RICE BEAN (*see also* **BEANS**) – A native of Asia, the rice bean (*Phaseolus calcaratus* = *Vigna umbellata*) grows wild from the Himalaya Mountains through central and southern China to Malaysia. It is cultivated to some extent in Asia and in the East Indies for its seed, although the young pods and leaves are also cooked as a vegetable. The seeds are generally eaten with rice, hence the name.

Common names and synonyms: Frijol arroz, haricot riz.

See in addition: "Beans, Peas, and Lentils," Part II, Section C, Chapter 3.

RICEGRASS – Also called "Indian ricegrass" because it was an important food for Native Americans, ricegrass (*Oryzopsis hymenoides* and *O. aspera*) is a bunch grass that grows throughout central North America. Its grain was ground into meal for bread and porridges.

Common names and synonyms: Indian ricegrass.

Rice wheat – *see* **EMMER**

RIESLING (*see also* **GRAPES**) – A white wine grape, the Riesling (*Vitis vinifera*) makes the great wines of Germany's Rhine and Mosel valleys as well as many of those from Alsace in France. The grape is also one of the two major white grapes grown in Washington State. In California, the grape is called Johannisberg Riesling. Oregon is also a major producer. Rieslings can vary from very dry to sweet, dessert-type wines, although most tend to the dry side.

Common names and synonyms: Johannisberg Riesling, white Riesling.

ROSE (*see also* **ROSE HIPS**) – Roses (genus *Rosa*) are ancient plants that grew wild in Asia and have found culinary uses for thousands of years. The petals are used in salads, candied in desserts, and made into syrups and jams. Rose water (and rose essence, a more concentrated distillation of rose water) adds flavor and aroma to various dishes – especially curries and rice dishes – and has long been used to flavor milk drinks, desserts, and cakes.

Common names and synonyms: Rose essence, rose water, wild rose.

See in addition: "Spices and Flavorings," Part II, Section F, Chapter 1.

ROSE APPLE – Often confused with the Java apple because of similar scientific as well as common names, the rose apple (*Eugenia jambos* or *Syzygium jambos*) belongs to the family Myrtaceae, which includes myrtle, clove, and allspice. The fruits of an evergreen tree native to Southeast Asia, rose apples grow in clusters of four or more. When ripe, they are about 2 inches long, white or yellow with pink streaks, with a relatively large seed and the aroma of rose water (hence their name). The quality of the fruits varies considerably, and many are not juicy enough to deliver an excellent flavor. Those that are juicy are sometimes eaten raw, but as a rule rose apples are made into jams and jellies.

Common names and synonyms: Jambos, jambu, wax apple.

Rose-essence – *see* **ROSE**

ROSE HIP(S) (*see also* **ROSE**) – The red- to orange-colored, urn-shaped fruits of the rose that appear in late summer and early fall, rose hips (*Rosa canina* and *R. rugosa*) are actually the bases to which the flower's petals are attached. Once considered sacred, the hips were used by Catholic believers during the Middle Ages to count prayers or series of prayers – hence the name of the string of beads called a "rosary." Most rose hips are gathered from wild rose bushes and are utilized to make tea, jellies, and preserves and, in parts of Europe, a syrup used as a tonic. Rose hips are extremely high in vitamin C.

Common names and synonyms: Dog rose, wild rose.

Rosella – *see* **ROSELLE**

ROSELLE – Probably a native of West Africa (it is a close relative of okra), roselle (*Hibiscus sabdariffa*) is also called "rozelle," "Indian sorrel," "red sorrel," "Jamaican sorrel," and just plain "sorrel." The young shoots and leaves of the plant are eaten raw or as a cooked vegetable, and the flowers (actually the calyx), which constitute the main reason for the cultivation of roselle, are used to make beverages, jellies, sauces, preserves, and chutneys.

Roselle was introduced in Brazil in the seventeenth century but may have reached the West Indies even earlier – both of these introductions probably occurring via the slave trade. In addition, the plant has been under cultivation in Asia for some three centuries; extensive roselle cultivation was begun in Australia at the turn of the twentieth century and in the Dutch East Indies during the 1920s. Today, India, Java, and the Philippines are major producers.

Common names and synonyms: Indian sorrel, Jamaican sorrel, Java jute, red sorrel, rosella, rozelle, sorrel.

