritative resources* that refer to the nature and use of capacities to control the doings of others, and (4) *allocative resources* that refer to the nature and capacities of control over material resources.

While Giddens's treatment of structuration is widely regarded as the most innovative aspect of his synthesis of collective and agentic dimensions of social life, he also contributes new directions to the sociological understanding of social morphology—that is, enduring patterns of social relations. Giddens begins with familiar images of systems and networks composed of links between nodes. However, whereas mid-twentieth-century social morphologists such as Peter Blau, Mark Granovetter, and Ronald Burt generally conceive collective patterns of relations as emergent entities, Giddens conceives them as patterns of relations reproduced in social practices that "stretch" across time and space. Thus, in structuration theory, the familiar links-between-nodes imagery that represents networks in a virtual social space becomes a series of reproduced relations that Giddens terms *circuits of reproduction.* Within these circuits, some of the links may be reproduced in regularly scheduled face-to-face encounters, while other links may be forged through media of communication and transportation that span diverse settings across time and space. Initially, Giddens devised this imagery of the time-space distanciation of social relations from his readings of time geographers such as Torsten Hägerstrand and Allan Pred. In addition, Giddens incorporated key insights from functional analysis to account for the organization of social systems, although his only original contribution here is to eliminate the illegitimate hypostatization of functional systems by insisting on conceptions of systemic coordination and control that operate through social praxis. Giddens's conception of the time-space distanciation of social systems is not only one of the basic elements of structuration theory, it also serves as the basis for his analyses of late modernity—that is, the social and cultural circumstances of our time. Here, Giddens argues that the late-modern era, or what he terms posttraditional society has been shaped in substantial ways by instantaneous electronic communications media and increasingly rapid and efficient transport media that "stretch" the reach of social systems indefinitely around the globe. As spelled out in Giddens's own writings and those of other theorists of globalization such as David Harvey and David Held, this idea of the full eclipse of time and the partial eclipse of space has transformed philosophical speculation about what is truly new in modern life into empirically researchable sociological propositions.

Structuration theory includes a comprehensive and balanced account of the political dimensions of social life. Like Max Weber, Giddens distinguishes between power as a ubiquitous feature of conduct, and power as a characteristic set of relations of domination between superordinates and subordinates in institutional orders. Like Weber, Giddens views relations of domination as an inescapable feature of all large collectivities. But unlike Weber, Giddens does not rest content to focus exclusively on domination from a "top-down" point of view. Indeed, his most noteworthy

contributions to theories of power in collectivities look at relations of power between the dominant and the dominated with an eye toward the balance of power between them.

Whereas most theories of power stress the capacity of powerholders to realize their objectives, Giddens proposes a dialectic of control. In this concept, as in most others, dominant groups hold their power through their control of scarce resources, the nature of which varies depending on historical circumstances. However, powerholders cannot realize their objectives without the active compliance of the dominated. Through their compliance or resistance to the orders they receive, the dominated maintain some degree of leverage over their political circumstances. When this leverage is skillfully employed, as is most easily illustrated in the case of strikes and other tactics used by labor unions, subordinate groups may claim some rights to autonomy from the dictates of those who control the most powerful resources. Beyond labor unions, one may see examples of the dialectic of control on a large scale in the origins of citizenship rights that commoners wrested from nobles and aristocrats in Western polities and, on a small scale, in the control of domestic arrangements by women in conventional bourgeois families where men controlled the dominant cultural and social capital as well as the bulk of the economic resources.

No full-scale social ontology can avoid an account of human consciousness and motivation. Giddens's account (see especially 1991, chap. 2) is both a strength and a weakness of his thought. On one hand, it introduces a way of conceiving consciousness that is well suited to the praxiological orientation of structuration theory. On the other hand, it leaves many human capacities for existential meaning and emotional experience unaddressed (see Craib 1992). To begin, Giddens divides human consciousness into three segments: (1) discursive consciousness, which is the familiar idea of fully focused thought and fully engaged attention; (2) practical consciousness; and (3) the unconscious. Although fully focused thought plays a substantial role in Giddens's theoretical analyses of modernity, Giddens's conceptions of practical consciousness and the unconscious are more central to the development of structuration theory.

Practical consciousness refers to the tacit form of awareness that is all that actors require when they perform familiar routines or when they recognize familiar elements of social situations. Although this tacit form of consciousness takes account only of the unexceptional and commonplace elements of human experience, it acquires great importance in structuration theory on two grounds. First, practical consciousness is maintained in the mundane routines that reproduce social life in the duality of structure. Second, practical consciousness is tied into what Giddens proposes as a basic and generalized human need for ontological security, a need that arises in the human unconscious.

Ontological security is a condition in which humans feel comfortable with their activities, their environment and with their fellow actors with whom they interact. The connection between routine praxis and ontological security is obvious: Routine praxis produces ontological security. However, ontological security is an unconscious state of mind that is generally inaccessible in everyday life. The existence of this need becomes evident during wars and catastrophic disasters. In these circumstances, when most of the practices that structure social life are no longer possible, actors experience the acute psychic effects of anomie. In these circumstances, actors will go to great lengths to establish a new daily round of activities. While some of these activities may be necessary for material survival, the recurrent and predictable familiarity of the routine quickly begins to serve as both a social and psychological anchor for daily life. The powerful urge to devise and maintain basic processes of structuration that is so evident in these situations supports Giddens's insights into ontological security as a basic need. However, Giddens has nothing to say about whether humans also have ontological needs for meaning or emotional attachments. Thus, primordial philosophical questions about human ontology lie beyond the scope of structuration theory.

SUMNER, WILLIAM GRAHAM

William Graham Sumner (1840–1910) is credited with teaching the first sociology course in the United States. He

was one of the founders of the American Sociological Society movement and its second president. Sumner was greatly influenced by Herbert Spencer and became an American proponent of social Darwinism and laissez-faire.

Sumner was born in Paterson, New Jersey, and spent his childhood in Hartford, Connecticut. His parents had emigrated from England and raised William in a strict religious environment. After spending four years at Yale (1859–1863), Sumner attended the Universities of Geneva, Goettingen, and Oxford (1863–1866) in preparation for the ministry. While in Europe he changed his religion from the Congregational to the Protestant Episcopal faith, becoming ordained a deacon in 1867. Sumner began doubting mystical theory and shifted his focus to the concrete facts and theories of social science. In 1872, he solidified his decision by accepting a position as professor of political and social science at Yale. He taught Spencer's *Study of Sociology* and almost lost his position in 1881 because of it. Sumner had become a complete advocate for social evolutionism and the expansion of industrial and capitalist society in the United States.

Sumner's most significant contribution to sociological theory rests with his best-known work, *Folkways* (1906), a book that describes the origins of *folkways* found in society and their consequential influence on manners, customs, mores, and morals. Folkways are a societal force produced by frequent repetition of petty acts, often by great numbers acting collectively or, at least, when acting in the same way when faced with the same need. As Sumner explained in *Folkways*,

> Folkways are habits of the individual and customs of the society which arise from efforts to satisfy needs, they are intertwined with goblinism and demonism and primitive notions of luck and so they win traditional authority. . . . they become regulated for future generations and take on the character of a social force. (p. iv)

Folkways are made unconsciously, they are the product of recurrent habits, guided by recurrent needs of the individual and of the group. As Sumner had learned from Spencer, "guidance by custom" is the most common thread among diverse groups of people. *Custom* is the product of concurrent action, over time, by mass actions driven by mass needs and wants. Mass action is stimu-lated by the desire of people to act collectively with one another. Sumner stated that there are four great motives of human action: hunger, sex passion, vanity, and fear (of ghosts and spirits). Associated with each of these motives are interests. Human life revolves around satisfying these interests. Society dictates which courses of action (folkways) are proper in the attempt to satisfy basic needs and desires.

When certain folkways become associated with philosophical and ethical issues of proper behavior, they are elevated to another plane. These coercive and constraining norms are called *mores.* Mores come down to us from the past and take on the authority of facts. Each individual is born into them and are subjected to their "legitimacy." Mores serve as regulators of the political, social, and religious behaviors of individuals, and they are not affected by "scientific facts." Mores often consist of *taboos,* which indicate the things that must not be done. Taboos are linked to past behaviors that have been proven to cause unwelcome results and therefore contain reference to a reason as to why specific acts should not be allowed. Sumner acknowledged that folkways, mores, and taboos vary from society to society and therefore promotes the field of ethology. *Ethology* is the term he used for the study of manners, customs, usages, and mores, including the study of the way in which they are formed; how they grow or decay; and how they affect the interests of those who are affected by them. The sociologist in particular must pay attention to the folkways and mores of a society, for they have a great impact on human behavior.

Sumner applied Spencer's survival-of-the-fittest approach to the social world. Those who work hard—the fittest—will find a way to survive in society. He believed that poverty could be eliminated in a few generations if people simply worked hard; were industrious, prudent, and wise; and raised their children to do likewise. Sumner felt that it was the duty of everyone to be self-reliant, to look to oneself for help and certainly not to look for aid from others. One either survives or perishes. The "survival of the fittest" concept is viewed as a *natural* law and not a social creation. From this approach, society is viewed as constantly improving, or evolving—the strong, or fit, survive, while the weak, or unfit, die off. Consequently, any interference, especially by the government, could cause a negative disruption in the social order. Sumner opposed governmental sponsorship, believing that each member of society must bear his or her own burdens. Sumner embraced the idea of *laissez-faire,* which he described as the unrestrained action of nature without any intelligent interference by man. Sumner stated that *laissez-faire* means, "Do not meddle; wait and observe; be teachable. Do not enter upon any rash experiments; be patient until you see how it will work out" (Keller and Davie 1934b:472). Sumner was against all forms of paternalism—state assistance to the poor and needy—especially when applied through legislative methods. Sumner's worry over of the role of government is reflected in his concern for individual rights and liberties.

The concept of *liberty* is of great appeal to Sumner; he used it over and over to justify his views on many issues. He associated liberty primarily as a justification for the right of competition and *laissez-faire*, even to the extent to justify

industrial warfare. Sumner contended that individuals are guaranteed the use of all their powers and means to secure their own welfare. Consistent with the laissez-faire school of thought, Sumner viewed property rights as a primary concern and supported the human rights of traditional democracy that does allow for governmental interference with an individual's pursuit of personal welfare. The American ideal of such things as "natural" rights is due to the fact that such rights originate in the mores of society. Sumner stated, "the notion of 'natural' rights is the notion that rights have independent authority in absolute right, so that they are not relative or contingent, but absolute" (Keller and Davie 1934a:358). Inevitably, interests of individuals come into conflict with the interests of others. Determining rights arise from within the in-group. Sumner believed that rights come with responsibilities. Rights and liberties are to be protected by civil law. Law should not restrict liberty, but it should provide proper discipline and punishment to protect the rights of citizens. In addition, Sumner recognized the right of individuals to protect themselves collectively.

As many sociological thinkers believe, Sumner felt that conflict is a natural response to competition over scarce resources. In the struggle for survival, life conditions often create conflict situations between members of the same society. Ironically, individual members of society also depend on one another for their daily survival needs. Sumner (1906) coined the term *antagonistic cooperation* to draw attention to this paradoxical feature of human life. He pointed out that individuals are brought into association and held there by the compulsion of self-interest. He believed that human cooperation exists simultaneously with suppressed antagonisms. Thus, conflict and cooperation are often intertwined and built-in realities of intragroup behavior.

SURVEILLANCE AND SOCIETY

TRADITIONAL SURVEILLANCE

An organized crime figure is sentenced to prison based on telephone wiretaps. A member of a protest group is discovered to be a police informer. These are instances of *traditional surveillance*—defined by the dictionary as, "close observation, especially of a suspected person."

Yet surveillance goes far beyond its popular association with crime and national security. To varying degrees, it is a property of any social system—from two friends to a workplace to government. Consider, for example, a supervisor monitoring an employee's productivity, a doctor assessing the health of a patient, a parent observing his child at play in the park, or the driver of a speeding car asked to show her driver's license. Each of these also involves surveillance.

Information boundaries and contests are found in all societies and beyond that in all living systems. Humans are curious and also seek to protect their informational borders. To survive, individuals and groups engage in, and guard against, surveillance. Seeking information about others (whether within or beyond one's group) is characteristic of all societies. However, the form, content, and rules of surveillance vary considerably—from relying on informers to intercepting smoke signals to taking satellite photographs.

In the fifteenth century, religious surveillance was a powerful and dominant form. This involved the search for heretics, devils, and witches, as well as the more routine policing of religious consciousness, rituals, and rules (e.g., adultery and wedlock). Religious organizations also kept basic records of births, marriages, baptisms, and deaths.

In the sixteenth century, with the appearance and growth of the embryonic nation-state, which had both new needs and a developing capacity to gather and use information, political surveillance became increasingly important relative to religious surveillance. Over the next several centuries, there was a gradual move to a "policed" society in which agents of the state and the economy came to exercise control over ever-wider social, geographical, and temporal areas. Forms such as an expanded census, police and other registries, identity documents, and inspections appeared, blurring the line between direct political surveillance and a neutral (even in some ways) more benign, governance or administration. Such forms were used for taxation, conscription, law enforcement, border control (both immigration and emigration), and later, to determine citizenship, eligibility for democratic participation, and in social planning.

In the nineteenth and twentieth centuries, with the growth of the factory system, national and international economies, bureaucracy, and the regulated and welfare states, the content of surveillance expanded yet again to the collection of detailed personal information to enhance productivity

and commerce, to protect public health, to determine conformity with an ever-increasing number of laws and regulations, and to determine eligibility for various welfare and intervention programs such as Social Security and the protection of children.

Government uses, in turn, have been supplemented (and on any quantitative scale, likely overtaken) by contemporary private sector uses of surveillance at work, in the marketplace and in medical, banking, and insurance settings. The contemporary commercial state is inconceivable without the massive collection of personal data.

A credentialed state, bureaucratically organized around the certification of identity, experience, and competence depends on the collection of personal information. Reliance on surveillance technologies for authenticating identity has increased as remote non-face-to-face interactions across distances and interactions with strangers have increased. Modern urban society contrasts markedly with the small-town or rural community where face-to-face interaction with those personally known was more common. When individuals and organizations don't know the reputation of, or can't be sure of, the person with whom they are dealing, they may turn to surveillance technology to increase authenticity and accountability.

The microchip and computer are, of course, central to surveillance developments and, in turn, reflect broader social forces set in motion with industrialization. The increased availability of personal information is a tiny strand in the constant expansion of knowledge witnessed in the last two centuries, but it is exemplary of the centrality of information to the workings of contemporary society.

THE NEW SURVEILLANCE

The traditional forms of surveillance noted in the opening paragraph contrast in important ways with what can be called the *new surveillance,* a form that became increasingly prominent toward the end of the twentieth century. The new social surveillance can be defined as, "scrutiny through the use of technical means to extract or create personal or group data, whether from individuals or contexts." Examples include video cameras; computer matching, profiling, and data mining; work, computer, and electronic location monitoring; DNA analysis; drug tests; brain scans for lie detection; various self-administered tests; and thermal and other forms of imaging to reveal what is behind walls and enclosures.

The use of "technical means" to extract and create the information implies the ability to go beyond what is offered to the unaided senses or voluntarily reported. Much new surveillance involves an automated process and extends the senses and cognitive abilities through using material artifacts or software.

Using the broader verb *scrutinize* rather than *observe* in the definition, calls attention to the fact that contemporary forms often go beyond the visual image to involve sound, smell, motion, numbers, and words. The eyes do contain the vast majority of the body's sense receptors, and the visual is a master metaphor for the other senses (e.g., saying "I see" for understanding). Yet the eye as the major means of direct surveillance is increasingly joined or replaced by other means. The use of multiple senses and sources of data is an important characteristic of much of the new surveillance.

Traditionally, surveillance involved close observation by a person, not a machine. But with contemporary practices, surveillance may be carried out from afar, as with satellite images or the remote monitoring of communications and work. Nor need it be close, as in detailed—much initial surveillance involves superficial scans looking for patterns of interest to be pursued later in greater detail. Surveillance has become both farther away and closer than in previous times. It occurs with spongelike absorbency and laserlike specificity.

In a striking innovation, surveillance is also applied to contexts (geographical places and spaces, particular time periods, networks, systems, and categories of person), not just to a particular person whose identity is known beforehand. For example, police may focus on "hot spots" where street crimes most commonly occur or seek to follow a money trail across borders to identify drug smuggling and related criminal networks. The new surveillance technologies are often applied *categorically* (e.g., all employees are drug tested or all travelers are searched, not just those whom there is some reason to suspect).

Traditional surveillance often implied a noncooperative relationship and a clear distinction between the object of surveillance and the person carrying it out. In an age of servants listening behind closed doors, binoculars, and telegraph interceptions, that separation made sense. It was easy to distinguish the watcher from the person watched. Yet for the new surveillance with its expanded forms of self-surveillance and cooperative surveillance, the easy distinction between agent and subject of surveillance can be blurred.

In analyzing the rise of modern forms of social control the French philosopher Michel Foucault (1977) drew on British legal theorist Jeremy Bentham's idea for the *panopticon.* Bentham proposed a highly organized system for managing large populations within physically enclosed structures, such as prisons, factories, or schools, in which authorities could see all but not be seen. From a standpoint of social control, this created uncertainty. Inmates could never be sure when they were being watched, and hence through self-interest and habit, it was hoped they would engage in self-discipline.

Well-publicized contemporary warnings (e.g., that an area is under video surveillance) reflect this pattern in seeking to create self-restraint. A general ethos of self-surveillance is also encouraged by the availability of products that permit individuals to test themselves (e.g., for alcohol level, blood pressure, or pregnancy).

In related forms, subjects may willingly cooperate—submitting to personal surveillance to have consumer benefits (e.g., frequent flyer and shopper discounts) or for convenience (e.g., fast track lanes on toll roads in which fees are paid in advance).

Implanted chips transmitting identity and location, which were initially offered for pets, are now available for their owners (and others) as well. In some work settings, smart badges worn by individuals do the same thing, although not with the same degree of voluntarism.

The new surveillance relative to traditional surveillance has low visibility or is invisible. Manipulation as against direct coercion has become more prominent. Monitoring may be purposefully disguised, as with a video camera hidden in a teddy bear or a clock, or it may simply come to be routinized and taken for granted as data collection is integrated into everyday activities (e.g., use of a credit card for purchases automatically conveys information about consumption, time, and location).

With the trend toward ubiquitous computing, surveillance and sensors in one sense disappear into ordinary activities and objects—cars, cell phones, toilets, buildings, clothes. and even bodies. The relatively labor-intensive bar code on consumer goods that requires manually scanning may soon be replaced with inexpensive embedded RFID (radio frequency identification) computer chips that can be automatically read from short distances.

The remote sensing of preferences and behavior offers many advantages, such as controlling temperature and lighting in a room or reducing shipping and merchandising costs, while also generating records that can be used for surveillance.

There may be only a short interval between the discovery of the information and the automatic taking of action. The individual as a subject of data collection and analysis may also almost simultaneously become the object of an intervention, whether this involves triggering an alarm or granting (or denying) some form of access (e.g., to enter a door, use a computer, or make a purchase).

The new forms are relatively inexpensive per unit of data collected. Relative to traditional forms, it is easy to combine visual, auditory, text, and numerical data. It is relatively easier to organize, store, retrieve, analyze, send, and receive data. Data are available in real time, and data collection can be continuous and offer information on the past, present, and future (ala statistical predictions). Simulated models of behavior are created.

The new surveillance is more comprehensive, intensive, and extensive. The ratio of what individuals know about themselves relative to what the surveilling organization knows is lower than in the past, even if objectively much more is known. One way to think about the topic is to note that many of the kinds of surveillance once found only in high-security military and prison settings are seeping into the society at large. Are we moving toward becoming a *maximum security society* where more and more of our behavior is known and subject to control?

Six features of the maximum security society are (1) a *dossier* society in which computerized records play a major role; (2) an *actuarial* society in which decisions are increasingly made on the basis of predictions about future behavior as a result of membership in, and comparisons to, aggregate categories; (3) a *suspicious* society in which everyone is suspected; (4) an *engineered* society in which choices are increasingly limited and determined by the physical and social environment; (5) a *transparent* society in which the boundaries of time, distance, darkness, and physical barriers that traditionally protected information are weakened; and (6) a *self-monitored* society in which autosurveillance plays a prominent role.

SURVEILLANCE STRUCTURES

Several kinds of social structure define surveillance relationships. There is an important difference between *organizational surveillance* and the *nonorganizational surveillance* carried about by individuals.

Large organizations have become ever more important in affecting the life chances of individuals. Organizations are the driving force in the instrumental collection of personal data. At the organizational level, formal surveillance involves a constituency. *Constituency* is used broadly to refer to those with some rule-defined relationship or potential connection to the organization, whether this involves formal membership or merely forms of interaction with it, such as renting a video or showing a passport at a border. All organizations have varying degrees of internal and external surveillance.

The many kinds of employee or inmate monitoring, such as within the "total institutions" studied by Goffman (1961), are examples of the *internal constituency surveillance* found in organizations. Here individuals "belong" to the organization in a double sense. They belong as members. They also in a sense are "belongings" of the organization, being directly subject to its control in ways that nonmembers are not. There is often a loose analogy to the ownership of property.

External constituency surveillance involves watching those who have some patterned contact with the organization—for example, as customers, patients, malefactors, or citizens subject to laws of the state—but who do not "belong" to the organization the way that an employee or inmate does. Credit card companies and banks, for example, monitor client transactions and also seek potential clients by mining and combining databases. Or consider the control activities of a government agency charged with enforcing health and safety regulations. Such an organization is responsible for seeing that categories of persons subject to its rules are in compliance, even though they are not members of the

organization. Nongovernmental organizations that audit and grant ratings, licenses, and certifications have the same compliance function.

Organizations also engage in *external nonconstituency* surveillance in monitoring their broader environment in watching other organizations and social trends. The rapidly growing field of business intelligence seeks information about competitors, social conditions, and trends that may effect an organization. Industrial espionage is one variant. Planning also requires such data, although it is usually treated in the aggregate rather than in personally identifiable form.

With the widespread accessibility (democratization?) of surveillance techniques and the perception that they are needed and justified, whether for protective, strategic, or prurient reasons, *personal surveillance,* in which an individual watches another individual apart from an organizational role, is commonplace.

This may involve *role relationship surveillance* as with family members (parents and children, the suspicious spouse) or friends looking out for each other (e.g., monitoring location through a cell phone). Or it can involve *nonrole relationship surveillance,* as with the free-floating activities of the voyeur whose watching is unconnected to a legitimate role.

With respect to the roles played, we can identify the *surveillance agent* (watcher/observer/seeker) who desires personal information about a *surveillance subject.* All persons play both roles, although hardly in the same form or degree, and this shifts depending on the context and over the life cycle, and as noted the roles are sometimes blurred.

Within the surveillance agent category, the surveillance function may be *central* to the role, as with police, private detectives, spies, work supervisors, and investigative reporters. Or it may simply be a *peripheral* part of a broader role whose main goals are elsewhere, as with checkout clerks who are trained to look for shoplifters, or dentists who are encouraged (or required) to report suspected child abuse when seeing bruises on the face.

A distinction rich with empirical and ethical implications is whether the situation involves those who are a party to the generation and collection of data (*direct participants)* or instead involves a *third party.* A third party may legitimately obtain personal information through contracting with the surveillance agent (e.g., to carry out drug tests or to purchase consumer preference lists). Or personal information may be obtained because confidentiality is violated by the agent or because an outsider illegitimately obtains it (wiretaps, hacking). The presence of third parties raises an important "secondary use" issue—that is, can data collected for one purpose be used without an individual's permission for unrelated purposes? In Europe, the answer generally is "no," although that is less the case in the United States where a much freer market in personal information exists.

An important distinction that often involves power differentials is whether the surveillance is *nonreciprocal* or *reciprocal.* The former is one-way, with personal data going from the watched to the watcher (e.g., employers, merchants, police, wardens, teachers, parents). With reciprocal surveillance, it is bidirectional (e.g., many conflicts, contests, and recreational games).

Surveillance that is reciprocal may be *asymmetrical* or *symmetrical* with respect to means and goals. Thus, in a democratic society, citizens and government engage in reciprocal but distinct forms of mutual surveillance. For example, citizens can watch government through freedom-of-information requests, open hearings and meetings, and conflict-of-interest and other disclosures required as a condition for running for office. But citizens cannot legally wiretap, carry out Fourth Amendment searches, or see others' tax returns. In bounded settings, such as a protest demonstration, there may be greater equivalence with respect to particular means (e.g., police and demonstrators videotaping each other).

In organizational settings, power is rarely all on one side, whatever the contours of formal authority. Lower-status members are not without resources to watch their superiors and to neutralize or limit surveillance. Video and audio monitoring tools are widely available. Employees may document harassment and discrimination with a hidden recorder and file complaints that will mobilize others to scrutinize a superior.

Even without equipment, being on the scene permits surveillance through the senses. In spite of the power differences, butlers, servants, and valets are often believed to know much more about their employers than the reverse, although this is not formally defined by the role.

Many settings of organizational conflict show *symmetrical reciprocated surveillance* in which the contending parties are roughly equivalent. Games such as poker involve this, as do some contractual agreements and treaties (e.g., the mutual deterrence of nuclear arms control sought through reciprocal watching).

Symmetrical forms may be present even in the absence of formal agreements. Spies (or more neutrally) intelligence agents, whether working for countries, companies, or athletic teams are often mirror images of each other. They offensively seek to discover their opponent's information and defensively to protect their own.

Agent-initiated surveillance, which is particularly characteristic of compliance checks such as an inspection of a truck or a boat, can be differentiated from *subject-initiated surveillance* such as submitting one's transcript, undergoing osteoporosis screening, or applying for a job requiring an extensive background investigation. In these cases, the individual makes a claim or seeks help and essentially invites, or at least agrees to, scrutiny.

With agent-initiated surveillance, the intention is always to serve the goals of the organization. Yet this need not

necessarily conflict with the interests of the subject; consider, for example, the protection offered by school-crossing guards or efficient library service dependent on good circulation records. Public health and medical surveillance have multiple goals, protecting the community as well as the individual. Efficiently run companies provide jobs and services. Providing a limited amount of personal information on a warranty form and having a chip record usage of an appliance such as a lawn mower or a car may serve the interest of both consumers and businesses (e.g., being notified if the manufacturer finds a problem or offering proof of correct usage if the device fails).

Subject-initiated surveillance may reflect goals that serve the interests of the initiator, but these goals often overlap the goals of the surveilling organization. Consider some protection services that have the capability to remotely monitor home and business interiors (video, audio, heat, gas, motion detection) or health systems for remotely monitoring the elderly and ill (e.g., an alarm sent if the refrigerator of a person living alone is not opened after 24 hours). As forms of surveillance more likely to involve informed consent, these are less controversial than surveillance carried out secretly by an agent.

What is good for the organization may also be good for the individual, although that is not always the case and, of course, depends on the context. Social understanding and moral evaluation require attending to the varied contexts and goals of surveillance. The many settings and forms of surveillance preclude any easy explanation for what causes it. A multiplicity of causes at different levels can be identified, and their relative importance varies over time and across areas and on the kind of question asked (e.g., the development of a technology, patterns of diffusion, initial adoption vs. continued use or disappearance).

Two broad opposed views of the new surveillance can be identified. One optimistically places great faith in the power of technology and welcomes ever more powerful surveillance as necessary in today's world where efficiency is so valued and where there are a multiplicity of dangers and risks. More pessimistic is the Frankensteinian/Luddite view that surveillance technology is inhuman, destructive of liberty and untrustworthy. Clearly, surveillance is a sword with multiple edges. The area is fascinating precisely because there are no easy scientific or moral answers.

Value conflicts and ironic conflicting needs and consequences make it difficult to take a broad and consistent position in favor of, or against, expanding or restricting surveillance. For example, we value both the individual and the community. We want both liberty and order. We seek privacy and often anonymity, but we also know that secrecy can hide dastardly deeds and that visibility can bring accountability. But too much visibility may inhibit experimentation, creativity, and risk taking.

In our media-saturated society, we want to be seen and to see, yet we also want to be left alone. We value freedom of expression and a free press, but we do not wish to see individuals defamed or harassed. We desire honesty in communication and also civility and diplomacy. We value the right to know but also the right to control personal information. The broad universalistic treatment citizens expect may conflict with the efficiency-driven specific treatment made possible by fine-honed personal surveillance.

Whatever action is taken, there are likely costs, gains, and trade-offs. At best, we can hope to find a compass rather than a map and a moving equilibrium rather than a fixed point for decision making.

Surveillance practices are shaped by manners, organizational policies, and laws that draw on a number of background value principles. Many of these were first expressed in the Code of Fair Information Practices developed in 1973 for the U.S. Department of Health, Education and Welfare.

The code offered (1) a *principle of informed consent* that says the data collection is not to be done in secret—individuals are to be made aware of how it will be used and, under ideal circumstances, consent to it; (2) a principle of *inspection and correction* that says individuals are entitled to know what kind of information has been collected and to offer corrections and emendations; (3) a *principle of data security* that says the information will be protected and precautions must be taken to prevent misuses of the data; (4) *a principle of validity and reliability* that says organizations have a responsibility to ensure the appropriateness of the means used and the accuracy of the data gathered; and (5) *a principle of unitary usage* that says information gathered for one purpose is not to be used for another without consent.

As new surveillance technologies and problems have appeared, additional principles have emerged. These include (1) a *principle of minimization* such that only information directly relevant to the task at hand is gathered; (2) a *principle of restoration* such that in a communications monopoly context those altering the privacy status quo should bear the cost of restoring it; (3) *a safety net or equity principle* such that a minimum threshold of information should be available to all; (4) a *sanctity of the individual and dignity principle* in which there are limits (even with consent) on the commodification and offering of personal information; (5) a *principle of timeliness* such that data are expected to be current and information that is no longer timely should be destroyed; (6) *principle of joint ownership of transactional data* such that both parties to a data-creating transaction should agree to any subsequent use of the data, including the sharing of benefits if appropriate; (7) a *principle of consistency* such that broad ideals rather than specific characteristics of a technology govern surveillance practices; (8) a *principle of human review* such that an automated decision is always subject to review by a person; and (9) a *principle of redress* such that those subject to

inappropriate surveillance have adequate mechanisms for discovering and being compensated for the harm.

SYMBOLIC INTERACTION

Symbolic interaction is a perspective in sociology that places meaning, interaction, and human agency at the center of understanding social life. This perspective grew out of the American philosophical tradition of pragmatism, an approach developed in the late nineteenth century by Charles Peirce, William James, and John Dewey. Challenging the assumptions of classical rationalism, these thinkers regarded people as actors rather than reactors, treated "reality" as dynamic and pluralistic, linked meanings to social acts and perspectives, and viewed knowledge as a key resource for problem solving and reorganizing the world.

George Herbert Mead brought pragmatist philosophy to sociology, working its assumptions into a theory and method for the social sciences. Drawing on the ideas of the pragmatist founders, as well as the theories of Charles Horton Cooley, Charles Darwin, and Wilhelm Wundt,

Mead developed a distinctly sociological account of human consciousness, selfhood, and action. He presented this perspective in a series of social psychology lectures that became the basis for his best-known book, *Mind, Self, and Society* (1934). Mead's insights impressed many of his students, notably Herbert Blumer, who later became a distinguished sociologist at the University of California at Berkeley and president of the American Sociological Association. Blumer's compilation of writings, *Symbolic Interactionism* (1969), is still widely acknowledged as the major statement of the symbolic interactionist perspective. Mead and Blumer belonged to a group of other early sociologists, including Robert Park, W. I. Thomas, and Everett Hughes, who studied related topics such as roles, selves, social definitions, and socialization. Because most of these scholars were affiliated with the University of Chicago, symbolic interactionism is often referred to as the Chicago School of Sociology, even though another variant of the perspective emerged later at the University of Iowa.

Blumer coined the label "symbolic interactionism" in 1937 while writing an essay on social psychology for a social science textbook. In that essay, Blumer emphasized how Mead's work could provide the basis for a new social psychological approach that would transcend the deterministic theories of the time. Mead is usually credited as the originator of symbolic interactionism, even though Blumer's analysis drew heavily on the ideas of other theorists and, according to some critics, differed in important respects from Mead's writings.

Blumer, along with Everett Hughes, influenced cohorts of graduate students he taught at the University of Chicago in the 1940s and early 1950s. These students, including Howard Becker, Fred Davis, Elliot Friedson, Erving Goffman, Joseph Gusfield, Helena Lopata, Tamotsu Shibutani, Gregory Stone, Anselm Strauss, and Ralph Turner, further developed the symbolic interactionist perspective and shaped a number of its subfields, such as deviance, social problems, self and identity, and collective behavior. They have since become recognized as the Second Chicago School.

GUIDING PRINCIPLES AND ASSUMPTIONS

Blumer (1969) articulated the core premises of symbolic interactionism:

The first premise is that human beings act toward things on the basis of the meanings those things have for them. . . . The second premise is that the meaning of such things is derived from, or arises out of, the social interaction that one has with one's fellows. The third premise is that these meanings are handled in, and modified through, an interpretive process used by the person in dealing with the things he [or she] encounters. (p. 2)

Other related assumptions inform and guide this perspective:

1. *Human beings are unique in their ability to use symbols.* Because people rely on and use symbols, we do not usually respond to stimuli in a direct or automatic way; instead, we give meanings to stimuli and then act in relation to these meanings. Our behavior is different from that of other animals or organisms, which act through instincts or reflexes. We learn what things mean as we interact with others. In doing so, we rely heavily on language and the processes of role taking and communication it facilitates. We learn to see and respond to symbolically mediated objects— objects that have names such as water, ground, student, professor, book, and library. These objects become part of the reality we create and negotiate through interaction.

2. *People become human through interaction.* Through social interaction, we learn to use symbols, to think and make plans, to take the perspective of others, to develop a sense of self, and to participate in complex forms of communication and social organization. Interactionists do not believe that we are born human. They argue instead that we develop into human beings only through interaction with others. Interactionists acknowledge that we are born with certain kinds of biological "hardware" (e.g., a highly developed nervous system) that gives us the potential to become fully human, but they contend that involvement in society is essential for realizing this potential.

3. *People are conscious, self-reflexive beings who shape their own behavior.* The most important capacities that we develop through our involvement in social interaction are the "mind" and the "self." By developing the capacity to see and respond to ourselves as objects, we learn to interact with ourselves, or think. As we think, we shape the meaning of objects in our world, accepting them, rejecting them, or changing them in accord with how we define and act toward them. Our behavior, then, is an interplay of social stimuli and our responses to those stimuli. In making this assertion, interactionists embrace a voluntaristic image of human behavior. They suggest that we exercise an important element of autonomy in our actions. At the same time, interactionists understand that a variety of social factors, such as language, culture, race, class, and gender, constrain our interpretations and behaviors. Thus, interactionists can be characterized as "soft determinists"; they presume that our actions are influenced but not determined by social constraints.

4. *People are purposive creatures who act in and toward situations.* For interactionists, we don't "release" our behavior, like tension in a spring, in response to biological drives, psychological needs, or social expectations. Rather, we act *toward situations.* Our actions are based on the meaning we attribute to the situation in which we find ourselves. This "definition of the situation" emerges from our interactions with others. We determine the meaning of a situation (and our subsequent actions) by taking account of others' intentions, actions, and expressions. We select lines of behavior that we believe will lead to our desired ends. Our predictions may be wrong; we do not necessarily act wisely or correctly. Nor do we always pursue goals in a clear-cut or single-minded way. Once we begin acting, we may encounter obstacles and contingencies that may block or distract us from our original goals and direct us toward new ones. Our actions and intentions, then, are dynamic and emergent.

5. *Society consists of people engaging in symbolic interaction.* Following Blumer, interactionists conceive of the relationship between society and the individual as both fluid and structured. This relationship is grounded in individuals' abilities to assume each other's perspectives (or "role take"), to adjust and coordinate their unfolding acts, and to interpret and communicate these acts. In emphasizing that society consists of people interacting symbolically, interactionists part company with psychologistic theories that see society as existing primarily "in our heads," either in the form of reward histories or socially shaped cognitions. Interactionists also depart from structuralists who conceive of society as an entity that exists independently of individuals, dictating our actions through imposed rules, roles, statuses, and structures. We are born into a society that frames our actions through patterns of meaning and rewards, but we also shape our identities and behaviors as we make plans, seek goals, and interact with others in specific situations. That which we call "society" and "structure" are human products, rooted in joint action. Thus, "'society' and 'individual' do not denote separable phenomena" (Cooley 1902/1964:36–37). People acquire and realize their individuality (or selfhood) through interaction and, at the same time, maintain or alter society.

6. *Emotions are central to meaning and behavior.* Since the late 1970s, interactionists have attended more to the importance of emotions in understanding social life. Although other sociologists have bracketed emotions, relegating them to the psychological or biological realm, interactionists have recognized that "social factors enter not simply before and after but *interactively* during the experience of emotion" (Hochschild 1983:211). Arlie Hochschild, Candace Clark, Spencer Cahill, Sherryl Kleinman, and other interactionists have studied feeling rules—guidelines for how we are expected to feel in particular situations—and the emotion work we do when our feelings do not measure up to situational norms. Feelings may also put our moral identities into question: Can we believe we are good people if we have feelings that violate our ideals? Groups and organizations have different cultures of emotions; participants expect members to experience

particular emotions and to display them. In their research, interactionists ask not only what objects mean to participants but also how they feel about them and whether those feelings fit with or challenge the norms of the group.

7. *The social act is the fundamental unit of analysis.* Interactionists contend that the social act, or what Blumer referred to as joint action, is the central concern of sociology. A "social act" refers to behavior that in some way takes account of others and is guided by what they do; it is formulated so that it fits together with the behavior of another person, group, or social organization. It also depends on and emerges through communication and interpretation. This covers a diverse array of human action, ranging from a handshake, a kiss, a wink, and a fistfight to a lecture, a beer bash, a funeral, or a religious revival. Whenever we orient ourselves to others and their actions, regardless of whether we are trying to hurt them, help them, convert them, or destroy them, we are engaging in a social act. We align our behaviors with others, whether acting as individuals or as representatives of a group or organization.

In focusing on social acts, interactionists are not limited to examining the behavior of individuals or even small groups. They also consider the social conduct of crowds, industries, political parties, school systems, hospitals, religious cults, therapeutic organizations, occupational groups, social movements, and the mass media. Inspired by Herbert Blumer (1969), they regard the domain of sociology as "constituted precisely by the study of joint action and the collectivities that engage in joint action" (p. 17).

8. *Sociological methods should enable researchers to grasp people's meanings.* Blumer noted that people act on the basis of the meanings we give to things. Interactionists believe it is essential to understand those meanings, seeing them from the point of view of the individuals or groups under study. To develop this insider's view, researchers learn to empathize with—"take the role of"—the individuals or groups they are studying (Blumer 1969). In addition, interactionists observe and interact with these individuals or groups in their "natural" setting. This in-depth approach enables researchers to learn how social actors accept, defy, or reconstruct their everyday worlds.

RECENT TRENDS AND NEW DIRECTIONS IN INTERACTIONIST ANALYSIS

Critics contend that interactionists' emphasis on how people make roles, define situations, and negotiate identities leads them to ignore or downplay how our individual behavior is constrained by social structure. Yet analysis of the link between individual agency and social structure has a long history in interactionist thought, especially in the writings of Mead, Cooley, Blumer, and Goffman. In recent years, it has become the focus of interactionist studies of social organization and collective action, power and inequality, and the nature and foundations of the self.

Social Organization and Collective Action

Symbolic interactionism addresses issues that extend beyond microsociological concerns. Even in the early years of interactionism, Herbert Blumer wrote about organizations in his studies of collective behavior, industrial relations, and race relations. As a professor at the University of Chicago, Blumer served as a labor negotiator and deeply appreciated the power of unions, corporations, and interest groups. During the past couple of decades, interactionists have addressed macrosociological issues through the concept of *mesostructure,* an intermediate level of analysis between the microstructural concerns of social psychology and the macrostructural concerns of organizational theory (Maines 1977). Mesostructure refers to the level of organization within which interaction occurs.

In examining mesostructure, interactionists analyze how power relations and social constraints play out in organizational actors' behaviors. For example, Harvey Farberman studied how the practices of used car dealers are shaped by the structure of their relationships with car manufacturers. The manufacturers impose a system of sales on the dealers that force them to operate with a small profit margin. Consequently, the dealers have to squeeze every dollar they can from their customers, exploiting them through a variety of money-making "rackets," including "charging for labor time not actually expended, billing for repairs not actually done, replacing parts unnecessarily, and using rebuilt parts but charging for new parts" (Farberman 1975:457).