ROSEMARY – An aromatic herb, rosemary (*Rosmarinus officinalis*) is a Mediterranean native whose Latin name means "dew of the sea," presumably because it was frequently found growing close to the coast. The plant was known to the Romans, who used it mostly for medicinal purposes. Early in the Middle Ages, however, although its medical applications continued, rosemary joined a host of other herbs employed for culinary reasons, especially in the kitchens of the European royal and noble courts. Today, rosemary is more utilized in Italian cooking than in any of the other Mediterranean cuisines; in northern Europe, it is sometimes used in sausage making. The needle-like leaves of the rosemary plant are used both fresh and dried, but they have to be crushed, crumbled, or chopped to release their bold flavor and (especially in the case of fresh rosemary) to avoid spearing the consumer. Rosemary is wonderful with poultry, beef, lamb, and fish, and goes well in sauces. It is also used in salads, salad dressings, soups, and stews, and to make tisanes.

ROUGE VIF D'ÉTAMPES (PUMPKIN) (*see also* **PUMPKIN, SQUASH AND PUMPKIN**) – The French crafted this elegant pumpkin variety, the *Rouge Vif d'Étampes* (*Cucurbita maxima*), from more basic American stock. Also called the "Cinderella pumpkin," it is a heavily fleshed pumpkin that is generally regarded as the best of all pumpkins for baking, and especially for soup making.

Common names and synonyms: Cinderella pumpkin.

See in addition: "Squash," Part II, Section C, Chapter 8.

ROUGH BINDWEED – A European plant, rough bindweed (*Smilax aspera*) has roots that yield a kind of sarsaparilla.

Common names and synonyms: Bindweed, bindweed root.

ROUND GOURD – Known also as the "round melon," the round gourd (*Praecitrullus fistulosus*) is grown primarily in India and is practically unknown in the West. The round gourd is cooked as a vegetable while immature, and its seeds can be roasted.

Common names and synonyms: Round melon.

Round melon – *see* **ROUND GOURD**

ROWANBERRY (*see also* **BERRIES**) – The rowan tree (*Sorbus aucuparia*) is a small, attractive native of Europe and western Asia that produces orange-red rowanberries. The species name *aucuparia* means "bird-catching," referring to the trees' ancient use as bait. The berries have a long history of magical as well as culinary uses. Ancient northern Europeans comforted themselves with the belief that rowanberries guarded against the spells of witches, demons, and the like. The berries' juice makes a fine jelly that historically was eaten with game or cold meats. Rowanberries have also been fermented and used for distilling liquor. A similar species yields the whitebeam berry, which is like the rowanberry and was once used to make wine. Another, the service tree, yields serviceberries, which are now less common.

Common names and synonyms: Serviceberry, whitebeam berry.

Rozelle – *see* **ROSELLE**

Rucola – *see* **ARUGULA**

RUE – A Eurasian plant, rue (*Ruta graveolens*) has been used for many centuries in medicines and as a disease preventive. Indeed, rue was once credited with warding off the plague known as the Black Death and was called "herb-of-grace." The bitter, pungent leaves have also been employed as a potherb – first in Europe and later, after the plant became naturalized, in the southern United States.

Common names and synonyms: Herb-of-grace.

RUTABAGA – Closely related to the turnip, the rutabaga (*Brassica napobrassica*) is a relatively modern vegetable that resulted from a cross between a Swedish turnip and a cabbage. Called a "Swede," the rutabaga spread from Sweden to central Europe and had reached England by 1800. It was grown in the United States by the beginning of the nineteenth century. However, many rutabagas come to the United States from Canada, which has led to the nickname "Canadian turnip." The rutabaga's flesh is yellowish, and its taste is milder than that of the turnip.

Common names and synonyms: Canadian turnip, swede, Swedish turnip, yellow turnip.

See also: "Cruciferous and Green Leafy Vegetables," Part II, Section C, Chapter 5.

RYE – A native of central Asia, rye (*Secale cereale*) is a widely cultivated cereal grass with seeds that are used for flour, for making whiskey, and as livestock feed. The grain has been cultivated for millennia, but not always deliberately. Beginning some 4,000 years ago, rye started a westward movement, generally as a weed in fields of wheat (a close relative) and barley. Rye came to be appreciated when its hardiness kept it standing while the more valued crops failed. However, in the Mediterranean region, a mild climate prevented rye from displaying its quality of hardiness, and the grain was reportedly despised by the ancient Greeks.

Rye expanded during Roman times – but apparently not with the assistance of the Romans – and was cultivated mostly outside the empire, especially in northern Europe (from about the first century A.D.), where the climate was colder and the plant could grow in soils too poor for wheat. It was brought to North America by European colonists, and became an important staple in early New England, where it may also have played a disruptive role. Rye is especially prone to infection by ergot, a fungus that can cause hallucinations, convulsions, and even gangrene and death, and some historians suspect that ergot-poisoned rye may have been behind the strange behavior of the Salem "witches."

Certainly ergotism was a deadly disease in Europe for hundreds of years, and today rye is carefully inspected for the ergot fungus. Although generally thought of as "poor man's flour," rye remains popular in Scandinavia and eastern Europe. Rye flour is normally mixed with wheat flour to make rye bread. In addition, rye flakes, cracked rye, and whole rye "berries" are used in breakfast cereals, muffins, soups, and casseroles. A major product of rye over the last few hundred years has been the excellent malt it furnishes for the brewing and distillation of alcoholic beverages. The relatively small crop produced in the United States is divided between food and alcohol production on the one hand, and animal feed on the other hand.

See also: "Rye," Part II, Section A, Chapter 8.

RYEGRASS – Any of several species of the genus *Lolium* are called ryegrass. They are European plants that have become naturalized throughout North America. Some, such as Italian ryegrass (*L. multiflorum*), which is much used for hay, or English ryegrass (*L. perenne*) probably served as food for Old World humans in the past. In the New World, the grains of darnel (*L. temulentum*) were consumed by some Native American groups.

Common names and synonyms: Darnel, English ryegrass, Italian ryegrass.

SAFFLOWER – A thistle-like herb, the safflower plant (*Carthamus tinctorius*) is native to Asia or perhaps Egypt but is now cultivated throughout the world. The plant has red and yellow flowers that were once used as a seasoning (a saffron substitute), whereas its seeds have served for millennia in India as the base of medicines, paints, and cosmetics. But the main use of the seeds is to press them for an oil employed in cooking. Safflower oil is light, with a neutral taste, and is used in salads and for stir-frying.

SAFFRON – This spice comes from a species of crocus (*Crocus sativus*), in the form of saffron "threads," which are the stigmas (the parts that catch pollen for the ovary) of the flower. It has been estimated that, at three stigmas per plant, upwards of 250,000 of these crocus flowers are required to yield a pound of saffron. These numbers, coupled with the fact that the work is all done by hand, serve as a powerful explanation for saffron's distinction as the world's most expensive spice.

Native to the eastern Mediterranean, saffron was used in cooking for thousands of years before the Romans built their empire. Indeed, some credit Phoenician traders with introducing it in Spain – the country that today is the leading producer for the commercial market.

The word saffron comes from the Arabic word for "yellow," and its distinctive color and taste grace Spanish, Cuban, French, and Indian cuisines, especially their rice dishes. It is a vital ingredient in an authentic bouillabaisse or paella as well as the saffron bread of a traditional Swedish feast. Saffron also goes well with poultry, in tomato-based sauces and stews, and in liqueurs such as Chartreuse. The spice is marketed as dried threads and in ground form. Unfortunately, much adulteration of ground saffron occurs, including its near-total replacement with turmeric – a crime that in fifteenth-century Germany drew a penalty of execution by burning or burying alive.

Sagaloo – *see* **CALLALOO**

SAGE – The aggressive flavor and smell of sage (*Salvia officinalis*) doubtless helped to convince numerous peoples – from the ancient Greeks, Arabs, and Romans to the Europeans of the Middle Ages – of its medicinal properties. There are numerous varieties of this small Mediterranean native, with its long and narrow, not to mention pungent, leaves. Exactly when sage became more important in cooking than curing is not clear. Its leaves were brewed into a tea that was used as a spring tonic, and during the Middle Ages the plant gained a reputation (and its common name) for imparting wisdom and improving memory.

But for many centuries, sage has also been flavoring Italian veal, German eels, and French sausages, along with other meats such as pork. In the United States, the herb is a vital ingredient in many seasoned poultry stuffings; fresh sage leaves are universally employed in flavoring pickles, salads, and cheeses and are sometimes made into a tisane. Sage can be purchased in whole leaves (fresh or dried), and in dried and crumbled form (rubbed sage). Today it is cultivated in eastern and western Europe, around the Mediterranean, in the United States, and to a limited extent in West Africa and the West Indies at altitudes of over 1,500 feet.

Common names and synonyms: Common sage, garden sage, rubbed sage.