Since the late 1970s, interactionists have used mesostructural analysis to study a wide array of organizations, including hospitals, churches, restaurants, court systems, the mass media, the arts, welfare agencies, scientific groups, athletic teams, educational institutions, and even civilizations. They have used concepts such as meaning, frame, network, career, metapower, and negotiated order to examine the links between "micro" and "macro" levels of social reality.

They have shown how interactions in local organizations, such as a business, emerge from and are influenced by the structural conditions in which they are embedded. For example, restaurants strive to fit into a market niche. Every owner wants to develop a strong and loyal customer base so that the restaurant will be predictably profitable. To do this, the owner must consider likely customers, their culinary desires, and how much they are willing to spend. These factors influence how much the owner or manager spends on food, how many cooks he or she hires, and how much he or she pays them. Ultimately, the restaurant as an organization depends on its customers and on the owner's need for profit. As a result, many dishwashers or "potmen" are high school students, undocumented immigrants, or

individuals with developmental disabilities. In each case, the restaurant management hires those who are willing to work for minimum wage, largely because of their structural position in our society. Thus, although a restaurant is an interactional arena, it is also an organization that operates within the structural parameters of a market economy. The dynamics of this economy shape the structure and interactions that occur within the organization (Fine 1996).

In addition to studying how people reproduce structure within the interactional arena of organizations, interactionists have turned their attention to the dynamics of collective action and social movement organizations. David Snow and his colleagues (1986) have illustrated how social movements are organized through "frames" and frame alignments that shape the outlooks and behavioral choices of participants. Members of social movements search for frameworks of meaning to answer the question, "What is going on here?" Some frames legitimate violent protest (the frame of oppression), whereas other frames (the frame of moral justice) diminish the probability of violence.

Interactionist analyses of social structure and collective action have revealed how organizational relations are shaped and reproduced by means of symbolic negotiation, thus sharing common features with smaller-scale, face-to-face negotiations. Even large-scale organizations—governments, multinational corporations, and international social movements—depend on symbolic meaning and are grounded in and sustained through patterns of interaction.

POWER AND INEQUALITY

Some interactionists analyzed power and politics over 30 years ago, but others were slow in following their lead. During the past decade, interactionists have done more extensive research on political power, conflict, and negotiation, especially when examining the construction of social problems. In exploring how issues get defined as social problems, interactionist scholars have studied the interpretive, claims-making activities of social problems of entrepreneurs. Scholars have pointed out how these activities unfold in a context of competing and conflicting claims—a context in which some actors are privileged over others for various political and structural reasons.

This approach to social problems has led interactionists to analyze broader sociohistorical changes in U.S. society, such as the medicalization of deviance. Interactionists have examined how people use metaphorical images and rhetorical strategies to define certain phenomena as social problems and to build consensus that action needs to be taken to constrain the behaviors of others. Studies of social problems have enabled interactionists to integrate macrosociological questions more fully into their analyses and, in so doing, to develop the foundations for a "critical interactionist" approach to social life.

Perhaps the best example of a critical interactionism is found in the work of Michael Schwalbe, who has blended the insights of Marx and Mead in studying the labor process, identity work, and the reproduction of inequality. Recently, Schwalbe and his colleagues (2001) have identified four generic social processes through which inequalities are created and sustained. These include (1) *oppressive othering* (how powerful groups seek and sustain advantage through defining members of less powerful groups as inferior), (2) *boundary maintenance* (how dominant groups protect their economic and cultural privileges by maintaining boundaries between themselves and subordinate groups), (3) *emotion management* (how groups suppress or manage potentially destabilizing feelings, such as anger, resentment, sympathy, and despair), and (4) *subordinate adaptations* (how members of subordinate groups adapt to their unequal status and, in some cases, reproduce it). These four social processes provide links between local, everyday interactions and larger structural inequalities.

Peter Hall has integrated neo-Marxist and interactionist perspectives in analyzing power, politics, and the organization of the policy process. Hall has examined how politicians, including U.S. presidents, manage impressions and manipulate symbols to "reassure" the public, promote the public's quiescence, and discourage people's participation in the political process. In his investigations of policymaking, Hall has revealed how and why the organizational context of policy shapes and mediates the policy process.

Another variant of critical interactionism is found in analyses that blend feminist and interactionist perspectives. What distinguishes these analyses is their focus on how everyday practices sustain or disrupt gender inequalities. For example, Candace West and Don Zimmerman (1987) used feminist, interactionist, and ethnomethodological insights to explain how people "do gender" through their routine conversations and interactions. West and Zimmerman highlight how people perform and reproduce gender, individually and institutionally. By showing that gender is a performance, West and Zimmerman acknowledge that people can change or undermine the gender order.

Scholars adopting a feminist interactionist approach have also analyzed power relations, studying how men exercise and maintain conversational advantage through interruptions, topic changes, and language style. In addition, they have studied the "sexual politics" that characterize family relationships, organizational life, and a wide range of face-to-face communications.

Feminist interactionism has had a large impact on the sociology of emotions. Research conducted at airlines, law firms, power plants, police departments, alternative health care clinics, and weight loss associations reveal how organizations manufacture sentiments and regulate emotional display while requiring women to engage in unrecognized and devalued work.

The Nature and Foundations of the Self

Interactionists have always emphasized the social nature and roots of the self. As Mead noted, people develop the capacity for reflexive selfhood through interacting with others. It is through interaction that we learn to take the role of others and see ourselves as social objects, much like other social objects. Moreover, it is through interaction that we experience, sustain, and transform our sense of who we are. Our sense of selfhood, then, is inextricably linked to our relationships with others. It is both a social product and a social process.

Interactionists generally agree about how the self emerges and develops, but they differ in the relative weight they accord to the structure of the self, on one hand, and the processes through which the self is created and enacted, on the other. Scholars who place emphasis on the structure of the self are sometimes referred to as "structural interactionists." They focus on the nature and relevance of the "self-concept," or the overarching view that an individual has of himself or herself. In analyzing the self-concept, structural interactionists highlight its contents and organization and consider how it shapes a person's behavior across different situations. They also propose that it is best to study and measure the self-concept through traditional quantitative methods (e.g., survey questionnaires or laboratory experiments).

Interactionists who emphasize the self-as-process focus on how people create and enact selves; they also assert that the self is best studied through ethnographic methods. Some of these "processual interactionists" embrace Erving Goffman's dramaturgical perspective. In this view, there is no "real" self, only a set of masks and situated performances that a person enacts. Instead of carrying a core self from situation to situation, the person fashions a self anew in each social interaction, generating expressive cues and managing the impressions of an audience to realize desired identities and outcomes. Other processual interactionists adopt a less situational perspective on the self. They acknowledge that people bring fairly stable self-concepts to social situations while also recognizing that these self-concepts change over time. Some analysts focus on the broad changes in American culture that have produced differences in the places where people anchor their fundamental images of self. In the 1950s and 1960s, Americans had relatively enduring and consistent conceptions of self that were anchored in the social institutions to which they belonged, such as families, workplaces, churches, or schools. More recently, Americans have developed a "mutable" sense of self, anchored more in impulses than institutions and flexibly adaptive to the demands of a rapidly changing society (Turner 1976).

Although differing in the relative weight they accord to the structural and processual aspects of the self, the vast majority of interactionists acknowledge the influence of social structural factors (e.g., race, class, gender, and culture) on the development and expression of selves. Their disagreements revolve around the degree of agency that people have in addressing and negotiating these structural constraints. Even postmodern interactionists, who are less structural in orientation than many interactionists, link the expression of the self to the dynamics of late capitalist or "postmodern" societies. For example, Gergen argues that the faster pace of life and communications in postmodern societies has overwhelmed people, leaving them with selves "under siege." Consequently, identities have become fragmented and incoherent. Under postmodern conditions, the concept of the self becomes uncertain and "the fully saturated self becomes no self at all" (Gergen 1991:7). People face a daunting challenge in building and sustaining an integrated sense of self because the social structures that surround the self are fleeting and unstable. As James Holstein and Jaber Gubrium (2000) observe, contemporary times are challenging for the self because it is being produced in a rapidly growing, widely varying, and increasingly competitive set of institutions. Self-construction has become a big business, characterized by the proliferation of institutions that make it their stock-in-trade to design and discern identities for us. Gubrium and Holstein call for interactionists to shift the focus of their analyses beyond the situational construction of selves toward the institutional production of selves. By doing so, interactionist scholars can continue to push their perspective beyond traditional social psychological concerns and toward the domains of macrosociology.

FUTURE PROSPECTS

Symbolic interactionism is likely to maintain an influential voice in sociology, especially through its academic journal (*Symbolic Interaction*) and its ongoing contributions to various substantive areas and theoretical debates. Given recent trends, interactionist researchers will place greater emphasis on the development of macrolevel concepts and analyses, attending not only on mesostructural phenomena but also on the construction, dynamics, and interrelations of large-scale social structures. Interactionism will become characterized by even greater theoretical and methodological diversity in the next few decades, making it necessary to abandon the old (and somewhat illusory) distinction drawn between the Chicago and Iowa Schools and to speak of interactionist sociologies rather than interactionist sociology. And symbolic interactionism may become a victim of its recent and continuing theoretical successes, hastening its "sad demise" and eventual disappearance within sociology (Fine 1993). As the concepts of interactionism become the concepts of sociology, its voice will become increasingly integrated with, and indistinguishable from, the other voices that make up the

discipline. This has already become evident in the analyses that can be found in many prominent sociological books and journal articles.

Symbolic interactionism's prospects in the twenty-first century will be determined largely by its central mission. If interactionists decide that their key mission is to continue formulating a pragmatic approach to social life—the power of symbol creation and interaction that is at the heart of the sociological imagination—then the future of interactionism will be bright. Guided by this goal, interactionists can expect to build on and extend the inroads they have gained within sociology in recent years. They can also expect their work to have a growing impact on related disciplines, such as gender studies, communication studies, cultural studies, education, and psychology.

T

TAYLOR, CHARLES

Charles Taylor (b. 1931), Canadian social theorist and philosopher of modernity, is an advocate of the hermeneutic approach to social scientific research and author of the highly regarded *Sources of the Self: The Making of the Modern Identity* (1989). Educated at McGill and Oxford, Taylor combines Anglo-American and Continental philosophies to address problems across the social and human sciences. Most notably, Taylor has offered a sustained critique of the naturalist and reductionist accounts of human behavior that have predominated in modern philosophy and social science. More recently, this critique has addressed the nihilistic implications of postmodern and poststructuralist philosophies. As an alternative for the social sciences, Taylor proposes a hermeneutic understanding of human behavior that valorizes the integrity and agency of persons. Human beings are self-interpreting animals who struggle to articulate their position within culturally constituted frameworks of meaning and moral worth. In elaborating this perspective, Taylor has written on issues of broad concern to the social sciences, including epistemology, ethics, language, the self, multiculturalism, the liberal-communitarian debate in political philosophy, and religion. Taylor situates his project within the tradition of philosophical anthropology, indicating his interest in tracing the history of the changing conceptions of human nature in Western philosophy and culture. Although this philosophical anthropology is most clearly exemplified in *Sources of the Self,* its influence on Taylor's method of research and style of argument is also apparent in shorter essays such as his often-cited "The Politics of Recognition" (1994). Taylor is also recognized as an interpreter of the German idealist philosopher Georg Hegel and a commentator on Canadian politics, especially on the question of Quebec's sovereignty within Canada.

Taylor's critique of reductionist social science extends as far back as his first book, *The Explanation of Behavior* (1964), in which he criticizes behaviorist psychology for its efforts to explain human behavior through the lawlike statements exemplified in the natural sciences. In the 1970s and the 1980s, he extended this critique to cognitive psychological and neurophysiological explanations of behavior. Similarly, in "Interpretation and the Sciences of Man" (1971), Taylor finds fault in the kind of political science scholarship that reduces the shared meanings contained in political cultures to the interests of atomistic individuals. Common to these social sciences is the expectation that reductive theories provide explanations of human behavior that can be verified against empirical evidence. This hope, Taylor claims, is dangerously misplaced, because it leads to the elaboration of sciences that cannot help us to understand important aspects of human life. In this respect, Taylor shares much in common with postmodern and poststructuralist authors who aim to deconstruct the scientistic, foundationalist, and individualistic bias of Western thought. However, even as he sympathizes with authors such as Michel Foucault and Jacques Derrida, Taylor argues that poststructuralism reproduces the epistemological errors of Western philosophy by ignoring the integrity of lived personal experience. As such, Taylor advocates a hermeneutic epistemology in which the self-possessed interpretive capacities of human beings assume center stage. Human beings are self-interpreting animals who understand and reflect on the meaning of their lives and their relations to other people. This kind of self-interpretive activity is not based on a priori epistemological principles but on practical knowledge and everyday encounters with cultural frameworks. Furthermore, Taylor marks himself as a philosopher of morality by arguing that interpretation necessarily involves evaluations of moral worth. Human beings are not simply self-interpreters, but they are the kind of interpreters for whom things matter. Precisely what matters is worked

out as individuals articulate their position within the moral spaces constituted by historical communities.

Taylor's hermeneutic project is supported by a philosophy of language that makes appearances throughout his writings but that is most thoroughly developed in the essays contained in the first volume of his philosophical papers, *Human Agency and Language* (1985a). Here, twentieth-century philosophy is characterized by its concern with language and the relation between language and meaning. Two conceptions of language have vied for superiority in twentieth-century thought. Taylor traces the first of these conceptions to Enlightenment scholarship, and in particular, to the influence of John Locke. On this "designative" view, language serves the utilitarian purpose of accurately picturing or representing a preexistent reality. In contrast, the Romantic counter-Enlightenment, as represented in the work of Johann Gottfried von Herder and Jean-Jacques Rousseau, provides a "constitutive" or "expressive" conception of language. In this view, language does not represent a preexisting reality but gives expression to unarticulated sensibilities and feelings. The act of articulation clarifies the meaning of these feelings and constitutes new forms of human understanding. Insofar as they are constituted in language, these newly articulated understandings are communal possessions that deepen self-awareness. While twentieth-century social science has been committed to the designative view of language, Taylor argues that language is most properly an expressive medium.

These philosophical arguments come together in Taylor's history of the modern self, *Sources of Self: The Making of the Modern Identity*. In this book, Taylor argues that selfhood and morality are inextricably intertwined, and he sets out to describe the history of the relation between the self and the good. Taylor is particularly critical of the strand of modernism that seeks to objectify and naturalize all accounts of human selfhood. He deems these incapable of providing an account of the self that captures the depth of personal experience. Nevertheless, Taylor argues that there are elements of modernity that potentially provide for a rich account of the self. Taylor's task, then, is not to reject the modern project but to recover those elements of the project that revivify the idea of authentic selfhood. These arguments overlap with Taylor's work in political philosophy. Like his project on the self, Taylor views his work in political philosophy as an effort to define the political culture of modernity. In this capacity, Taylor has written on the liberal-communitarian debate, defending the communitarian position against the atomism and methodological individualism of political liberalism. As a Canadian in Quebec, Taylor has written on the topic of French-English relations in Canada and has also been called on by parliamentary commissions to address the viability of a continuing Canadian federalism. In these capacities, Taylor has passionately argued for a renewed federalism in which cultural diversity is deepened and sustained through ongoing efforts at cross-cultural communication and mutual understanding. Here, Taylor has also addressed broader issues of nationalism, multiculturalism, and ethnocentricity. He argues that debates about multiculturalism and ethnocentricity emerge from the modern concern with a demand for recognition. While the liberal perspective employs a procedural mechanism to ensure that all cultures are granted equal opportunity for recognition, Taylor adopts a communitarian stance to argue that cross-cultural encounters should involve conversations about the relative worth of cultures and their valued goods.

TELEVISION AND SOCIAL THEORY

Television has been the object of theoretical reflection beginning with debates on "mass society" that heated up in the years following World War II. Residual concerns over the totalitarian temptation to which the vanquished Axis nations fell prey leading up to the war, the rise of the consumer capitalist economy in the West, and Cold War politics focusing on the Soviet Union and its allies made for serious discussion concerning the role of television within democratic society. In the postwar period, researchers and theorists turned the formerly pejorative phrase "mass society" into a descriptor of popular democracy and "liberal-pluralism triumphant." (Bennett 1982:40)

Television loomed large in this rethinking of postwar liberal democracy.

The relationship between the academic study of social communication and the development of contemporary social theory is surveyed by Hanno Hardt in *Critical Communication Studies: Communication, History & Theory in America* (1992). This comprehensive overview identifies two primary tendencies within the field. As it concerns television in specific, the pragmatic tradition in the United States manifests itself in empirically oriented "effects" research, which concerns the psychology of individual reception and the social psychology of resultant group behavior. The challenge to the tradition of "administrative research" is represented by British Cultural Studies beginning in the 1950s, whose intellectual heritage reaches back to the Frankfurt School of critical theory. More recent developments include critiques that owe to feminism, postmodernist thought, critical race theory, and a return to institutional-historical approaches to television and social theory.

So far as any discussion of the relationship between television and social theory is even addressed, the research questions asked by those interested in the "effects" of television tend to assume that the political and economic order that gave rise to this new postwar mass medium of communication is in itself not problematic. Contrary to this approach, those writing specifically about television in the cultural studies tradition understand that the very basis of the sociocultural, political, and economic system needs to be examined in understanding both the mundane reality and transformative potential of the medium. Moreover, the empiricist thrust of conventional research on television in the United States is "marked by a built-in inconclusiveness that forestalls the linkage with social theory, the proper goal of research in the social sciences" (Hamamoto 1989:10).

Most social science literature on television, despite its pose of objectivity, is informed by liberal pluralist social theory whereby conflicting beliefs and values compete for supremacy within a fictive marketplace of ideas. From this matrix of supposedly free exchange has emerged a political-economic system—capitalism—that has proved its fitness by its sheer ability to deliver the greatest good to the largest number within the polity. *The People Look at Television: A Study of Audience Attitudes* (1963) by Gary A. Steiner is a prime example of social science research that legitimates the for-profit system of the three U.S. national networks of the day. Financed by CBS and conducted under the aegis of the Bureau of Applied Social Research at Columbia University, the report combines an argument laden with populist and democratic rhetoric (*vide* "The People") with a show of social science data marshaled to blunt then-current criticism of network television by the Federal Communications Commission (FCC).

The landmark study by Raymond Williams, *Television: Technology and Cultural Form* (1975) represents a rejection of abstracted empiricist social science research in communications. It also put to rest the "technological determinism" of Marshall McLuhan's *Understanding Media: The Extensions of Man* (1964), which had exerted much influence both within academia and among the educated public. Instead, Williams argues that technologies such as television must be understood as the outcome of historical forces arising from bourgeois class interests within advanced capitalism while appreciating the communitarian and democratic values of television's vast audience.

The preliminary attempt by Williams to delve more deeply into the phenomenology of the television viewing experience characterized by what he calls "flow" was taken systematically to a new level by John Fiske in *Television Culture* (1987). This foundational study draws from a number of seminal methodological strategies, including semiotics, discourse theory, ideological criticism, and feminist insights into issues of gender. Fiske advances the claim that audiences often "resist" the dominant reading of television texts and thereby poses a challenge to its otherwise hegemonic power.

Specific television genres such as the "soap opera" and TV creations such as pop star Madonna have been examined from a variety of critical approaches under the heading of "feminist" theory. Liberal, Marxist, poststructuralist, and postmodern feminist theory have given rise to an array of scholarship that explores the relationship between women and patriarchy within capitalist society. The strict focus on women as the object of analysis in feminist theory more recently has been broadened to address more general questions of gender in society. Bearing the influence of postmodern feminist strains of thought in their study of audience "consumption" of TV, Ien Ang and Joke Hermes (1991) argue that even in the face of "hegemonic gender discourse" a fluid gender identity is ever in the process of being "articulated, disarticulated, and rearticulated" (p. 321).

It seems inevitable that the medium of television as a postwar "technology and cultural form" would become emblematic of the "postmodern condition." According to David Harvey in *The Condition of Postmodernity: An Enquiry into the Origins of Cultural Change* (1989), the emergence of postmodernity can be attributed to the proliferation of television viewing in almost all societies. The intertextual semiotic excess, self-reflexive irony, and multivalent meanings generated by TV programs in all their sheer pervasiveness within the larger consumer capitalist culture seem to embody all that is unique to postmodernity. The internal debate among theorists of the postmodern ranges widely and is rife with dubious claims and counterclaims. Where postmodern theory pertains specifically to television studies, however, John Fiske warns against divorcing critical reflection from the politics of capitalist society. He stresses that postmodern critique must remain rooted in material realities.

Race, racial identity, and racism have long been minor components of empirically inflected social science research in television studies. Qualitative and interpretative approaches in television studies emerging from the humanities similarly relegated race to the category of second-class status. Perhaps in response to the political ineffectuality of high theory as it had become enshrined in academia, a return to "race" as a basic category of sociocultural analysis began in earnest beginning in the 1990s. Inspired by pioneering work by J. Fred MacDonald who recounts both the repressive social climate and institutional barriers to racial equality in *Blacks and White TV: Afro-Americans in Television Since 1948* (1983), Darrell Y. Hamamoto provides a radical analysis of U.S. militarism, empire, and immigration and relates this conflicted history to the portrayal of yellow peoples in *Monitored Peril: Asian American and the Politics of TV Representation* (1994).

With the appearance of *Communication and Race: A Structural Perspective* (1998) by Oscar H. Gandy Jr., social constructivist theories of race and racism have been pushed to the foreground in current discussions of the private, for-profit "media system." In particular, the growing body of contemporary scholarship described as critical race theory has done much to shed explanatory light on the origins of institutionalized racism within the system of corporate oligopoly television.

Douglas Kellner in *Television and the Crisis of Democracy* (1990) views the capitalist foundations and imperatives of the commercial "broadcasting system" as antithetical to democracy itself. Respectful of the critical theory tradition while rejecting the tendency of its more elitist proponents to be dismissive of mass media and popular culture, Kellner sees the interlocking system of government, the FCC, and television networks as depriving the television audience of truly democratic communication due to the lack of corporate accountability, highly restricted access to the airwaves, and the narrowness of political perspective presented.

By the turn of the century, the problems identified by Kellner have only expanded and intensified with the supranational global reach of U.S. television and allied media, such as films, recorded music, and publishing. The "global media system" in its megacorporate manifestations is presented in exacting detail by Robert W. McChesney in *Rich Media, Poor Democracy: Communication Politics in Dubious Times* (1999). He argues that the concentration of power among vertically integrated corporate oligopolies poses a grave threat to the free flow of information and diverse opinion vital to the sustenance of democratic society. McChesney concludes with an agenda for "structural media reform" that will allow television to realize its potential for the spread of democratic values and social practices.

THEORY CONSTRUCTION

Theory construction is the process of developing theories in accord with criteria for their production and analysis. A number of texts offer methods for constructing sociological theories; however, at the present time, the field of sociology has no widely agreed-upon set of criteria for building and evaluating theories.

This entry presents criteria for theory construction and theory analysis that are consistent with some of the sociological prescriptions and, more important, with criteria that are widely accepted in other sciences. Before doing so, it is first necessary to discuss briefly some broader issues.

THE CONTEXT OF THEORIES

Theories are repositories of general knowledge. Through testing and refinement, scientific theories change over time in ways that lead them to provide increasingly accurate explanations for ever-widening ranges of phenomena. Their accumulated wisdom far exceeds the ability of common sense to explain the complex world around us. However, sociologists hold different conceptions of what a theory actually is and so do not all agree on criteria for building and evaluating them. Some use the term very broadly so that it includes virtually any sociological conjecture. Others apply more stringent criteria that actually rule out much that usually is called "theory" in sociology. The compromise

adopted here is to distinguish two different kinds of intellectual products: theories and quasi-theories.

Quasi-theories are known by a variety of labels, including *perspectives, frameworks, orientations, metatheories,* and somewhat confusingly, *theories.* As will be illustrated shortly, there are explicit criteria for defining, constructing, and evaluating theories. In contrast, there is no such thing as a uniform set of criteria for quasi-theories. They are loosely bound areas of theoretical work that may include raw ideas, classic statements, discussions about theories or other quasi-theories, sensitizing concepts, empirical observations, research strategies, provisional generalizations, expressions of values, authoritative proclamations, and so on. Despite their indefinite form, however, quasi-theories have played a key role in sociology's development, mainly because they inspire research and new theorizing.

Quasi-theory is just one of several contextual factors that influence the development of theory. Others include prior theories and research findings. Brand-new theories are relatively uncommon, and most new theoretical developments build on existing theories in response to empirical observations. Sociologists of science and other scholars identify still more factors that influence theories directly and indirectly: norms and mechanisms for funding; review and publication practices; the politics of academic disciplines; and even personal characteristics of the theorists themselves. These affect theory primarily by coloring value judgments regarding which issues warrant attention, but they also may introduce bias into the process whereby theories are accepted or rejected. However, upholding rigorous standards for theory construction (and for the empirical testing of theories) at least reduces the unwanted impact of factors unrelated to the accuracy of the theory's claims.

THE ELEMENTS OF THEORIES

A well-constructed theory should have several identifiable components that work together as a system. Although some theorists develop these components in an explicit and self-conscious way, this is generally not the case. However, inattention to a theory's form can impede its function by making it more difficult to identify weaknesses. The various components of theories and their connections to the empirical world are identified next. Following that, there is a discussion of some of the qualities that distinguish better theories.

Arguments

At the heart of every theory is an *argument.* The author of the theory offers the argument in an attempt to convince readers that one or more *conclusions* must follow from a series of assumptions or *premises.* The reader is under no obligation to believe a theory if the premises do not actually support the conclusion or if the theory is ambiguous because some of its terms are undefined. In other words, the theorist is obliged to communicate the theory so that the meanings of its statements are clear to members of an intended audience and the logic by which its conclusions are reached is accessible to anyone interested in using the theory. When inadequate attention is paid to an argument's logical structure, closer inspection often reveals that the conclusions the author wishes to derive do not actually follow from his or her premises—that the conclusions are *invalid.* When this is the case, empirical tests are irrelevant until the problems are repaired.

Ideally, theoretical statements are organized in accord with some explicit logic that provides rules for manipulating statements and deriving new conclusions from them. The theorist may choose from a variety of logical systems, depending on the kinds of statements he or she wants to express. For instance, *sentential logic* applies to natural language statements, and mathematical systems such as *calculus* or *graph theory* apply to statements expressed using specialized symbolic languages.

Premises

In discussions of the logic of argumentation, a *premise* is a conditional statement that links two simpler statements. For example, consider these three simple statements: (A) A group is stratified. (B) A group has a division of labor. (C) Workers are highly productive. These can serve as building blocks for compound statements that serve as premises of a theory:

> **Premise 1**: If a group is stratified, then it has a division of labor.
> **Premise 2**: If a group has a division of labor, then its workers are highly productive.

These may be written symbolically as

A → B (Premise 1)
B → C (Premise 2)

The first simple statement in each premise is the *antecedent condition,* and the second statement is the *consequent.* A well-formed theory contains two or more premises, although they can appear in other formats (e.g., English, algebraic, graphical) and may be referred to by other labels (e.g., *propositions, assumptions, axioms,* or *postulates*) or even obscured by a mountain of extraneous text. More important than formats or labels, however, is their role within the structure of theories: Premises specify the relationships that the theorist assumes to be true and from which

implications may be derived and tested. Furthermore, to play any role in the theoretical argument, each premise must "connect" with one or more other premises—a criterion fulfilled by Statement B in the example.

Conclusions

It is by virtue of their interconnectedness that premises and rules of logic may combine to generate and justify a *conclusion*—another term with special meaning in the world of logic. Conclusions are akin to premises in that they are conditional statements, and they may appear under various labels, including *derivation, theorem,* and *hypothesis.* A conclusion is derived from two or more premises by applying an explicit logical or mathematical principle. For example, a complete argument can be formed using the premises introduced earlier:

$$A \rightarrow B \text{ (Premise 1)}$$
$$B \rightarrow C \text{ (Premise 2)}$$
$$\overline{\phantom{A \rightarrow B \text{ (Premise 1)}}}$$
$$A \rightarrow C \text{ (Conclusion)}$$

In this case, the conclusion is a new statement that takes the argument beyond what was asserted by the premises. It was derived from the two premises by applying a logical principle known as the "Law of Hypothetical Syllogism." Although the logic is fairly intuitive in this case, with richer sets of premises and logical systems it is often possible to generate unexpected and counterintuitive conclusions. If these hold up under empirical testing, they provide compelling evidence that the theory behind them is sound.

Terms

The burden of communicating the precise meanings of a theory's statements rests on its *terms*—the set of words or symbols chosen by the theorist to express premises. Whereas attending to the logical form of a theory helps ensure that its conclusions follow from its premises, attending to a theory's semantic form increases the likelihood that the authors' intended meanings will follow from the terms used to express them.

All terms fall into three categories: *primitive terms, defined terms,* and *logical connectives.* Logical connectives are components of a theory's logical system. They may include terms such as *if*, *then*, and *therefore* in sentential logic, or symbols such as $=, +,$ and Σ if a mathematical framework is used. Logical connectives need not be defined within the theory because they are well defined within the logical framework that the theory invokes.

Primitive terms also are not defined within the theory. They must be chosen by the theorist with the intended readership in mind, and they provide the foundation for the theory's terminological system. If the primitive terms fall short insofar as accurately communicating the theorist's intended ideas, the theory's assertions will be misunderstood by some readers. This will lead to problems in attempting to validate the theory via empirical testing. Whether or not a given test is valid may come down to the interpretation of a single theoretical term. Therefore, the theorist must know what terms will be understood without explicit definition.

Words do not have inherent meanings. To assume so would be committing the "fallacy of essentialism"—that is, assuming that a given term has a "true" or essential meaning. Terms have only the meanings that people give to them. When a theorist cannot be certain that members of the theory's intended audience will share the meaning that he or she intends for a term, then an explicit definition is warranted. Ideally, a definition should specify criteria necessary and sufficient to identify any empirical instance of the term.

Terms used in a definition are part of the theory and so must be chosen with care. The reason for having primitive terms is simple: One cannot define all terms in a theory because of the "infinite regress" problem. Terms in definitions would have to be defined, then all the terms in *those* definitions must be defined, and so on. Instead, primitive terms create a foundation, new terms are defined using those primitive terms, and more specialized terms may be defined using primitive terms and/or previously defined terms. Just as one may diagram the interrelationships of the statements comprising the theoretical argument, one may also diagram the structure of the terminological system to ensure that there are no circularities or gaps.

Scope

For a variety of reasons, a theorist may wish to state provisional limits on the applicability of his or her theory. *Scope conditions* place abstract and general boundaries around the domain in which a theory is intended to apply. Newer theories may be expected to have narrower scope, but with time and the accumulation of research, the scope conditions of the maturing theory are gradually relaxed. From the theorist's standpoint, scope conditions protect the theory from being tested under conditions never intended by the theorist. At the same time, the constraints imposed by scope conditions are abstract and general, and so even a theory with many such conditions still in principle may apply to an infinite number of empirical cases.

Hypotheses

Theoretical statements exist in an abstract world of their own, referring to general classes of phenomena but to nothing in particular. If they are to be convincing, sociological

theories must connect to observable phenomena, and they must conform to those phenomena in reliable and accurate ways. Although sometimes the term is used differently, here we treat *hypotheses* as theoretically motivated statements about relationships between empirical phenomena. Ultimately, a theory must be tested through hypotheses consistent with both theoretical statements and empirical observations.

For abstract theoretical statements to produce hypotheses that pertain to phenomena in the "real world," connections must be established between terms of the theory and *indicators* for those terms. To illustrate using the earlier example, the derived conclusion was "A → C" or "If a group is stratified, then workers are highly productive." To test this claim, we would need to use the definitions of the theoretical terms ("group," "stratified," "workers," "highly productive") to guide the selection of empirical instances. This translation process goes by various names, including *operationalization, instantiation,* and *interpretation.* Finally, the same logical connectives that frame the theoretical statement are used to complete the hypothesis. These relationships may be diagrammed as follows:

From the Theory: $\quad$ A $\rightarrow$ C
Operationalizations:
Hypothesis: $\quad\quad\quad$ $a \rightarrow c$

For example, suppose that the definition of *group* used by a particular theory is "A set of actors, each of which identifies himself or herself as belonging to a common entity." Then one possible operationalization could be "Sociology 330, University of South Carolina, Fall semester 2002," if it is indeed the case that all members of this class would identify themselves as such in a questionnaire or interview. If this class also satisfies the theory's definition of *stratified*, then the antecedent condition of the hypothesis is fulfilled. If *c* is observed—that is, if "highly productive workers" are observed as specified by the definitions of those terms—then the hypothesis is confirmed and we would be justified in raising our confidence in the theory.

Hypotheses may fail tests for any of a number of reasons, some pertaining to the theory, some pertaining to measurement procedures. In other words, a failed test does not immediately necessitate revising or discarding the theory. This is especially true if the theory is well corroborated by other tests and if there is some uncertainty about the empirical methods used in the falsifying test. On the other hand, if the failed hypothesis clearly does operationalize an explicit theoretical assertion and there is high confidence in the integrity of the test itself, then the relevant community of scholars would be obliged to lower their confidence in the theory.

BUILDING GOOD THEORIES

Merely describing the elements of theories neither justifies them nor explains the process by which they evolve over time. One way to address both issues is to review some of the desirable qualities that characterize theories built with explicit attention to these elements, and some of the undesirable qualities that theorists should strive to avoid.

Self-Contradiction

A single contradiction can invalidate an entire argument, so it is very much in the theorist's interest to employ a set of tools designed to detect and eliminate such problems. Careful attention to the theory's logical structure greatly reduces the potential for mutually contradictory statements, circular arguments, invalid deductions, and any number of other fallacies that characterize informal discourse.

Ambivalence and Ambiguity

If there are terms in a theory with multiple meanings, or if the meanings of some terms are unclear, it is highly unlikely that the theory can be communicated effectively to its intended audience. The consequences are important. Readers not applying rigorous standards for theory construction will readily infer meanings for undefined terms. They will assume, often incorrectly, that the meanings they infer are accurate reflections of the theorist's intended meanings. A healthy research-driven discipline depends on accurately communicated theories so that members of a *community* of scholars may submit them to analyses and tests. If a misunderstanding leads to an invalid operationalization of theoretical terms, results of empirical tests have no bearing on the theory and valuable time and resources will have been wasted.

Abstractness and Generality

If theories were supposed to be descriptions of phenomena that occur in specific places and times, there would have to be a theory for each phenomenon at each time and place. Instead, a theory uses *abstract* terms that may connect it to potentially limitless numbers of specific cases and that capitalize on underlying connections between what may appear to be unrelated phenomena. This permits the development of *general* theories—that is, theories that accurately explain wide-ranging phenomena under broad-scope conditions.

Tests and Testability

At crucial points in their development, *tests* subject the implications of theories to the harsh light of empirical

reality. The more tests a theory survives, the more believable the theory. Furthermore, a theory is more compelling to the extent that its tests are stringent and diverse, and that the tested theory performs better than any alternative theories. If a theory is not *testable,* it is not credible. The testability of a theory is diminished by problems with its language or its logic. For example, a theory may be so ambivalent that it can never be disproved, in the same way that "If *x,* then either *y* or not *y*" cannot be falsified. The most powerful theories tend to be those that make the riskiest claims in the sense that there are clearly stipulated ways for them to fail tests.

Parsimony

All else being equal, small and simple theories—those having fewer and simpler terms, premises and scope conditions—are preferable to big complex theories. This is the criterion of *parsimony.* Simpler theories are easier to evaluate and to communicate efficiently and accurately. The expression "theory *construction*" can be misleading in that theories sometimes are improved by *removing* components such as redundant terms and statements with no logical connection to the theory's central arguments.

Evolutionary Progress

In a progressive discipline, theories are not created to be put on display for future generations to admire. They are works in progress that become more general, precise, parsimonious, and so on, through trial and error over extended periods of time. The trial-and-error process operates on several fronts: Definitions are adjusted and sharpened, new conjectures are formulated and tested, old premises are subsumed and extended by new ones, scope conditions are relaxed. The long-term effect is an evolving, ever-improving theory.

THOMAS, WILLIAM ISAAC

William Isaac Thomas (1863–1947), American sociologist and social psychologist, directed the field of sociology away from the abstractions of an earlier generation of "system builders" to concrete studies of group life and social behavior. Thomas was widely regarded as one of the University of Chicago's most productive and original scholars, first as a graduate student (1893–1896) and then as one of the sociology faculty (1896–1918). His greatest, most lasting influence was as a framer of sociological concepts and methodologies, establishing the *life history* (a self-reported narration of life) and the personal document (letters, diaries, archival records) as basic sources for social research. Thomas proposed that social problems required an understanding of both "social organization" and the subjective (experiential) aspects of social reality and a commitment to sociology and social psychology, respectively. He was also an early champion of comparative methods in social science, pioneering comparative studies in culture and personality. *The Polish Peasant in Europe and America* (1918–1920), written with Florian Znaniecki, has been regarded as one of the most important works in American social science and was the subject of several scholarly reappraisals in the years after its publication, the first by Herbert Blumer in 1939. The influence of Thomas on U.S. sociology was also felt through his close friendship and association with Robert E. Park. They met at the 1910 International Conference on the Negro held at the Tuskegee Institute, a meeting that eventually led to Park's appointment at Chicago and their lifelong collaboration.

Thomas was born in rural Virginia and entered the University of Tennessee at Knoxville, graduating in 1884, where he remained as a teacher of Greek and modern languages while undertaking graduate studies in English literature and modern languages, receiving a doctorate in 1886. By his own account, he was moved to pursue learning through the examples of two teachers—a professor of Greek language and culture and a natural scientist who taught him evolutionary science, fields of study that remained part of his distinct interdisciplinary focus throughout his life. In his "Life History," Thomas described his youthful "conversion" to the intellectual and scientific life and his plans to travel to Germany to pursue that life through the study of modern and ancient languages. While on a leave from Tennessee from 1888 to 1889, he studied at Göttingen and Berlin, working in languages and in the new fields of ethnology and the folk psychology of Moritz Lazarus and Heymann Steinthal.

On his return to America in 1889, he accepted his first full-time academic post at Oberlin College as a teacher of English and comparative literature. These early years of reading, learning, and teaching he described as "the most satisfactory of my life." At Oberlin, his interest in social

science was further stimulated by his reading of Herbert Spencer's *Principles of Sociology* from which he took his evolutionary and anthropological view of human development. In 1893, Thomas went to the newly established University of Chicago to pursue a second doctorate in sociology, working under the direction of Albion W. Small and Charles R. Henderson. Thomas's second doctoral dissertation, "On a Difference of the Metabolism of the Sexes," was later developed and published as *Sex and Society: Studies in the Social Psychology of Sex* (1907) and is numbered among the early sociological studies of the social aspects of sexual behavior and relations. It is also an example of Thomas's interest in the social problems of his day that evoked intense moral discussion, such as prostitution and sexual behavior, issues he addressed as problems of "human behavior," using research methods from anthropology, clinical case studies, and fieldwork.

In a second visit to Europe (1896–1897), the year after receiving his doctorate in sociology and while on faculty leave from Chicago, he began to formulate a method and topic he called a "comparative study of European nationalities" and began to outline a study of European peasants and the problem of *immigration.* In 1914, he began a four-year collaboration with Florian Znaniecki that culminated in *The Polish Peasant in Europe and America,* a five-volume work regarded as monumental both for its insights into groups and group processes and for its range of topics: life historical method, including the life history of Wladek, a Polish peasant; theories of personality, culture, and culture change; an attitude-value schema where "attitudes" are the meanings of individual subjects and "values" are the objective social and situational conditions of social actors. This work incorporated a new definition of "attitude," a concept then in use in sociology and psychology; attitudes are distinguished from psychic states and involve a disposition to act toward an object according to its meaning.

A period of major changes in Thomas's professional life began in 1918 with the sudden termination of his faculty appointment at Chicago following a public scandal closely recounted in the *Chicago Tribune.* The charges, violation of the Mann Act and false hotel registration, were later dismissed, but the publicity led to his swift dismissal by the university president and trustees. At age 55, Thomas was never again to secure another full-time academic position. He moved to New York in 1918 where he worked for a year on the Carnegie Corporation's Americanization Studies and collaborated with Robert Park on *Old World Traits Transplanted* (1921). He relied for many years on the support of philanthropists, private foundations, and research institutes for the continuance of his work and for occasional appointments, including research projects culminating in *The Unadjusted Girl* (1923) and another published as *The Child in America* (1928). The latter, sponsored by the Laura Spellman Rockefeller Memorial, was written in collaboration with the sociologist and demographer Dorothy Swaine Thomas whom he married in 1934 and who was elected the first woman president of the American Sociological Society in 1952. His first marriage to Harriet Park, with whom he also collaborated on works of social reform and social policy, ended in divorce in 1934. Thomas worked on the staff of the Social Science Research Council from 1932 to 1933 and lectured at Harvard in 1936 and 1937. His last book *Primitive Behavior* (1936) was a study of cultural history from a "sociopsychological standpoint." Thomas died at age 84 in Berkeley, California.