Sage tree – *see* **CHASTE TREE**

SAGO – Sago is a starch taken in large quantities from several varieties of tropical (sago) palms of the genus *Metroxylon.* The palms grow wild in low-lying, swampy areas of Southeast Asia, Oceania, and northern South America. When mature (at about 10 to 15 years of age), the tree is felled, the trunk split open, and the pith scooped and rasped out to be made into a powdery starch. A single tree may yield from 600 to 800 pounds of starch, which is cooked like rice pudding (it resembles tapioca) and used as a food thickener. "Pearl" sago, produced by putting a sago paste through a sieve and then drying the "pearls," is often used for desserts. Pearl sago is generally the only kind of sago available outside of the tropics. Sago provides much in the way of carbohydrates but lacks most other important nutrients and must be supplemented with foods containing protein, such as fish and local vegetable foods.

Common names and synonyms: Pearl sago.

See also: "Sago," Part II, Section B, Chapter 4.

Sago fern – *see* **TREE-FERN**

SAGUARO (*see also* **PITAHAYA**) – A giant columnar cactus of northern Mexico and southern Arizona, the saguaro (*Cereus giganteus* or *Carnegiea gigantea*) served as a staple food for Native Americans of the region, who often gathered saguaro fruits that had fallen to the ground and had been naturally dried by the sun. These they stored for later use. The red pulp of the fruit can also be eaten fresh, pressed into juice, and made into a syrup. In addition, the seeds can be turned into a paste. The fruits are sometimes called *pitayas,* and the saguaro cactus a *pitayo.*

Common names and synonyms: Pitaya, pitayo.

SAIGON CINNAMON (*see also* **CINNAMON AND CASSIA**) – Like its relatives cinnamon and cassia, "Saigon cinnamon" (*Cinnamomum loureirii*) is a tree cultivated for its bark, which is processed into a spice. Probably a native of Southeast Asia, the tree is now grown primarily in China, Japan, and Java. Also known as "cassia" (which promotes some confusion), Saigon cinnamon is sold as cinnamon and is widely used in industrial baking and food processing in the United States.

Common names and synonyms: Cassia.

Saint-John's-bread – *see* **CAROB**

SAINT-JOHN'S-WORT – A Eurasian plant, now growing in North America and known throughout the world for its alleged antidepressant properties, "Saint-John's-wort" (*Hypericum perforatum*) produces lemon-scented leaves that have served humans as food for thousands of years and have also been used to make a tea. In addition, the flowers have been consumed, as have the flower buds and leaves of "great Saint-John's-wort" (*H. pyramidatum*).

Common names and synonyms: Great Saint-John's-wort.

Salad savory – *see* **KALE**

SALAK – Salak (*Salacca edulis*) is the native name in Malaya for a fruit that grows on a palm, looks like a pear, and tastes like a pineapple.

SALAL – A close relative of wintergreen, salal (*Gaultheria shallon*) is a shrub of the northwestern Pacific coast of North America. It bears fruits that are dark, sweet, juicy, and about the size of the common grape. When these berries ripened in the autumn, they were consumed in great amounts by Native Americans of the region, who also dried them for use in the winter.

Salamander tree – *see* **BIGNAY**

SALEP – A starchy powder, ground from the dried roots of various Old World orchids of the genera *Orchis* and *Eulophia,* salep is employed in Asian cookery. When mixed with boiling milk, it makes a kind of pudding that is enjoyed by children. In a diluted form, salep was formerly sold on the streets to London laborers as an early-morning drink. Salep stalls, however, long ago gave way to coffee stalls.

SALMONBERRY (*see also* **BERRIES, CLOUDBERRY**) – This edible berry grows on a prickly shrub (*Rubus spectabilis*) that is a native of the coastal regions of the U.S. Northwest. Actually a raspberry, the fruit is a yellow-pink "salmon" color, hence its name. Both the berries and the young shoots of the plants were eaten by Native Americans.

Common names and synonyms: Thimbleberry.

Saloop – *see* **SASSAFRAS**

SALSIFY (*see also* **SCORZNERA**) – A perennial plant, thought by some to have a taste similar to that of an oyster (and consequently nicknamed "oyster-plant" and "vegetable-oyster"), salsify (*Tragopogon porrifolius*) is native to the Mediterranean region, where it has been cultivated since at least the sixteenth century. It is a parsnip-like root vegetable with light brown skin and a whitish flesh that is much more appreciated in Europe than in the Americas, although the plant has existed in North America for a couple of centuries and is grown commercially there.

At the top of the seed heads of this interesting plant grows a fluffy tuft that has prompted another nickname – "purple-goat's-beard." (A black variety of salsify is known as *scorzonera*.) Salsify has edible leaves that grow upwards of 2 feet in length and are used in salads or cooked as a vegetable. After the roots (an excellent winter vegetable) are unearthed, they are normally scraped, then prepared – like parsnips – by steaming or parboiling and sautéeing. Salsify provides the consumer with some measure of the B-vitamins and vitamin C.

Common names and synonyms: Oyster-plant, purple-goat's-beard, vegetable-oyster, white salsify.

SALTBUSH – A member of the goosefoot family (Chenopodiaceae), the four-wing saltbush (*Atriplex canescens*) has foliage that tastes salty. Native Americans used its seeds for meal and ate the new shoots and leaves as greens. Several other species of *Atriplex* were similarly employed. Another plant called saltbush – desert holly (*A. hymenelytra*) – may or may not have ever served as human food.

Common names and synonyms: Desert holly, four-wing saltbush.

SAMPHIRE (*see also* **GLASSWORT**) – A plant that inhabits Old World coastal areas from the British Isles along the shores of western Europe to the Mediterranean, samphire (*Crithmum maritimum*) has fleshy leaves that are used in salads. A member of the parsley family, saphire is also called "glasswort." Another plant with the name samphire is *Philoxerus vermicularis,* which is common along the beaches of the southeastern United States. It also has fleshy, edible leaves.

Common names and synonyms: Glasswort.

SAND CHERRY (*see also* **CHERRY**) – One of the many wild cherries of eastern North America, the "sand cherry" (*Prunus pumila*) is a low-growing cherry that likes sandy soil. The fruit is black, with a taste that ranges from sweet to very acidic. Native Americans pounded sand cherries (including the pits) into a jelly-like mass that could be shaped, dried, and stored for the winter. There is also a "western sand cherry" (*P. besseyi*) – of western North America – which bears a large fruit that is generally quite sweet.

Common names and synonyms: Western sand cherry.

Sand leek – *see* **GARLIC**

San Domingo apricot – *see* **MAMMEE**

Sand pear – *see* **ASIAN PEAR**

SANGIOVESE (*see also* **GRAPES**) – A red wine grape of central Italy (especially Tuscany), the Sangiovese (*Vitis vinifera*) is the primary grape used to make Chianti – the most popular wine of Italy. It is also used to make some of the other Tuscan red wines as well as medium-bodied reds in California.

See in addition: "Wine," Part III, Chapter 13.

Santa Fe Grande – *see* **WAX PEPPERS**

SAPODILLA – A tropical American species, the sapodilla (*Manilkara zapota*) is a tree that seems to have had its origins in southern Mexico, Central America, and perhaps northern South America, but it is now widespread from the West Indies to the East Indies – and with good reason. The bark contains a milky latex, widely known as "chicle" (an ingredient of chewing gum), and the tree bears fruits that are both juicy and sweet when ripe. The latter (also called "naseberries") are small, round, and reddish brown, with a yellowish pulp that can be spooned out of the skin. In addition to being eaten out of hand, sapodillas are used in salads and desserts.

Common names and synonyms: Chicle (tree), chico, chico sapote, chico zapote, chiku, dilly, mammee sapota, marmalade plum, naseberry, nispero, zapote, zapotillo.

Sapota – *see* **BLACK SAPOTE, MAMEY SAPOTE, WHITE SAPOTE**

SAPUCAIA NUT – Several trees of the genus *Lecythis,* which are native to Brazil, Guiana, and Trinidad, produce sapucaia nuts. Also called the "paradise nut," it is a sweet, oily nut that resembles the Brazil nut in taste, although some find that of the sapucaia to be superior. Like Brazil nuts, sapucaia nuts are formed inside an urn-shaped container. But this vessel – commonly called a "monkey pot" – is considerably larger than that of the Brazil nut. The problem is that unlike Brazil nuts, the sapucaia is not protected by a hard shell, and at maturity the cap of the "monkey pot" loosens, scattering the nuts over the jungle floor to be consumed by monkeys and other animals, and those that are not consumed are difficult to find. Thus, only a very small portion of sapucaia nuts are ever consumed by humans, and those reaching U.S. markets tend to be expensive.

Common names and synonyms: Paradise nut.

SARSAPARILLA – The dried roots of American tropical plants of the genus *Smilax* yield an extract that was used in London for one of the first "soft drinks" – "Dr. Butler's Ale," first made around the turn of the seventeenth century. Sarsaparilla was later a common base for soft drinks made in the United States.