Thomas is often identified with the concept of the "four wishes" (desires for new experience, mastery, recognition, security), an emphasis in his early thought and work on human instincts and desires. His concept of the "definition of the situation" represents Thomas's later "situational" approach to the study of human behavior, which argues that all determinants of behavior require study and should not be assumed by postulating needs, instincts, or wishes. How situations are defined is a problem about the group and its standards, codified in norms and laws. But it is also a matter of how situations are defined by individuals, since different social experiences lead to different and unique perceptions and evaluations of situations. Human action always begins with this process of defining the situation, but the outcomes of these processes in action are always real: "If men define situations as real they are real in their consequences" (1928:572).

The situational theory of human behavior, the topic of his 1927 presidential address at the American Sociological Society ("Situational Analysis: The Behavior Pattern and the Situation"), shows the influence of, among others, the pragmatist philosophers on his thinking, particularly their efforts to depart from the notion of human beings as mechanisms: Human actions occur in group structures and according to cultural norms, but their activities include the idea that human beings assume attitudes toward these situations and act according to their own definitions of what those situations mean.

TILLY, CHARLES

Charles Tilly (b. 1929) is a U.S. social historian who revolutionized the way that social scientists think about revolutions, social movements, and social change. Educated at Harvard, Oxford, and Angers (France), Tilly provides the metatheoretical and historical framework for resource mobilization and political process theories of collective action, social movements, and social change in his analyses of state making, revolution, and enduring inequality. Tilly incorporates elements of utilitarianism (John Stuart Mill), Max Weber, and Karl Marx in a scathing critique of Émile Durkheim's approach to social change and offers a synthetic theory of collective action based on Marxian interests, Millian opportunities, and Weberian organization. Tilly applies this model in historical analyses of state making and capital accumulation as these affect and are affected by changing forms (*repertoires*) of political protest, particularly in England and France, circa 1500 to 1900. Much of this research was focused on the organization of, and opportunities for, political protest, but his recent work includes a return to the topic of interests, their base in exploitation and opportunity hoarding and their reproduction and institutionalization through processes of emulation and accommodation. Thus, Tilly completes the synthesis of Marx and Weber, leaving unresolved the Millian (utilitarian or rational choice) concerns with rationality and game theory and the relationship between individual and organizational processes. Tilly remains an organizational theorist who uses Mill and Weber to specify the organizational processes through which state making and capitalism have transformed and been transformed by political challenges (based on interests, opportunities, and organizations).

Tilly's dissertation (Harvard 1958), expanded and published as *The Vendee* in 1964, offered French historians a sociological perspective on how urbanization affected the interests and organization of various local actors who mobilized in opposition to the Revolution of 1789. By 1978, in *From Mobilization to Revolution,* Tilly had developed both theory and method to guide the work of social historians and students of social movements and social change. He began with Marx's materialist, relational model of interests rooted in exploitation and added Weberian concepts of political organization to construct a mobilization model in which interest, organization, and opportunities predict collective action. Interests predict organization, and both interests and organization predict the mobilization of resources in preparation for collective action. Interests also affect political opportunity (or threat) for gains (or losses) from collective action and the likelihood and extent of repression (or toleration or facilitation) by governments or other polity members (this, in turn affects power, which, together with mobilization, also predicts opportunity or threat).

Based on this model, Tilly predicts collective action based on mobilization, opportunity or threat, and power. Thus, Tilly challenged the prevailing wisdom of the 1970s by arguing that collective action was rational and purposive rather than affective and expressive. Tilly maintained that collective action was rational at the organizational level (but not necessarily at the individual level) and generally sided with Mill and the utilitarians in opposition to Durkheim and the functionalists, but he insisted that interests were rooted in social relations rather than in personal predispositions. This was particularly evident in his tribute to George Homans (his former teacher) and his scathing review of Durkheim, in *As Sociology Meets History* (1981). Thus, Tilly anticipated the concerns of rational choice while offering a base in classical theory for resource mobilization and political process theories, which became the dominant perspective on social movements and social change in the 1980s.

Equally important, Tilly introduced history as both cause and effect of collective action. Collective action in any particular time and place is rooted in the familiar ways in which people protest injustice, but these repertoires of collective action—these arrays of interactive performances—change substantially in form and content over time. Tilly argues, in *The Contentious French* (1986), that between 1650 and 1850 popular protest was parochial and patronized. Between 1850 and 1980, the modern social movement was born, as the repertoire of collective action became increasingly national and autonomous. The general change from local festivals to modern demonstrations was in large part a response to state making and capitalism, which significantly altered interests, organizations, and opportunities for collective action. Tilly documents a similar change in *Popular Contention in Great Britain, 1758–1834* (1995). Here, however, Tilly clarifies two important points. First, repertoire changes differ across countries, just as state making and capitalism differ. Second, repertoire change is

not determined by changes in economic and political institutions. In fact, collective action is not simply an effect of institutional change but is also a contributing cause.

Tilly argues, in *Roads from Past to Future* (1997), that political challengers are a necessary if not sufficient cause of the revolutionary situations from which modern states and modern capitalism emerged. Here, he shifts emphasis from the effects of institutions on collective action to the effects of collective action on institutional change. This was, however, a major concern in his initial conceptualization. Tilly consistently distinguished *revolutionary situations,* where control of the state is challenged, from *revolutionary outcomes,* which involve a transfer of governing authority to the challengers. Tilly argues, in *European Revolutions, 1492–1992* (1993), that there was considerable variation in revolutionary struggles over time and place but that these variations were explicable within the general framework of the mobilization model. Specifically, variations in interests and organization associated with demands of state making (particularly taxation) and opportunities (including powerful allies and vulnerable authorities) combined to create very different types of revolutionary situations and outcomes.

By 1998, Tilly had returned to the problem of the foundational basis for identifying interests and explaining enduring inequality. In *Durable Inequality* Tilly argues that categorical distinctions (e.g., male-female) are used by organizations to establish, accommodate, or reproduce inequality in organizational relations (e.g., supervisor-supervised). The foundation or goal in establishing these relations is either exploitation (surplus appropriation, as defined by Marx) or opportunity hoarding (monopolizing life-chances, as defined by Weber). Particular instances of inequality (e.g., race) endure, however, because organizations find it cost-effective (efficient, as Millians might define it) to reproduce (or emulate and thereby generalize) forms of inequality that exist in the larger society. Organizations similarly attempt to accommodate these general forms of inequality by adapting organizational relations and thereby institutionalizing this form of inequality as part of the taken-for-granted external environment within which the organization must operate.

TIME AND SOCIAL THEORY

Social theorists writing about time generally agree that in the hands of humans this single linear, objective, natural physical dimension is transformed into multiple structured sociocultural dimensions. "Social" time is overlaid with meaning and value, and the linearity of physical time is reshaped by convention into all manner of "unnatural" forms. Beyond the agreement that *social* must be distinguished from *natural* time, however, there is a great deal of diversity in how social theorists see time and temporality and their relevance to understanding the social.

Social theory's questions begin by asking whether there is a "social" time distinct from both natural-cosmological time and personal-subjective time. How are social processes conditioned by their temporality? How is social reality constituted in and across time? Are there multiple social times associated with different social structures?

THREE BRANCHES

Treatments of time in social theory can be somewhat crudely divided into three categories. The first includes the work of thinkers who have made explicit attempts to do a "sociology of time." The second is composed of work that deals with time explicitly in the course of theorizing other social phenomena. In the third category, we find social theories in which time plays an important, if only implicit, role.

"Sociology of time" perspectives include attempts to define social time, catalog forms of temporal regularity, describe multiple temporalities associated with different forms of social organization, and explain cross-cultural or transhistorical differences in the experience and organization of time. Representative authors in this category are Émile Durkheim, Marcel Mauss and Henri Hubert, Pitirim Sorokin and Robert K. Merton, Georges Gurvitch, Wilbert Moore, Julius A. Roth, and Eviatar Zerubavel.

The second strand—corollary theories of time—has to do with theories of social time elaborated as key components of theories of other phenomena. Included here is work by Karl Marx, Max Weber, Karl Mannheim, George Herbert Mead, Alfred Schütz, Norbert Elias, Niklas Luhmann, Michel Foucault, and Anthony Giddens.

The third strand includes theories of diverse social phenomena—social change, development, diffusion, planning, for example—in which, even though not explicitly thematized, time plays a critical role.

DISTINGUISHING PHILOSOPHY OF TIME FROM SOCIAL THEORY OF TIME

Although there are many overlaps and interdependencies, it is useful to distinguish "time and social theory" from "the philosophy of time." To the latter are generally left questions such as what time is, whether time is real, how time is perceived or experienced, and how human existence is conditioned by its temporality.

Philosophical theories variously identify the origins of temporality in the actual experience of change, birth, growth, decay, and death and the experience of memory, planning, and expectation. For Aristotle (Book IV of the *Physics*) the "sense of time" depends on the mind registering change. St. Augustine, in *The Confessions,* argues that time is a creation of God who is outside of time. Isaac Newton, to the contrary, argued that time is independent of both motion and God. For Immanuel Kant, time is real insofar as all experience is in time, but it is also ideal because it is a form of intuition, logically prior to experience, a contribution of the mind. Henri Bergson distinguished between the time of experience and the mind from the objectified time of clocks, mathematics, and physics. Edmund Husserl employed the phenomenological method to analyze the experience of inner time consciousness. William James described the temporality of the stream of consciousness. Martin Heidegger looks at *Dasein's* continual participation in its coming into being and its being toward death.

From these writers and others, philosophy has bequeathed social theory several dualities which, even if rejected by many theorists, continue to serve as theoretical touchstones. These include *chronos* (time/interval/while) versus *kairos* (opportunity, critical/right moment in time), *aeternitas* (spreading out of time) versus *tempus* (differentiation between past and future), *temps* (objective time) versus *durée* (flow of duration), and linear versus cyclical time.

SOCIOLOGY OF TIME: TIME AS THE OBJECT OF SOCIAL THEORIES

Durkheim is often seen as the founder of the sociology of time. His *Elementary Forms of the Religious Life* is ostensibly about the nature of religion, but its overarching goal is to demonstrate, contra Kant, the social origin of the categories of thought—time, space, class, causality. He locates the social epistemologically between the empiricists' "mind as *tabula rasa*" and the a priorists' "mind as hardwired." Durkheim acknowledges the reality of the subjective experience of time, but suggests that this is not the "time" we are talking about when we ask what time is. As a category, time is not for me, but for us. The framework against which things are temporally located is taken from collective social life. "A calendar expresses the rhythm of the collective activities, while at the same time its function is to assure their regularity. . . . what the category of time expresses is a time common to the group, a social time, so to speak. In itself it is a veritable social institution" (Durkheim [1915]1965:23).

Hubert and Mauss extended this idea, showing how social perception allowed groups to assign to mathematically equal times socially unequal meanings as when the year between 20 and 21 brings new legal rights, but that between 30 and 31 is relatively uneventful. This theme is continued and extended by Sorokin and Merton (1937) who argue that social time is not merely different from astronomical time but that it admits of many variants—social time varies qualitatively across social space. Different calendars, systems of time reckoning, and meanings of temporality are to be expected in different societies, locations within societies, and even in association with different activities.

The idea of a multiplicity of social times is taken up by Gurvitch in *The Spectrum of Social Time* (1964). Gurvitch identifies eight kinds of social time, each associated with specific manifestations of sociability (communion, community, and mass) or "levels of we-ness," types of social groupings, and degrees of continuity-discontinuity and contingency-certainty. "Enduring time" is the time of kinship, families, and local demography, the enduring nowadays of everyday life. "Deceptive time" is the time of the daily round with its routines and surprises. "Erratic time" is the time of irregular life and world events, the uncertainties of ongoing history. "Cyclical time" is the time of dependable recurrences in life. "Retarded time" is the time of social symbols and institutions, which, by the time they attain "reality," they are anchored backward in the past. As tradition and convention, they are used in life moving forward, but are marked by permanence that is backward reaching. By contrast, "alternating time" is the time of rules and algorithms and recipes. It is also based on the past and settled, but it is used in moving forward toward change. The time of economy and industry is alternating time—it depends on what has been learned but is not about mere repetition. "Pushing forward time" is the time of aspiration and innovation. In it, we reach out to the future, pulling the present forward. Finally, "explosive time" is the time of collective creation and revolution. It is the time that allows existing structures to be superseded and replaced.

A different tack on the multiplicities of social time was taken by social ecologists and functionalist thinkers. Here, we see explicit concern with developing taxonomies and typologies of temporal patterning associated with different forms of social organization. Sorokin identified synchronicity and order, rhythm and phases, periodicity and tempo; Hawley focused on rhythm, tempo, and timing. Moore discusses synchronization, sequence, and rates as fundamental sociotemporal processes with respect to a variety of institutions (the family, career, organizations, voluntary associations, and the city). He examines the phenomena of temporal concentration and segregation (as when fresh food wholesaling takes place in the wee hours so that produce is in the stores during shopping hours), temporal complementarity and schedule staggering that ease loads on systems (as when flextime reduces rush hour traffic) but that can also result in temporal mismatches between individuals or institutions (as when shift-working spouses never see one another or working mothers cannot chaperone school trips). Roth described "timetable norms" as collective understandings of proper timing of life events (such as when one can expect to be up for promotion or how long a couple can date before they ought to "get serious").

Zerubavel, in several influential works, consolidates much previous work and explicitly aims to establish a sociology of time (e.g., Zerubavel 1981, 1985) by examining phenomena such as schedules, calendars, public or private time, the week, and holidays. In contrast to more ecological approaches above, which focus on the temporal patterning of social life, Zerubavel's objective is to elucidate the *social foundations* of temporal patterning. By analogy to Goffman's public order, he focuses on "sociotemporal order," which he differentiates from biotemporal and physiotemporal orders. His analysis is built around the recognition of four forms of sociotemporal regularity that are neither natural nor individually voluntaristic but are, rather, conventional: (1) sequential structure (collective agreement about the proper temporal order of activities), (2) duration (how long things should last), (3) temporal location (what should be done when—schedules), and (4) rates of recurrence (how often things occur). These forms can be found at scales ranging from cognition and social interaction to organizations and whole societies. They are typically overlaid with normative prescriptions, and temporal ordering is implicated in the general social order.

COROLLARY THEORIES OF TIME

Many writers have developed treatments of time and temporality as corollaries to the investigations of other phenomenon. Time plays a role, for example, in Schütz's theory of social action, Mannheim's sociology of knowledge, and Giddens's theory of structuration. Mead, Elias, and Luhmann are often cited as theorists of time, but here,

too, their analyses of temporality are in service of other issues. Yet another set of theorists who deal with temporality in their analyses of the rationalization of society includes Marx, Weber, and Foucault, among others.

Temporal considerations in Alfred Schütz's work on the meaning of action, routinization, social relationships, and multiple realities are important both in the field of phenomenological sociology and beyond it. Schütz used Husserl's phenomenology to provide a social psychological foundation for Weber's theory of meaningful social action. If meaning is retrospective and requires reflection, how can forward-looking action be meaningful? How can an actor be consciously rational, aware of his or her "in-order-to" motive? Schütz employs Husserl's theory of inner time consciousness to show how a future act can be apprehended in the future perfect tense and hence be a part of the actor's choosing projects of action. Routinization is the process whereby such chosen, meaningful courses of action become typified and taken for granted as "I can do it again." The world of others is temporally structured. Schütz divides it first into those who are temporally inaccessible (predecessors and successors) and those who are temporally accessible. Those with whom we share time are further divided into those who are spatially not accessible (contemporaries) and those who are (consociates). With the latter group, there is the possibility of sociation in its ideal form, the We-relation, in which, Schütz says, our inner times gear into one another and we "grow older together." In addition to everyday waking reality, Schütz has theorized "multiple realities" of fantasy, dreaming, and scientific theory. Each reality, according to Schütz, has its own distinctive "temporal style."

Marx's analysis of ideology introduced the idea that knowledge and ideas are historically contingent. More generally, Mannheim's sociology of knowledge implies a temporal component in the meaning of all social and cultural phenomena. He also introduced the idea of time as identity and social location, and generations as collective identities in his essay "The Problem of Generations" (1952). Contemporary work on cohorts and historical generations, the importance of biographical phases, and the life course as a structure of analysis continues this tradition.

Giddens's theory of structuration is an attempt to transcend structure-agency dualism by holding that structure and agency are recursively related: Structures both constrain and enable actors even as actions constitute and reproduce those structures. From Hägerstrand's time geography Giddens borrows five basic spatial-temporal constraints: (1) the indivisibility of the body; (2) the finitude of life span; (3) duration/sequence/one task at a time; (4) movement in space is always movement in time; and (5) finite packing capacity of time/space. Giddens suggests that the central task in social theory is to explain "time-space distanciation"—the stretching of social systems across space and time—in the face of these fundamental

constraints. Time, however, is not a mere environment of action, a dimension against which it takes place. Social life—from the reflexive self to enduring social institutions—is both subject to and constitutive of social temporality. Three "times" are key here: (1) the time of Heidegger's *Dasein,* the basic finite temporality of being which is always a part of human existence; (2) *durée,* the time of the day-to-day flow of intentional action; and (3) *longue durée,* the time of institutional duration. These times and their corresponding structures and practices are not hierarchical building blocks of one another. Rather, they are always co-constituting; everyday routine involves all three.

If Durkheim and his descendants had built a sociology of time around the dualism of natural and social time, others begin with the analysis of the origins of "social" time and move toward subsuming natural time. Mead develops his ideas about time in the context of his general theory about the evolution of consciousness and society. In *The Philosophy of the Present*, Mead (1959) suggests the primacy of sociality as constitutive of mind and self, which, in turn, apprehend time as the emergent contrast of past and future with the present. For Mead, the social and the psychological are an instance of "nature," so this explanation of the psychology and sociology of time is an explanation of time itself.

Luhmann develops a similar perspective on time in his systems theory. Like Mead, he sees time as emerging from the difference between past and future relating to one another in the present, and like Mead, he sees temporality not as uniquely human but as a part of the natural world of which humanity finds itself a part.

Several theorists posit changes in the meaning of time, attitudes toward time, and ways of experiencing time as a component or effect of cultural evolution. Elias suggests, for example, that as societies develop they require more complex forms of coordination and so from generation to generation, humans acquire improved capacity for symbolizing time and using it as a "means of orientation." Weber and others describe the progressive rationalization of time as a component of the rationalization of society beginning with the development of the Rule of St. Benedict. The primary theme here is change from "natural" and preindustrial time to "rationalized" time. The former is continuous and spontaneous, while the latter is subdivided and regimented. More recently, Foucault has written about the microdivision of time as a manifestation of power, echoing and generalizing the observations of critics of F. W. Taylor's scientific management time and motion analyses. Marx, Tönnies, and Simmel all allude to the replacement of natural pace with artificial and standardized pace of life as city time displaces the time of villages. "In the city," Lewis Mumford famously wrote, "time becomes visible" (Mumford 1938:4).

TIME AS AN IMPLICIT COMPONENT OF SOCIAL THEORIES

A discussion of time and social theory would not be complete without mention of how time and temporality are frequently implicit components of social theories, most often as a taken-for-granted dimension along which a process plays out. Despite making little or no attempt to problematize time, these lines of thought offer potentially fertile territory for theoretical exploration in examining their unexamined temporal content.

Time is implicit in theories of social change, social mobility, cultural lag, life course and life cycle, careers, diffusion, planning, narrative, biography, and collective memory.

Nineteenth-century social theory paid a lot of attention to the question of how societies evolve and develop in an attempt to understand where European society had been and where it was going. Condorcet, Comte, Hegel, Marx, and Spencer all offered teleological theories of the stages of societal development in which time is a taken-for-granted dimension. Social mobility theories invoke time as a measure of movement in social space. Cultural lag theories depend on a background temporal dimension. Life course, life cycle, and career theories look at lives in time. Studies of information and innovation diffusion connect social space and time. Time scales are also implicated in planning. Recent work implicating time includes investigations of collective memory, narrative, and network dynamics.

TOCQUEVILLE, ALEXIS DE

Alexis de Tocqueville (1805–1859) was a French statesman, political thinker, and founder of comparative-historical sociology. Tocqueville was born in Paris to an aristocratic family that had suffered the depredations of the French Revolution. He traveled to the United States in 1831–1832—on the pretext of researching the novel penitentiary system of Pennsylvania and New York—and based his masterpiece *Democracy in America* on his observations and inquiries of American society. Shortly after returning to France, Tocqueville got involved in politics and served in the Chamber of Deputies from 1839 to 1851, participated in drafting a new constitution in 1848, and served briefly as Louis Bonaparte's Minister of Foreign Affairs. Tocqueville left public office in 1851 after protesting Bonaparte's coup d'état and immediately set to work researching and writing *The Old Regime and the French Revolution.* Tocqueville's most significant contributions to social theory include his arguments on democratization as a world-historical process of transformation, his views on the role of voluntary associations in democracies, and his analysis of the disintegration of the *ancien régime* and the transformations wrought by the French Revolution.

Tocqueville presented his views on democratization most clearly in *Democracy in America.* Tocqueville asked two central questions about democratic society in the United States in the 1830s. First, how did democratic society, characterized above all by the equality of social conditions and liberty, come to be? Second, he asks, how could Americans safeguard democratic society and democratic political institutions against the tendency to slide into uniformity, mediocrity, and despotism? The equality of social conditions refers not to economic equality or even formal political equality in Tocqueville's work. Rather, the equality of social conditions refers above all to the result of the gradual elimination of hereditary distinctions of titles and honors. Furthermore, Tocqueville's notion of the equality of social conditions entails that occupations and professions are open to all, regardless of birth. It refers to the absence (or the successful abolition) of the power and privilege of an aristocracy (Aron 1968:24; Tocqueville 1969: 50–60).

The process of democratization occurred over the course of centuries. In Tocqueville's view, war had battered the nobility of medieval Europe, distributing their lands and encouraging the development of municipal institutions and liberties in the towns. The introduction of gunpowder weaponry leveled social distinctions on the battlefield. The printing press and rudimentary postal systems spread ideas of equality and liberty to villages, towns, and cities across the continent. Furthermore, the Reformation introduced many strains of Protestantism, which preached that all persons stand in a direct relationship to God and therefore broke the Church's monopoly on the means of salvation. The discovery and colonization of America, moreover, provided manifold opportunities for aggrandizement regardless of social rank (Tocqueville 1969:11).

In Tocqueville's view, democratic society in the United States, with its proclivity for liberty and equality, had emerged for three central reasons. First, the geographical location of the United States meant that it had few military risks and an abundance of land (1969:23–30). Second, according to Tocqueville, the laws of the colonies promoted liberty, which in turn influenced the emphasis on federalism and the protection of liberty in the Constitution (1969:31–46). Third, Tocqueville argued that the religious devotion of American colonists promoted customs, beliefs, and manners conducive to freedom: "Religion is considered as the guardian of mores, and mores are regarded as the guarantee of the laws and pledge for the maintenance of freedom itself" (p. 47). For Tocqueville, the customs, beliefs, and manners of the people were paramount in the establishment of American democracy.

According to Tocqueville, the equality of social conditions—and therefore democracy—in the United States had several negative consequences. First, it tended to encourage a tyranny of the majority in both politics and opinion (1969:250–59). Second, the tyranny of the majority promoted mediocrity (p. 257). Third, under certain circumstances—for example, "when free institutions seem to be functioning badly" (Aron 1968:284)—equality comes into conflict with freedom. Finally, the relentless pursuit of equality at the expense of freedom could lead to the centralization of administration, as was the case in France (Aron 1968:285). When this is the case, Tocqueville maintained, people in democratic societies—which he assumed are also commercial and industrial societies—tended to turn toward individualism in their pursuit of material gain and pleasures. This leads not to interdependence (as in, for example, Adam Smith's view) but to isolation, which threatens democratic societies with despotism.

While Tocqueville's description and diagnosis of the United States in the 1830s appears obsolete for many reasons—for example, today we tend to emphasize the lack of equality at the time—his account of the institutions that counter the slide toward despotism is still quite powerful. Tocqueville wrote at length about the separation of powers in the U.S. Constitution and the freedom of the press, but his most trenchant argument in this respect focuses on the role of voluntary associations in maintaining American

democracy. The thrust of Tocqueville's argument consists of the claim that the laws and mores of American democracy bind people, or at least encourage them, to participate in politics. Tocqueville (1969) extends this line of argumentation to participation in associations: "There are not only commercial and industrial associations in which all take part, but others of a thousand different types—religious, moral, serious, futile, very general and very limited, immensely large and very minute" (p. 513). Tocqueville remarks that in Europe, one would find states or territorial magnates taking up these roles, while in the United States people form associations. The crucial conclusion to make here is that, for Tocqueville, associations counter the centrifugal force of individualism by teaching people how to act out of self-interest yet in cooperation with one another, thus countering the threat of despotism and centralization in democracy.

Tocqueville's study of *The Old Regime and the French Revolution* attempts a sociological explanation of a profound historical transformation. His sociological explanation of the collapse of the *ancien régime* and the revolution emphasizes the importance of conflict between the orders and estates of the old regime and the emerging social classes of modernity, the spread of ideas of liberty and equality, irreconcilable political and social divisions between the elites, the prerevolutionary centralization of the state administration and political power, and the financial crisis of the late 1780s. Moreover, Tocqueville ties the collapse of the old regime and the consequences of the revolution to the tendency of democracy in France toward despotism. The republican and imperial administrations continued the centralizing, bureaucratic trends that were already occurring under the *ancien régime,* thus further undermining the power of representative institutions.

TÖNNIES, FERDINAND

Ferdinand Tönnies (1855–1936) is considered one of sociology's founding fathers. He studied in Strassburg, Jena, Bonn, Leipzig, and Tübingen where he received his doctorate in classical philology in 1877. His famous *Gemeinschaft und Gesellschaft* served as his *Habilitationsschrift* in 1881. His father's wealth enabled him to follow his private, especially political, interests and to be relatively distant from the academic milieu. Nevertheless, he was appointed to a chair for economics and statistics in 1913 from which he retired only three years later. He resumed teaching sociology as professor emeritus in Kiel in 1921.

Tönnies took an active interest in the socialist and trade union movements and in consumer cooperatives. He joined the Social Democratic Party, protesting against the National Socialist Movement, which led to the discharge from his position as professor by the Hitler government in 1932–1933. Tönnies was president of the German Sociological Society from 1909 to 1933, which he had founded together with Georg Simmel, Max Weber, and Werner Sombart.

Tönnies perceived of all human interactions as creations of thought and will. This distinguishes Tönnies's concept of the social from a behavioristic view, which regards any kind of interaction as social. Social entities in Tönnies's sense are creations of their members' will so that they are felt as a quasi-objective reality with its own obligations and rights. They can be classified roughly as social collectives (*Samtschaften*), social corporations (*soziale Körperschaften*), and social relationships (*soziale Verhältnisse*). Social relationships exist insofar as they are willed by their participants (even though they may well, as in the case of parent and child, rest on a psychological or biological basis). They are prevalent within social corporations and social collectives, as well. Social collectives (which as a concept is found only in Tönnies's later writings) stand for unorganized groups that have grown enough in size to be independent of the participation of particular individuals. The concept of social corporation refers to groups capable of acting collectively through representatives. They constitute the most "artificial" level because the participants' will to maintain a social relationship becomes manifest in their conformity with specific rules and norms.

Tönnies uses the term *will* in a broad sense. Similar to Max Weber's distinction of four ideal types of social action, Tönnies differentiates the will that creates a social entity according to its relation to ends and means. The main distinction here is between *Wesenwille* (derived from Arthur Schopenhauer and Wilhelm Wundt) and *Kürwille* (which stems from Thomas Hobbes and the rationalist tradition of natural law). The latter corresponds to Weber's purposive-rational orientation of social action and is derived from

an ancient Germanic word for choosing. The action is consciously motivated toward an end, and the actor chooses among several possible means to achieve that end. In contrast, *Wesenwille* manifests the actor's nature and has several degrees of rationality according to affect, tradition, and value orientation.

In applying these classifications to social entities, Tönnies distinguishes between *Gemeinschaft* and *Gesellschaft,* which was meant as a conceptual framework for the analysis of modern society. Certain entities are willed for their intrinsic value and depend on the members' sympathy, habit, and shared beliefs (e.g., clubs, sects, family, neighborhood). Other entities must be conceived of as means to specific ends such as the business association that constitutes the paradigm of the "*Gesellschaft*" and "*Kürwille*"-type of social entity. Kinship, neighborhood, and spiritual community form prototypes of "community." Contractual relationships and special-purpose associations stand for "society." Like Weber, Tönnies sees these categories as ideal types. In reality, we find neither pure *Gemeinschaft* nor pure *Gesellschaft.* Rather, social entities are *more or less Gesellschaft-* and *Gemeinschaft*-like because human conduct is never exclusively determined by reason or sympathy. Tönnies illustrates this concept by comparing the ideal types to chemical elements that are combined in different proportions. Accordingly, Tönnies identifies empirical mixtures that he combines with the question whether social relationships are conceived of as equal or unequal. A *Genossenschaft* is a *Gemeinschaft*-like relationship of equal peers, whereas *Herrschaft* implies social super- and subordination. The relationship of husband and wife constitutes a mixture of perceived equality and superordination. *Gesellschaft*-like types of social entities create inequality by delegating authority to certain members while at the same time assuming a conceptual peer equality.

Tönnies's conceptual framework of social entities aims at a synthesis of the social theories of rationalism with romantic and historical concepts of society. It tries to overcome the antagonism of organicist and contractual views of society. According to Tönnies, these seemingly irreconcilable concepts lay within the realm of sociology as real historical phenomena. Consequently, he reconciled Aristotle's *zoon politikon* with Hobbes's pessimistic *homo homini lupus* and conceptualized the relation between individual and society in a new way, leading to the division of society into subdivisions of analysis and calling for a basic systematization of divergent social phenomena. Some social entities must be seen as prior to individual will, while other social relationships are the result of contractual agreement. Thus, all social relationships and human conduct can be conceptualized as voluntaristic, existing only insofar as they are created by acting individuals. The object of social theory becomes pluralistic without being fragmented.

Tönnies laid the foundation for a sociology that was further developed by Durkheim, Weber, and Simmel. Tönnies's conceptual framework has become so much taken for granted that it is difficult to specify exactly his influence on social theory. The *Gemeinschaft-Gesellschaft* distinction can be found in Parsons's pattern variables, in Habermas's distinction between communicative and instrumental types of action, between system and lifeworld, and in Coleman's asymmetric society.

TOTAL INSTITUTIONS

Erving Goffman created the concept of total institution in his essay "On the Characteristics of Total Institutions" published in 1961 in *Asylums.* Total institutions are social hybrids, part residential community and part formal organization intended for the bureaucratic management of large groups of people. Goffman (1961) offers this definition:

> A total institution may be defined as a place of residence and work where a large number of like-situated individuals, cut off from the wider society for an appreciable period of time, together lead an enclosed, formally administered round of life. (p. xiii)

Goffman provides this taxonomy of the five groups of total institutions:

Institutions that care for those who are incapable of caring for themselves but are considered harmless—the blind, aged, orphaned, and indigent

Institutions that sequester groups who are incapable of caring for themselves and pose a threat to others—sanitarium, leprosarium, or mental hospital

Institutions designed to protect the community from those perceived as threats where the welfare of the inmates is not a concern—prisons, prisoner of war camps, and concentration camps

Institutions established to pursue a worklike task—army barracks, ships, boarding schools, and work camps

Institutions that form cloistered retreats or monastic orders designed for training and the pursuit of a religious vocation

Supported by the National Institute of Mental Health, Goffman spent a year from 1955 to 1956 conducting fieldwork in a mental hospital, St. Elizabeth's Hospital in Washington, D.C. He developed this analysis drawing on eclectic evidence from the sociological literature on prisons and organizations and from ethnographies, novels, autobiographies, and theology. Despite the breadth of this scholarship, the formal concept of total institution focuses primarily on psychiatric institutions, and his intention was to explore the social world of the patient and the subjective, lived experiences of inmates.

Total institutions are distinguished by their varying degrees of closure or separation from the outside world. All activities of the daily round occur in the same place, under a single authority, and in the immediate company of a large batch of others. Total institutions create the rationalization of life through tight scheduling, regimentation, and bureaucratic rules that foster the disciplinary control of inmates. Thus, the bureaucratic management of inmates and *batch living* promote the rational plan or official purpose of the institution (Burns 1992).

Goffman identifies the radical split between the *inmate world* and the *staff world* as a critical feature of these institutions. He offers a detailed discussion of the *moral career of mental patients,* documenting the systematic stripping of their socially constructed conventional identity in the outside home world by the denigrations, mortifications, and humiliations of the admissions process. Through welcoming ceremonies, staff members take a life history, photograph, weigh, fingerprint, assign numbers, search, list personal possessions for storage, undress, bathe, disinfect, cut hair, and issue institutional clothing. Without access to civilian clothing, towels, soap, shaving kits, and bathing facilities, inmates are stripped of their usual appearance and suffer a personal defacement. Through obedience tests and abusive welcome rituals, inmates come to understand their powerlessness. Inmates may be required to hold their body in a humiliating stance and provide humiliating verbal responses to staff members as part of the enforced deference pattern of total institutions.

Once persons are transformed into patients and enter the inmate world, they experience a civil death that denies them adultlike autonomy and control over their fate. From the most mundane or trivial matters to important life decisions, patients no longer act with agency or self-determination. The structure of the hospital regulations as enforced by staff and staff decisions, and justified by therapeutic rationales, determines the fate of inmates.

Although patients suffer the loss of their socially constructed identity grounded in their home world, they strive to reconstruct their social self and protect themselves from the mortification of self so characteristic of life in total institutions. Patients use secondary adjustments, "practices that do not directly challenge staff but allow inmates to obtain forbidden satisfactions or obtain permitted ones by forbidden means." (Goffman 1961:54) Secondary adjustments provide evidence that the patient can act with agency and can claim an inner soul beyond the reach of institutional profanations.

Patients also achieve a degree of personal reorganization and recovery of self through conformity to house rules and the opportunities and rewards available to them through the privilege system. Good behavior and compliance ostensibly demonstrate improving mental health and are rewarded by privileges and the prospect of a timely release. In addition, inmates are resocialized into the inmate social system—a parallel and countercultural complex of values, meanings, and informal structures that oppose bureaucratic regimentation or psychotherapeutic rationales. Instead of the belief that time spent in treatment is beneficial, patients learn that time spent in the institution is wasted time in exile from living. Rather than learning to take responsibility for one's actions, the inmate belief system instructs patients about externalizing responsibility and blaming others. Patients construct *sad tales* to explain how bad luck or forces outside their control brought them to the institution. Through solidarity and defiance, inmates create cliques and adopt strategies of withdrawal and intransigence. Other inmates become colonizers as they view the institution as their home. Most inmates adopt a combination of secondary adjustments and coping strategies, responding to situations by embracing the stance of *playing it cool* to maximize their chances of getting out of the institution without physical or psychological injury.

The staff world defines these institutions as storage dumps where staff members, motivated by the constraints of institutional efficiency, work on people as a kind of biosocial material. This staff rationale conflicts with the idealized public aims of the institution and the Kantian ethical imperative that people are ends in themselves and are deserving of humane standards of care. The staff articulates a theory of human nature that depersonalizes each patient, equating the inmate with the cluster of symptoms associated with the diagnosis.

The concept of total institution incorporates the key ideas of the dominant sociological theoretical perspective in the 1950s—structural functionalism—and the work of Talcott Parsons (1951) and Amitai Etzioni (1961). A total institution is a structural form, a formal organization and residential community that adopts institutional ceremonies and strategies to integrate staff and inmate worlds into a functional social system by elaborating complementary roles

between inmates and staff. Goffman's conceptualization of total institutions created a unique descriptive and analytic framework by which to understand the structural determinants of the inmates' subjectively experienced social reality.

Goffman's reliance on a structural analysis of the roles, rules, and relationships between inmates and staff members differed from his earlier work, *The Presentation of Self in Everyday Life* (1959). Here, he developed a *dramaturgical analysis* of social interaction within social institutions by viewing interaction as theater where actors use fronts, scripts, and props, and collude with others to enact impression management before various audiences.

The concept of total institutions has enjoyed a long and influential career. Theorists in interpretive sociology and labeling theory (Howard Becker), ethnomethodology (Harold Garfinkel), the antipsychiatry movement (Thomas Szasz, R. D. Laing), the sociology of organizations, and policymakers concerned with deinstitutionalization and community mental health have been influenced by Goffman's work (Steudler 2001).

As a theoretical construct, total institution has significant limitations. By constructing an ahistorical formal theory in the spirit of Georg Simmel (Weil 2001) and incorporating a structural-functional dynamic, Goffman emphasized the legitimate exercise of bureaucratic authority in total institutions. He largely ignored the question of political ideology, domination, and power in the wider society where the total institution was situated. Power, domination, and social conflict were never problematic for Goffman. For example, Stalinist work camps (gulag), the Soviet abuse of psychiatry to stifle internal political dissent after World War II, and Nazi concentration camps illustrate how totalitarian regimes have employed total institutions as a means to abuse power and to oppress citizens. Concentration camps were total institutions dedicated to racial purification through state-sponsored genocide and crimes against humanity. For Goffman, however, total institutions were a social form that existed in a social vacuum, without blood or social conflict and unrelated to ideology or dogma.

Goffman formulated a taxonomy of the types of total institutions and an analysis of the structural-functional aspects of this social form derived from his fieldwork and an examination of mid-twentieth-century institutions. He did not concern himself with the historical development of total institutions in the West during the transition to modernity from the seventeenth through nineteenth centuries. Goffman never addressed the questions raised by the important work of his contemporary, French theorist Michel Foucault, who examined the formation of the asylum, the birth of the clinic, the establishment of the modern penitentiary, and the elaboration of official *discourse,* the systematized knowledge that situated elites like psychiatrists

employ as a key medium of power within the bureaucratic state and total institutions (Foucault 1965).

TOURAINE, ALAIN

Alain Touraine (b. 1925) is a French sociologist and engaged public intellectual in the democratic socialist tradition. He has been involved in a long-term project that seeks to assess the transformative potential of collective social actors, particularly in the advanced industrial nations. In so doing, Touraine has sought to articulate an antifunctionalist and post-Marxist theoretical perspective that he has described as both a "*sociologie actionnaliste"* and the sociology of the "self-production of society." His work reflects a distinctive engagement with the sociological classics, resulting in a unique blend of Marxist and non-Marxist social theory. Unlike contemporary theorists who have sought to unite agency and structure into one comprehensive theoretical framework, Touraine has tended to simply ignore structure because he is convinced that action is antecedent to structure and thus the latter is to be understood within the framework of action. His perspective is thus a version of social constructionism, although unlike most interpretive theories, one that is preoccupied with the collective actor rather than the individual.

Educated at the École Normale Supèrieure, he has taught at the University of Paris-Nanterre and worked for both the French National Research Council (CNRS) and as a senior researcher at the École des Hautes Études en Sciences Sociales. He founded the Center for Sociological Analysis and Intervention in 1981 and is currently professor of sociology at the École des Hautes Études en Sciences Sociales. Touraine has published over 20 books, about half of which have been translated into English. While he has had a major impact on French sociology, his reception in the English-speaking world is decidedly more mixed.

In his earliest publications, Touraine engaged in a series of empirical inquiries into the changing character of the class structure of postwar French society, which included studies of workers at Renault and agricultural workers. He sought to challenge the literature of the time that proclaimed the embourgeoisement of the working class and thus the end of the conflicts that have pitted labor against capital throughout the history of industrial capitalism. However, what separated him from those Marxists and neo-Marxists who sought to find in various sectors of the working class new potential locations for revolutionary vanguards, he does not consider the present to be a revolutionary era. Moreover, in the wake of the student movement that shook the foundations of French politics in May 1968, he began to view the university rather than the factory as an increasingly crucial locus of political and cultural conflict.

This perspective is connected to his claim that the advanced industrial nations were rapidly moving into a postindustrial era. In the late 1960s, Touraine was one of the key figures associated with discussions about the advent of postindustrial society, which focused on the shift from manufacturing-based economies to information-based ones. His contribution reveals his penchant for viewing the world in terms of sharp dichotomies. Thus, in an early formulation, he suggested that the transition from industrial to postindustrial society amounted to a developmental leap akin to the transition from agrarian to industrial society. He contended that we were entering societies "of pure change, without structure or nature" (Touraine 1977:6). Reflecting a particular moment in the history of the contemporary welfare state, he argued that the economic realm no longer functioned autonomously, but instead, economic decisions were increasingly made at the political level, and therefore the boundaries between the economic and the political increasingly dissolved, with political decision making being of paramount importance in shaping the economy. Under the influence of Weberian thought, he contended that these changes amount to the bureaucratisation of society as decision making became increasingly centralized in the state apparatus. It is in this sense that he suggests that a synonym for postindustrial society is the programmed society. In such societies, knowledge takes on a new importance, and as a consequence, universities come to play an increasingly pivotal role in training the new cadres of information elites necessary for the functioning of advanced industrial economics.

Whereas Daniel Bell, the other key formulator of the postindustrial concept, contended that the tensions within postindustrial societies came about because the economic, political, and cultural realms operate on different axial principles, Touraine saw the state increasingly subsuming control of the economy, while in the cultural realm, it increasingly seeks to manipulate public opinion. In this scenario, the enormous power of the state can lead to a paralysing of social actors intent on challenging the programmed society, thereby posing a threat to democracy. Within this general perspective, Touraine concluded that the working class could no longer be seen as the main challenger to domination. Although he was not prepared to write them off as potential social actors as was, for example, Andre Gorz, he saw them as representing only one of several potential progressive social movements.

In this view, 1968 was to postindustrial society what 1848 was to industrial society: a preview of the new conflicts characteristic of the emerging new social order. Touraine's perspective on social movements begins with his attempt to fuse two central concepts: historicity and class relations. Historicity refers to the self-production of society based on its capacity to act on the nonsocial world, its methods for determining ways of investing economic surpluses into noneconomic ventures, and the cultural framework that informs social actors about their capacity for social transformation. A legacy of the Marxist heritage, class relations are viewed in dichotomous terms, pitting a dominant or ruling class against a dominated popular class. These are meant as analytical terms that involve congeries of collectivities. The dominant class includes technocrats, managers, political elites, economic entrepreneurs, and the like, while the popular class is best seen reflected in the new social movements that have emerged in recent decades, which in addition to the labor movement includes the environmental, student, antinuclear, and feminist movements.

Cognizant of the manipulative power of the dominant class to marginalize conflict, Touraine sees a novel role for sociology as an interpretative tool. He contends that social movements can use sociology to achieve a heightened level of self-awareness that can help them act, not merely defensively, but as truly contestatory participants in the self-production of society. Like resource mobilization theory, he views social movements as rational responses to institutionally embedded discontents, and he considers their chances of success to be partially determined by their capacity to muster sufficient organizational, financial, and ideological resources and their ability to make appropriate strategic decisions. He differs from resource mobilization theorists insofar as he is always intent on determining the transformative potential of various movements or, in

other words, on their ability to change the course of social development that has been advanced by the dominant class.

Touraine believes that sociology has an especially critical role to play in assisting social movements in making these determinations. To this end, his role as an engaged sociologist took the form of developing a method of analysis that he termed "sociological intervention," whereby sociologists work in the interests of segments of the popular class rather than the state apparatus. Thus, the purpose of sociological intervention is to promote societal transformation rather than social integration. More explicitly, the method is intended to assist progressive social movements in acquiring the ability to engage in self-analysis as a prelude to locating their sense of collective identity and their definition of opposition and domination in a way that transcends the limits of movement ideologies and raises consciousness to that of a system of historicity. The sociologist functions for the collective actor as a psychoanalyst does for the individual, by helping to make visible social relations that are "masked by order and domination" (Touraine 1981:139) and distorted by ideology. The techniques used in intervention, developed in collaboration with Michel Wieviorka and other researchers at the Center for Sociological Analysis and Intervention, were detailed in *The Voice and the Eye* (1981). A number of publications appeared as the result of sociological interventions, including books on solidarity in Poland and the antinuclear, workers, and student movements in France.

In his more recent work, Touraine has explored the challenges posed by modernity in the era of globalization and the central dilemmas of citizenship in the wake of multiculturalism as ideology and social policy. He has sought to articulate an appropriate response to the rise of neoliberalism in the Western democracies that accepts the persistence of capitalist markets without abandoning the prospect of challenging the inequities that unbridled markets bring in their wake. In all this work, there is a remarkable continuity with publications dating back to the 1960s insofar as he remains insistent that autonomous collective social actors from the popular class are capable of playing a significant role in shaping the contours of social change.

TRUST

Scholars as well as ordinary citizens agree that trust is an important lubricant for social relations and that trust helps build a prosperous society. Beyond the importance of trust in our social and personal lives, however, there is little consensus concerning the nature and function of trust. Even the broadest definition of trust as an expectation of natural and social order, a definition on which many Westerners agree, meets objections in some non-Western cultures. For example, a Japanese person will never say, "I trust that the sun will rise again tomorrow." Furthermore, trust as expectations of the trustee's *ability* to perform a trusted action is different from trust as expectations of the trustee's *intention* to perform the same action (Barber 1983). The lack of consensus among the social scientists interested in trust reflects the fact that trust is a multifaceted concept. The definitions and theories of trust vary as different facets of the concept are examined.

There are three common usages of the word *trust*. First, the word trust is used to refer to *trustworthiness*. When people talk of the "decline in trust in American society," this meaning is being employed. Second, trust is used to refer to *trustfulness*. Scales used to measure trust by psychologists (e.g., Rotter 1971) are measuring individual differences in the degree to which individuals expect others to be trustworthy. Third and finally, trust is used to refer to the *act of trust.*

The act of trust is easy to define. The most common and the easiest way to understand what we mean by the act of trust is illustrated in the game of trust. The game of trust is played by two players. One of the players, Player A, makes a choice to trust (T) or to not trust (NT) the second player, Player B. When A chooses NT, the game ends there, and the status quo is maintained. When Player A chooses to trust, the game continues and Player B is given a choice between honoring Player A's trust (H, honor trust) and not honoring Player A's trust (NH, not honor trust). The outcome for Player B if he chooses *not to honor* Player A's trust is better than the outcome for Player B if he chooses *to honor* Player A's trust (NH > H for B). The outcome for Player A if Player B chooses not to honor her trust (NH) is less than the status quo (NH < 0 for A), and the outcome for Player A if Player B chooses to honor her trust (H) is greater than the status quo (H > 0 for A). If Player A believes that Player B will honor her trust, T is a better

choice for him than NT. If Player A does not believe that Player B will honor her trust, NT is a better choice than T. Thus, A's choice in this game reflects his trust in B, and B's choice reflects her trustworthiness in this relationship. If we assume that both players are rational in the sense that they care only about their own welfare, and expect that others are similarly rational, B will not honor A's trust. Thus, A, expecting that B will not honor her trust, will not choose T. However, most experimental studies using the game of trust between anonymous players find that a substantial proportion of B's choose to honor the trust of A's (H). *And* they find that a sizable proportion of A's choose to trust B's (T). Social scientists are interested in finding out why people behave in both a trustworthy manner and a trustful manner.

The degree to which the game of trust is embedded in a larger social and cultural context provides a key to the question posed above. There are factors in the social context surrounding the game of trust that encourage trustworthy behavior. Examples of such factors are long-term relationships, social mechanisms that effectively spread reputations, and legal systems that detect and punish untrustworthy behavior. When these factors are present, not only trustworthy behavior but also trustful behavior becomes a rational choice for individuals. Many social scientists seek to identify these contextual factors and describe the ways in which they encourage trustworthy behavior. The decision to trust or not to trust in a particular game of trust is often determined by an individual's ability to correctly read the presence or the absence of these contextual factors. Russell Hardin (2002) refers to this understanding of trust as the "encapsulated" interest of the trusted.

While Hardin views trustfulness as a reflection of encapsulated contextual ingredients that encourage the trustee to behave in a trustworthy manner, other researchers understand trustfulness differently. In David Lewis and Andrew Weigert's (1985) words, "Trust begins where simple prediction ends" (p. 976). According to these scholars, the act of trust involves not only the reading of the encapsulated ingredients that make the trusted behave in a trustworthy manner but also a willingness to take *social risks*. Toshio Yamagishi and his colleagues argue that trust as social risk taking is grounded in the adaptive role of trust. Specifically, trust as social risk taking is viewed as adaptive because it reduces the opportunity costs for remaining in a committed social relation in which transaction costs are small. Ironically, institutional arrangements that encourage trustworthy behavior reduce the need to trust others (or take social risks) since trustworthy behavior is then institutionally ensured. In a society in which an individual's behavior is completely monitored and sanctioned (such that cheating is impossible), people no longer need to trust others.

Ultimate explanations of trust, including both trustworthiness and trustfulness, reside in the identification of the sociocontextual factors that encourage trusting and trustworthy behaviors. When the sociocontextual factors lead to short-term personal rewards for trusting (or when the consequences of trust are calculable), trust is explained as a rational behavior. When the personal rewards of trust take a long time to accrue, trust can be conceived as irrational and yet *adaptive*. For example, it is irrational to behave in a trustworthy or a trustful manner in a game of trust that is artificially created in a laboratory. However, acquiring a psychological mechanism (i.e., values, beliefs, heuristics, emotion, or a cognitive module such as a cheater detection module) encouraging people to disregard some of the immediate incentive features and behave in a trustful or trustworthy manner can be adaptive if, for example, such behavior helps establish a good reputation of the actor as a desirable exchange partner. What makes an irrational behavior adaptive or not is whether the long-term benefits of behaving in an irrational manner outweigh the immediate costs. Trust can be rational, irrational and adaptive, or irrational and maladaptive, depending on the nature of the social context.

TURNER, BRYAN

Bryan Turner's (b. 1945) work is best understood as an attempt to revive action sociology from the perspective of embodiment. Together with "emplacement" (the relation of humans to the environment), embodiment is understood to be a universal category of human experience. Turner's work is a critique of both social constructionism and cultural relativism. The body is theorized as the material basis for social solidarity with the potential to transcend cultural difference and social variation. In the application of this

theory, embodiment and emplacement are explored as the basis for a universal theory of citizenship and human rights. In particular, the need for companionship and the material facts of bodily frailty and vulnerability are articulated as the incentive for the formal recognition of sympathy and practice of empathy at the level of civil society. Aspects of Heidegger's ontology, especially the emphasis on being and choice, are enlisted to develop a sociological approach centered on the phenomenology of the body.

Turner's recent work introduces the concept of *cosmopolitan virtue* to elaborate the argument. As a contribution to the theory of social action, the concept introduces six dimensions: (1) *irony*—the recognition of the contingency and partiality of perspective; (2) *reflexivity*—the location of values and action in the context of biography, history, and structure; (3) *skepticism*—the distrust of grand narratives and totalitarian politics; (4) *care for others*—the recognition of sympathy, mutuality, and reciprocity; (5) *social inclusiveness*—the cohesion of the body politic and civil society around principles of sympathy, mutuality, and reciprocity; (6) *nomadism*—a version of *flanerie,* attributing travel and displacement as sources of sympathy, mutuality, and reciprocity in civil society.

Turner's sociology is firmly located in the classical tradition, especially the writings of Max Weber. It is committed to the investigation of the subjective meaning of social actions. Unlike some other versions of action sociology, notably symbolic interactionism, exchange theory and ethnomethodology, it emphasizes the *situated* character of the social actor in both the historical and comparative dimensions. Although Turner sees the state as both the enabler and abuser of human rights, it highlights processes of globalization and the porosity of national boundaries. Following Foucault, embodiment and emplacement are understood as shaped by a network of *social institutions of normative coercion.* The state is a significant agent, but so are the corporation, the media, education, medicine and the professional-knowledge class. To some extent, Turner's work elaborates Thomas Hobbes in regarding human life as "nasty, brutish and short." Human beings are considered to be ontologically frail and to inhabit natural environments that are precarious. A variety of social consequences follow from this, which are explored historically and comparatively in terms of the means and ends of social action. The theory of citizenship and human rights aims to invest social institutions of normative coercion with a binding system of moral conscience and accountability and to acknowledge a global dimension in civil society.

This concern with the question of social integration reflects Turner's reading of Parsons, in as much as it holds that all human societies face economic dilemmas of resource allocation and political issues of goal definition. This reinforces the emphasis placed on embodiment and emplacement as universal categories in human society that constitute a common basis for government. It also identifies scarcity as fundamental in investigating social cohesion and change. However, unlike Parsons, Turner's approach assigns greater analytic weight to social conflict deriving from inequality and the clash of human values. For example, his discussion of vulnerability and rights holds that the increasing fragmentation and hybridity of culture threaten social solidarity.

Turner's perspective holds that there are identifiable, cumulative research traditions that are independent of contexts of class, gender, race, and culture and repudiates a priori reasoning. It submits that sociological investigation must be *attentiste* rather than relativist and is committed to the production of value-free knowledge, which presupposes a consistently reflexive approach to social enquiry. It is distanced from linguistic or discursive approaches to social investigation because it maintains that societies constitute material systems of cohesion and restraint that are independent of language. In as much as this is the case, his perspective is skeptical about both the cultural and linguistic turns, preferring instead to treat society in Durkheimian terms as a *social fact* that exerts priority, externality, and constraint over the individual. However, it also regards the normative institutions of coercion as enabling and subject to critical revision by actors. Indeed, one function of sociology is to continuously subject these institutions to critical investigation.

These concerns are explored in an impressive range of enquiries into, inter alia, medicine, the body, disability, social stratification, citizenship, generations, equality, human rights, religion, Islamic society, and classical and contemporary social theory, making Turner one of the most prolific postwar sociologists. With hindsight, one might say that he prepared his understanding of cosmopolitan virtue *practically,* by way of a variety of academic appointments in Lancaster, Aberdeen, Essex, the Netherlands, and Australia. He is currently professor of sociology at the University of Cambridge.

TURNER, JONATHAN

Over the last 35 years, Jonathan H. Turner (b. 1942) has advocated a positivistic view of sociological theory, arguing that the goal of sociology is ultimately the production of abstract laws or principles and analytical models that explain basic social forces operating in all times and places (e.g., Turner 1991). For many years, Turner engaged in metatheoretical analysis, formalizing both early and contemporary theories into propositions and models. The goal of these efforts was to highlight the scientific contribution of the classical theorists to explaining the operative dynamics of the social universe (e.g., Turner 2002b; Turner, Beeghley, and Powers 2002) and to argue that some contemporary theories are better than others as scientific theory. As this advocacy and metatheorizing was being produced, Turner also began to implement his strategy for developing scientific theory. This strategy revolved around formalizing existing theories to see what they had to say about a given topic, extracting the useful elements of these theories, and adding new elements in order to produce a more robust theory. Generally, Turner produced abstract models that displayed in visual space the causal flow of social forces, highlighting the direct, indirect, and reverse causal effects of forces in the social universe. Along side these models, Turner would also produce a list of abstract propositions that stated the fundamental relationships among forces in the social universe. The goal of these theories was to define concepts clearly, to specify precisely the nature of their relationship to each other, and to list the conditions that changed the value of each concept.

Turner's work is thus synthetic, pulling together diverse strands of thought, making necessary corrections and additions, and then presenting a theory in a formal way so that, in principle, it can be tested. Early work revolved around the process of conflict (beginning with Turner 1973), especially in the context of ethnic relations (Turner and Singleton 1978). These works became part of a general theory of societal stratification (1984) that conceptualized stratification along several dimensions (the unequal distribution of power, material wealth, and prestige; the formation of homogeneous subpopulations; the ranking of subpopulations; and mobility across subpopulations). For each of these dimensions, a formal law, stated mathematically, was formulated.

In the late 1980s, Turner produced a theory of social interaction that sought to synthesize existing theories into a series of analytical models on motivational, interactional, and structuring processes (e.g., Turner 1987). Motivational dynamics are those processes that energize actors to behave, interactional processes revolve around the mutual signaling and interpreting of people in face-to-face contact, and structuring processes are those dynamics that stabilize the flow of interaction in space and time. Over a decade later, Turner produced a new theory of interaction, incorporating some of the ideas of this earlier theory but adding an entirely new framework as well as ideas on emotional dynamics that he had developed during the course of the 1990s and into the new century (2000, 2002a). This new theory adopted a conceptual scheme developed in the course of work on more macro-social processes (Turner 1995), and it appears that this simple conceptual edifice is influencing all of Turner's current theorizing. The scheme simply argues that the social universe unfolds at three levels: micro, meso, and macro. These are more than analytical distinctions; in Turner's view, they are reality. For each level of reality, there are forces that drive the formation and operation of structures at that level. At the micro level, the key structure is the encounter; at the meso level, the generic structures are corporate units (with a division of labor organized to achieve goals) and categoric units (the social distinctions that people use to define others); and at the macro level, the units are institutional systems. Each unit is embedded in the other, as well as in human biology. Thus, institutions are composed of corporate and categoric units; the latter are built from encounters, and encounters are possible only because of the biological makeup of humans. But in contrast to much theorizing that seeks to connect the micro and macro, Turner argues that each level of reality is driven by its own distinctive forces, and these forces are to be the subject of theoretical principles (Turner 2002a). That is, the goal of sociological theory is to isolate those forces that drive each level of social reality, and for each force, theorists should be able to state an abstract principle about its dynamic properties and, if desired, to develop an analytical model that lays out the causal connections among those properties of the social world that influence values and valences of each force.

In his most recent work on micro-social processes, Turner (2000a, 2002b) has specified six forces driving encounters: emotions, transactional needs, symbols, roles, status, and demographic/ecological properties. Earlier in the 1990s, Turner (1995) developed a theory of macrodynamics that sought to explain those forces driving the formation of institutional systems. In this work, Turner postulated that there are seven forces driving the social universe at the macro level: population, production, distribution, power, space, differentiation, and disintegration. Turner has yet to work out a theory of mesodynamics, although his earlier theory of stratification hints at some of the dynamics that drive the formation of categoric units.

While these more general theoretical schemes were in development, Turner also pursued inquiry into human biology and evolution, arguing that sociologists must conceptualize biological processes to fully understand the social universe. Most of this evolutionary theorizing has involved analysis of humans' closest relative, the primates, to see what clues they offer to the hominid ancestors of humans. Turner

has produced a number of works, ranging from a reanalysis of human nature (e.g., Maryanski and Turner 1992) to a theory on the evolution of human emotions (Turner 2000). At the same time, Turner has sought to revive and revise stage model theories of evolution by examining with a theory of selection processes and with principles of macrodynamics the development of institutional systems (Turner 2003). In this way, Turner hopes to overcome the obvious flaws of earlier functional theories of societal evolution.

Thus, Jonathan Turner is one of the few "grand theorists" remaining in sociology.

— Charles Powers

U

URBANIZATION

THE NATURE OF URBANIZATION

Urbanization is the process whereby large numbers of people congregate and settle in an area, eventually developing social institutions, such as businesses and government, to support themselves. Urban areas, or those pockets of people and institutions thereby created, are generally characterized as relatively dense settlements of people. Furthermore, it is claimed, they sometimes originate from the effort by authorities to consciously concentrate power, capital, or both at a particular site.

The process of urbanization has gone on throughout history. Large congregations of people have existed across the world, from ancient China to ancient Rome and Greece. Although the numbers of residents of such cities pale by comparison with urban areas today, the relatively large and dense congregations of people still helped to foster new institutions and, in general, to make urban life in many ways preferable to that of living in relatively isolated rural areas. Urban residents typically benefit from better forms of education, improved medical care, the availability and distribution of information, and the greater supply of life-sustaining goods, such as food and shelter.

Today, more than half the world's population resides in urban areas. Furthermore, demographers project that between 2000 and 2025 the population growth of urban areas will constitute about 90 percent of all world population growth. Major concentrations of people today can be found on all continents (see Table 1).

Yet urbanization is more than just the process leading to dense settlements. Social theorists across the ages have wrestled to understand it. Indeed, one might say that the process of urbanization is a focal point for many sociological concerns; the urban area serves, in effect, as a major stage on which social change plays itself out. If one takes a

Table U.1   Fifteen Largest Metropolitan Areas of the World

Name	Size
Tokyo (Japan)	33,750,000
Mexico City (Mexico)	21,850,000
New York (United States)	21,750,000
Seoul (South Korea)	21,700,000
Sao Paulo (Brazil)	20,200,000
Bombay (India)	18,800,000
Delhi (India)	18,100,000
Los Angeles (United States)	17,450,000
Osaka (Japan)	16,700,000

dim view of such change, then urbanization tends to be criticized for the evils it unleashes. Yet if one takes a positive view of social change, then urbanization is claimed to produce many benefits. The next section examines the varying theories of urbanization more closely to discover how, and why, social theorists differ in their views of the process.

THEORIES OF URBANIZATION

Even though observers generally agree on the nature of urbanization, there is widespread disagreement both as to its social sources and consequences. Moreover, there is also disagreement over the extent to which human actors can intervene in the process. Here, some of the leading views

are considered, noting how, and why, they differ from one another.

The German Perspective

One of the first theorists to acknowledge the deep and important impact of urbanization on social life was the German scholar, Georg Simmel. Simmel developed a sociology that focused on the special ways that forms, such as the numbers of people in groups, influenced social life. His effort to understand the nature of urbanization and, in particular, the metropolis of the late nineteenth and early twentieth centuries, displayed his characteristic method of analysis.

In a famous article, "The Metropolis and Mental Life," Simmel argued that there were certain features of the modern metropolis that rendered it different from all prior forms of social organization. In particular, life in the metropolis requires that people engage in social interactions with large numbers of different people. It also requires that they carry on their social life with a good deal more rapidity than other forms of settlement. The characteristic type of relationship in the metropolis, he suggested, was the relationship between the customer and clerk in a business exchange. Both treat one another not as intimates but, rather, simply as people engaged in business with one another. The impersonal and instrumental qualities of such relationships were, Simmel argued, essential features of the modern metropolis. Moreover, these features extended to life throughout the metropolis. People tend not to know one another as individuals but, rather, as passersby or mere acquaintances. The consequence of all such relationships was to give life in the modern metropolis an air of anonymity. Money, not interpersonal trust, lies at the heart of the metropolis, so Simmel insisted.

Simmel was not the only German theorist to take the difference between the metropolitan form and prior social forms seriously. Ferdinand Tönnies, a fellow German, insisted on a somewhat similar contrast. Unlike Simmel, who cast his argument in terms primarily about the modern form, that of the metropolis, Tönnies developed a theoretical polarity between what he termed *Gemeinschaft,* on one hand, and *Gesellschaft,* on the other. The former represents the close-knit community, whereas the latter refers to society. *Gemeinschaft* suggested intimacy, warmth, and human closeness, whereas *Gesellschaft* clearly suggests impersonal exchanges, based on forms such as business exchanges. Like Simmel, Tönnies's intention was to capture in theoretical analysis a real social change that was unfolding across Europe over the course of the eighteenth and, especially, nineteenth centuries.

The Chicago School

These themes—impersonality, anonymity, and economic exchange in the metropolis—heavily influenced the writings of American sociologists in the early twentieth century as they sought to unravel the nature of the expanding metropolis. The influence was by no means accidental. The leading figure of what came to be known as the Chicago School of Sociology—so-called because all the sociologists were located at the University of Chicago—was Robert Park, a man trained as an American journalist who studied in Germany with Georg Simmel.

The central theoretical argument about the nature of urbanization, the metropolis, in particular, is to be found in the writing of Chicago sociologist, Louis Wirth. In another famous article, "Urbanism as a Way of Life," Wirth (1938) amplified themes that first appear in the writing of Simmel and, to a lesser extent, Tönnies. Wirth insisted that urbanism, or urbanization, produced any of several important social consequences among people: (1) impersonality and anonymity in everyday life, (2) loss of trust among people, and (3) various forms of social disorganization, as in higher rates of crime than in rural areas. Yet unlike Simmel and Tönnies, there was growing empirical evidence on which Wirth could draw. Like other members of the Chicago School, his attention was principally focused on the city of Chicago and the period of the late nineteenth and early twentieth centuries during which it multiplied in size enormously. Chicago, in fact, seemed to fit all the theoretical forecasts of urbanism, showing, among other things, a high crime rate and an abundance of urban gangs. In effect, the theoretical portrait that first emerged in the writings of Simmel and Tönnies, later appearing in that of Wirth, was more than just a social theory: It was a theory that seemed to be well grounded in empirical facts.

While Wirth's work expanded on the broad social consequences of urbanization, other Chicago sociologists expanded on other parts. Ernest Burgess, a longtime collaborator of Robert Park, produced a famous model of the growth of the urban area. The model consisted of a series of concentric zones. Each zone was composed of a different set of businesses and residential characteristics. The interior zone, for example, consisted of major business and financial firms; the immediately adjacent zone consisted of the red-light district as well as certain ethnic settlements, such as Little Sicily. And in the farthest reaches of the metropolis, one found wealthier residents as well as the apartment houses and fancier hotels. The model was based entirely on the city of Chicago, yet it eventually gave rise to many efforts to discover the extent to which it reappeared in many other growing metropolises. Moreover, there were additional efforts to show that the concentric pattern of growth was not the only one; other theories suggested, for example, that cities could develop in the form of a variety of different social and economic nuclei.

Human Ecology. Besides the theory of urbanism and the concentric pattern of metropolitan growth, the Chicago School

also gave rise to a general theoretical perspective on the nature of the metropolis, one rooted in a view of the city in terms of its population and broad social environment. Robert Park was the major developer of this view. And because it was inspired by the writings of ecologists—again an influence Park came under in Germany—it became known as the "human ecology" paradigm. The human ecology perspective was especially focused on the ways in which the population of areas expanded or declined. It concentrated its attention on how the change of specific areas of the city occurred, and which economic social actors were winners and losers in the process. Any of several outcomes could happen, Park believed—among them, conflict, accommodation, and in certain cases, assimilation by the newcomers of the cultural patterns of the natives. Indeed, it was Park's conception of human ecology and the city that eventually gave rise to his theory of the race relations cycle, and the nature of assimilation among immigrants, in general.

Park's theory was relatively simple and never extensively developed as a fully integrated theory. Amos Hawley, a sociologist who taught at the University of Michigan and North Carolina, took it upon himself to make the human ecology paradigm far more systematic. He fleshed out the ideas of the environment as well as the processes of adaptation and competition through which social groups adjusted both to one another and to the environment. Moreover, he advanced certain ideas about the nature of dominance and power among actors, among them the claim, later confirmed, that metropolitan areas with higher concentrations of professional and managerial workers would be more effective in getting broad civic actions implemented than those with smaller concentrations.

Theoretical Alternatives to the Chicago School

The Chicago School's theories of urbanization remained dominant among sociologists until the early 1970s. Then they were challenged by other points of view. The result was to create both reforms in the theories as well as to provide other theories grounded in different principles about the working of societies.

The City as Neighborhood and Community. One of the first and most important critiques of the Chicago School view of the city came from the sociologist Claude Fischer. Fischer challenged the Wirth/Simmel interpretation of the city. Fischer argued that the city was not characterized by impersonality and anonymity but, rather, by a variety of social ties and subcultures that connected people to one another. Fischer found the characteristic form of urban life in the neighborhood, not, as Wirth and Simmel had, in business or economic exchanges. Thus, he insisted, cities are not sites of impersonality but, rather, sites of trust and friendship:

Such relationships are to be found in the neighborhood, not in the department store.

The Political Economy Perspective. The dominant critique and most substantial alternative to the view of the Chicago School came, as one might anticipate, in the writings of Marxist scholars who began to build their alternative theory in the early 1970s. There are several variants of this perspective; although each is a rich and compelling portrait by itself, the discussion here must be abbreviated because of space limitations.

The leading Marxist theorist on the city is Henri Lefebvre, a French scholar. Lefebvre argued that the urbanization process is not one driven by population expansion and mobility, per se, but rather by the actions of key social actors. Social agents, he insisted, produce, and reproduce, the spaces in cities; and, to the extent that such agents reflect the dominant forms of social and economic inequalities, those inequalities will be re-created in the nature of metropolitan space. Lefebvre extended his basic insights in several directions, insisting that we must study not simply the different parts of the metropolitan area but also the way that social rhythms are created therein, such as the rhythm to work life and that to the nature of life on the streets.

Lefebvre inspired several important theorists. Among them are the sociologist Manuel Castells. Castells leveled the most major charges at the Chicago School view of the city. He argued specifically that it was not simply population growth that created the various forms of social disorganization, such as higher crime rates in the city, but instead it was the forces of capitalism. Capitalism created the inequalities, between residents as well as between sectors of the city. Moreover, Castells suggested, the Marxist view of the world, when applied carefully to the city and to the process of urbanization, emphasized the forces of collective consumption, not those of production, as Marx himself originally argued. Thus, Castells argued, it is the conditions of public housing and of other forms in which urban laborers are exploited as consumers, to which sociologists, studying urbanization, must turn their attention and seek to correct.

A third Marxist writer on urban areas is the British geographer, David Harvey. Harvey has had the widest influence over modern writings about the city. He maintains that from a Marxist perspective the major economic activity in urbanization is that which deals with the use and value of land. Thus, those social actors, such as real estate developers and bankers, actually exploit the value of urban space through their investment and selling strategies. Whereas capitalist employers secure profit by, for example, paying workers low wages, real estate developers and bankers secure their profits by setting high prices on the land in cities. Furthermore, Harvey argues, the inequalities characteristic of urban areas, such as the wide differential in values between suburban and inner-city areas, are also the product of how capitalism

manipulates the value of land. There is nothing natural to the disparate values of suburban and inner-city land; it is simply that bankers and real estate developers constantly seek to divest themselves of property that produces little income, as within the interior of the city, and reinvest their funds in other portions of the city, those especially in the outlying areas, where they can expect both to set higher prices and secure greater profits from the sales of land and housing. In recent years, it might be noted, that process has been reversed to some degree, as bankers and developers now turn their attention back to the central city, creating new housing developments where they can expect to lure both wealthy young professionals and older former suburban residents.

Other writers, taking a similar political economic perspective on urbanization, have developed similar critiques of the Chicago School as well as their own special theoretical portraits. John Logan and Harvey Molotch, in a famous work, argue that the city must be viewed as a "growth machine." Cities expand not because of the dynamics of population but, rather, because there are key social groups that benefit from such expansion. Such groups include, among others, real estate developers, bankers, and even political officials. All of them profit from growth, Logan and Molotch insist: Developers and bankers gain financial profit, while political officials garner the key political support of the business community if they insist on expansion.

MODERN FORMS OF URBAN GROWTH

Urbanization today is different in important respects from its form in the past. Here are a few of the significant twists and turns it has taken.

The Megalopolis

In the early 1960s, the urban scholar Jean Gottesman sought to capture the novelty of the growing interconnectedness of various major metropolitan areas in the world. He claimed that regions such as that from Boston south to Washington, D.C., along the Eastern seaboard of the United States represented new forms of metropolitan expansion in which major cities came to overlap with one another. He insisted that in the future more and more such megalopolises would emerge in the world, providing ever more dense concentrations of people. Such patterns, in fact, are to be found increasingly in the United States, in the West as well as the Southwest. There are many other countries as well, such as Japan, in which similar patterns of urban expansion are also to be found.

Suburbanization

Urbanization that produces new residential communities on the outskirts of major cities has become known as suburbanization. In the United States, suburbanization has become the fundamental form of urban growth since the end of World War II, suburbs taking root outside virtually all major cities. There are different explanations for the process. Unlike the Chicago School, which insisted that suburban growth was a simple part of the inexorable expansion of the city, the historian Kenneth Jackson has argued convincingly that the suburb represents a symbolic place rooted deep in American culture, a setting rooted in the imagination wherein people come to expect they can live a satisfying life, with their own yards and neighbors, intimately embedded in the natural environment. But Jackson has also shown that political actors play a key role in the creation of suburbs. In particular, he shows, the Federal Housing Agency after World War II provided low-interest loans to returning veterans, the effect of which was to make suburban housing far more affordable than it had ever been in the past. To this day, the process of suburbanization continues to engage the writings of social scientists as they seek to better understand the nature of urban growth, especially in the United States.

Edge Cities

Yet an even newer wrinkle to the process of urbanization today is the growth of what the journalist, Joel Garreau, has called "edge cities." Edge cities are those congregations of people, residences, and businesses that have grown up alongside major thoroughfares and, especially, highways around cities. They seem to occur everywhere that the highway system transports people, and they account for much of the most recent urban growth. Places such as Naperville, Illinois, and Georgetown, Texas, serve as examples of such expansion: Indeed, without the highway system, such rapidly growing cities would never have developed.

Global Cities

The growth of megacities such as London, Shanghai, and Mexico City, cities that number in the millions, has given rise to various explanations. Some, of course, would simply see such cities as the inevitable outcome of the urbanization process. But other scholars see in such megacities a new historic phenomenon.

The most popular writer on large cities today is the sociologist Saskia Sassen. Sassen argues that over the course of the last three decades the urbanization process has produced a tendency for people to congregate in enormous numbers on relatively small spaces. Three cities typify the process of urban globalization: Tokyo, New York, and London. All three cities, Sassen finds, are based on new and emerging economic foundations, in particular, the concentration of financial, real estate, and communications industries. Moreover, the growth of these cities has also led to their bifurcation along economic lines. Two major economic groups have emerged: on one hand, a large and

expanding class of service employees and, on the other hand, a much smaller but far more wealthy group of professional workers. The effect, she argues, is to increase economic inequalities in the city; moreover, she insists, the growth of the service sector jobs has also prompted the influx of many immigrants who are willing to take on the low-paying positions. Finally, she argues that these global cities have become disconnected from their nation-states; they tend to act as strong political and economic actors on their own, relatively autonomous from nations. Sassen's argument has proven very influential, but it also has its critics, some of whom charge that she underplays the key political role of the nation-state in today's world.

It is notable that among these major novelties to urban growth in the recent past, only the work of Sassen on global cities and globalization is based on important theoretical work. The other new elements, such as edge cities and even suburbanization, are regarded by urban scholars as significant, although they have not yet prompted extensive theoretical work by sociologists.

POVERTY, IMMIGRATION, AND URBANIZATION

New patterns of urban expansion have helped to modify the earlier theoretical views of the city and suggested not only the limitations of such theories but also the importance of human actors in the construction of the metropolis. One of the most important areas of contemporary work on urban expansion and change lies in research on poverty and immigration.

Poverty and Urbanization

The sociologist, William Julius Wilson, has had an important impact on these writings. In his various writings Wilson inspired a line of research on the modern city in which work, and its absence, he believed, played a powerful role in shaping the urban area. His claim is that over the course of two decades, from about 1970 until 1990, the nature of cities in the United States changed dramatically. Parts of the city declined, while other parts expanded. Those parts that declined, almost always located in the inner-city areas inhabited by black residents, did so, he insisted, because major industries abandoned these areas in favor of labor markets elsewhere, especially overseas. The result was to create a huge group of unemployed people, those whom he came to describe as the "underclass." In turn, new jobs tended to show up on the fringe of urban areas, at those sites generally occupied by the white middle class. Moreover, such jobs became part of the suburbanization phenomenon, even in many cases integral to the emergence of "edge cities."

Unlike the Chicago School of sociologists, however, Wilson believed that such decline was not inevitable but, rather, directly traceable to the decisions of industries to leave the city. Hence, he became a strong advocate of efforts to encourage new public policies that would promote a revitalization of the inner city along with efforts to increase the growth of low-income housing in the suburbs, thereby bringing low-income people closer to the location of the new employment opportunities.

This work on poverty has also led to further studies of the nature of social disorganization and decline in the inner-city areas of the modern metropolis. Sociologists such as Robert Sampson have argued that some neighborhoods are much more able to deal with issues of social disorganization, attributing their success to the "collective efficacy," or the capacity of residents to take common and effective local action. Many other social scientists are following up similar leads, with efforts now under way to create more viable and successful communities among the poor and minority residents of the inner city.

Immigration and Urbanization

Immigration in the contemporary period also represents an important new social element to the picture of urban growth. In the past, immigrants tended to settle in the interior of major cities, partly because that is where they first arrived and partly because, in the absence of highways, mobility to the outlying areas was virtually impossible. Today, however, there are new patterns of immigrant growth and communities in urban areas. Part of the difference is to be found in the vast numbers and movement of people across the world. Since 1945, there have been massive shifts of people from one country to another, most of whom settle in or around urban areas. In cities from London to Paris, Berlin to Toronto, one can find new and relatively large immigrant settlements. Some such settlements have arisen because of a government's selective use of guest worker programs, like the *bracero* program in the United States or the *Gastarbeiter* program in Germany; but many others have emerged simply because immigrants come to a new place for the job opportunities it offers. In the United States, today's immigrants are remaking the metropolitan area, not only through the introduction of groups of people from Latin America, Asia, and Africa—nations formerly underrepresented—but also by a host of new settlements across the entire metropolitan region. Thanks to the system of highways and public transportation, today's immigrants can settle not only in the inner core of the metropolis but also on the suburban fringes as well. Because of such new patterns of settlement by immigrants in the metropolis, sociologists have modified their older theories and developed new arguments about the growth of a multicultural metropolis.

THE FUTURE OF URBANIZATION

Urbanization will continue as long as people form communities, move from one place to another, and settle in sites where new friends, old family, and good job opportunities

can be found. Whether it will tend to improve the condition of humankind, or detract from it, depends on many things. One thing is now very clear: Human beings and social institutions can play a far more important role in the shaping of urban areas than early twentieth-century theorists ever thought possible. Indeed, one might say that the early theorists tended to view urbanization as a broad structural process, in part simply to make the new enterprise of scientific sociology a legitimate one. Today's urban writers and thinkers tend to see the process of urban expansion both as one more subject to the exercise of human agency as well as one heavily influenced by events and actions rooted in international circumstances.

UTOPIA

THE INVENTION OF UTOPIA

The term *utopia* was coined by the English writer Sir Thomas More in his book, *Utopia* (1516). More combined, in a punning way, two Greek words, *eutopia* = the good place, and *outopia* = no place. Utopia is therefore the good place that is nowhere.

This would seem to lend itself to the most fantastic products of the imagination, unchecked by any considerations of reality or rationality. The wider reaches of science fiction, as well as the fantasies of the dream, would seem to belong to its province. If utopia, by definition, is not and never can be somewhere, why restrict ourselves to the merely practicable, let alone the realistically probable? Why not give the freest plays to our fancies, let our imaginations rip in the devising of schemes for the fullest fulfillment of our desires?

There are indeed, it seems, at all times and in all societies, forms of thought and popular culture that express this kind of longing. Nearly all societies have traditions of Paradise or the Golden Age, a time and a place where the pain and privations of everyday life did not exist and all lived freely and blissfully. There are folk images of the Land of Cockaygne and Schlaraffenland, places of exuberantly unrestrained wishes and more or less instant gratification. There are El Dorados and Shangri-las where people live in peace, harmony, and everlasting contentment.

But these are not utopia—not, at least, as that form has been understood and practiced for more than 500 years in the West. From the very beginning, from More's own rational and restrained vision in his Utopia, utopia has displayed a certain sobriety, a certain wish to walk in step with current realities. It is as if it has wanted deliberately to distinguish itself from the wilder fancies of the popular imagination. Typically, it has been a form of the high literary culture of the age. Certainly it has wished to go beyond its own time and place. It has sought to create a picture of a good, even perfect, society. But it has wanted to remain within the realm of the possible. It has wanted to work with the human and social materials at hand; it has accepted the psychological and sociological realities of human society. The realm of utopia is wide, but it is not boundless. Utopia, while it liberates the imagination, also sets limits. This is perhaps the source of its fascination—and its strength.

More's *Utopia* initiated a tradition of social thought that has had a continuous history ever since (More's own book, remarkably, has been in print in one language or another without a break since its original publication). In addition to *Utopia,* certain major utopian works inspired by it—Anton Francesco Doni's *I Mondi* (1553), Johann Valentin Andreae's *Christianopolis* (1619), Tommaso Campanella's *City of the Sun* (1623), and Bacon's *New Atlantis* (1627)—achieved great fame among European men of letters. All utopian writers were aware of these great exemplars even when they sought, as in Bishop Hall's *Mundus Alter et Idem* (1605) or Jonathan Swift's *Gulliver's Travels* (1726), to satirize or rebut them (thus inventing the anti-utopia or dystopia). Right down to the twentieth century, we can trace the continuing influence of the great early modern utopias.

UTOPIA AND SOCIAL THEORY

With his *Utopia,* More coined not just a new word, but he invented a new form. Not that there were not important precursors. More was influenced by works such as Plato's *Republic* (fifth century BCE) and in general the Hellenic literary genre of devising the ideal city. He was probably also influenced by Christian monasticism and the Christian idea of the millennium, from the Book of Revelation in the New Testament. But neither Plato's *Republic* nor the Christian millennium looks like More's *Utopia.* The *Republic* is essentially a treatise on justice, while, apart from the fact that More's Utopians are pagans, the Book of Revelation's sketch of the coming millennial dispensation is shadowy in the extreme. What the Hellenic ideal city contributed to utopia was the element of design, the planning of the perfect city or society. What the Christian millennium contributed was the element of time or history. The expectation of Christ's second coming, which would inaugurate a terrestrial millennium of peace and plenty, gave to utopia a sense of urgency and hope. There would be an "end of days," an end of history, which would lead to the annulment of the old order and the commencement of the new. Utopia was slow to incorporate this dynamic dimension in its imagination—it is not found, for instance, in More's *Utopia.* Not until the eighteenth century, with the decisive temporalization of European thought, did the millennial theme come fully into its own in utopian thought.

So classical and Christian ideas have undoubtedly played their part in the utopian tradition. But in synthesizing them, More went beyond them in inventing a new literary form. Utopia is a form of fiction closely related to the novel—indeed, it probably contributed to the development of the novel form as it emerged in the eighteenth century. It uses all the techniques of the novel—plot, characterization, incident—to paint its picture of the ideal society. This distinguishes it from the form of social and political theory that, following Friedrich Engels, we might call "utopian social theory." Examples of such theory would be the writings of Robert Owen, Henri Saint-Simon, Charles Fourier, and indeed those of Karl Marx. These give an account of future societies in which misery, injustice, oppression, and pain have been eliminated.

To that extent they are utopian. But their accounts are couched in the terms of social-scientific analysis. They claim to be giving scientifically truthful accounts of history and society. Indeed so concerned are they to do so that they are markedly hesitant, especially in the case of Marx, in giving full-blooded accounts of the new society ("I do not," Marx wrote contemptuously, "write recipes for the cookshops of the future"). This may have advantages in certain respects, but in comparison with the utopia proper, it also suffers from a serious weakness.

What makes the literary utopia superior to other ways of promoting the good society? We can compare, say, the accounts of socialism in the writings of theoreticians such as Marx and Engels and those provided in socialist utopias such as Edward Bellamy's *Looking Backward* (1888) and William Morris's *News from Nowhere* (1890). We have many testimonies to the effect that, while impressed by the theoretical writings of the socialists, it was these socialist utopias that converted many Europeans and Americans to socialism. There can be many reasons for this, including the obvious one of the attractions of a well-told story over abstract analysis. But there is also the point that utopias are more persuasive because they allow us to make a more honest test of theory than abstract formulations, however profound.

The utopian mode of persuasion is to paint pleasing pictures of daily life, such that we are driven to want to make the world they portray. They are concerned as much with what Miguel Abensour calls "the education of desire" as with the particular portrait of the good society. But in painting such pictures, utopian writers are forced to provide the wealth of details of daily life that are entirely lacking in abstract theory. Unlike the theoretician, who asks us to accept as it were on trust that the desirable consequences will follow from the application of the relevant theoretical principles—that happiness will, indeed, follow upon "the expropriation of the expropriators," for example—the utopian writer is under the obligation to present a fully developed and detailed picture of the happy world that is expected to result from the application of the relevant principles. We see people at work and at play, at home and in the public spaces of society, in their personal and in their political lives. We experience, through involvement with characters and events, as well as through the descriptions of the scenes and settings of daily life, a "good day" in the new society. We can therefore judge of both the plausibility and the desirability of the life so presented. When William Morris, in *News from Nowhere,* vividly depicts the revitalized and rebeautified landscape of the Thames valley in a transformed socialist England of the future, we intensely want to be there, to experience such beauty. But we also understand, in a way not possible from a reading of socialist theory, what precisely might be involved in the construction of the new society, and how far we can imagine such things coming about. It is exactly in this way, too, because we can see in detail how it looks and feels, that we can choose between the competing visions of socialism offered by Bellamy and Morris—Bellamy's utilitarian paradise where the machines do all the work and Morris's more arcadian vision where work is restored to everyone as a labor of love.

UTOPIA IN SPACE AND TIME

The utopias of the sixteenth and seventeenth century—those of More, Campanella, Bacon, and others—can be called objects of contemplation. They were philosophical speculations, sometimes religious in inspiration, on the nature of

good and evil, and how humans might aspire to lead the good life, so far as it might be humanly possible on earth. Typically, they held up a satiric mirror to their own societies, using the utopian society as a foil to their own disordered societies. There was little suggestion that they were intended as practical schemes of human betterment. Even Bacon's utopia of science, *The New Atlantis,* merely suggested the boundless possibilities opened up by the new scientific and technical discoveries of the age. Although the House of Saloman has often been seen as anticipating the foundation of the Royal Society in 1660, its social and political setting in *The New Atlantis* gives no guide whatsoever as to how to achieve the scientifically advanced society that spawns it.

With the growth of the idea of progress in the eighteenth century, utopia took on a more secular and realistic form. It now came to be inserted in history, in the story of humanity's growth in knowledge and power. Utopia was displaced from space—the space of contemplation—to time, the time of the culmination of human development. Utopia would be found not on some hitherto unknown island nor in a remote mountain valley on the other side of the world, but in the future. Louis Sebastien Mercier's utopia, *L'An 2240* (1770) decisively sounded the new note. The epigraph was taken from Leibniz: "The present is pregnant with the future."

There was however an unexpected side to this development. While Enlightenment utopias made full use of the new temporal resources, the occurrence of the French and Industrial Revolutions prompted the thought that utopia might not be some distant eventuality but a more or less imminent possibility. In the hands of Saint-Simon, Comte, and their sociological successors, in the thinking of the socialists Owen, Fourier, and the early Marx, utopia passed into a species of social science in which it was argued that the good society could be constructed with the tools at hand and that, moreover, it was a society struggling to be born in the thinker's own times. There seemed no need, and no room, for imaginary pictures of the good society. Utopia proper went for a while into abeyance. Its place was taken by schemes for reform and regeneration that, drawing on the new social sciences, offered to show the way to utopia as a strictly rational and scientific enterprise. Most prominent among these were the varieties of socialism.

But although utopia, as a literary form, underwent a temporary suppression, the temporalizing impulse underlying social thought remained powerful in the evolutionary schemes of the social scientists, to mark strongly the utopias that reemerged toward the end of the nineteenth century. Ironically, it was the very failure of socialism to generate the expected support or to realize its aims that seemed to have stimulated the revival of utopia. Socialists came to see the need to show society as it might be, in all its glowing colors. That was the aim of Bellamy's *Looking Backward,* Morris's *News from Nowhere,* H. G. Wells's *A Modern Utopia* (1905), and a host of others that crowded the field at the end

of the nineteenth and the early twentieth centuries. In nearly all these, the temporal dimension was paramount. Society needed time to develop the fullness of its powers and the consciousness of its members. In such a way, and to such an extent, did the millennial underpinnings of utopia—the supplying of the elements of hope and of history—continue to show their power up until recent times.

THE FATE AND FUTURE OF UTOPIA

The twentieth-century world, at least in the first part of the century, was markedly inhospitable to utopia. Two world wars, a global economic depression, fascism and communism, Hiroshima and the subsequent "balance of terror" between the West and the Soviet bloc: All these not unnaturally militated against the hopes that had sustained utopia throughout "the long nineteenth century." All these developments equally naturally provided rich material for utopia's *doppelgänger,* the anti-utopia. Evgeny Zamyatin's *We* (1920), Aldous Huxley's *Brave New World* (1932), and George Orwell's *Nineteen Eighty-Four* (1949), with their chilling portraits of totalitarian societies governed by scientific techniques and power-hungry elites, were the works that stamped themselves on the imaginations of Western societies in the first half of the century and beyond. Equally persuasive were varied works such as Arthur Koestler's novel *Darkness at Noon* (1940) and the philosopher Karl Popper's *The Open Society and Its Enemies* (1945), both of them swingeing attacks on the utopian temperament and the pass to which it had brought the world.

There were some isolated attempts, especially in the Marxist camp, to keep the utopian flame alive, of which Ernst Bloch's voluminous *The Principle of Hope* (1949) was the most exuberant expression. The psychologist B. F. Skinner's *Walden Two* (1948), a utopia of "behavioral engineering," was also a brave attempt to revive utopian hopes in dark times. And indeed in the second half of the twentieth century, despite the ever-present threat of nuclear war between the two superpowers, utopia found new forms and new ideas. Partly this may have been the result of the enormous vitality shown by Western economies in the post-1945 period, allowing many thinkers to argue that "the economic problem" had been solved. Certainly, this seemed the underlying assumption of the upsurge of utopian thought that was found in the student movements and the "counterculture" of the 1960s (right on cue, the old anti-utopian Aldous Huxley stepped forward to answer his own critique with a sex-and-drugs utopia, *Island* [1962], which fused Western science and Eastern philosophy). In the French "May Events" of 1968, Parisian students for a short time even attempted to put utopia into practice by turning the city into a liberated zone of spontaneity and pleasure.

Out of the movements of the 1960s also came two new kinds of utopias—the ecological utopia or "ecotopia" and

the feminist utopia. Neither was entirely new—Morris's *News from Nowhere* was an ecotopia in all but name, and the feminist utopia had precedents in works such as Charlotte Perkins Gilman's *Herland* (1915). But both showed that the utopian imagination was far from exhausted and was capable of being put to effective use in the new concerns of the age. Ernest Callenbach's *Ecotopia* (1975) named the form, although some of its best expressions were to be found in genre science fiction, such as Frank Herbert's portrait of the Fremen in *Dune* (1965). Ecological sympathies were generally also strong in the feminist utopia, such as Marge Piercy's *Woman on the Edge of Time* (1976) and, most notably, Ursula Le Guin's *The Dispossessed* (1974). And in a familiar fashion, these vigorous utopias were matched by equally energetic anti-utopias, such as John Brunner's *Stand on Zanzibar* (1969)—a warning against overpopulation—and Margaret Attwood's *The Handmaid's Tale* (1986), in which women are simple breeding machines and the playthings of men.

The problem for recent utopias has been that, unlike earlier ones, they tend to be addressed to, and read by, the faithful. It is mainly those already possessed by an ecological or feminist consciousness that tend to be attracted to these utopias. Utopia does not, as with Bellamy's *Looking Backward* or Skinner's *Walden Two,* become a hotly disputed vision of present and future society. It has been exiled to the margins of society, becoming a subgenre of science fiction or feminist literature. So far, this too seems to have been the fate of the "virtual utopia," the many private utopias to be found scattered all over the Internet. The anti-utopia seems to have fared better, at least in the popular medium of the cinema, judging by the success of films such as *The Matrix* trilogy (1999, 2003, 2003) and *Minority Report* (2002). And perhaps it is in the new visual technologies that utopia, too,

will find new themes and forms, if it has a future. That at least has been the view of certain theorists of postmodernity, such as Frederick Jameson and David Harvey. But it is hard to see how the typical postmodernist attitude—skeptical, ironic, playful, distrustful of the "grand narratives" of reason and history—can stimulate utopian thinking.

Utopia has had a more or less continuous 500-year history. In our own era of globalization, the information technology revolution, splintered societies, and mass migrations, one would think that never was there more need for unifying and clarifying visions. That has been utopia's function throughout its long history. It is difficult to imagine that it has now ceased. Social and political theory has its invaluable contribution to make, but it is utopia that issues the clarion call.

V

VEBLEN, THORSTEIN

Thorstein Veblen (1857–1929), along with Max Weber, Vilfredo Pareto, and Werner Sombart, worked at the intersection of economics and sociology. Veblen's memorable concept of "conspicuous consumption" formed a lasting link between economics and sociology by focusing attention on status seeking, which motivates a great deal of economic behavior but must be understood in sociological rather than in purely economic terms. Veblen is also remembered as one of the founding figures of the "institutional economics' tradition in economics, with its focus on legal forms and developments in governance. Finally, Veblen was an insightful social critic who helped shape the thinking of subsequent generations of analysts like C. Wright ("the power elite") Mills.

Thorstein Veblen was an economist who, in the process of trying to understand the economy, underwent a transformation that carried him clearly into sociology. Veblen's departure from conventional economics began with his rejection of the idea that most behavior is guided by rational calculation aimed at maximizing material well-being. A key to understanding Veblen is his awareness of human beings as status seekers. Veblen viewed society as a giant arena in which people struggle to acquire social approval. His enduring contribution unfolds from the recognition that what often appears as materialism is actually status seeking in disguise.

Veblen maintained that the specific steps people take to pursue recognition will be constrained by the character of the property system, the nature of banking, and other institutional forms. Informed economic analysis must consequently pay considerable attention to organizational and legal forms as they have evolved over time in different countries. Although he was indebted to the German "historical" economists in this regard, Veblen is nevertheless remembered for having provided some of the intellectual inspiration and energy for the subdiscipline of "institutional" economics.

Thorstein Veblen's parents were Norwegian immigrants farming in Wisconsin when Thorstein Veblen was born in 1857, the sixth of 12 children. The family moved to a larger farm in Minnesota in 1865, where Veblen grew up speaking Norwegian in a rural, religiously conservative setting. Smart and acerbic, Veblen didn't fit in very well when he was sent to newly established Carleton College to train for the Lutheran ministry. Veblen generally disliked Carleton when he was there (1874–1880), but he did grow close to one faculty member, and this proved to be very important. The faculty member was John Bates Clark (1847–1938), who had just completed his graduate studies in Germany, where he had studied economics with Wilhelm Roscher and Karl Knies of the historical school of economics.

After graduating from Carleton, Veblen taught at a local school for a year. He began graduate studies at Johns Hopkins in 1881 and rather quickly transferred to Yale where he completed a doctorate in philosophy in 1884. Veblen's mentor at Yale was Yale's president, the Reverend Noah Porter, and Veblen was also very close to William Graham Sumner. But Veblen was unable to find a faculty position on completion of his program of study, so he returned to Minnesota where he married former Carleton classmate Ellen Rolfe in 1888. They moved to one of her father's farms in Iowa, where they shared a life of hard work but also studious reflection about the state of America's farm economy. Beginning in the late 1880s, there was a serious drought in the upper plains states, lasting five years. Farm foreclosures reached record proportions in some areas. Within a short time Veblen enrolled in graduate school at Cornell University to study economics (1890–1892). Upon leaving Cornell in 1892, Veblen accepted an entry-level position as a teaching fellow in

economics at the University of Chicago. He remained at the University of Chicago until 1906, producing his best-known work, *The Theory of the Leisure Class* (1899), editing the *Journal of Political Economy* for a time, and enjoying lively collegial exchange with some of the best minds of his time but never feeling fully appreciated.

Thorstein Veblen's *The Theory of the Leisure Class* introduces the observation that rich and near rich and merely prosperous, and even rather poor people in America, engage in conspicuous consumption as a way of elevating their status by flaunting things people equate with success or interpret as signs of accomplishment and worth. Conspicuous consumption is easiest to use as a strategy for acquiring social recognition in a country like the United States where there is a lot of geographic movement and people are very busy and are therefore apt to make quick judgments on the basis of visible signs. But status accrued through conspicuous consumption is not necessarily deserved. Veblen saw rich people in general and absentee owners in particular as social parasites who impede rather than foster the advancement of society. His evolutionary view of a society's development focused on technology that makes new things possible (a good thing), class structure that tries to fossilize old inequalities (a bad thing), and institutions that (no longer contemporary, having evolved in the past) can act as a brake inhibiting further progress unless they evolve with the times.

Veblen's *The Theory of the Leisure Class* was an instant success and attracted a cult following for its insightful social criticism. His later books were less successful, however. Veblen's *The Theory of Business Enterprise* (1904) is difficult to read and antagonized a lot of people because of its antibusiness stance. This put Veblen at the center of a firestorm at the University of Chicago. And when the firestorm was not about his critical analysis of the American economy it was about his social life, for Veblen was accused of having too much magnetic appeal for members of the opposite sex.

In 1906, Veblen went to Stanford University, but controversy regarding his social life followed him. His wife left him for good, and he moved to the University of Missouri in 1910. While at Missouri, Veblen produced *The Instinct of Workmanship* (1914), *Imperial Germany and the Industrial Revolution* (1917), and other works, extending ideas introduced in his first books. After America entered World War I in 1917, Veblen held advisory posts in the government, but he provided advice that would have been politically difficult for the administration to embrace. After the war, Veblen moved to New York City to edit *The Dial,* a politically charged, reformist-minded magazine. Veblen's editorship ended after one year. He was then invited to join the faculty of the New School for Social Research. At the New School, Veblen was renowned but somewhat marginal. In 1927, aging and losing energy, he returned to California where he led a rather impoverished existence until his death in 1929.

VERSTEHEN

In contrast to explanation, the listing of the causal rules governing events, scientifically observable processes, or functional relationships, "understanding" addresses itself toward meaningful human behavior and the resultant meaningful objectified forms this behavior takes on within the fields of economy, politics, culture, and the arts. In comparison to the (philosophical) term *knowledge*, *understanding* is as a term more extensive, yet at the same time subject to greater limitations. It is more extensive in that it connotes a familiarity with the lifeworld, and everything belonging to this context. For this familiarity constitutes a precondition for the acquisition of knowledge through reason. The limitations of the term become apparent in relation to the interpretation of individual constructs of meaning: values, behavioral patterns, and motives. However, these very same constructs of meaning cannot be adequately interpreted either through identifying the laws of causality behind them or by recourse to "nomological" insights attained through pure reason. Only the interpretative reconstruction of the meaning behind the given behavior achieves this end. Although the additional knowledge gained through this interpretative understanding is in comparison to explanation on the basis of observation "bought at the price of the fundamentally more hypothetical and fragmentary character of the results won

through interpretation," these gains attained through the process of understanding designate "exactly the specific nature of sociological knowledge" (Weber [1922] 1978:15, § 1).

CONSTRUCTION AND RECONSTRUCTION

Sociology, insofar as we mean it in Max Weber's sense of the term, has disclosed that the human processes of perception, recognition, understanding, and explanation establishes images and constructions of "reality," believe these constructions to be real, define them as reality, and orient themselves according to them. The transcendental-philosophical, Kantian development in the theory of perception carried on by Husserl; the social theories and protosociologies of Schütz, Berger, and Luckmann in this context; the anthropological expansion of the phenomenological point of view by Scheler, Plessner, and even Gehlen: all these have contributed to the systematic description and analysis of this phenomenon. A construct's attainment of meaningful intersubjectivity within a monadic community (Husserl), the subjects of the "social constructions of reality" with an egologic perspective (Berger and Luckmann 1966, 1970) the social constitution of the "structures of the life-world" (Schütz and Luckmann 1979, 1984), and the principally symbol boundedness of human perception and action (Peirce, Wittgenstein, Buehler) all serve here as examples.

Sociology as the science of reality aims to comprehend and explain all social constructions: the products of human activity, the forms of socialization and economy as well as the conceptions of the world, interpretive figures, and world outlooks. It presupposes that the symbol boundedness of human perception and action conceives of all social constructions in "symbolic forms" (Cassirer), that we move, interpreting, through a human preinterpreted and overinterpreted world, that we are trapped in our own symbols and fictions or constructions of reality, and that, in the orientation of our actions, we must grapple with the reality or, respectively, with the validity of these fictions and constructions.

It does not follow that the social sciences and humanities must once again fight the battles against realism, empiricism, and idealism fought by Carneades, Augustinus, Kant, and Husserl just because some natural scientists and cyberneticists—quite belatedly and with astounding coarseness—have uncovered (or discovered) what for them are new insights. The realization that subjects construct "their" reality according to their type-specific and individual abilities and that which is collectively held to be "real" is indeed a social construct, is of great consequence. However, this insight is not new. Thus, it should not lead to the repetition of old debates about our inability to perceive an outside world per se. Rather, the social sciences must address the various social constructions and offer comparative explanations for these sketches of reality as a result of their historical and social structural conditions. Sociology is primarily hindsighted prophecy—the reconstruction of social constructions and the conditions of constructions of reality. Thus, sociological prognoses are made up of the—often dubious—attempt to imagine one's self and others on the basis of scientific interpretations and reconstructions of past realities, possibilities, or probabilities of "new" social sketches of reality.

EVERYDAY AND SCIENTIFIC CONSTRUCTIONS

From a pragmatic perspective, the everyday actor must—however faulty the results may be—prognosticate. Otherwise, setting goals and planning actions would not be possible: Survival requires more of us than reaction. In contrast, before he or she dares to prognosticate, the social scientist must first deal with the description and analysis of the particular construction on which the actions and plans of members of society in everyday, pragmatic perspectives are based. These are the first order constructions—the everyday, sociohistorically anchored types, models, routines, plausibilities, forms of knowledge, resources of knowledge, and (often implicitly) conclusions.

In that the social scientist is occupied with it, the reconstruction does not double the constructs of everyday action. Indeed, in the processes of describing, understanding, and explaining the construction of "the everyday," a network of categorizations, ideal-typical suppositions, ex-post conclusions and causalities, or finalizations is established ("in order to" and "because motives"). In short, one designs second-order constructions. These are (demonstrable theoretically as well as in formal models) controlled, methodically examined and checkable, comprehensive reconstructions of the first-order constructions.

There is more than just a logical difference between first- and second-order constructions. When a reconstruction begins, the action to which it refers is already finished, past, and unrepeatable. Insofar as it is open to interpretation, it must be represented in certain data, and it "presents" itself in the data as a completed action. Since social scientists are interested in testable—that is, intersubjectively, rationally understandable—reconstructions, they can neither understand the action in the same way as the actor, nor can they project themselves into the souls and minds, thoughts and feelings of the actor. Instead, they develop "reconstructive-hermeneutic" models of possibilities for the processes of action as well as for the actor.

The data recording past events are, after all, *not* the "original" situations in which the action took place but their records. To the same small degree, the interpretations are *not* the repeated and "rationally explicit" original action in the reconstruction. Rather, they are models of objectively

possible symbolic figures that are based on and refer only to the records of the action (indeed for the purpose of interpretation, all human products share the status of records of action). Thus, interpretations do not "contain" "the actor who truly existed" (or, respectively, the first-order constructions formed by partners in action in specific situations) anymore but, rather, models of the actors. These, in turn, are put in a situation that they did not choose themselves—in no small part due to the way a social scientist has posed the question with which he or she is concerned. "He [or she] has created these figures, these homunculi," in order to understand and explain their doings according to his or her own as well as general conceptions of comprehensible and rational action. In the case of all logical, "existential" differences between everyday perception, interpretation, action, and understanding on one hand and, on the other hand, the scientific reconstruction of the first-order constructions on which they rely and the conditions of their reconstruction, it can be determined that everyday and scientific constructions are based on the same framework (that of the human condition) and on a largely shared repertoire consisting of experiences, sociohistorically conveyable and learnable skills and methods. In other words, our everyday and our scientific actions and interpretations are each part of different "provinces of meaning" (Schütz) and each represents a different attitude, a different method of recognition with regard to ourselves and the world around us, but the scientific capacity to understand is to a great extent structured similarly to everyday life—from which science derives and the methods and criteria of which are borrowed more subconsciously and implicitly than consciously and in a controlled manner.

Despite all attempts to distinguish between the two, the results of scientific (which remain mostly inexplicit) and prescientific comprehensions demonstrate a series of similarities. Both meet in the formulation of explanations, and these explanations rest often enough on nothing other than standards of plausibility that seem to be closely tied to a supposed common sense. These certainties, in turn, are derived from unknown or no longer known routines of typifications and connections of standard experiences, from processes of "interpret however" and collective semantics that are no longer questioned. It is similar to or the same for the prescientific and the scientific explications of experiences that their explanations are typified and classified observations, enumerations, and relations of data that have always been rationally constructed. The social world is constructed understandably, and we move interpreting in a preinterpreted and overly interpreted world, a sociohistorical symbolic a priori.

With regard to their basic structure, scientific comprehension and explanation are probably analogous to everyday thought but have been more formalized and institutionalized. In contrast to past paradigms of interpretation and

comprehension, both methods of explanation—the scientific and everyday—are generally equally unreflective. Of course, social scientists in particular like to deal with the "ideologies" and "myths of the everyday," but seldom do they pursue the question of how much their own myths rely on exactly those of the everyday, how much they are derived from the latter, or—in case this compositional wrong tree has not been barked up—whether and to what degree they differ at all structurally or formally analytically from quasi-mythological thinking.

UNDERSTANDING AND EXPLAINING

A systematic examination of the structural conditions for the constitution of these myths is even more seldom undertaken in practical research: the genres and types of narration, symbolism, and components of construction; historical lines of argumentation and quotation ("discourses"); the process of the construction of perspective, expectation, and consensus. If, however, the subject is meant to be the description, an interpreted understanding and explanation of social orientation as well as social action and its products, then one cannot get around these fundamental analyses—unless, of course, one is content with these individual myths.

The analysis of human subjects, "groups," or societies' historical, "individual," or "collective" conception of self is not possible without the identification, description, and analysis of the "practices," "rules," "patterns." and "communicative types of presentation"—foregoing all the constructions of "contents," opinions, dogmas, and worldviews—that we employ when we orient, reassure, and acquaint ourselves—when we act, produce, and interpret. There can be no rational sociology of the content of knowledge and of action without a sociology of the forms that shape knowledge and action and without which both would be rendered unrecognizable as well as not sustainable. Often enough, "contents," opinions, and convictions are nothing more than decorations—colorful trim on the forms that practically lend action social sense and are content—"forms are the food of faith" (Gehlen 1988)

It may be fascinating to be devoted to ideas, assertions, and convictions; to read and "reread anew" certain authors and books; to introduce, for example, to the Marxist method of reading from yesterday something new from today. As long as a historical-reconstructive analysis of the structures of the text and argumentation and the symbolic networks and discursive references of Marxist texts are partially tackled and, in Bultmann's sense of the word, *de-mythologized*, while at the same time this same method is not applied to the description of the patterns of reception, of the series of quotes and recitations rampant in them, there is nothing to expect of the "new" literature other than a continuation of the never-ending story of old approaches. Something totally different would be a literature on the horizon of

sociology, a sociology that has as a necessary component a developed and systematically proceeding sociology of comprehension.

The scientific "comprehension of something" necessarily requires the description and explication of the implicit procedures and perspectives of comprehension—the comprehension of comprehension itself. In the same way, speaking of sociology as a "science of experience" only then makes sense, when it is not simply understood as a collection of and an analytical historicizing renarration of experiences, but as a science of the social constitution, recording, and transmission of experiences as well.

Inasmuch as one understands sociology in a "social scientific hermeneutical," a basic theoretical, "protosociological" (Luckmann) as well as a practical research sense, it will appear—theoretically necessarily—as the sociology of knowledge. This means no more and no less than the science of the reconstruction of the social constitution of experiences and the social construction of reality. Only as a "comprehensive," hermeneutic-reconstructive science of the social can sociology fulfill its role as the science of reality *and* experiences.

Pulling together the thoughts of Max Weber and Alfred Schütz, one can help bring to an end a widespread prejudice, which, simplifying Schleiermacher, states that social scientific comprehension concerns itself inductively and more or less empathically with the specific, while explanations according to preset principles subsume the specific to a general. Beyond this, "comprehension" is more a process of humanities, "explanation" more a natural science-oriented method. One does not encounter this prejudice in just the shrinking, dedicated community of colleagues who work with theoretical models, pure quantification, or both. Rather, this is also seen in various conventicles in the colorful camp of "qualitative social research"—by those who use expressions such as "hermeneutics" and "comprehension" as war cries against explanative = mathematicalizing, overmeasuring, and soulless—in short, Cartesian sociology.

Max Weber's ([1922]1978) famous definition of "interpretive" sociology, in the first sentence of the first section of *Economy and Society,* has either been forgotten or was never taken particularly seriously. "Sociology . . . is a science concerning itself with the interpretive understanding of a social action and thereby with a causal explanation of its course and consequence" (p. 4, § 1). The methodological consequences of this definition can be sketched onto four steps: observe, describe, understand, explain.

Scientific "observation," which assumes a limited inquiry and a preliminary establishment of what the case should be, is to be understood here as controlled investigation and production of data. At the same time, the observer's perception as such cannot at all be controlled, or at best, only to a certain degree. Attention, then, must be directed all the more closely to those processes in which, in connection with—nonlingual—perception, linguistically set data are derived from impressions. The social scientist in this case becomes a scribe. Actions are translated into language, speaking into writing. The written text lends a new and different structure—that of text—to the structure of action, conversation, or both. The structure of text has its own rules of organization and procedure. Its chronological and procedural structures have hardly anything in common with those of nonlingual action and its perception. In this way, the immediate, reciprocal relationship in which interaction partners perceive and react to each other, for example, is turned into a dramatic text broken up into sequences and made up of director's comments and dialogue. The perception of the simultaneous becomes a sequence of text.

Controlling the difference between observation and transcripts of observation is as much a part of controlling the description as it is a reflection on the fabrication and "artificiality" of the data. Limiting what the case should be provides benefits not only for the selection of what the description will entail but also often for the style of presentation. Aside from implicit and explicit contextual judgments, just through its formal arrangement (or its belonging to a specific genre: from an ostensibly neutral explanatory text to the report oriented closely on the field to the narration enhanced by literature), it contains its own explanatory rules for subsequent interpretations. Whatever may be the result of the control, it leads principally to the insight that the scientific interpretation of data is a secondhand interpretation of life.

Scientific understanding (the controlled putting forth of data to which of course all products and documents of human activity count as or can be made into natural data) can only then begin systematically and methodically reflectively if the data are provided discursively. They must be recorded in some way. It must be possible for interpreters to examine them, interpret them, and turn them around again and again. In short, the "fleeting," as it is not fixed, attention of everyday interaction can, by way of the establishment and continuous recallability of the data, be made permanent. Then even "the most unremitting attention," as Dilthey ([1900]1962) knew,

> can become a skillful method, in which a controllable degree of objectivity is reached, only if the expression of life is fixed and we are able to return to it again and again. We call such skillful comprehension of constantly fixed expressions of life exegesis or interpretation." (p. 318)

Beyond this, it becomes apparent that both scientifically "constructed" and "natural" data are actually constructions. Both are given (back) the status of first-order constructions if one inquires beyond their specific contexts, integrates them into a more general horizon of understanding, and thereby

indicates their objectively possible, general potential for meaning—that is, if the case-specific significance of action is made evident in contrast to a general horizon of significance. Such an interpretation aims for a reconstruction of a social first-order construction, oriented along the lines of the case structure of the documented action. It is case specifically laid out, elaborating for the case, "interpretive understanding" of social action in Weber's sense of the term.

The path from the interpretive understanding to the "causal" explanation of the procedure and the effects of social action passes through the construction of a *theoretically pure type* of subjective meaning attributed to the hypothetical actor or actors in a given type of action: a second-order construction. Only in the realm of the ideal-typical constructions of rational action can it be decided how an actor "would act in a scenario of ideal rational action" and would have acted. Only with the help of these ideal-typical constructions, which better serve their purpose terminologically, classificationally, and heuristically the more "abstract and unrealistic" they are, can comparisons with the documented actors be made. Only then is it possible "to explain causally" the gap between action in ideal-typical rational action on one hand and documented action on the other so that the elements of the case being examined that were mixed in with the "pure rational action" can be identified.

The specific individual case is thus exclusively causally explained with regard t*o its distance from and difference to the terminologically "pure" ideal type of rational action.* The individual case cannot be understood by the causal explanation of the difference—the opposite is true. By way of the interpretive understanding of social action, the constructions of ideal types can be found, which in turn cast light on the individual case and help it get its just deserve. In that they explain the case's difference to the ideal type, they aid in the understanding of a case in its singularity and concretion.

In this sense, sociology is the progressive interpretive understanding of social action that takes seriously the individual case and thereby people, their orders, and their history. The scientific second-order constructions, the historic-genetic ideal types, aim exactly and equally for this historical understanding of the individual case and the understanding of history.

Social scientific, historic reconstructive hermeneutics is thus much more than a methodology and the repertoire of procedures that spring from it. It is a specific historic self-reflexive style of perception with the background supposition that there is no conclusive, ahistorical, ensurable knowledge, no social theory of a final solution. And this style of perception succeeds in naming good reasons for its background supposition.

— Hans-Georg Soeffner

VIDEO AND COMPUTER GAMES

An ever-expanding category, the term, *computer games*, may refer to almost any recreational activity that can be performed using digital technologies and may include games played on self-contained machines within an arcade space, games played on self-contained platforms (Nintendo, Sega, X-Box, Sony PlayStation) attached to the television set, games played on the personal computer, games played online, and games played using portable handheld technologies. An inherently imprecise category, the term collapses distinctions historically drawn between games, sports, toys, play, stories, and role-playing.

The first games were played on computers within the programming community starting in the early 1960s, but they did not reach the commercial marketplace until 1971 with the introduction of the first arcade technologies and in 1972 with the release of the first home computer game consoles. From this modest start, and following some commercial setbacks in the 1980s, computer games have expanded into one of the most profitable sectors of the American entertainment industry and a significant force for technological and aesthetic innovation.

The medium had an enormous impact on the generation of American youth that has come of age since the early 1980s. Some studies have found that as many as 92 percent of Americans between the ages of 2 and 17 have played games, with adolescent males typically the heaviest game players. Some evidence suggests that boys' earlier and more frequent interactions with computer games makes them more self-confident in their relationships with new media technologies and thus contributes to a gender gap in computer access and use. Periodically, the games industry has made efforts to broaden its offerings to attract female consumers with mixed results. The number of girls playing computer games has dramatically increased over the past decade but still lags behind boys in almost every classification; the notable exception would be Web-based games where women slightly outnumber men.

Games technologies emerged at a moment when American youth had diminished access to real-world play space, and the technology seemed to respond to the need to provide entertainment and recreation to a generation of latchkey children who spent much of their out-of-school hours at home. In many ways, the traditional values and activities associated with boys' backyard play culture were mapped onto digital space, with the computer offering more opportunities for exploratory play than these youths would have experienced otherwise. Paralleling traits that E. Anthony Rotundo identified in boys' culture historically, players saw digital space as a realm of autonomy from adult supervision, sought recognition from their peers on the basis of daring and risk-taking, used games as a means of demonstrating self-control and mastery and as a means of social bonding through competition, and relied on digital environments to enact adult roles. With the emergence of multiplayer online games, opportunities for team-based competition expanded, with advocates claiming that participating in "brigades' might offer teens some of the same opportunities for building self-confidence and developing leadership and collaboration skills as traditional team sports. Other games-related activities, such as amateur-level design and game modification might be read as the contemporary equivalent of building crystal radios, constructing balsa wood models, or working with erector sets, hobbies that helped boys develop technical skills and insights.

Game arcades inherited a space in American teen culture previously occupied by pool halls or pinball parlors and also inherited adult concerns that these gathering places encouraged truancy and gang-related activities. As games moved into the home, the concern shifted from the idea that games drew kids together outside of school toward the idea that games were socially isolating and addictive, distracting kids from schoolwork or social interaction. Games also embraced and built on a tradition of blood and thunder imagery that had run through boys' books since the nineteenth century and remained a persistent concern of adult reformers; with each improvement in computer technology, games perfected the ability to represent graphic violence through game play and thus provoked anxieties about whether media violence contributed to real-world aggression.

Over several decades of debate, two strands of thinking about youth access to game technologies has emerged: (a) one seeing games as a normative part of childhood culture and largely continuing traditional forms of boys' play into digital realms and (b) the other seeing games as disruptive technologies with a largely negative impact on child development. A series of school shootings in the late 1990s, including those in Paducah, Kentucky, and Littleton, Colorado, intensified this debate. The marketing of media violence to youths became the focus of a series of congressional hearings and governmental investigations; court cases were filed in several jurisdictions by parents whose children had been killed in school shootings seeking claims against specific game companies whose products had been found in the shooters' possession; state and local ordinances sought to regulate youth access to violent or sexually explicit video games drawing parallels to the regulation of youth access to cigarettes, alcohol, or pornography.

David Grossman (1999), a military psychologist, has emerged as the most visible reformer, echoing many of the same concerns raised by previous generations of media reformers, such as Frederick Wertham's charges that comic books contributed to an alleged increased in juvenile crime in the 1950s: "If we had a clear-cut objective of raising a generation of assassins and killers who are unrestrained by either authority or the nature of the victim, it is difficult to imagine how we could do a better job. The inflicting of pain and suffering has become a source of entertainment and vicarious pleasure rather than revulsion. We are learning to kill, and we are learning to like it." Citing the use of games in military training, Grossman argued that games were murder simulators that would desensitize their users to the consequences of real-world violence and thus psychologically prepare them to pull the trigger. Grossman's criticisms of video game violence have attracted support from other reform groups, most notably The Lion and the Lamb Project and the National Institute on Media and the Family. They are also embraced by a range of political leaders, including Senator Joseph Lieberman (D-CT.) and conservative think tank leader William Bennett.

Others, such as journalist Jon Katz (2001), challenges such arguments, noting that despite the pervasiveness of games in contemporary youth culture, federal crime statistics indicate that youth violence was at a 20-year low. They charged that the moral panic about youth access to video games was inspiring adult authorities to punish young gamers, citing the use of recreational habits as a criteria in many school districts for determining whether teens needed

to receive therapy, or the suspension or expulsion of students for ideas expressed in classroom discussions or in assigned papers dealing with the controversy. Some writers, notably Gerard Jones (2002), go further, making an affirmative case that aggressive fantasies play important developmental roles for children, helping them to work through their aggression and antisocial impulses and granting them a space of fantasy empowerment at a time in their lives when they feel limited control over their physical surroundings.

Mirroring larger debates in the social sciences, these disagreements often center on competing research methodologies: The reformers most often rely on quantitative evidence, mostly derived from the media effects tradition, whereas critics of the reform movement rely primarily on qualitative findings, mostly from ethnographic research, with a few researchers also examining broad sociological trends or correlational research. Some powerful organizations, such as American Psychological Association and American Academy of Pediatrics, issued reports claiming conclusive links between media and real-world violence, whereas other equally influential bodies, including the U.S. Surgeon General and the Australian National Censorship Board, concluded that the case had not yet been satisfactorily made. A group of scholars, representing a diverse range of academic disciplines and affiliated with the Free Expression Network, filed a succession of amicus briefs in court cases testing the regulation of violent game content, arguing that the media effects research significantly distorted the cultural phenomenon it sought to document, reducing game play to simple variables that could be tested in a laboratory.

Much of the controversy centered on titles, such as *Quake, Doom,* and *Grand Theft Auto 3,* which the industry itself rates as inappropriate for teens. These titles emerged as the industry sought more mature content to reflect its market demographics, which showed that 66 percent of all PC gamers and 54 percent of all platform gamers were over 18. The generation that grew up with Nintendo in the 1980s was continuing to play games but now demanded new content. Many parents still perceive games as predominantly a children's entertainment and often fail to distinguish adult from youth-oriented content. The Federal Trade Commission charged the games industry with actively marketing the more violent game titles to underage consumers, although the same study found that 85 percent of game purchases for youth consumers were made either by parents or by parents and children together, suggesting that adults were important mediators between the games industry and their younger consumers. Reform groups called for tighter enforcement of ratings at the point of sale, while the industry argued for greater efforts to educate parents about game content.

Adult uncertainty about the place of games in American youth culture reflects a significant generational gap in access and comfort with digital technologies. As with earlier communications technologies, youth are often early adopters and display greater competence with the emerging media than do their parents. One can also position the controversy within the context of a long-standing debate about whether theatricality and role-playing constitutes forms of deception that are apt to lead participants to confusion about the line between fantasy and reality, as well as a much more recent debate about the place of play in adult life, which reflects the expansion of consumer and leisure culture in the twentieth century. Finally, by the early twenty-first century, the number of people under the age of 18 in the United States equaled the number of people in the so-called baby boom generation, placing generational issues front and center on the American political agenda.

In the midst of these controversies, educational technologists began to make the case that games could become a powerful force in American education. For some, such as Marc Prensky (2000), the argument rests on the need to develop new modes of teaching for the so-called "twitch generation," whose learning style was shaped by their early and consistent access to digital technologies. Others, such as MIT's Education Arcade project, make the case that games can enable powerful simulations inside and outside the classroom, enable and support peer-to-peer learning, become important motivators of learning, and encourage exploratory play and intuitive experience of complex content. Mark Lepper's educational psychology research group at Stanford examined games as an extraordinary example of intrinsically motivated play and developed principles of designing engaging instructional materials based on studies of video game players. Other groups, such as the OnRamp project in South Central Los Angeles, worked with teams of kids to plan and develop Web-based games, seeing the design process as itself educationally beneficial.

VIRILIO, PAUL

Paul Virilio (b. 1932), the French self-styled "urbanist" and "critic of the art of technology," was, until his retirement in 1998, professor of architecture at the École Spéciale d'Architecture in Paris. Virilio's importance for understanding contemporary culture arises from his constant engagement with many of the most significant theoretical questions within the field of cultural studies. In his writings Virilio has made a vital and wide-ranging contribution to the understanding of the cultural features of modern architecture as well as offering critical studies of urban planning, speed, and war, including several volumes of critique on cinema, technology, political organizations, social hierarchies, and aesthetic practices. Encompassing "military space" and "dromology" (the study of the compulsive logic of speed), Virilio's "war model" is a highly stylized methodological line of attack on postmodern culture that spurns the analysis of such concepts and realities as mere objects for cultural or theoretical reflection. By way of his conception of the "aesthetics of disappearance" (art founded on retinal and materially persistent reality), Virilio has also idiosyncratically reinterpreted the cultural history of modernism, inclusive of the writings of artistic revolutionaries, philosophical leaders, and technoscientific thinkers such as Filippo Tommaso Marinetti, Maurice Merleau-Ponty, and Albert Einstein.

Accordingly, in *Bunker Archeology* (1994), Virilio focused his attention on the military space of the Atlantic Wall—the 15,000 Nazi bunkers constructed during World War II along the French coastline to prevent an Allied landing. Virilio and the French architect Claude Parent's *The Function of the Oblique* (1996), by contrast, argues for the establishment of an urban system founded on the theory of the "oblique function." Introducing sloping planes and corporeal dislocation, the theory nonetheless culminated in the concrete edifice of the bunkerlike Church of Sainte-Bernadette du Banlay at Nevers. Likewise, Virilio's *The Lost Dimension* (1991) is not literally involved with the inner city and structural design. Rather, it is concerned with urbanism and architecture as the military spaces of the "overexposed city" that is permeated by "morphological irruption," "improbable architecture," and critically, those new political "speed-spaces" of information, communications, and vision technologies such as the Internet.

Virilio's conception of speed-space may persuade readers to contemplate merely the overexposed city. But adhering to the terminology created in his *Speed & Politics* (1986), the genuine difficulties of the development of "dromocratic" culture and society emerge from its unending "state of emergency." Dromology has nothing to do with urban peace and, as in the military space of war, everything to do with the increasingly technologically induced death of

distance that has become a planned certainty effecting immense sociocultural consequences, while it also ties in with the annihilation of space during wartime. Virilio's "dromological" war model therefore tracks the metropolitan, architectural, and technopolitical vectors of the military machine. Hence, the "logistics of perception," maintains Virilio in his *War and Cinema* (1989), elucidate a future in which the technological functioning of contemporary civilian vision machines (e.g., surveillance cameras) and war machines progress simultaneously. Harmonizing the tasks of the human eye and the technology of weaponry, the military field of perception turns into a machine that produces a telescopic regime that lies far beyond the capacities of human sight. In *Popular Defense & Ecological Struggles* (1990), by comparison, Virilio reflects on "pure power," the enforcement of surrender without engagement, and "revolutionary resistance" to war. In so doing, he refuses to comprehend, for instance, the present-day Palestinian struggle as simply "popular defense," insisting that it is also a "popular assault" against its own geopolitical disappearance.

While modernism rather than postmodernism is the focus of Virilio's *The Aesthetics of Disappearance* (1991), artistic, philosophical, and technoscientific ideas have increasingly assumed greater intricacy in his *The Vision Machine* (1994), *The Art of the Motor* (1995), *Open Sky* (1997), and *Polar Inertia* (1999). Specifically, Virilio's conception of the aesthetics of disappearance permits vision and other technologies to be observed from his stance as a critic of the art of technology. Effectively, Virilio questions the aesthetics of disappearance and particularly the extraordinary bias it retains for contemporary cinematic or televisual and videographic disappearance over ancient appearance-based art such as Greek marble sculptures. It is a further affirmation of the creative cultural power of Virilio's texts that the current crises in contemporary "motorized" and other cybernetic forms of art converge on their "disappearance" into the Internet and the elimination of the difference between here and now.

Critical assessments of Virilio's writings have to entail an acknowledgment that they presently contemplate a space ruled by speed or what he labels *A Landscape of Events* (2000), as against what the American postmodern cultural theorist Fredric Jameson (1991:16) calls the contemporary domination of categories of speed by space. Yet in *The Information Bomb* (2000), Virilio frequently appears ensnared in binary logic. Certainly, Virilio gives the impression of being unacquainted with "deconstructive" debates over the critique of binary oppositions (e.g., "civilianization" over "militarization") that structure his cultural theory. Virilio's work might then profit from an engagement with the French poststructuralist Jacques Derrida's concept of "différance" where the meaning of binary terms is constantly reconstructed. Finally, it is important to appraise Virilio's texts on the Gulf and Kosovo wars in *Desert*

Screen (2002) and *Strategy of Deception* (2000) because it is only lately that other cultural critics have acknowledged his exceptional contribution to the understanding of war at the speed of light. Visualizing the wars of the future, in these works Virilio pinpoints the move from territorial or industrial warfare to extraterritorial or postindustrial information warfare conducted in "real time." Arguing that we currently exist in a duplicitous realm of global terror and surveillance, spatial and temporal disintegration, he depicts an uncaring world in which the strategic deliberations and politics of state- and military-controlled new information and especially mass media technologies prohibit any ethical or diplomatic debates. It is appropriate, then, that Virilio's most recent book, on the attack and repercussions of the terrorist assault on and ruin of the World Trade Center in New York City on September 11 2001, *Ground Zero* (2002), is currently being fervently examined by an increasing number of cultural theorists.

VOCABULARIES OF MOTIVES

Efforts to explain human behavior simply cannot avoid questions of motives. To ask "why" human beings do what they do necessarily involves inquiry into the forces, social factors, energies, drives, or mechanisms that push along human acts. Social science and lay theorists alike must ascertain the motives that lie behind or channel their own and others' past, present, and likely future behaviors. However, social science theories differ in the way they conceptualize motives and understand them to operate in human affairs. The notion of "vocabularies of motives," most primarily credited to Charles Wright Mills, offers a thoroughly sociological version of the nature and operation of motives by understanding them as arising socially—from a person's social circles—rather than as forces or drives innately a part of human nature or somehow rooted in biology.

Although Mills's (1940) now famous paper titled "Situated Actions and Vocabularies of Motive" is recognized as the single most powerful articulation of the idea, his thinking on motives is part of a longer intellectual lineage. In particular, the idea that we best conceive motives as visible only when people must explain socially questionable actions appears in the multiple and complex works of Kenneth Burke (1936, 1945, 1950), a theorist and literary critic who sought to understand the linkages among language, power, cultural discourses, and symbolic actions. Building on Burke's observation that motives are the linguistic names given to acts, Mills reads motives as located in the immediate acting situation of an individual rather than within the person (or as part of their psychic structure, as Freudian psychoanalytic theory would have it). In their well-known book *Character and Social Structure,* published after his initial analysis, Mills and Hans Gerth (Gerth and Mills 1953) draw inspiration from Max Weber who defined motive as "a complex of meaning, which appears to the actor himself, or to the observer to be an adequate ground for his actions" (p. 116). Motives, in short, are intrinsically social since they are learned and are tied intimately to the expectations of others in the immediate contexts of our behaviors. Motives are "conceived as acceptable grounds for social action" (p. 117).

Essential to Mills's theorizing is the observation that different contexts are often circumscribed by quite different ideologies, thus requiring different explanations for conduct. Just as symbolic interaction theorists advocate the idea of "multiple realities," there are multiple vocabularies of motives that both channel behaviors and are available to justify one's acts. Vocabularies of motives vary from one social circle to another, vary in different institutions and organizations, and like all symbolic systems, are subject to change. Acceptable explanations for behavior will, for example, differ in military, business, religious, and educational institutions. Moreover, vocabularies of motives are lodged within the larger frame of history. Justifications for behaviors that might make sense in one situation or point in time may well be viewed as illegitimate in other times and settings.

Different historical periods are guided by what Carl Becker (in his 1952 book *Modern History*) has called different "climates of opinion" that shape consciousness and behaviors. The United States, for example, has witnessed the rise, over the last half century, of a therapeutic culture. Americans are now prone to think of deviant, often morally reprehensible behaviors, as propelled by flawed selves that can and ought to be repaired via therapy. A "recovery" vocabulary is reflected in institutions such as television talk shows and self-help programs. There is a linear connection between pervasive cultural discourses, the emergence of

particular institutions bounded by these explanatory schemas, and ultimately, the ways individuals account for their everyday acts.

Motive talk is, in fact, a central feature of everyday experience. It provides one of the organizing techniques of social interaction, determining how acts are interpreted, including the moral evaluations attached to them. To explain our motives when actions are seen as deviant or identity damaging, we use linguistic devices called "accounts." In an extension of the vocabulary of motives idea, Stanford Lyman and Marvin Scott (1968) define an account as a verbal statement made to explain "unanticipated or untoward behavior."

Accounts, Lyman and Scott argue, can take the form of excuses or justifications for questionable behaviors in a given situation. Excuses (for example, "We had a flat tire and couldn't get home on time") appeal potential charges of deviance by citing events beyond a person's control. Justifications, alternatively, are used to neutralize possible negative definitions of acts by providing nondeviant interpretations of them (for example, "It's true we harassed them but, after all, they were being unpatriotic"). Motive talk may also take the form of "disclaimers" (Hewitt and Stokes 1975), which are verbal strategies used *in advance* to counter negative evaluations that could result from intended conduct (for example, "This may seem strange to you, but . . ."; "Don't get me wrong, but . . ."). Because different settings are defined by different vocabularies of motives, explanations of conduct acceptable in one setting may not work elsewhere. In this regard, people who routinely offer culturally unacceptable motives for their behaviors may be labeled mentally ill.

The vocabulary of motives idea has been greatly influential because it so clearly links motives to social life rather than to mysterious and invisible forces within persons. While Mills's treatment leaves unresolved questions about a person's "true" motives, it nevertheless seems clear that any view of motives discounting social expectations is incomplete. In this regard, Mills's thinking has been powerfully influential in framing social science understandings of behaviors such as rape or domestic violence that are often seen as instances of psychopathology only. The vocabularies-of-motives notion does not require that we accept, applaud, or agree with others' explanations for their behaviors. It does require, however, that social science theories of behavior move beyond reductionist biological or psychological explanations to consider how available social vocabularies generate, sustain, and justify the extraordinary range of what human beings think, feel, and do.

W

WALLERSTEIN, IMMANUEL

Immanuel Wallerstein (b. 1930) is certainly among the most influential social theorists of his generation despite his explicit denials of the possibility of general theory in social science. Wallerstein's conceptual approach to world history, what he has called the "world-systems perspective," has had a wide and deep impact in both the social sciences and the humanities wherever scholars and organic intellectuals have tried to penetrate what Giovanni Arrighi has called "the fog of globalization." He is the cofounder, with Terence Hopkins, of the Fernand Braudel Center at Binghamton University and is now a senior research scholar at Yale. Wallerstein is past president of the International Sociological Association and has published more than 30 books and over 200 articles and book chapters.

With Samir Amin, Andre Gunder Frank, and Giovanni Arrighi, Wallerstein discovered, or rediscovered, the modern system of societies as it arose with European hegemony. Born in 1930, Wallerstein grew up in the pungent broth of the New York Left. The *Monthly Review* scholars were putting together the third worldist rendering of Marxism, and Wallerstein took up the political sociology of African nationalism and pan-Africanism. Dependency theory emerged from the effort of Latin American social scientists and activists to confront sociological modernization theory (Talcott Parsons and his minions) with the realities of 500 years of European colonialism and U.S. neocolonialism. Wallerstein saw the relevance of this approach to the history of Africa, and when he read Fernand Braudel's *The Mediterranean* and Marian Malowist's studies of sixteenth-century Poland, he realized that core-periphery relations have been fundamental to the rise of capitalism in Europe for centuries. Thus, did Wallerstein discover the core-periphery hierarchy as a crucial dimension for understanding the last 500 years of world history.

Wallerstein's metatheoretical stance is signified by his use of the term *historical system*, which is meant to radically collapse the separation in the disciplinary structure of the modern academy between social science and history—the contrast between nomothetic ahistoricism and idiographic historicism. His narrative of the history of the modern world-system tells the story of a hierarchical intersocietal system in which class relations, state formation, nation building, race relations, geopolitics, capitalist competition, and core-periphery domination and resistance have constituted the main outlines of social change.

Wallerstein formulated the modern core-periphery hierarchy as an asymmetrical division of labor between producers of highly profitable core commodities and producers of much less profitable peripheral goods. He also asserted the systemic importance of an intermediate zone, the semiperiphery. This tripartite spatial division of labor, reproduced over the centuries despite some upward and downward mobility, is the most important of the conceptual schemas that Wallerstein's historical-structural analysis of world history has produced.

Wallerstein's big point is that it is impossible to truly understand and explain the development of modern capitalism without attention to the core-periphery hierarchy. The ability of core capitalists and their states to exploit peripheral resources and labor has been a major factor in the competition among core contenders, and the resistance to exploitation and domination mounted by peripheral peoples has also played a powerful role in world history.

There have been two major critiques of Wallerstein's work. Some Marxists have alleged that Wallerstein pays too little attention to class relations as the key to capitalist development. His claim that peripheral class relations—serfdom and slavery—have played a fundamental role in shaping the modern world-system is alleged to water down Marx's insistence on wage labor as the sine qua non of modern capitalism. And Wallerstein has been lumped with other "Smithian

Marxists" (such as Paul Sweezy) because his emphasis on the centrality of core-periphery relations is argued to privilege the importance of exchange relations (trade) over production relations (the appropriation of surplus value by capitalist exploitation of wage labor). These oft-repeated critiques have allowed many Marxists to continue to indulge in an analysis of societal class relations as if national societies were separate and autonomous entities, at least until the allegedly recent emergence of globalization.

The second main critique has come from those who contend that Wallerstein has privileged economic factors over and above politics and states. Some political sociologists have argued that Wallerstein's focus on the core-periphery division of labor glosses over important differences between the institutional structures of particular state apparatuses and struggles over policy changes that have occurred in the realm of politics. Curiously, both the point-of-production Marxists and the "bringing the state back in" political sociologists seem to have missed the specifics of Wallerstein's narrative account of the historical development of the modern world-system. He repeatedly tells how differences in regional or national class structures led to significant outcomes such as Portugal's leading role in fifteenth-century European expansion or the rise of the Dutch and British hegemonies. Wallerstein's insistence on the study of the whole world system and his resonant avowal of the relevance of historical and comparative knowledge scare those scholars whose specialized expertise is spatially or temporally narrow.

Despite all the breathless claims about globalization having changed everything since 1960, Wallerstein contends that globalization is as much a cycle as a trend and that the wave of global integration that has swept the world in the last decades is best understood by studying its similarities and differences with the wave of international trade and foreign investment in the last half of the nineteenth century. Wallerstein insists that U.S. economic hegemony is continuing to decline, and he sees the current U.S. unilateralism as a repetition of the mistakes of earlier declining hegemons who attempted to substitute military superiority for economic comparative advantage. Once the world system cycles and trends, and the game of musical chairs that is capitalist uneven development are taken into account, Wallerstein sees far more continuities than radical transformations. The title of one of his essays is "What Globalization?"

Wallerstein's stellar performance as brilliant historical sociologist and brave public intellectual demonstrates that social theory is not merely a pastime for academics. It still has voice on the stage of world politics.

WEBER, MARIANNE

Marianne Schnitger Weber (1870–1954) is best known for her marriage to sociologist Max Weber and her efforts to ensure his scholarly legacy by editing 10 volumes of his writings and penning his biography, published in 1926. In Germany during the latter part of the nineteenth and early twentieth centuries, Weber was recognized as a feminist intellectual who wrote and spoke widely on women's issues. Her feminist theoretical writings provided a counterpoise to sociological theories by contemporaneous male academicians, which brought to sociological discourse a focus on women's roles in society. Weber rejected the assumption that sociological theory written from a male standpoint is applicable to all social actors.

In 1896, Weber was one of the first generation of women to study at the University of Heidelberg. Here, she joined a feminist organization and began to develop her sociological investigations that begin with women's experiences and situations. Weber completed a dissertation at the University of Freiburg titled, "Fichte's Socialism and Its Relationship to Marxist Doctrine" (1900). In 1904, she traveled to America, meeting a number of women activists, reformers, and educators, including Jane Addams and Florence Kelly of Hull House and Lillian Wald of the Henry Street Settlement. It was M. Carey Thomas, president of Bryn Mawr College, and Ethel Puffer Howes, professor of philosophy and psychology at Wellesley College, however, who most shared Weber's belief that women should be given the opportunity for intellectual development through coeducation. Weber based her arguments concerning women and education not on economic opportunity but on feminist Charlotte Perkins Gilman's thesis that women would experience financial and marital freedom through paid employment. Weber's critique, informed by an awareness of social differentiation as well as current statistics assumed that the majority of women would endure the double burden of low-wage physical labor plus the duties of motherhood and housekeeping. Weber argued that housework and child care be given economic value in her essay "On the Valuation of Housework" (1912). In this essay, Weber posits that the underlying

moral and economic operative within marriage should be one of equality rather than based on a patriarchal system of inequality. A new valuation of the partnership calls for a means of economic independence so wives have freedom to shape their personal lives. Weber notes that constant economic dependency relevant to the subjective responses of another is demeaning. The subordinate loses self-respect and is induced to using methods of trickery and deception as found in the master-slave relationship. To alleviate this destructive marital pattern, Weber proposes the enacting of marriage laws so that a fixed amount of the husband's income be apportioned for household and personal use by the wife. She is aware that the redistribution of familial economic power by a patriarchal legislation will not readily occur; her ulterior objective is to raise public consciousness concerning marital economic inequity and transform not only marital law but marital custom.

Weber penned a series of writings titled *Reflections on Women and Women's Issues* (1904–1919). Her writings presage Carol Gilligan's work on difference as well as other feminists who find that using male models and male culture obscures the riches found in female culture. In 1907, she published an in-depth study, *Marriage, Motherhood and the Law,* critiquing the historical and structural development of marital relationships as dictated by patriarchy. Her 1912 composition, "Authority and Autonomy in Marriage," looks critically at how marital relationships based on subordinate and superordinate positions are destructive to both men and women. Her 1913 essay, "Woman and Objective Culture," is a treatise responding to Georg Simmel's supposition that men create objective culture and women, due to an undifferentiated nature, are engaged by subjective culture. In addressing Simmel's dialectical method of defining men and women, Weber disputes his thesis that a dramatic metaphysical difference exists between the genders. She brings a focus to their similarities, framing the sexes as overlapping circles. Each circle maintains its unique areas of distinction; however, areas of commonality are greater than differences. Weber notes that the creation of objective culture requires rationality, objectivity, and goal orientation, human qualities applicable to both men and women. She states that due to social regulation women are excluded from the realms where objective culture is created, and she draws a link between women's work and the transference of objective culture into subjective knowledge. Her thesis is that women's participation in the development of objective culture would expand and enrich cultural arenas.

Weber's writings coupled with her feminist activism led to her being the first woman elected to the legislature in Baden (1919). In 1920, the year Max died unexpectedly of pneumonia, she was chair of the Federation of German Women's Organizations, Germany's largest and most active feminist group. After Max's death, Weber withdrew from public life for several years. In 1924, she was awarded an honorary doctorate from the University of Heidelberg for her compilation of Max's works and her own scholarly writings. In 1936, she published the book *Women and Love,* and in 1948 completed her autobiography *Memoirs of a Life.* These works have not yet been translated into English. The largest impediment to the study of Weber's theoretical writings for those who speak only English is a lack of translated works.

WEBER, MAX

Max Weber (1864–1920) was born in Prussia in 1864. His father started his career as a journalist, became a local city official in Erfurt, and then moved to Berlin on his election to the parliament as a National Liberal—the political party that supported the chancellorship of Bismarck and hence the unification of Germany under Prussian rule. His mother was descended from a rich family of international merchants based in Frankfurt. She was brought up somewhat severely in a beautiful villa overlooking the River Neckar and the old town of Heidelberg. She was devoutly religious but in an ethical rather than a superstitious way. In Berlin, she supported the social-evangelical movement whose aim was to improve the welfare of the poor through the work of the church and through reform politics. She was not a Calvinist, as is often (mistakenly) stated.

Weber studied history and law at the universities of Heidelberg, Göttingen, and Berlin. His doctoral dissertation investigated how legal forms of partnership were developed to spread the risk on medieval trading ventures. His habilitation thesis, required for teaching in a German university,

examined the changing forms of property ownership in ancient Rome. Both studies required an intensive involvement in primary materials (and so foreign languages and handwritten documents). Weber, in this and also his other intellectual interests, was a beneficiary of the research seminar, which had placed the German universities in the forefront of research in the study of cultures, history, theology, languages, and archaeology. One of Weber's greatest achievements was the comparative study of the economic ethics of the world religions, an achievement made possible in large part by German scholarship and the techniques of interpreting documents.

He rose to national academic prominence with the publication in 1892 of an empirical survey of large landowners in the eastern provinces of Germany. The study was started when he was still completing his research on ancient Rome, and he was only 29 when he presented the findings in Berlin in 1893 to Germany's premier social policy association. The survey investigated the reasons behind the crisis in agricultural profits, the move of farm-labourers off the land, and the use of migrant labourers from Poland and the Ukraine. Prussia's rise to hegemony over all other German states had been based for over two centuries on its well-disciplined armies conscripted from peasants in the eastern provinces. During the decade of the 1890s, Weber pursued the controversial political question of how Prussia's ruling class (the Junkers) were using protectionist measures to support their own, uneconomic, farms while at the same time using cheap immigrant wage labourers and so displacing the settled German farmworkers.

Weber is pivotal to the "conversation" of social theory, and it needs to be made clear how his social theory relates to social science and how social science relates to politics and social policy. The farm study is beyond doubt firmly rooted in empirical social science methods. But what Weber brought to the survey was a demand to include the psychological or subjective factors of why farmworkers were leaving their traditional villages. What part did the desire for freedom and independence (from their Junker landlords) play in their decisions to move to the cities? This was a question additional to and separate from the Marxist thesis of immiserization that regarded the flight from the land solely in material terms. The "psychological magic of freedom" had to be placed alongside "bread and butter questions" as Weber expressed it. In addition, Weber considered what political conclusions should be drawn and debated from the fact that politicians were benefiting directly from state economic policies at the cost of national defence (of the eastern border against Russia).

In short, what Weber presents in the 1890s are the triple and interrelated issues of social science, questions of social and cultural meaning, and the debating of political and policy questions. He formulated his solution to this set of issues in a series of pathbreaking essays on methodology.

But first Weber needs to be placed in context. He has been greatly misconstrued during the twentieth century, not least by social and cultural theorists. Weber, as Karl Löwith (1982) has commented, wanted to make intelligible how we are today, how we have become, and to show to us the history of the present that in universal historical terms is only an excerpt in the destiny of humankind. This acute sense of historicity (that has been so overlaid by the uniformity of modernity) and the anticipation of what can happen in the future, in its turn, is understandable only by returning for a moment to the outlook of around 1900.

WEBER'S VIEW OF THE TWENTIETH CENTURY

Weber viewed the coming twentieth century in ways not dissimilar to how today's conventional wisdom views the twenty-first. He assumed the widespread development of capitalism on a rational, systematic basis in emerging countries like Russia and China and that there would be growing international markets in trade and finance. He thought the socialist alternative to capitalism, while once a threat, to have receded as a possibility. International relations would remain conflictual since the major national states wished to extend their influence beyond their borders, but he did not envisage major and sustained war on a global basis. Religions would decline in proportion as education and science increased. The modern world would experience a degree of disenchantment—that is, a loss of magic, revelation, and the mystery of the unknown—but Weber was also concerned that substitute religions could be a source of irrationality and instability.

The twentieth century, however, became "Weberian" only in its last decades. The outbreak of a world war in 1914 was completely unexpected by Weber, although he had noted an increased tension between the major European states. He died soon after the war, in June 1920, not realizing the full extent and enormity of the conflict or the causes for its outbreak. The maleficent legacy of that war led to European fascism, another world war culminating in the greatest technological violence, and the institutionalization of ideological politics on a global scale. This has meant that all readings of Weber in the twentieth century have been overdetermined by events. In the 1920s, he was ignored as a German intellectual; in the 1930s, he was shunned for political reasons; and after the Second World War, he became a weapon in the ideological struggle against Marxist communisms—the "bourgeois Marx," as it was then said. In Germany, the reception of Weber has been highly ambivalent, with the Frankfurt School regarding him as condoning the formal rationality of capitalism and ignoring its irrationalities (Marcuse [1965]1971) and with liberals condemning his national viewpoints (Mommsen 1984). But to return to 1900, capitalism was a progressive force, and it was for politics to decide on reform agendas, and the idea

of nationalism was still connected to nation building and democracy (Scott 2000:33–55).

In the last two decades of the twentieth century, there has been a cultural turn in the social sciences and a less ideologically encumbered appreciation of his work (see Scaff 1989; Whimster and Lash 1987). There has been a return to the issues of science, knowledge, and politics that Weber considered crucial for a mature understanding of the dynamics, both cultural and societal, of modernity. Weber argued that politics was a realm of competing values, that there were no longer any fundamental beliefs from which norms and values could be prioritized, and that the validity of scientific knowledge did not rest on fixed and undisputed foundations. The condition of living in modernity required a maturity to come to terms with these new realities.

Over 1904–1905, Weber published his essay "The Protestant Ethic and the Spirit of Capitalism" and his methodological essay "The 'Objectivity' of Knowledge in Social Science and Social Policy." These two works contain the components of the Weberian programme: (1) social and cultural theory that addresses the meanings that direct and mould people's lives, (2) the methods used to validate such knowledge, and (3) how the implications of investigative findings are to be debated and acted on.

THE PROTESTANT ETHIC STUDY

The Protestant Ethic and the Spirit of Capitalism (*PESC*) ([1904-1905]1930) addressed an association that had been long recognized but hitherto unexplained. Capitalistic enterprises appeared to flourish in Protestant inhabited areas, more so than in Catholic areas. This statistical evidence was of the same nature as Durkheim's observation that suicide rates were lower in Catholic areas and countries, compared with Protestant regions. Given these facts, how can the respective issues be explained? For Durkheim, the explanation resided in the suicidogenic forces that different levels of collective consciousness generated; forces generated at the level of society act as external forces on people's individual lives. For Weber, the emergence of the distinctive form of modern capitalism, as systematically rational, is an effect or repercussion of individually held meanings. The everyday behaviour of Puritans is the outcome of a religiously determined psychology where individuals look inward to their conscience as a regulator of their actions. Puritanism, in its various forms—and Weber provides historical case studies of Calvinism, Pietism, Methodism, and the Baptist sects—is a religion of reform that constantly admonishes the individual to control and monitor his or her conduct. Puritanism abolished the mediation of church and confession, made accessible sacred texts in the vernacular language, and placed an enormous responsibility on each person to remain pure according to the salvation message of the sacred text. The case of

Calvinism is psychologically more complex, for here, actions alone do not suffice to secure salvation and avoid damnation. Calvinist beliefs posited the idea of predestination: that an unknown and unseen god has already determined the salvation of each individual prior to his or her birth. The resulting salvation anxiety was allayed by acting as if one had been chosen (predestined) to go to heaven.

Weber's social-cultural theory identifies an irrational belief held with great intensity as a crucial causal factor in the development of modern capitalism. These beliefs—more generally, cultural meanings—result in a systematic style of life. The Puritans avoid pleasure, they work hard, they save their money. Weber refers to this as "inner-worldly" asceticism. A lifestyle as austere and pleasure averse as the Puritans involves training. In Christianity, as well as other religions, asceticism is practised by monks, usually within the closed community of the monastery. Weber terms this "other-worldly" asceticism. Monasteries are cut off from the rest of the world and follow their own regime of disciplined observance. The Puritan lives within the world, carrying out normal social and work activities. Strong religious meanings structure the personality of the Puritan, permitting an ascetic style of life carried on within the world with all its temptations of a more relaxed code of life. The Puritan always is aware of the salvation message. This is his or her "calling" or vocation. Religious beliefs become solidified in ascetic practice, and Weber terms this a style of life (*Lebensstil*) or a conduct of life (*Lebensführung*).

In a further step in his argument, Weber holds that conduct of life is passed on as a social form, irrespective of its religious origins. He provides the example of the American entrepreneur, scientist, and diplomat, Benjamin Franklin, whose father was a Calvinist. Franklin was secular in his outlook but nevertheless retained the discipline of his upbringing. Indeed, he formulated a kind of lifestyle handbook that provided an instruction manual on how to get on in business and life by improving one's ability to work. Once this attitude or mentality becomes generalized through a population (here a Protestant population), the social scientist can then frame the thesis that such a mentality will have significant economic consequences. In causal terms, Weber frames this as codetermination. There already existed in Northwestern Europe fairly advanced forms of capitalist trade, banking, technology, and legal frameworks. Puritanism did not produce capitalism "out of a hat"; Puritan sects that settled in Patagonia did not produce an economic miracle; they remained farmers. But where this systematic, sober, rational approach to life existed in conjunction with an already developing capitalism, then to use Weber's phrase there was an "elective affinity" between the two. There occurred a sort of chemical bonding, to produce the distinctively new compound, modern rational capitalism.

The last pages of *PESC* pursues the argument to a final stage, and it has been highly influential in social and

cultural theory; indeed its phrases have entered popular consciousness as a shorthand way of thinking about the rigidities and impersonality of modern capitalism and modern life. Weber speaks of asceticism being released from the monastic cell into everyday life, "building the tremendous cosmos of the modern economic order." It was an order bound to the technical and economic conditions of machine production that controlled the lives of those born into the mechanism and that had become an "iron cage" (Weber 1930:181). Talcott Parsons's translation used "iron cage" in place of the more accurate "a housing as hard as steel," so emphasizing imprisonment over rigidity. But either image is a powerful metaphor of the loss of individual autonomy in the face of an impersonal, rational order. This was a theme that Weber also developed in his analysis of modern bureaucracy that has come to dominate in any large organization, whether voluntary, business, or governmental. Bureaucratic apparatus was the organizational equivalent of mechanical production, allowing precision, speed, certainty, knowledge of the files, continuity, discretion, unity, strict subordination, reduction of friction, and reduction of material and personal costs. Business was conducted according to calculable rules and without regard for the status of the person and, as such, represents a move to dehumanization (Weber 1968:973–75).

Rational conduct on the basis of the idea of calling comes to pervade not only modern capitalism but modern culture as well (*PESC:*180). Any achievement in the modern world is a specialized one and involves what Weber termed "the renunciation of the Faustian universality of man." That latter idea was part of the Renaissance ideal of the "universal man"—the courtier, the artist, the scientist, the poet, the soldier as all the varied accomplishments of a single person. Religious duty undermined such an ideal, regarding it as a creaturely vanity that needed to be replaced by dogged pursuit of a single vocation. Weber's contemporary, the novelist Stefan Zweig, illustrated this phenomenon in his Chess novella (translated as *The Royal Game*). On a trans-Atlantic liner, two chess-masters compete. One is an educated humanist and the better, and faster, player. The other is a chess specialist, ignorant of everything but chess, where he is ploddingly efficient. The humanist makes an unforced error and loses to the specialist, and rational efficiency wins out over amateur brilliance. In sport, business, politics, education, and administration, the specialist type today is of course completely prevalent. In his 1915 essay, "Intermediate Reflection," Weber expanded the idea of specialism into the fragmentation of life orders with their own autonomous values. The decisive life orders in modernity were politics, economics, and science; the other life orders were more personal and consolatory and included aesthetics and the erotic. And in "The Vocation of Politics," Weber went on to argue that the demand of politics follows its own internal logic that is incompatible with Christian ethics.

Goodness and love of one's neighbour transposed to the unforgiving arena of politics will produce outcomes vary much at variance with those virtues (Weber 2003:259–62). The modern individual, then, pursues a life separated into individual spheres with no overarching scheme of values. The individual person, Weber suggests, has to choose in which sphere and by what guiding values he or she will live life—as politician, businessperson, scientist, artist, or lover.

At the end of *PESC,* Weber concludes, of this "last stage of cultural development, it might well be truly said: 'Specialists without spirit, sensualists without heart; this nullity imagines that it has attained a level of civilization never before achieved'" (*PESC:*182). Weber here is expressing Nietzsche's contempt for modern civilization that brings forward the type who Nietzsche refers to as "the Last Man" who makes everything small and who Nietzsche compares to a fly—inexterminable. This is strong language, where irony and contempt are used to scathing effect. Overall, Weber is expressing a mood of cultural pessimism as an old civilization makes the transition to modern, rational industrial-based capitalism. The loss of this older, less knowing, and more personal world Weber refers to as disenchantment. In the Nietzschean formulation, the specialist is vilified as a nonentity and the search for happiness as illusory. The rudiments of modern happiness, for Nietzsche, consisted of material well-being and security without any other aspiration. In the Nietzschean view of the world, the higher ideals could include religious and philosophical insight, artistic perfection, and courage, any of which are likely to exclude material happiness.

Weber is far more realistic about material well-being, for his comparative economic sociology demonstrated the search for wealth as a universal feature of humankind. Likewise, following his visit to America in 1804, he failed to share some of his German colleagues' distaste for American consumerism. But even allowing for Weber's acceptance of consumerism, the above quotes certainly express a disquiet that happiness could, or should, be a goal in itself. This suggests that other values, as goals in themselves, were worth pursuing. This theme has been taken up fairly recently in Weber commentary. David Owen (1994) argues that an alternative idea of happiness underlies Weber's standpoint. Happiness in this conception is the Aristotelian notion of human flourishing. Wilhelm Hennis (2000a, 2000b) has interpreted the Nietzschean theme in Weber in terms of conduct of life. The Puritan had through religious belief and everyday behaviour formed a coherent way of life. Likewise in Weber's comparative sociology, the Confucian mandarin and the Hindu Brahman had a way of life whose values and beliefs remained beyond question that was embedded within an existing social structure. Modernity, to use Karl Polanyi's phrase, disembeds conduct from social structure. Hennis's response to this predicament is a philosophical anthropology that seeks

to reconnect the higher-level values, such as integrity, truth, and professionalism, to the social process of upbringing and education.

These debates, while being at the heart of contemporary social and cultural theory and also can be extended to the work of Foucault (Gane 2002; Gordon 1987), cannot be said to be strictly scientific. As Weber admonishes himself, "But this brings us to the world of judgements of value and faith, with which this purely historical discussion need not be burdened" (*PESC:*182). To see how he handles the inter-relation of science to matters of belief and values, his methodological position needs to be understood.

METHODOLOGY AND SOCIAL THEORY

"The 'Objectivity' in Social Science and Social Policy" was published in the *Archiv für Sozialwissenschaft und Sozialpolitik* in the same year (1904) as the Protestant ethic essay was appearing. Immediate points to note are the title of the journal and that "Objectivity" appears in quotation marks. The journal, whose editorship Weber had taken over along with the economic historian Werner Sombart and the banking expert Edgar Jaffé, was committed to the analysis of economic phenomena and their cultural relevance. As the title says, it was a social science journal with a reformist social policy agenda. So its function was to analyse culture and economics, be committed to science, and to comment on policy implications. It was to pursue truth dispassion-ately without party political bias and, most certainly, with-out a totalizing worldview like scientific monism, Marxism, or Hegelianism. Yet Weber's concept of objectivity was not to be confused with an objectivist account of reality. By today's standards this programme sounds contradictory, and this is one of the reasons why Weber's legacy has been split into empiricist, interpretivist, and positivist strands (see Eliaeson 2000).

The unity of Weber's scientific method, however, can be grasped only if the deliberate paradoxes of his position are understood. Objectively valid truths belong to the domain of the sciences of cultural life. Truth is arrived at by a valid conceptual ordering of empirical reality. But the domain of science is constituted not by the objective relation between things but by relations between problems in thought (and what is now termed "constructivism") (Weber 2003:365). "The real" for Weber is a constant and chaotic flux that can never, ever be contained and explained by a system of sci-entific thought. Reality is not only in flux; it is infinite in its extension through time and infinite in its complexity at any one point in time. There is no inherent patterning within this reality, and it is a grand conceit and illusion to believe that the human mind can discern laws that determine the infinite complexity of social and cultural reality. This was an assumption he took from the neo-Kantian philosopher Heinrich Rickert.

However, the scientist does have ways of coming to terms with what would appear to be insuperable difficulties. Scientific thought starts, for Weber, with the invention of the concept. Concepts give humankind a handle on the rep-resentation of reality, although not reality itself. Moreover, Weber's notion of truth is not the Platonic one that equated truth with timeless forms. Weber can be identified with an older tradition that can be traced back to Democritus where reality is assumed to possess no timeless structure but con-sists of the flux of atoms. Concepts, for Weber, are postu-lates or hypotheses thrown out like a beam of torchlight to interrogate reality—an idea comprehensively (and subse-quently) developed by Karl Popper.

Weber's second large assumption is that human beings are cultural beings and as such are endowed with the capacity to lend meaning to an otherwise external and hostile world. This capacity separates a science of culture from a science of nature. In a science like biology, classificatory systems reflect an empirical reality of life forms. In a cultural science, the scientist forms a relationship with reality. The social scientist chooses a topic or a problem that has interest and significance for research, and in turn, this reflects an ongoing problematic like "orientalism" or "the underclass." This iso-lates a class of phenomena for causal analysis and explana-tion, and the class itself is defined by selection through cultural interest. This, argues Weber, is the only way to grasp a part of social reality's infinite complexity.

Some features of Weber's position run parallel to Richard Rorty's (1991) on objectivity. For both, science is not a "mirror of nature" where truth can be faithfully represented by a scientific language. The findings of science, for both, do not correspond to a knowable reality "out there." Rorty's cultural being is always in an unending and nongraspable (in sense of closure) conversation with self, others, and the world, where no truth can be underpinned and values cannot be derived from a scientific truth. Science, for Rorty, is a powerful tool for getting what one wants from the world; his pragmatism concerns questions of "how" not objective def-initions of "what is." This interaction with the world does not allow the specification of timeless truths.

Weber's programme for social science appears close to Rorty's pragmatism. There is no objective reality that can be represented through scientific language. The researcher is always in an interaction with the world, and a research problematic is generated within the social and cultural world and is not derived from science itself. But Weber turns what for Rorty is a problem for science into a solution. Because we are endowed with the capacity to confer meaning on the world, our interaction becomes a framing device defining a portion of infinite reality. Within this frame, truth can be verified at the level of specific causes and effects. Compared with Platonic truth, this might be a prosaic ver-sion of truth, but nonetheless it is empirical and concerns the ascertainment of facts. Social theorists who, like Rorty,

enlist Nietzsche in their attack on the impossibility of social science, need to be wary of including Weber as part of their argument. Both Nietzsche and Weber draw on non-Platonic understandings of external reality—a brute and chaotic force. This creates an obligation on the individual both to cognitively master this reality and to endow it with values. Unlike Rorty, Weber specifies a scientific methodology for establishing regularities in social reality.

The ideal type is the specific method employed by the cultural scientist. Social and cultural reality is a non-logical chaos of meanings. It is like a crowded party where the noise in the room is an undifferentiated hubbub until one starts listening to particular conversations. In listening, one creates a relation or "rapport" with a conversation. In history and other cultural sciences that interpret the past, the conversation can be imaginatively re-created. This is often referred to as empathetic understanding, an idea Weber took from Wilhelm Dilthey who had established it as a method in the historical sciences.

Meanings have to be isolated and placed within a specific context. This is a scientific operation. Isolation is achieved through the accentuation of a specific meaning to its logically pure state. Weber gives the example of church and sect. For the historian and theologian, these terms each have multiple and overlapping meanings. In Weber's [(1905]2002) hands, they are construed as oppositional concepts, the church open and the sect closed with different criteria of membership. The motivational logic of a sect will be entirely different to a church. But in empirical reality, these distinctions will be obscured. Actual sects, in the present or in the past, are then compared to the ideal-typical yardstick. Where they approach the pure type, they can be presumed to generate specific communal motivations among its members. Churches, on the other hand, as a pure type generate specific associational forces. Complex social reality, then, is dissected by these two ideal-type instruments and the causal forces at work can be weighted. (Note: A heuristic should not be confused with a hermeneutic. Heuristics are analogous to modelling in natural science. Indeed, Weber invokes the idea of a limiting case, like a perfect vacuum. Only through such a device can the constant force of gravity be isolated and demonstrated. By contrast, a hermeneutic is a totalizing device that attempts to intuit an empirically existing cultural artifact.)

Broadly speaking, Weber refers to two sorts of causality. People either react to impersonal forces—such as climate, population growth, their own biological structure, and market forces—or they have their own reasons for acting, and these reasons are derived from the cultural context of which they are part. Returning to the *PESC,* modern capitalism was in part the outcome of impersonal forces like demography, technology, geography, and markets, but it was also an indirect outcome of a strongly religiously determined context of

meaning. The former is the determination of outside forces on the individual and group; the latter, the grounds, reasons, or motives for actions by an individual or group.

Using ideal types, so to speak parting the tangled undergrowth of past reality, the historian can assign empirical validity to specific concrete causes having particular outcomes. Truth can be ascertained at the level of the concrete. For example, neo-Calvinist sects in the seventeenth century Low Countries really did have a formative effect on the capitalist economy. This is Weber's concept of objectivity and, to repeat, it is confined to the level of concrete cause and effect. Objectivity is not able to achieve total certainty; even at the level of the concrete, knowledge remains partial, so truth can never be validated with full certainty—there may be other, unknown factors to be discovered.

This tends to condemn social and cultural science to permanent adolescence, says Weber. New questions and new problematics come along, and the old issues are left aside not fully resolved. Complete truth remains elusive, and general laws are a chimera, but despite this, the determination of factual truth is a scientific obligation.

The framing questions or problematics posed by the scientist are relative to society and its values, but factual truth can be confirmed by the social scientist, and in this sense truth is universal.

Scientific objectivity is compatible with *conviction*. The latter term is a strong word for value judgements. In the area of policy analysis, social scientists can undertake scientific analyses, say, of the causes of the "underclass" phenomenon. They can also undertake predictive studies on policy solutions and their outcomes. Weber recognized that differences will exist among social scientists as well as politicians as to what counts as a desirable outcome. Social science cannot scientifically validate the differing ends desired by people. One policy scientist might wish to promote the maximisation of happiness, another the maintenance of inequality (very roughly the difference approximates to liberal vs. neoliberal values). Weber argued that scientific analysis of causes and policy solutions must proceed impartially to whatever personal values an individual scientist holds. But outside the field of science, the social scientist can plead for his or her values as much as the next citizen. A moment's observation of the contemporary university and think tank will demonstrate that this scientific ideal is comprehensively breached, and with this comes an accompanying loss of scientific reputation of the social "sciences." Gunnar Myrdal was an exemplar in the Weberian mould. He conducted policy analysis in a way that was "objective," realizing that such analyses raised questions of values choice (Eliaeson 2000:118–22.); or as Weber expressed it, his own journal stood for "the training of judgement in respect of practical problems arising from social circumstances," and his "Objectivity" essay explains how this is achieved (Weber 2003:359).

It is important not to "overcook" Weber's writings from a methodological point of view. His insistent message is that human and cultural values have to be analysed and debated. The social and cultural scientist takes a position on values in deciding what to study, and social scientific analysis with the help of the ideal type sifts through the complexity of values. Issues of judgement, choice, and debate follow on after the social scientific investigation. Subsequent to Weber, the "demarcationists" (of the Vienna Circle, Popper's critical rationalism, and other neopositivist schools) have pencilled in thick black lines that stipulate that "valid" science must exclude the analysis of cultural meanings and that value judgements are no part of the scientific enterprise. With Weber these are, rather, dotted lines. His methodology strongly argues against perverse procedures, such as allowing a person's prior values to be legitimated through a scientific procedure, or the incursion of semi-religious worldviews into social science. But social science—and this is his contribution to the canon of scientific humanism—is about values and their analysis.

At the end of *PESC,* Weber issued a warning that the "immense economic cosmos" and the "iron cage" had the potential to eject the *Mensch* and the pathos of human values and install the automaton of the *Fachmensch.* The social pathologies of the twentieth century—the death camps, the soulless bureaucracies, the separation of the administration of people from justice for people—can all be analysed along Weberian lines, as Zygmunt Bauman, unforgettably, has shown (Bauman 1989). Weber himself did not think he was issuing a storm warning. He probably thought that he had achieved enough by showing that social and cultural theory, used correctly and incisively, can reveal fundamental contradictions in the nature of modernity—that modern capitalism in its formative stage was constructed to honour an absent god. The significance of this finding indicated a rationalization process that distanced the modern individual from religious, ethical, and community values and an integrated sense of self. It is probably a lesson relevant for the twenty-first century.

WERTURTEILSSTREIT (VALUE JUDGMENT DISPUTE)

The *Werturteilsstreit* is part of the methodological controversies dominating the historical social and cultural sciences, especially in Germany, in the late nineteenth and early twentieth century. The central issue was the problem of whether those sciences were legitimated and able to derive ultimate and universally binding value judgments (*Werturteile*) from their empirical findings and explanations.

The most important advocate of a value-free social science in this sense was Max Weber. At the same time, however, he stressed that as far as the selection and forming

("*Auswahl und Formung*") of their subjects is concerned, no science could do without a value relevance (*Wertbeziehung*) and that values and judgments are of course an important issue of the cultural sciences.

The most determined criticism of the postulate of value freedom always came from those who wanted to engage and employ the social sciences for their own political (or religious) purposes.

This interest was the stronger the more marked or more radical the particular political and ideological position was. Therefore, it is not surprising that the criticism of the postulate of ethical neutrality was uttered with particular strictness from the right and left pole of the political spectrum. Initially, Max Weber encountered the political abuse of the social sciences in the works of the nationalist historian Heinrich von Treitschke, whereas in the *Verein für Socialpolitik* (Association for Social Politics) he had to argue above all with moderate Leftist colleagues, the so-called Kathedersozialisten (see Nau 1996). Absolutely intolerable and even life threatening was the postulate of an ethically neutral science in both of the totalitarian systems of the twentieth century. And in the socialist or communist parts of the student movement of the 1960s and 1970s, it became the pivotal element of the non-Marxist, bourgeois science in general and the sociology in particular that had to be overcome (Weiss 1998). That's why the controversies of that time, at least in Germany, are frequently referred to as "second *Werturteilsstreit*" (Adorno et al. 1984).

As long as this interest was sufficiently strong, the *Werturteilsstreit* went on for years, with changing front lines and varying intensity. It seems, however, to be finally settled. As far as Weber's actually irrefutable logical and methodological arguments meet a general approval, one can, at least in this regard, almost refer to a generalized Weberianism in the social sciences.

Almost no one still claims that from a theoretical or empirical analysis of societal facts or tendencies a "scientific" moral or political strategy can be deduced. Likewise only rarely the opinion can be found that correct and relevant sociological findings were to be gained only within the framework of a specific moral or political orientation. As far as these fundamental questions are concerned, the *Werturteilsstreit* does not exist anymore. Despite this, very different ideas remain prevalent as to whether or not sociology has to regard itself as an integral part of the societal and political process (as Pierre Bourdieu believed) or if for the sake of its intellectual independence and honesty it must keep itself away from any sort of political engagement (as, for example, Niklas Luhmann demanded and practiced). In logical and empirical respect, the better arguments lie on the side of the second position. Nevertheless, one can argue, if not by formal logical but by pragmatic and maybe also transcendental logical reasons, that sociologists at least should suspend (as the value basis of their research) those

kinds of moral or political options that are incompatible with the requirements and objectives of free scientific research, like the totalitarian ideologies of the twentieth century. In this case, there is a kind of value relevance that derives from the reflection on the meaning and the prerequisites of science itself.

WHITE, HARRISON

Harrison Colyar White (b. 1930), American sociologist, structuralist thinker, network phenomenologist, and mathematical modeler, contributes theory, models, and

conceptualization that focus on concrete, interconnected sets of actors beyond the level of the individual person or group but below the level of total cultures or societies. Having earned doctorates in theoretical physics (at MIT) and in sociology (at Princeton), White addresses problems of social structure that cut across the range of the social sciences. Most notably, he has contributed (1) theories of role structures encompassing classificatory kinship systems of native Australian peoples and institutions of the contemporary West; (2) models based on equivalences of actors across networks of multiple types of social relation; (3) theorization of social mobility in systems of organizations; (4) a structural theory of social action that emphasizes control, agency, narrative, and identity; (5) a theory of artistic production; (6) a theory of economic production markets leading to the elaboration of a network ecology for market identities and new ways of accounting for profits, prices, and market shares; and (7) a theory of language use that emphasizes switching between social, cultural, and idiomatic domains within networks of discourse. His most explicit theoretical statement is *Identity and Control: A Structural Theory of Social Action* (1992), although several of the major components of his theory of the mutual shaping of networks, institutions, and agency are also readily apparent in *Careers and Creativity: Social Forces in the Arts* (1993), written for a less-specialized audience.

The relation of White's work to strands of classical European structuralism is evident in his first book, *An Anatomy of Kinship* (1963), which includes in an appendix a translation (by Cynthia A. White) of a portion of Chapter 14 of Claude Lévi-Strauss's *Elementary Structures of Kinship* (1949, English translation 1969). Like André Weil, a mathematician who endeavored to formalize a portion of Lévi-Strauss's kinship theory, White is interested in the algebraic modeling of social relations. In his 1963 book, however, White brought to bear several distinctive themes that he has been developing throughout his later work. One of these is based on the observation of a certain similarity between charts of kinship roles among native Australian peoples and tables of organization for modern businesses. The more general concern is what White termed "structures of cumulated roles." In his first book, this preoccupation with roles led to the formulation of eight axioms relating clan structure to marriage rules for Australian societies (e.g., children whose fathers are in different clans must themselves be in different clans), derivations of ideal-type models of all possible societies that conformed to the axioms, and comparison of these models against extant anthropological accounts.

In subsequent work, White and collaborators loosened up the models (moving from algebraic group theory to the algebra of semigroups) so as to make them applicable to organizations and informal groups in a modern, Western context; now he defined role structures as positions of social actors across multiple networks of social relations (such as friendship, enmity, and the provision of help). In particular, in a seminal 1971 paper, White and François P. Lorrain defined "structural equivalence" with reference to sets of individuals who are placed similarly with respect to all other such sets, to the extent that relations and flows across multiple networks are captured by an aggregation of detailed relations. This equivalence concept allowed the representation of complex networks by reduced-form images that were obtained by aggregating equivalent actors. Further loosening of the underlying mathematics led White and collaborators to many analyses of social networks under the term *blockmodeling* (reviewed in White 1992).

Another concept that bridges several of White's contributions is duality. Anthropologists' notions of dual organization appeared in White's first book to motivate his interest in classificatory kinship systems that are invariant under transformations of matrilineal into patrilineal descent conventions. In the modeling of social mobility presented in *Chains of Opportunity* (1970), White defines duality as invariance in models of social structure and process under the interchange of named individuals and named jobs. A key innovation of this work was to stand conventional mobility modeling on its head, as applied to certain systems of moves of individuals between organizations. Vacancies, not individual persons, are free to move between categories according to fixed-transition probabilities, in White's view; therefore, conventional mobility models such as Markov chains should be applied to a study of the vacancies, not directly to analyze the mobility of persons. The latter can nonetheless be inferred from White's system models for mobility in organizations, as illustrated in his empirical analyses of the mobility of Episcopalian, Methodist, and Presbyterian clergy among congregations. In this work, careers of vacancies are seen not only as dual to, but as causally prior to careers of persons. More recently, in *Markets from Networks* (2002), the duality concept appears in White's characterization of the relation between upstream markets (with their emphasis on buyers "pulling" from their suppliers) and downstream markets (where producers are "pushing" their chosen volumes of product). Upstream and downstream markets are dual in the sense that producers' commitments are not directly governed by the underlying network of firms' concrete relations, which nonetheless constrain them. White therefore characterizes the upstream-downstream relation as a duality of decoupling and embeddedness.

In addition to concepts and principles (such as cumulated role, structural equivalence, duality, and reduced-form, ideal-type images of social networks) that cut across many of White's contributions and provide some considerable degree of unity to them, there has also been, over the course of his work to date, an evolution away from a formal structuralism and attendant concern for abstract patterning

of relations and toward an enhanced focus on action, agency, cultural meaning, and concern with institutional practices. Searches and struggles for identity and control are taken as the trigger for all social action in White's 1992 volume rethinking network theory. Here the ties in networks are seen in their narrative aspects, and a social network is conceptualized as a network of meanings. "Switching" is a concept that White and Ann Mische use in their exploration of how conversations transit across multiple domains and sets of expectations, and in *Markets from Networks,* White also uses the concept to indicate shifts between the different market modes, noting that switching implies agency (purposive action) and disruption.

WILLER, DAVID

Willer, David (b. 1937) is a theorist and researcher whose work exemplifies the use of formal methods for theory construction and experimental methods for testing derived predictions. His first book, *Scientific Sociology: Theory and Method* (1967), emphasized building models of social phenomena using systems of mathematical equations, and meticulous investigation aimed at developing and applying scientific laws to society. The work contended that such laws are not found by generalizing from empirical findings, a theme developed further in *Systematic Empiricism: Critique of a PseudoScience* (Willer and Willer 1973). This book developed a historically grounded analysis of empiricism and science. Its fundamental assertion was that sociology is a pseudoscience because of its reliance on empirical generalizations in lieu of abstract, general theories.

Believing that sociology could be scientific only by developing explicit, testable theories, Willer began work on a program of research driven by his new "elementary theory." The theory first appeared in *Networks, Exchange and Coercion* (1981), coedited by Willer and Bo Anderson. The theory builds on a foundation of simple defined concepts, combining them into more sophisticated concepts, and then into a small set of logically connected principles and laws used to predict social phenomena. *Networks, Exchange and Coercion* developed theoretical models for normatively controlled social exchange systems at the micro level and for structures of economic exchange and coercion at the macro level. Applied research reported in the book employed a variety of methods, including experiments, comparative-historical analysis, institutional analysis, and ethnographic case studies.

One of the basic principles in the theory, inspired by the work of Max Weber, is that actors are strategically rational. That is, actors' decisions take into account behaviors expected to be enacted by others. Karl Marx's thinking also has influenced Elementary Theory through the assumption that actors' values reflect the social structures and relations in which they are embedded. This contrasts with egocentric rationality assumptions in economics and allows Elementary Theory to account for a broad array of phenomena affected by social structures and contexts. Willer's next book, *Theory and the Experimental Investigation of Social Structures* (1987), reported a series of laboratory experiments investigating structural conditions for exchange and coercion. Elementary Theory identified commonalities between the structural conditions that produce power differences in social exchange networks and conditions in coercive structures. In other applications, Willer found that strong power differences are produced by mobility in hierarchies and by exclusion processes in exchange structures.

Soon after the 1987 book, Willer's collaborative work on the Network Exchange Theory (NET) branch of the Elementary Theory also came to fruition. The seminal article "Power Relations in Exchange Networks" (Markovsky, Willer, and Patton 1988) was the first to offer the Graph Theoretic Power Index. This mathematical model uses patterns of network connections to predict relative power for all positions in a network based on broader patterns of connections with other positions. It also predicts when and how larger networks will decompose into smaller networks, and when structural changes in one part of a network will or will not affect exchanges in other parts of the network.

Willer supports the idea that competition among different theories promotes rapid advancements in science. Thus, in 1992 he edited a special edition of the journal *Social Networks* that compared predictions from five competing theories of power in social exchange networks. Soon thereafter, published experiments identified NET as the most accurate. Subsequent collaborations have extended NET to

more subtle "weak power" structures, and work continues toward the goals of increasing the theory's generality, precision, and parsimony. Progress in NET's development over the course of more than a decade is reviewed and analyzed in Willer's edited volume *Network Exchange Theory* (1999).

The future development of the science of sociology is, according to Willer, bound up with the development of advanced instrumentation for precisely testing theories. Fortuitously, the need for such instrumentation comes at the same time as the growth of the Internet. Willer has taken the lead in developing software for the construction and execution of experiments administered via the Internet. Interested scholars will be able to run experiments under the umbrella of Elementary Theory or modified to suit the testing requirements of other theories.

Although extensively tested in the laboratory, a central concern of Elementary Theory remains institutional and historical explanations and predictions. Theory provides the common ground for all of these empirical endeavors; however, natural settings place special demands on the theories. For instance, it may be difficult or impossible to control all of the factors in natural settings that impinge on the phenomenon of interest or to ensure that empirical tests satisfy all of a theory's scope conditions. To deal with this issue, Elementary Theory now includes a typology of seven structural power conditions, each with a unique set of properties. The implications of all seven have been tested in experiments, both individually and in combination.

In the course of extending Elementary Theory into new domains, Willer has contributed to the process of building integrative bridges to some other long-standing group process theories. For example, by linking his Elementary Theory to the theory of Status Characteristics and Expectation States, we now have a better understanding of the relationships between status, power, and social exchange. Similarly, connections forged to theories of legitimation help to explain interactions between power, network, and legitimacy phenomena. As such integrative projects develop further, increasingly rich and complex social phenomena may be expected to fall within the purview of Willer's program.

— Barry Markovsky

WORLD-SYSTEMS THEORY

The world-systems perspective is a strategy for explaining social change that focuses on whole intersocietal systems. The main insight is that important interaction networks (trade, alliances, conflict, etc.) weave polities and cultures together since the beginning of human social evolution, so the explaining of change needs to take intersocietal systems (world-systems) as the units that "develop."

The intellectual history of world-systems theory has roots in classical sociology, Marxian revolutionary theory, geopolitical strategizing, and theories of social evolution. But in explicit form, the world-systems perspective emerged only in the 1970s when Samir Amin, Andre Gunder Frank, and Immanuel Wallerstein began to formulate the concepts and narrate the analytic history of the modern world-system.

This entry uses an intentionally inclusive definition of "world-systems/world systems theory" (with and without the hyphen). The hyphen emphasizes the idea of the *whole system,* the point being that all the human interaction networks small and large, from the household to global trade, constitute the world-system. It is not just a matter of "international relations" or global-scale institutions such as the World Bank. Rather at the present time it is all the people of the Earth and all their cultural, economic, and political institutions and the interactions and connections among them. This said, the hyphen has also come to connote a degree of loyalty to Wallerstein's approach. Other versions often drop the hyphen. Hyphen or not, the world(-)systems approach has long been far more internally differentiated than most of its critics have understood.

The world-systems perspective looks at human institutions over long periods of time and employs the spatial scale required for comprehending whole interaction systems. Single societies have always interacted in consequential ways with neighboring societies, so intersocietal interaction must be studied to understand social change. This does not mean that all the important processes causing social change are intersocietal but, rather, that enough of them are so that it is usually disastrous to ignore intersocietal relations.

The world-systems perspective is neither Eurocentric nor core-centric, at least in principle. The main idea is simple: Human interaction networks have been increasing in spatial scale for millennia as new technologies of communications and transportation have been developed. Since the emergence of oceangoing transportation in the fifteenth century, the multicentric Afroeurasian system incorporated the Western Hemisphere. Before the incorporation of the Americas into the Afroeurasian system, there were many local and regional world-systems (intersocietal networks). Most of these became inserted into the expanding European-centered system largely by force, and their populations were mobilized to supply labor for a colonial economy that was repeatedly reorganized by the changing geopolitical and economic forces emanating from the European and (later) North American core societies.

This whole process can be understood structurally as a stratification system composed of economically and politically dominant core societies (themselves in competition with one another) and dependent peripheral and semiperipheral regions, a few of which have been successful in improving their positions in the larger core-periphery hierarchy, while most have simply maintained their relative positions.

This structural perspective on world history allows us to analyze the cyclical features of social change and the long-term trends of development in historical and comparative perspective. We can see the development of the modern world-system as driven primarily by capitalist accumulation and geopolitics in which businesses and states compete with one another for power and wealth. Competition among states and capitals is conditioned by the dynamics of struggle among classes and by the resistance of peripheral and semiperipheral peoples to domination and exploitation from the core. In the modern world-system, the semiperiphery is composed of large and powerful countries in the third world (e.g., Mexico, India, Brazil, China) as well as smaller countries that have intermediate levels of economic development (e.g., the East Asian NICs, or newly industrialized countries). It is not possible to understand the history of social change in the system as a whole without taking into account both the strategies of the winners and the strategies and organizational actions of those who have resisted domination and exploitation.

It is also difficult to understand why and where innovative social change emerges without a conceptualization of the world-system as a whole. New organizational forms that transform institutions and that lead to upward mobility most often emerge from societies in semiperipheral locations. Thus, all the countries that became hegemonic core states in the modern system had formerly been semiperipheral (the Dutch, the British, and the United States). This is a continuation of a long-term pattern of social evolution that Christopher Chase-Dunn and Thomas D. Hall

have called "semiperipheral development." Semiperipheral marcher states and semiperipheral capitalist city-states had acted as the main agents of empire formation and commercialization for millennia. This phenomenon arguably also includes organizational innovations in contemporary semiperipheral countries (e.g., Mexico, India, South Korea, Brazil) that may transform the now-global system.

This approach requires that we think structurally. We must be able to abstract from the particularities of the game of musical chairs that constitutes uneven development in the system to see the structural continuities. The core-periphery hierarchy remains, although some countries have moved up or down. The interstate system remains, although the internationalization of capital has further constrained the abilities of states to structure national economies. States have always been subjected to larger geopolitical and economic forces in the world-system, and as is still the case, some have been more successful at exploiting opportunities and protecting themselves from liabilities than others.

In this perspective, many of the phenomena that have been called "globalization" correspond to recently expanded international trade, financial flows, and foreign investment by transnational corporations and banks. The globalization discourse generally assumes that until recently there were separate national societies and economies and that these have now been superseded by an expansion of international integration driven by information and transportation technologies. Rather than a wholly unique and new phenomenon, globalization is primarily international economic integration, and as such it is a feature of the world-system that has been oscillating as well as increasing for centuries. Recent research comparing the nineteenth and twentieth centuries has shown that trade globalization is both a cycle and a trend.

The great chartered companies of the seventeenth century were already playing an important role in shaping the development of world regions. Certainly, the transnational corporations of the present are much more important players, but the point is that "foreign investment" is not an institution that became important only since 1970 (nor since World War II). Giovanni Arrighi has shown that finance capital has been a central component of the commanding heights of the world-system since the fourteenth century. The current floods and ebbs of world money are typical of the late phase of very long "systemic cycles of accumulation."

An inclusive bounding of the circle of world(-)system scholarship should include all those who see the global system of the late twentieth century as having important systemic continuities with the nearly global system of the nineteenth century. While this is a growing and interdisciplinary band, the temporal depth criterion excludes most of the breathless globalization scholars who see such radical recent discontinuities that they need know nothing about what happened before 1960. The information age, the

new economy, global cities, the transnational capitalist class, and other hypothetically new and radical departures are seen as digging a huge chasm between recent decades and earlier world history. Those who believe that everything has changed must be left outside the circle.

A second criterion that might be invoked to draw a boundary around world(-)systems scholarship is a concern for analyzing international stratification, what some world-systemists call the core-periphery hierarchy. Certainly, this was a primary focus for Wallerstein, Amin, and the classical Gunder Frank. These progenitors were themselves influenced by the Latin American dependency school and by the third worldism of *Monthly Review* Marxism. Wallerstein was an Africanist when he discovered Fernand Braudel and Marion Malowist and the dependent development of Eastern Europe in the long sixteenth century. The epiphany that Latin America and Africa were like Eastern Europe—that they had all been peripheralized and underdeveloped by core exploitation and domination over a period of centuries—mushroomed into the idea that international stratification is a fundamental part of capitalist development and that core-periphery inequalities are systematically reproduced.

It is possible to have good temporal depth but still ignore the periphery and the dynamics of global inequalities. The important theoretical and empirical work of political scientists George Modelski and William R. Thompson is an example. Modelski and Thompson theorize a "power cycle" in which "system leaders" rise and fall since the Portuguese led European expansion in the fifteenth century. They also study the important phenomenon of "new lead industries" and the way in which the Kondratieff wave, a 40- to 60-year business cycle, is regularly related to the rise and decline of "system leaders." Modelski and Thompson largely ignore core-periphery relations to concentrate on the "great powers." But so does Giovanni Arrighi's masterful 600-year examination of "systemic cycles of accumulation." Andre Gunder Frank's latest reinvention of himself shines the spotlight on the centrality of China in the Afroeurasian world system and the allegedly abrupt rise of European power around 1800, a perspective that also largely ignores core-periphery exploitation.

So too does the "world polity school" led by sociologist John W. Meyer. This institutionalist approach adds a valuable sensitivity to the civilizational assumptions of Western Christendom and their diffusion from the core to the periphery. But rather than a dynamic struggle with authentic resistance from the periphery and the semiperiphery, the world polity school stresses how the discourses of resistance, national self-determination, and individual liberties have mainly been constructed out of the assumptions of the European Enlightenment. This is not wrong, but the focus on the ideology of distributive justice deflects attention from the real expansion of material global inequalities.

Most world-systems scholars contend that leaving out the core-periphery dimension or treating the periphery as inert are grave mistakes, not only for reasons of completeness but also because the ability of core capitalists and their states to exploit peripheral resources and labor has been a major factor in deciding the winners of the competition among core contenders. And the resistance to exploitation and domination mounted by peripheral peoples has played a powerful role in shaping the historical development of world orders. The comparison of the modern world-system with earlier regional systems has also revealed that all hierarchical world-systems have experienced a process of semiperipheral development in which some of the societies "in the middle" innovate and implement new technologies of power that drive the processes of expansion and systemic transformation. Thus, world history cannot be properly understood without attention to the core-periphery hierarchy.

COMPARING WORLD-SYSTEMS

It is often assumed that world-systems must necessarily be of large geographical scale. But systemness means that groups are tightly wound so that an event in one place has important consequences for people in another place. By that criterion, intersocietal systems have become global (Earthwide) only with the emergence of intercontinental seafaring. Earlier world-systems were smaller regional affairs. An important determinant of system size is the kind of transportation and communications technologies available. At the very small extreme, we have intergroup networks of sedentary foragers who primarily used "backpacking" to transport goods. This kind of hauling produces rather local networks. Such small systems still existed until the nineteenth century in some regions of North America and Australia. But they were similar in many respects with small world-systems all over the Earth before the emergence of states. An important theoretical task is to specify how to bound the spatial scale of human interaction networks. Working this out makes it possible to compare small, medium-sized, and large world-systems and to use world-systems concepts to rethink theories of human social evolution on a millennial time scale.

METATHEORETICAL ISSUES

Especially for Wallerstein, the study of the modern world-system was explicitly delineated as a perspective rather than a theory or a set of theories. A terminology was deployed to tell the story. The guiding ideas were explicitly *not* a set of precisely defined concepts being used to formulate theoretical explanations. Universalistic theoretical explanations were rejected and the historicity of all social science was embraced. Indeed, Wallerstein radically collapsed the metatheoretical opposites of nomothetic

ahistoricism/ideographic historicism into the contradictory unity of "historical systems." Efforts to formalize a theory or theories out of the resulting analytic narratives are only confounded if they assume that the changing meanings of "concepts" are unintentional. Rather, there has been sensitivity to context and difference that has abjured specifying definitions and formalizing propositions.

Thomas Richard Shannon's (1996) *Introduction to the World-Systems Perspective* remains the most valuable tool for introducing the main ideas to undergraduates. But Shannon displays a misplaced exasperation when he encounters apparently inconsistent terminological usages in Wallerstein's work. This is because Shannon's effort to explicate assumes a single and unvarying set of meanings, while Wallerstein allows his vocabulary to adapt to the historical context that it is being used to analyze.

Some theorists have adopted a more nomothetic and structuralist approach to world-systems theory with the understanding that model building can interact fruitfully with the more historicist approach. All macrosociologists may be arrayed along a continuum from purely nomothetic ahistoricism to completely descriptive idiographic historicism. The possible metatheoretical stances are not two, but many, depending on the extent to which different institutional realms are thought to be lawlike or contingent and conjunctural. Fernand Braudel was more historicist than Wallerstein. Amin, an economist, is more nomothetic. Giovanni Arrighi's monumental work on 600 years of "systemic cycles of accumulation" sees qualitative differences in each hegemony, while Wallerstein, despite his aversion to explicating models, sees rather more continuity in the logic of the system, even extending to the most recent era of globalization. Andre Gunder Frank now claims that there was no transition to capitalism and that the logic of "capital imperialism" has not changed since the emergence of cities and states in Mesopotamia 5,000 years ago. Metatheory comes before theory. It focuses our theoretical spotlight on some questions while leaving others in the shadows.

Because of alleged overemphasis on large-scale social structures like the core-periphery hierarchy, some critics have asserted that the world-systems perspective denies the possibility of agency. On the contrary, the focus is on both how successful power holders concoct new strategies of domination and exploitation, and how dominated and exploited peoples struggle to protect themselves and build new institutions of justice. The structuralist aspects of the world-systems perspective make it possible to understand where agency is more likely to be successful and where not.

THE FUTURE OF THE WORLD SYSTEM

Phillip McMichael has studied the "globalization project"—the abandoning of Keynesian models of national development and a new (or renewed) emphasis on deregulation and opening national commodity and financial markets to foreign trade and investment. This approach focuses on the ideological aspects of the recent wave of international economic integration. The term many prefer for this turn in global discourse is *neoliberalism,* but it has also been called "Reaganism/Thatcherism" and the "Washington Consensus." The worldwide decline of the political Left predated the revolutions of 1989 and the demise of the Soviet Union, but it was certainly also accelerated by these events. The structural basis of the rise of the globalization project is the new level of integration reached by the global capitalist class. The internationalization of capital has long been an important part of the trend toward economic globalization. And there have been many claims to represent the general interests of business before. Indeed, every modern hegemon has made this claim. But the real integration of the interests of capitalists all over the world has very likely reached a level greater than at the peak of the nineteenth-century wave of globalization.

This is the part of the theory of a global stage of capitalism that must be taken most seriously, although it can certainly be overdone. The world-system has now reached a point at which both the old interstate system based on separate national capitalist classes and new institutions representing the global interests of capital exist and are powerful simultaneously. In this light, each country can be seen to have an important ruling class faction that is allied with the transnational capitalist class. The big question is whether or not this new level of transnational integration will be strong enough to prevent competition among states for world hegemony from turning into warfare, as it has always done in the past, during a period in which a hegemon (the United States) is declining.

Neoliberalism began as the Reagan–Thatcher attack on the welfare state and labor unions. It evolved into the structural adjustment policies of the International Monetary Fund (IMF) and the triumphalism of the ideologues of corporate globalization after the demise of the Soviet Union. In U.S. foreign policy, it has found expression in a new emphasis on "democracy promotion" in the periphery and semiperiphery. Rather than propping up military dictatorships in Latin America, the emphasis has shifted toward coordinated action between the CIA and the U.S. National Endowment for Democracy to promote electoral institutions in Latin America and other semiperipheral and peripheral regions. William I. Robinson points out that the kind of "low intensity democracy" promoted is really best understood as "polyarchy," a regime form in which elites orchestrate a process of electoral competition and governance that legitimates state power and undercuts more radical political alternatives that might threaten their ability to maintain their wealth and power by exploiting workers and peasants. Robinson convincingly argues that polyarchy and democracy promotion are the political forms most congruent

with a globalized and neoliberal world economy in which capital is given free reign to generate accumulation wherever profits are greatest.

The insight that capitalist globalization has occurred in waves, and that these waves of integration are followed by periods of globalization backlash has important implications for the future. Capitalist globalization increased both intranational and international inequalities in the nineteenth century, and it did the same thing in the late twentieth century. Those countries and groups left out of the "beautiful époque" either mobilize to challenge the hegemony of the powerful or retreat into self-reliance or both. Globalization protests emerged in the noncore with the anti-IMF riots of the 1980s. The several transnational social movements that participated in the 1999 protest in Seattle brought globalization protest to the attention of observers in the core, and this resistance to capitalist globalization has continued and grown despite the setback that occurred in response to the terrorist attacks on New York and Washington in 2001. The 2003 global antiwar demonstrations against the Bush administration's "preventative" war against Iraq involve many of the same movements as well as some new recruits. The several transnational social movements face difficult problems of forming alliances and cooperative action. The idea of semiperipheral development implies that support for more democratic institutions of global governance will come from democratic socialist regimes that come to power in the semiperiphery. This has already happened in Brazil, where the new labor government strongly supports the movement for global social justice.

There is an apparent tension between those who advocate deglobalization and delinking from the global capitalist economy and the building of stronger, more cooperative and self-reliant social relations in the periphery and semiperiphery, on one hand, and those who seek to mobilize support for new or reformed institutions of democratic global governance. But in fact these strategies are complementary, and each can benefit by supporting the other. Self-reliance by itself, although an understandable reaction to exploitation, is not likely to solve the problems of humanity in the long run. The great challenge of the twenty-first century will be the building of a democratic and collectively rational global commonwealth. World-systems theory can be an important contributor to this effort.

WRIGHT, ERIK OLIN

Erik Olin Wright is a radical sociologist working within the Marxist tradition. Raised in a family of academics in Kansas, Wright studied history and social science at Harvard and Oxford University before entering the sociology program at Berkeley in the early 1970s. Upon completing his PhD degree in 1976, he secured a position in the Sociology Department at the University of Wisconsin, where he has been ever since. Wright thus made his appearance on the intellectual scene in the mid-1970s, along with an entire generation of young academics who were radicalized by the Vietnam War and the civil rights movement. What is remarkable about his career is not its initiation in Marxist debates—in this, it is not unlike many other careers of the "generation of '68"; rather, it is Wright's steady commitment to his research agenda for more than a quarter century, long after most of his peers had ended their dalliance with Marxist theory. Even more noteworthy is that, throughout this period, Wright has ceaselessly confronted mainstream sociology while at the same time carefully modifying his views in response to criticism. The result has been as unusual as it is significant: Over a long arc of theoretical innovation and conceptual clarification, Wright has quite successfully developed a nuanced and sophisticated version of Marxian class analysis and has managed to place it at the very core of contemporary social theory.

The Components of a Research Agenda. Wright's research agenda has been exceptionally clear and consistent. Throughout his career, he has been centrally concerned with interrogating the concept of "class" in Marxian theory. The bulk of this work has concentrated on how class operates as a mechanism for social differentiation in contemporary capitalism. In three successive book-length attempts, Wright has offered a careful discussion of the theoretical status of the term in Marxian theory and then proceeded to investigate how it maps on to contemporary society, mainly Europe and the United States. In addition to this component of his work, however, Wright has also expended considerable energy analyzing the importance of class on another axis in Marxian theory: its importance as a marker of qualitatively different social formations and a mechanism for the traversal from one historical epoch to another.

Class as a Mechanism for Social Differentiation. The trajectory of Erik Wright's theoretical innovations has been driven by a puzzle central to Marxism: how to marry the simple, polarized picture of class society to the empirically rich and quite diverse topography of capitalist societies—a puzzle that is most pointedly embodied in the problem of conceptualizing the "middle class." Marxists insist that, in every social formation, agents are slotted into two basic groups: producers, who generate a social surplus, and exploiters, who usurp a portion of this surplus. Every social formation is therefore characterized by two fundamental classes of exploited and exploiters. But it is also the case that this simple polarized picture does not sit easily with the reality of modern society. It is easy to find agents who, while technically belonging to one of the two "classes," also have features that set them apart from members of that same class. This is most famously exemplified in the case of professionals; while they do not directly control material productive assets, it strains our intuitions to slot them in the same category as workers on the production line. Wright's solution, which he briefly abandoned and then resurrected in a more nuanced version, is to conceptualize such members of social classes as simultaneously occupying locations in more than one class: they are in *contradictory class locations,* pulled in different and opposing directions (Wright 1978, 1985, 2000). The reason for this is that they reproduce themselves through mechanisms that include those typical of workers *and* those of capitalists. This allows Wright to move away from thinking of the middle class as a residual category, encompassing everyone who doesn't "fit" neatly into one of the two basic classes, to a category that is robustly defined.

Class and Historical Variation. The concept of class performs two functions in the broader Marxist theory of history. First, it serves as the central axis on which social formations are distinguished. Second, it is supposed to be the means through which these formations are propelled across time—through class struggle. But the notion of class struggle as the motor of history sits uneasily with another part of the Marxist canon, broadly known as technological determinism. On the latter argument, class struggle itself is subservient to a deeper force—namely, the developmental requirements of society's productive forces. Class struggle still plays a role but only to the extent that its outcomes are functional for the needs of the productive forces. The contingency and drama of class struggle is thus pit against a highly deterministic theory of technological development. Wright's solution to this tension has been a synthesis of sorts: He allows that there is a cumulative character to technological development across history. But technology does not drive history; rather, because humans tend to prefer greater productive power over less, technological achievements, when they occur, tend not to be abandoned. Technological growth therefore gives history a trajectory, preventing it from becoming a random walk. Within the broad trajectory imparted by this accumulation of productive power, there is enormous room for variation of social forms. And this variation is generated by the conflicts between classes. Which class wins, and which loses, is at best underdetermined by the needs of the productive forces. Class struggle is thus married to a weak technological determinism (Wright, Levine, and Sober 1993).

Wright has argued that this elevation of class struggle over the functional requirements of the productive forces comes at a cost: Marxists can no longer be confident that capitalism will necessarily give way to socialism, since the theory's determinism is now drastically weakened. Furthermore, after the collapse of the Eastern Bloc, it is no longer clear just what socialism entails. This implies that progressives must expend a great deal of energy on doing just what Marx himself strenuously abjured: drawing up designs—blueprints, as Marx called them—of the institutions necessary for a just social order, since they are no longer guaranteed by history and since the ones presented in the name of socialism failed on so many counts. In his most recent work, Wright has not only developed, but also sponsored through a series of conferences and book volumes, arguments about "Real Utopias"—realistic visions of a future society, inspired by the utopias of the present (see, e.g., Wright and Fong 2003).

Over the course of a quarter century, Wright has, in this fashion, explored the importance of class for the past, the present, and possible futures.

WUTHNOW, ROBERT

Robert Wuthnow (b. 1946), an American sociologist, is best known as a highly prolific, empirically oriented cultural sociologist and a sociologist of religion who has, along the way, created a novel theory of cultural change to use in his empirical investigations. Wuthnow received his BA from the University of Kansas and his PhD in sociology from University of California, Berkeley, in 1975 with a dissertation supervised by Charles Glock and Robert Bellah. He joined the faculty at Princeton University in 1976 and has been there ever since.

Like Pierre Bourdieu and Robert Merton, Wuthnow is a social theorist whose theories arise from and serve his empirical research into social life. For example, of Wuthnow's 22 published books, 9 edited volumes, and over 160 articles, few are devoted to sociological theory per se but are primarily devoted to topics in the sociology of religion and culture.

However, his theories have been influential because they provide tools for empirical investigations in the recently popular field of cultural sociology. Wuthnow's only purely theoretical book is *Meaning and Moral Order: Explorations in Cultural Analysis* (1987). The 730-page *Communities of Discourse: Ideology and Social Structure in the Reformation, the Enlightenment and European Socialism* (1989), apparently written at approximately the same time, is a detailed empirical study demonstrating his theory of cultural change.

Wuthnow is probably best known for the controversial proposal in these books to, in his words, go "beyond the problem of meaning" in cultural sociology. The dominant form of cultural analysis in the social sciences is what Wuthnow calls the "subjective" approach, where the analyst focuses on the beliefs, attitudes, opinions, or values of the individual. The point in this type of research is to figure out what is inside the person's head, and many readily accessible methods—such as opinion surveys—appear to be available for use. The problem of meaning is central in this tradition: What symbols "mean" to the individual is the central question.

According to Wuthnow, the primary problem with the subjective tradition is that we can never know what is really inside of people's heads—what people *really* think. We have access only to what they say, write, or do, from which we infer these inner states. Why not just use what we can observe and forget about the inner states of consciousness? Wuthnow's proposal is to stop investigating meaning and instead look at the patterns of observable symbolic codes such as words, movements, and texts. With this method, "Data are more readily observable kinds of behavior rather than being locked away in people's private ruminations" (1987:56). This results in a form of cultural structuralism, not unlike an analysis of Michel Foucault. We can, for example, identify the structure of codes in Protestant discourse—perhaps that the symbols "friend" and "Jesus" are more closely related in the more highly individualistic evangelicalism than in mainline Protestantism. While this does not tell us the "meaning" of these terms for any one Protestant, it is observable and can be correlated with observable action.

Where do these symbolic patterns come from? The relationship of culture to social structure is one of the original debates in sociological theory, and this is the other distinctive contribution of Wuthnow to social theory. Where, for example, did the set of symbols called "the discourse of the Protestant reformation" come from? His theory is premised on the insight that all symbols are explicitly produced by actors in particular environments; they do not somehow rise like ether from structural relationships. There are three stages of this cultural production. First, innumerable symbols are produced by innumerable people, a stage Wuthnow calls "cultural production." For example, Martin Luther was not the only person producing ideas during his life, but many others were as well. The next stage, "selection," explains why Luther's ideas become known. Some ideas are selected over others because they are able to obtain resources from the environment to be produced more broadly because they articulate with that environment. The final stage is "institutionalization," where routinized mechanisms are put into place for the continued production of the discourse. Publishing houses are set up, schools founded, denominations created—all devoted to the promotion of certain cultural symbols. Some cultural systems—like science—are so deeply institutionalized, with so many interlocking institutions devoted to their propagation, that we think of them as "reality." A critical part of Wuthnow's analysis is to ask why a particular cultural producer obtained the resources to institutionalize their preferred symbols.

Wuthnow's call to look at observable patterns of symbols, and to closely examine who exactly produced these symbols, along with a commitment to empirical research, has resulted in an unusual methodological stance among cultural sociologists. Bemoaning the fact that cultural sociology "has sometimes become a preserve for those disdainful of the positivism implicit in more dominant quantitative sub-fields" Wuthnow argues for "drawing on the hermeneutic literature" to be aware of interpretive limitations but to do "empirical work with as much attention to rigor and systematization as any unrepentant positivist might give" (1992:5). While he does not think this will produce positive knowledge, it will leave "tracks" of what was done so that the author's biases can be revealed. This call for positivist-like methods has meant that Wuthnow is one of the few advocates in cultural sociology of quantifying cultural symbols. For example, his students have quantified the symbols in flags, national anthems, popular songs, and academic texts.

Z

ŽIŽEK, SLAVOJ

Slavoj Žižek (b. 1949) is one of the most outspoken proponents of Lacanian psychoanalysis working in contemporary social theory. Born in 1949 in Ljubjlana, Slovenia, Žižek holds a PhD in philosophy from the Department of Philosophy, Faculty of Arts, Ljubljana and a PhD in psychoanalysis from the Université Paris-VIII. Over the last 15 years, the aptly nicknamed "Giant of Ljubljana" has attended over 250 international philosophical and cultural studies conferences, published over 25 books, and is currently the senior researcher in the Department of Philosophy at the University of Ljubljana. Not only is he an internationally recognized social theorist, he has also been known to dabble in politics, campaigning for the Slovenian presidency in 1990. Overall, Žižek is a provocative voice that has challenged many assumptions both inside and outside of academia.

While the scope of Žižek writings is far too vast to cover in this brief entry, there is a clear theoretical argument that runs throughout his work. His overarching theoretical program is perhaps best outlined in the book *The Sublime Object of Ideology* (1989) in which he presents a Lacanian-inspired form of ideological critique. For Žižek, ideology attempts to stitch together the fractured social field, which is traversed by inconsistencies and antagonisms. Social antagonisms, such as class struggle, are for Žižek equivalent to Lacan's notion of the Real as a traumatic kernel that resists symbolization. There are essentially two mechanisms by which ideology reconstructs the social as a unified, harmonious, and coherent totality. To effectively erase internal contradictions, ideology propagates sublime objects such as "the nation" or "the people." These symbolic fictions act as virtual stand-ins, repressing internal social antagonisms, which nonetheless reappear in the form of symptoms (e.g., class conflict, World Trade Organization [WTO] protests, global warming, or the increasing homeless population). Second, to purify its harmonious self-image, ideology not only represses social ambiguities but also externalizes them. In this manner, internal contestations are projected outward onto the proverbial other. Through ideology as a fantasy construct, the social is able to maintain its illusory integrity.

For Žižek, a Lacanian-inspired form of ideological critique is paramount to going through the social fantasy until the subject is able to identify with the symptom. As an example, Žižek references the Nazi construction of the Jew. Within the ideological fantasy of National Socialism, the Jew becomes the stumbling block that prevents the realization of the perfected Aryan race. The internal antagonisms found within the German social field are conveniently projected onto the Jew as the external other. To deconstruct this ideological projection, the subject should "traverse the phantasy" of Nazism, realizing that the traumatic kernel preventing the full realization of the Aryan myth is not external but internal to the Nazi project itself. Through the application of Lacanian concepts to the study of ideology, Žižek thus equips cultural critics with powerful analytical tools that complement and enlarge the leftist vocabulary.

In texts such as *Looking Awry* (1991), *Enjoy Your Symptom!* (1992), and *Everything You Always Wanted to Know About Lacan (But Were Afraid to Ask Hitchcock)* (1992), Žižek brings cultural studies and Lacan into dialog with one another. As a philosophical DJ, Žižek likes to mix it up, often employing a surprising combination of Kant, Marx, Hegel, Schelling, Badiou, and of course, Lacan to explore a wide range of contemporary cultural phenomena that include, but are by no means limited to, the Internet, Hollywood films, television, tea bag mantras, and other banal aspects of the American cultural sphere. While other cultural theorists see popular culture as merely an ideological mystification, Žižek believes that an understanding of the media is paramount to understanding the human psyche

as such. According to Lacan, the unconscious is quite literally the symbolic order, or the discourse of the Other. Rather than a deep, dark, secret hidden within our minds, the unconscious resides outside us, embedded within everyday institutions, media culture, and social practices. Taking advantage of the ubiquity and the popularity of the American media, Žižek often employs concrete examples drawn from mainstream culture to clearly elucidate rather opaque Lacanian concepts. In perhaps his most famous example, Žižek uses sitcom laugh tracks to demonstrate the Lacanian maxim "desire is the desire of the other." In a typical Žižekian inversion of commonsense assumptions, he argues that laugh tracks do not tell us when to laugh, instead they literally laugh for us. The symbolic order—that is, the Lacanian Big Other—has relieved the viewer of the burden to laugh, laughing in our place.

Žižek also uses the explanatory power of Lacanian concepts to analyze contemporary politics. In particular, Žižek attacks New Agers, liberals, feminists, postmodernists, and multiculturalists. For Žižek, these movements are forms of micropolitics that do not challenge the hegemonic rule of capitalism or its political counterpart, liberal democracy. In fact, identity politics are endorsed and even encouraged by the new, flexible, transnational capitalist order. In *The Ticklish Subject* (2000), Žižek observes, "The depoliticized economy is the disavowed 'fundamental fantasy' of postmodern politics" (p. 355). Through a Lacanian perspective, Žižek argues that these movements are in fact forms of "interpassivity." In psychoanalysis, the interpassive subject remains fanatically active to prevent something from occurring. Applying this term to the realm of politics, Žižek contends that postmodern social movements constantly produce new pleasures, new identities, and new desires that remain fully within the scope of capitalism, thus preventing radical social transformation. Although identity politics have made important strides that should not be forgotten or abandoned, Žižek nevertheless sees such forms of activism as limited.

Consequentially, Žižek calls for the recentralization or a repoliticization of the economy in leftist politics. In *Repeating Lenin* (2001), Žižek endorses the radical political imagination of V. I. Lenin as an intervention that does not accept the "natural" and "unavoidable" status of the global economy. Instead of simply returning to Lenin's political project, Žižek instead argues for a rehabilitation of the spirit of Lenin's radical break with the hegemonic status quo. As opposed to identity politics, which remain situated within the logic of the capitalist market and the ideologies of liberal democracy, an extreme break with the status quo would be the embodiment of a "Lacanian act," creating new horizons of political, cultural, and economic possibilities. Thus Žižek views Lenin's project as a true historical event—an articulation of the void at the heart of symbolic order that opens up a space for radical social and political alternatives.

In conclusion, Žižek is important for social theory because he has demonstrated the wide-reaching explanatory power of Lacanian psychoanalysis. While receiving praise for his theoretical innovations, Žižek is no stranger to criticism. In the book *Contingency, Hegemony, and Universality* (2000), Žižek, Judith Butler, and Ernesto Laclau enter into an extended debate concerning these three concepts. Butler in particular questions Žižek's ability to account for the historical specificity of trauma. From her perspective, his Lacanian approach reduces all forms of oppression to the ahistorical category of the Real. In response, Žižek has argued that Butler is in fact ahistorical, creating a teleological narrative that posits her own theory of performative identity as a universal "truth" rather than a historically and culturally embedded form of knowledge. Furthermore, the Lacanian real is not really ahistorical but is rather the traumatic, unsymbolized kernel that is unique to each historical period. Thus, Žižek remains a highly controversial figure whose theories are read and debated across disciplines.

ZNANIECKI, FLORIAN WITOLD

Florian Znaniecki (1882–1958) was a Polish and American sociologist and philosopher of culture, born on January 15, 1882, in Świątniki, Poland. He died on March 23, 1958, in Urbana-Champaign, Illinois. He formulated a theory of cultural systems with a humanistic coefficient that relates to the active experience of meaning and the axiological significance of cultural data. For Znaniecki, cultural data consist of values, and these differ from the mere "things" that are the object of research in the natural sciences. With his writings in Polish and English, Znaniecki developed a systematic sociological theory built on a theory of action that aimed at the understanding and explanation of

the social dynamics of culture, change, and creativity. Znaniecki considered sociology the centerpiece of the cultural sciences because all systems of culture in their existence depend on social interactions. Sociology is a special cultural science that takes systems of social actions as its subject matter. They bear on social values—individuals and collectivities—as they appear to others and to themselves. Social values are the most complex and changeable among all cultural values—economic, religious, aesthetic, and others. Znaniecki investigated the ontology and theory of cultural and interactional foundations of more complex social systems, as they emerged from social actions, in sociological studies of knowledge, education, and national cultures. Znaniecki was also a researcher of civilizational processes and of the world society. His remarkable contribution to the methodology of cultural sciences was shaped by the principle of the humanistic coefficient that demands the comparative study of the experience of individuals and collectivities as historical subjects, since every element of a cultural system is what it appears to be in the experience of people who are actively dealing with it. To this end, he relied on case studies and biographical methods and assumed as a general rule of qualitative methodology analytic induction leading to abstraction and generalization.

Znaniecki studied in Geneva and Zurich, as well as at the Sorbonne in Paris, and took a doctoral degree in 1910 at the Jagiellonian University in Cracow where he presented the dissertation *The Problem of Value in Philosophy* (in Polish). In addressing the debates between idealists and realists, Znaniecki formulated an original humanistic stance, which was subsequently developed into the system of the philosophy of culturalism. A synthesis of these theses was presented in *Cultural Reality,* published in Chicago in 1919. The basic principles of his system were actions and values, through which he assumed a constructivist, relativist, and pluralist view of reality as a changeable historical world. In this respect, he held much in common with pragmatists.

Znaniecki came to the United States in 1914 at the invitation of William I. Thomas, whom he met as the director of the Bureau of the Society for the Protection of Emigrants in Warsaw. He was lecturer in Polish history and institutions at the Department of Sociology of the University of Chicago in the years 1917 to 1919. Together with Thomas, Znaniecki wrote the classic work of the Chicago School *The Polish Peasant in Europe and America* (1918–1920), considered a turning point in the development of theory and method in the social sciences. Here, Thomas and Znaniecki made unprecedented use of personal documents, including the letters and memoirs of migrants. Znaniecki took the initiative to write the *Methodological Note,* in which were formulated the conceptions of values and attitudes comprised by people's definition of the situation. This provided a theoretical schema of social becoming through the interaction of subjective and objective factors—that is, the

interplay of personality and culture. Action patterns were analyzed focusing on social psychological factors such as wishes or motives for recognition, the need for security, the exercise of power, and the impact of new experiences. They also drew on sociological factors such as the formation of institutions and organizations.

In 1920, Znaniecki returned to Poland, where he took the chair of sociology and philosophy of culture at Poznań University. Further theoretical assumptions were formulated in *Introduction to Sociology* (1922, in Polish), articulating the conception of social systems. He argued that from elementary social action emerges the constructed reality of more complex, dynamic systems: social relations, social roles, and social groups. Later, Znaniecki incorporated into social systems analytically conceived societies—political, religious, and national, as well as the world society, the development of which he predicted. Connections between systems of social actions and social self elaborated in *The Laws of Social Psychology* (1926) were developed into the pioneering conception of social role in *Sociology of Education* (1928–1930, in Polish). In the years 1931 to 1933, he lectured at Columbia University, as well as directed research on education and social change.

After his return to Poland, *Present-Day People and the Civilization of the Future* (1934, in Polish) was published, based on the result of this project, in which he also continued to explore the issues earlier discussed in *The Fall of Western Civilization* (1921, in Polish). Znaniecki published a systematic synthesis of theoretical conceptions in *The Method of Sociology* (1934), in which rules of qualitative research of social systems based on the conception of the cultural data were formulated as well as of analytic induction and case study logic. The analysis and taxonomy of social actions as the dynamic systems of values culminated in *Social Actions* (1936). In 1939, Znaniecki lectured at Columbia University on complex relations between the creators and users of knowledge. Those investigations were published in the masterpiece *The Social Role of the Man of Knowledge* (1940). World War II and the subsequent installation of communism made Znaniecki's return to Poland impossible. From 1940, he worked at the University of Illinois, where he wrote *Modern Nationalities* (1952) and his magnum opus: *Cultural Sciences* (1952). The development of secular literary cultures and the growth of organizations for their expansion gave origin to modern national culture societies. The sociologist's task is to study axionormative models and patterns of actions and the mediation of social organization in the development and integration of various categories of cultural systems.

Further works on systematic sociology where published posthumously in *Social Relations and Social Roles* (1965). Proof of the recognition of Znaniecki's creative output was his election as president of the American Sociological Society in 1953.

There are many affinities between Znaniecki's theory and symbolic interactionism. The eminence and distinct character of Znaniecki's theory among other interpretative theories stems from assumptions of culturalism that makes it possible to avoid the microsociological bias inherent in many other interpretive theories. Social systems and axionormative cultural orders are intertwined. The constructivism of the conception of reality's creative evolution, and the historical changeability of worldviews through creating meanings and values in interactions, erase the dualistic oppositions of thought and reality, subjectivity and objectivity, and consequently, the neo-Kantian opposition of nature and culture. The epistemological equivalent of the ontological conception of values and actions is the conception of the humanistic coefficient of cultural data, applied to sociological data. A researcher of cultural systems, including the social one, comes into contact with phenomena that are always somebody else's data, given first in the active experience of the participants in culture who create and re-create them. Valuable sources of sociological knowledge are personal experience of the sociologist, observation by the sociologist, and the communicated experiences and observations conducted by other people as group members, including those expressed through literature. Phenomenological and interpretive method is legitimized but in the context of objective systems of actions.

For Znaniecki, the analysis of social systems is rooted in the study of civilizational processes as a social integration of culture and the vision of a more fluid and peaceful future civilization. By discerning the political society or the state from the national culture society, Znaniecki explained the specific, cultural objectivity of the nation's existence, the cultural sources of conflicts between nations as well as the possibility of their cooperation. The opportunity for the emergence of a supranational, worldwide social system on the grounds of relative cultural values has been emphasized.

Znaniecki created a comprehensive theoretical system of humanistic sociology, based on an ontology of cultural values and concentrated on the meaningful and axiological dimension of reality. Meaningful cultural data may have a negative or positive significance depending on different systems, and their axiological significance is relative. The analytical conception of social systems as the subject matter in the cluster of other cultural systems of actions and values also encourages a cross-disciplinary approach. Znaniecki proclaimed the need for efforts in the direction of a new way of thinking about culture and the cultural sciences, which should lead to casting off the dogmas of naturalism and formal rationalisms as well as idealism unable to grasp the creative evolution of meanings and values and also as duration and specific objectivity of culture that prevailed in the twentieth century. He underlined the need for researching the cultural differences in the dynamics of conflicts and social changes in order to understand and control them and also to properly prepare people for creative leadership and peaceful cooperation.

Chronology of Social Theory

Jon A. Lemich

Early Roots

1406   Abdel Rahman Ibn-Khaldun dies, leaving written works on social topics that closely resemble the sociology of today.

Early Enlightenment

1651   Thomas Hobbes's *Leviathan* announces that "Life is nasty, brutish and short."

1690   John Locke publishes *Essay Concerning Human Understanding* and *Second Treatise on Government.*

18th Century

1739   David Hume's *Treatise on Human Nature* insists on studying human nature through observation rather than through pure philosophy.

1748   Hume publishes *An Enquiry Concerning Human Understanding.*

1748   Charles de Secondat, Baron de Montesquieu anonymously publishes *The Spirit of Laws.*

1751   Hume completes his *Enquiry Concerning the Principals of Morals.*

1762   With Jean-Jacques Rousseau's *The Social Contract,* we go from a "stupid and unimaginative animal" to "an intelligent being and a man."

1776   The Age of Revolution begins, and the flames are fanned by Thomas Paine's *Common Sense.*

1776   Adam Smith releases *An Inquiry into the Nature and Causes of the Wealth of Nations.*

1776   A landmark of the American Revolution and statement of political theory, the Declaration of Independence of the United States of America is published.

1781   Immanuel Kant argues against Hume's radical empiricism in *Critique of Pure Reason.*

1788   Kant publishes *Critique of Practical Reason,* emphasizing free will.

1789   Jeremy Bentham develops a theory of social morals based on the greatest happiness principle in *Introduction to the Principles of Morals and Legislation.*

1791   Olympe de Gouges, a butcher's daughter, writes an alternate version of *Declaration of the Rights of Man* titled *Declaration of the Rights of Woman.*

1792   Mary Wollstonecraft publishes *A Vindication of the Rights of Woman,* urging women to "acquire strength."

1792   Parisians storm the Bastille, beginning the French Revolution.

1798   Thomas Malthus theorizes on the social and demographic effects of scarcity with his *Essay on the Principle of Population.*

1800–1850

1807   Georg Hegel publishes the *Phenomenology of Spirit.*

1817   David Ricardo offers a new vision for political economy with *The Principles of Political Economy and Taxation.*

1821   Claude-Henry de Rouvroy, Comte de Saint-Simon publishes *The Industrial System.*

1837   Hegel publishes the *Philosophy of History.*

1838   Harriet Martineau's *How to Observe Morals and Manners* argues that the goal of sociology is to describe the historically situated relationship between manners and morals.

1840   Alexis de Tocqueville, a French intellectual, offered an early insight into *Democracy in America.*

1841   Ludwig Feuerbach's *The Essence of Christianity* articulates a materialist influence contrary to Hegelian idealism, inspiring Karl Marx.

1830–   Auguste Comte describes a positivistic, evolutionary
1842   view of the world in his *Positive Philosophy.*

1843   Feuerbach inspires secular, humanistic, scientific study of human behavior with *The Philosophy of the Future.*

1843   J. S. Mill publishes *System of Logic* in which he refines logic in its applications to social as well as purely natural phenomena.

1844   Friedrich Engels publishes *Outline of a Critique of Political Economy.*

1844   Karl Marx completes what will become known as his *Economic and Philosophic Manuscripts of 1844;* however, the manuscript is not published in entirety until 1932. The manuscript highlights Marx's early humanistic thinking.

1846   Marx publishes *The German Ideology*, proposing a study of historical materialism.

1848   Marx and Engels publish and distribute *The Communist Manifesto,* which serves as a clarion call for revolution based on Marx's theoretical principles.

1848   Workers revolt across Europe.

1848   Mill debates the ideas of socialism in his *Principles of Political Economy.*

1850–1900

1850   Herbert Spencer publishes *Social Statics,* developing his basic ideas of social structure and change, as well as arguing for rights for women and children.

1851   Feuerbach publishes *Lectures on the Essence of Religion.*

1851   The Great Exhibition of the Works of Industry of All Nations is held in London, primarily inside the iron-and-glass Crystal Palace. It is the first of a series of extravagant world fairs that proclaim the arrival of the industrial revolution.

1852   Marx offers an analysis of the French Revolution titled *The Eighteenth Brumaire of Louis Bonaparte.*

1856   Tocqueville publishes *Ancien Regime in Old Europe.*

1858   Marx develops ideas that will later be refined in *Capital* in *Grundrisse: Foundations of the Critique of Political Economy.*

1859   Charles Darwin publishes *The Origin of the Species.* With Darwinian evolutionary theory, biology takes its first real steps into philosophy's traditional terrain.

1859   Mill publishes *On Liberty,* echoing Tocqueville's fears about democracy.

1863   Lincoln's Emancipation Proclamation decrees that all slaves in the United States "shall be then, thenceforward, and forever free."

1865   The 13th Amendment to the United States Constitution abolishes slavery.

1867   Marx publishes Volume 1 of *Capital: A Critique of Political Economy.*

1871   The Paris Commune is formed.

1872   Friedrich Nietzsche publishes *The Birth of Tragedy, Out of the Spirit of Music* declaring that modern Europe is Apollonian in spirit and needs a recovery of the Dionysian.

1873   Spencer publishes *Study of Sociology,* the textbook used in the first course in sociology in the United States.

1882   Nietzsche publishes *The Gay Science* pronouncing that God is dead.

1877–   Spencer publishes the three volumes of *The Principles of*
1882   *Sociology,* which later inspire Sumner's concept of social Darwinism.

1884   Marx (posthumously) publishes Volume 2 of *Capital: A Critique of Political Economy.*

1884   Engels publishes *The Origins of the Family, Private Property and the State,* declaring that women's subordination is the result of society, not biology.

1887   Ferdinand Tönnies publishes *Gemeinschaft und Gesellschaft,* comparing urban and small town society.

1890   William James publishes *Principles of Psychology* before Sigmund Freud's psychoanalytic methods have become widespread.

1890   Gabriel Tarde discusses the difference between the imitative and the inventive in *Laws of Imitation.*

1893   Émile Durkheim publishes *The Division of Labor in Society* explicating the evolution from mechanical to organic solidarity.

1894   Volume 3 of Marx's *Capital* is published.

1894   Durkheim joins Emile Zola and Jean Jaures in defending Captain Alfred Dreyfus, a Jew unfairly accused of spying. The affair highlighted French anti-Semitism, which Durkheim saw as a deep social pathology.

1895   Durkheim develops the notion of a social fact, the basis for positivism in modern sociology, in *Rules of Sociological Method.*

1897   Durkheim publishes *Suicide* an application of the principles of the new method of sociology. He shows that suicide is a social fact, not an individual problem.

1899   Thorstein Veblen coins the now-famous term "conspicuous consumption" in his *Theory of the Leisure Class.*

1900–1910

1900   Sigmund Freud publishes *The Interpretation of Dreams,* an early statement of Freud's psychoanalytic principals.

1900–   In *Logical Investigations,* Edmund Husserl establishes
1901   the basis for the science of phenomenology.

1900   Georg Simmel finishes his *Philosophy of Money,* a wide-ranging analysis that points to, among other things, the tragedy of culture.

1900   The most well-known World's Fair in Paris exhibits the latest industrial marvels.

1902   Charles H. Cooley publishes *Human Nature and Social Order* at the University of Michigan. His work there is closely associated with the Chicago School.

1903   W. E. B. Du Bois writes *The Souls of Black Folk,* introducing the important concepts of double consciousness and the veil.

1903   Durkheim publishes *Moral Education.*

1904   Robert Park publishes *The Crowd and the Public.*

1905   Max Weber relates the idea systems of Calvinism to the emergence of the "iron cage" in *The Protestant Ethic and the Spirit of Capitalism.*

1907   William James publishes *Pragmatism,* which later inspires the development of symbolic interactionism.

1907   William G. Sumner first develops the concept of social Darwinism in his book *Folkways.*

1908   Georg Simmel publishes *Soziologie,* a wide-ranging set of essays on social phenomena reflecting Simmel's distinctive approach.

1910–1920

1911   In *Political Parties,* Roberto Michels devises the Iron Law of Oligarchy to explain how oligarchy develops in bureaucracy.

1912   In *Elementary Forms of the Religious Life,* Émile Durkheim introduces anthropological evidence to argue that religious experience lies at the foundation of the social order.

1913   The term "behaviorism" is first used by J. B. Watson.

1914   World War I begins.

1915   Vifredo Pareto publishes *General Treatise on Sociology* a systemic, equilibrium-based theory of society.

1916   Ferdinand de Saussure's *Course in General Linguistics* forms the basis for structuralism.

1916   Lenin advances Marx's ideas in *Imperialism, The Highest Stage of Capitalism,* identifying the inherent global expansionistic tendencies of capitalist societies.

1917   The Russian Revolution, inspired by Marxist ideals, overthrows the Czars.

1918   With Florian Znaniecki, W. I. Thomas publishes *The Polish Peasant in Europe and America,* a study that draws on multiple investigative methods.

1919   Pitrim Sorokin's *System of Sociology* lays out his theory of cultural organization and helps develop the ontology of integralism.

1920–1930

1920   American women win the right to vote.

1921   Robert E. Park and Ernest W. Burgess write the first major textbook in sociology: *Introduction to the Science of Sociology.*

1922   Weber's *Economy and Society,* his comparative historical social theory, is published in three volumes.

1922   Bronislaw Malinowski discusses indirect exchange in the Kula rings of the Trobriand Islands in *Argonauts of the Western Pacific.*

1922   Sir James G. Fraser's controversial *The Golden Bough* shows that the Christian story of the man-god sacrificed on the tree is borrowed from other ancient myths.

1922   Cooley introduces the concept of the "looking-glass self" in *Human Nature and the Social Order.*

1923   György Lukács publishes *History and Class Consciousness.*

1923   The Institute of Social Research, also known as the Frankfurt School, is founded.

1923   Ernst Cassirer publishes the first part of "The Philosophy of Symbolic Forms," a series that examines various forms of symbolic representation.

1924   John Maynard Keynes offers a brilliant analysis of the effects of inflation and deflation in his most influential work, *A Tract on Monetary Reform.*

1925   Marcel Mauss develops his theory of gift exchange in *The Gift.*

1925   Burgess and Park publish *The City.*

1925   Maurice Halbwachs publishes *The Social Frameworks of Memory,* a pioneering text in social memory studies.

1927   Martin Heidegger publishes *Being and Time.*

1928   Margaret Mead drops the proof for her controversial *Coming of Age in Samoa* off at the publisher before embarking for New Guinea.

1929   Lucien Febvre and Marc Bloch found the *Annales* School, which is famous for its work on social history.

1929   Karl Mannheim develops his sociology of knowledge in *Ideology and Utopia.*

1929   The U.S. stock market crashes, leading to a worldwide depression.

1930–1940

1930   Psychiatrist J. L. Moreno invents sociometry, the keystone concept for network exchange theory.

1932   Alfred Schütz's *The Phenomenology of the Social World* extends the philosophy of phenomenology into social theory.

1933   Nazis open the first concentration camp at Dachau.

1934   George H. Mead's lectures are compiled and published as *Mind, Self and Society,* the basic text for symbolic interactionism.

1935   Mannheim proposes a planned society in *Man and Society in an Age of Reconstruction.*

1936   Keynes publishes *General Theory of Employment, Interest and Money,* the text that immortalizes his economic theory.

1937   Talcott Parsons publishes the *Structure of Social Action,* in which he introduces grand European theory to an American audience.

1938   B. F. Skinner publishes *The Behavior of Organisms.*

1939   The first shots of World War II are fired as German forces invade Poland.

1939   Norbert Elias publishes *The Civilizing Process* in which he links changes in everyday life to changes in broader social structure.

1940–1950

1940   A. R. Radcliffe-Brown writes *Structure and Function in Primitive Society,* which has a great influence on structural functionalism.

1927–
1940   Walter Benjamin compiles his notes on the Paris Arcades, which are published as *Das Passagen-Werk* in 1982.

1941   At Auschwitz, Nazis begin the use of Zyklon-B gas to murder Jews.

1942   Margaret Mead's *Growing Up in New Guinea* draws a parallel between the primitive Manus and Western civilization.

1942   Joseph Schumpeter revises Marx's predictions on the downfall of capitalism in *Capitalism, Socialism and Democracy.*

1943   Jean-Paul Sartre elaborates contemporary existentialism in *Being and Nothingness,* partially written in a German war prison from 1940–1941.

1944   Karl Polanyi analyzes the industrial revolution, free trade, and socialism in *The Great Transformation.*

1945   In the same year, Hitler commits suicide as America unleashes the atom bomb on Japan.

1947   In *The Accursed Share,* Georges Bataille values the concepts of excess, waste, and sacrifice in his social theory.

1948   Alfred Kinsey publishes *The Sexual Behavior of the Human Male* along with Wardell Pomeroy and Clyde Martin.

1949   Talcott Parsons publishes *Essays in Sociological Theory, Pure and Applied.*

1949   Claude Lévi-Strauss publishes *Elementary Structures of Kinship.*

1949   Max Horkheimer and Theodor Adorno seek to explain why the Enlightenment failed to deliver on its promises of progress, reason, and order in *The Dialectic of Enlightenment.*

1949   Robert Merton publishes *Social Theory and Social Structure.*

1949   Simone de Beauvoir publishes *The Second Sex* in which she provides an existential analysis of the concept of woman.

1950–1960

1950   David Reisman's *The Lonely Crowd* develops the concepts of inner- and other-directedness.

1951   C. Wright Mills publishes *White Collar,* a critical analysis of the work lives of Americans.

1951   Parsons publishes *The Social System* and *Toward a General Theory of Action,* which further refine his structural-functional theory and develop action theory.

1952   The American Psychiatric Association publishes the first edition of the *Diagnostic and Statistical Manual of Mental Disorders (DSM-I).*

1954   Abraham Maslow delineates his famous hierarchy of needs in *Motivation and Personality.*

1955   L. J. Moreno gives his book, *Sociometry,* to the American Sociological Association for publication.

1956   Mills publishes *The Power Elite,* anticipating Dwight Eisenhower's ideas on the military-industrial complex.

1956   Ralf Dahrendorf's *Class and Class Conflict in Industrial Society* becomes the basic text in conflict theory.

1956   Lewis Coser publishes *The Functions of Social Conflict* in which he integrates Simmel's ideas on conflict with a structural-functional approach.

1957   Roland Barthes examines myths and cultural objects as a language of signs in society in *Mythologies.*

1958   John K. Galbraith's *The Affluent Society* challenges the American myth of consumer sovereignty.

1959   Karl R. Popper debates the philosophy and rules of science in *The Logic of Scientific Discovery.*

1959   Mills articulates his famous view of sociology in *The Sociological Imagination,* where he also critiques Parsons's structural functionalism.

1959   Erving Goffman develops his dramaturgical theory and famous ideas of front- and backstage in *The Presentation of Self in Everyday Life.*

1960–1970

1961   George C. Homans publishes *Social Behavior: Its Elementary Forms,* the pioneering text in exchange theory.

1962   Richard Emerson's article, "Power-Dependence Relations" is published in the *American Sociological Review.*

1962   Thomas Kuhn develops a revolutionary rather than evolutionary theory of the advance of science in *The Structure of Scientific Revolutions.* This book also popularizes the term *paradigm.*

1963   Goffman publishes *Stigma,* a critical book for labeling theory.

1963   200,000 people march for civil rights in Washington, D.C. Martin Luther King Jr. gives his famous "I Have a Dream" speech at the Lincoln Memorial.

1963   The second wave of feminism is marked by Betty Friedan's *The Feminine Mystique.*

1964   Peter Blau develops a micro-macro theory of exchange in *Exchange and Power in Social Life.*

1964   Marshall McLuhan declares that the medium is the message in *Understanding Media: The Extensions of Man.*

1964   Herbert Marcuse publishes *One Dimensional Man: Studies in the Ideology of Advanced Industrial Society* describing society's destructive impact on people.

1965   Michel Foucault's *Madness and Civilization* is published.

1966   William Masters and Virginia Johnson publish *Human Sexual Response,* introducing large numbers of people to the study of sexuality.

1966   Peter Berger and Thomas Luckmann's *The Social Construction of Reality: A Treatise in the Sociology of Knowledge* extends phenomenology to macrolevel issues.

1967   Jacques Derrida finishes *On Grammatology,* which becomes a central text in the emerging field of poststructuralism.

1967   Guy Debord publishes *The Society of the Spectacle,* a critique of media and consumption in contemporary social life.

1967   Harold Garfinkel's *Studies in Ethnomethodology* creates a new micro-social theory.

1968   Student revolts form an epicenter in Paris and sweep through Europe.

1969   Herbert Blumer publishes *Symbolic Interactionism: Perspectives and Methods,* offering an overview of the symbolic interactionist perspective.

1970–1980

1970   Alvin Gouldner's *The Coming Crisis of Western Sociology* critiques many trends in Western sociology, especially Parsonsian structural functionalism.

1970   Jean Baudrillard releases *Consumer Society: Myths and Structures,* a groundbreaking text in the studies of consumption.

1971   Jürgen Habermas relates material interest to idea systems in *Knowledge and Human Interests.*

1972   The demolition of the modernist Pruitt-Igoe housing project in St. Louis marks the end of the reign of modernity for some postmodernist theorists.

1973   Howard Becker publishes *Outsiders: Studies in the Sociology of Deviance,* a key text in the sociology of deviance.

1973   Baudrillard's *The Mirror of Production* marks his break from his Marxian roots.

1973   Clifford Geertz publishes *The Interpretation of Cultures.*

1974   Herbert Marcuse publishes *Eros and Civilization: A Philosophical Inquiry into Freud* where he translates Freud for critical theory.

1974   The first part of Immanuel Wallerstein's 3-volume *The Modern World System* shifts the focus of Marxian theory to exploitation between nations on a global scale.

1974   First issue of *Theory & Society* published.

1974   Luce Irigaray's *Speculum of the Other Woman* argues that psychoanalysis is phallocentric and thus has no place for the feminine.

1974   Daniel Bell's *The Coming of Post-Industrial Society* predicts the coming of "knowledge society."

1974   Goffman's *Frame Analysis: An Essay on the Organization of Experience* creates a new theoretical methodology.

1974   Glen H. Elder Jr. argues for a life course perspective in social psychology in *Children of the Great Depression.*

1974   Henri LeFebvre publishes *The Production of Space* provoking social analysis of space.

1975   Randall Collins publishes *Conflict Sociology: Toward an Explanatory Science,* in which Collins develops a micro orientation to conflict theory.

1975   E. O. Wilson introduces the term *sociobiology* in *Socio-Biology: The New Synthesis.*

1975   Foucault publishes *Discipline and Punish: The Birth of the Prison* in which he depicts the origins of the carceral society.

1976   Baudrillard argues that the modern world has lost the ability to engage in symbolic exchange in *Symbolic Exchange and Death.*

1977   Pierre Bourdieu publishes *Outline of a Theory of Practice* formulating his constructivist structuralism and his concepts of habitus and field.

1978   Marcuse publishes *The Aesthetic Dimension: Toward a Critique of Marxist Aesthetics.*

1978   In *The Reproduction of Mothering: Psychoanalysis and the Sociology of Gender,* Nancy Chodorow draws on object relations theories to rethink gender and the mother-child relationship.

1978   Edward Said's *Orientalism* opens cultural studies to postcolonial theory.

1979   Arlie Hochschild's article "Emotion Work, Feeling Rules and Social Structure" is published, introducing social theorists to the effects of emotional labor.

1979   Theda Skocpol's *States and Social Revolutions* shows that state structures, international forces, and class relations contribute to revolutionary transformations.

1979   Jean-Francois Lyotard publishes *The Postmodern Condition.*

1979   Bruno Latour and Steve Woolgar publish *Laboratory Life: The Social Construction of Scientific Facts,* a key document for the social studies of science; it also inspires actor network theory.

1979   Richard Rorty's *Philosophy and the Mirror of Nature* rejects foundationalist and essentialist epistemologies and argues for the merits of pragmatic philosophy.

1980–1990

1980   Foucault publishes the first of his three-volume opus, *The History of Sexuality,* major works on poststructuralist and queer theory.

1980   In a famous essay of the same name, Stuart Hall introduces the "Encoding/Decoding" model of television viewing, arguing that audiences interpret the meaning of programs in many ways.

1980   Adrienne Rich writes her essay "Compulsory Heterosexuality and Lesbian Existence," creating the lesbian continuum and coining the term *compulsory heterosexuality*.

1982   First issue of *Theory, Culture and Society* is published.

1982   Niklas Luhmann develops his distinctive version of systems theory in *The Differentiation of Society.*

1982–   Jeffrey Alexander releases *Theoretical Logic in Sociology*
1983   in four volumes, paralleling Parsons's *The Structure of Social Action,* synthesizing and updating functionalism.

1983   Cook, Emerson, Gillmore, and Yamagishi publish "The Distribution of Power in Exchange Networks: Theory and Experimental Results."

1983   Baudrillard's *Simulations* develops the concepts of simulation and simulacra in society.

1983   Nancy Hartsock publishes "The Feminist Standpoint: Developing the Ground for a Specifically Feminist Historical Materialism," an article crucial to the definition of standpoint theory.

1983   Hochschild publishes *The Managed Heart: Commercialization of Human Feeling.*

1983   The first issue of *Sociological Theory* is published.

1983   French philosopher Paul Ricoeur publishes volume 1 of *Time and Narrative,* a series that describes the centrality of narrative to lived experience.

1984   Pierre Bourdieu publishes *Distinction: A Social Critique of the Judgment of Taste* in which he applies his

constructivist structuralism to consumption and culture in France.

1984   Anthony Giddens publishes *The Constitution of Society: Outline of the Theory of Structuration,* the most complete statement of his structuration theory.

1984   Habermas publishes *The Theory of Communicative Action,* vol. 1, *Reason and the Rationalization of Society,* reinterpreting and extending Weber's social theory and developing his ideas of communicative rationality.

1985   Gilles Deleuze and Felix Guattari oppose psychoanalysis and offer a political analysis of desire in *Anti-Oedipus: Capitalism and Schizophrenia.*

1985   Robert Bellah et al. publish *Habits of the Heart: Individualism and Commitment in American Life,* a micro-macro look at democratic community and individualism.

1985   Jonathan Turner's essay, "In Defense of Positivism" is published.

1986   Ulrich Beck completes *Risk Society: Towards a New Modernity,* which begins a widespread interest in the concept of risk in late modern life.

1986   Jacques Lacan publishes *Écrits,* in which he revises Freud's psychoanalysis in the context of Saussurian linguistics.

1986   Paul Virilio publishes *Speed and Politics,* introducing the concept of speed to social theory.

1987   Dorothy Smith combines phenomenology and feminism in *The Everyday World as Problematic: A Feminist Sociology.*

1987   Habermas explores the colonization of the lifeworld in *The Theory of Communicative Action,* vol. *2, Lifeworld and System, a Critique of Functionalist Reason.*

1988   Noam Chomsky and Edward Herman declare, in *Manufacturing Consent: The Political Economy of the Mass Media,* that the mass media is used as a tool of political propaganda.

1989   In *The Sublime Object of Ideology,* Slavoj Žižek draws on Lacanian psychoanalysis to develop his theory of ideology critique and cultural analysis.

1989   Zygmunt Bauman argues that the Holocaust is a consequence of modernity in *Modernity and the Holocaust.*

1989   David Harvey introduces the idea of time-space compression and develops social geography in *The Condition of Postmodernity: An Enquiry into the Origins of Cultural Change.*

1989   In his influential *Sources of the Self,* Charles Taylor explores the cultural and intellectual origins of modern selfhood.

1990–2000

1990   James S. Coleman publishes *Foundations of Social Theory,* laying the foundations for sociologically relevant rational choice theory.

1990   Judith Butler calls for the subversion of the hegemony of gender in *Gender Trouble.*

1990   Giddens publishes *The Consequences of Modernity,* introducing the idea of the juggernaut of modernity.

1990   Donna Haraway's essay "A Manifesto for Cyborgs: Science, Technology, and Socialist Feminism" becomes an important postmodern contribution to feminist theory.

1990   Patricia Hill Collins publishes *Black Feminist Thought: Knowledge, Consciousness and Empowerment,* where, among other things, she develops the concept of intersectionality.

1991   Frederic Jameson writes *Postmodernism, or, the Cultural Logic of Late Capitalism.*

1991   Kenneth Gergen publishes *The Saturated Self: Dilemmas of Identity in Contemporary Life,* an account of the chaos of postmodern selfhood.

1992   Marc Augé publishes *Non-Places: An Introduction to an Anthropology of Supermodernity.*

1992   Roland Robertson's *Globalization: Social Theory and Global Culture,* building on his work in religion, develops a series of ideas, including the concept of glocalization.

1992   Paul Gilroy revisits the origins of Atlantic African cultural diaspora in *The Black Atlantic.*

1993   George Ritzer extends Weber's theory of rationalization to the realm of consumption and culture in *The McDonaldization of Society.*

1994   Cornell West publishes *Race Matters.*

1995   Luhmann's *Social Systems* further develops his version of systems theory.

1996   Manuel Castells conceives of a world dominated by the flow of information in *The Rise of the Network Society.*

1996   Arjun Appadurai develops his concept of global "scapes" in *Modernity at Large: Cultural Dimensions of Globalization.*

1997   Chomsky publishes "Media Control: The Spectacular Achievements of Propaganda."

1998   Patricia Hill Collins's *Fighting Words: Black Women and the Search for Justice* further develops her theory of intersectionality.

1999   David Willer publishes *Network Exchange Theory.*

2000   In *Empire,* Michael Hardt and Antonio Negri propose that the age of imperialism is over, being replaced by an empire without a national base.