Saskatoon berry – *see* **SERVICEBERRY**

Saskatoon serviceberry – *see* **SERVICEBERRY**

SASSAFRAS – The spicy bark of both the trunk and roots of the North American tree *Sassafras albidum* is dried and used for flavorings. Sassafras tea has long been employed for medicinal purposes, and "saloop" – a kind of sassafras tea – not only was considered a remedy for many ailments but also, like salep, was sold on the streets of London to working men, much as coffee is now. In addition, sassafras twigs and leaves contain much mucilaginous matter, which is utilized in filé to flavor and thicken gumbos and other soups.

Common names and synonyms: Filé, saloop, sassafras tea.

Sassafras tea – *see* **SASSAFRAS**

Sauerkraut – *see* **CABBAGE**

Sauvignon – *see* **SAUVIGNON BLANC**

SAUVIGNON BLANC (*see also* **GRAPES**) – Also called Fumé Blanc, Sauvignon Blanc is a white wine grape (*Vitis vinifera*) that is employed to make some of the great dry wines of the Graves region of Bordeaux and the Loire Valley (important wine-producing areas of France) as well as many that are produced in California and Washington State. The wine Pouilly Fumé, of the Loire Valley, is 100 percent Sauvignon Blanc, as is Sancerre, and the grape is a major variety used in the production of Sauternes. Sauvignon Blanc grapes have been grown in California for over a century. The name Fumé Blanc was an invention of California wine maker Robert Mondavi that was intended to stimulate sales of his Sauvignon Blanc wine. To say simply that he succeeded is a colossal understatement.

Common names and synonyms: Blanc Fumé, Fumé Blanc, Sauvignon.

See in addition: "Wine," Part III, Chapter 13.

SAVORY – Summer savory (*Satureja hortensis*) and winter savory (*S. montana*) are both herbs that are native to the Mediterranean region. Their leaves have served to flavor foods since the time of the ancient Romans. Both have a faintly peppery taste, but that of summer savory is milder. Savory leaves are available both fresh and dried and go well with tomato-based dishes, legumes, stuffings, fish, salads, sauces, and sausages – to name but a few of the various foods this herb enhances.

Common names and synonyms: Summer savory, winter savory.

SCORZONERA – This vegetable (*Scorzonera hispanica*) was once believed by the Spaniards to cure snakebites as well as to just make people feel happy. Scorzonera is native to central and southern Europe, where it has been cultivated since at least the sixteenth century. The root is shaped like a carrot and is black skinned with white flesh. The flowers are yellow and the oblong leaves are hairy. A member of the Compositae family, scorzonera can be either eaten raw (often in salads) or boiled as a vegetable. The taste is often described as being similar to that of an oyster. Scorzonera is an annual plant and popular in Europe. It grows wild over much of the continent, from Spain in the south and west, north to Germany, and east to the Caucasus. Scorzonera is also commonly known as black salsify.

Common names and synonyms: Black oyster-plant, black salsify, viper-grass.

SCURVY GRASS (*see also* **ANGELICA, MOUNTAIN SORREL**) – There are a number of plants called "scurvy grass." These plants were generally those that appeared early in the spring and were consumed by humans after a winter of vitamin-C deprivation. This "official" scurvy grass (*Cochlearia officinalis*) is a denizen of northern regions that has extremely bitter foliage. It is also called spoonwort because of the shape of its leaves; needless to say, it does contain some vitamin C.

Common names and synonyms: Spoonwort.

Seabeach sandwort – *see* **SEA PURSLANE**

Sea bean – *see* **GLASSWORT**

SEA BUCKTHORN – A shrub found on the coasts of Europe and Asia, the sea buckthorn (*Hippophae rhamnoides*) has silver leaves and produces orangish red, edible berries.

SEA GRAPE – Also called the shore grape, the sea grape (*Coccoloba uvifera*) is a tropical American native found on sandy beaches from Florida throughout the West Indies to Venezuela. Not a grape (despite its name), the sea grape is a bushy, salt-tolerant, evergreen plant with clusters of purplish red fruits that are sweet. They are eaten raw, juiced, and made into jelly and wine.

Common names and synonyms: Shore grape.

Seagrass – *see* **GLASSWORT**

SEA HOLLY – A plant common in southeastern Europe (which has been introduced in North America) and credited over the centuries with medicinal properties, the sea holly (*Eryngium maritimum*) is also often called "eringo" or "eryngo." The plant was once believed to be an aphrodisiac. Its leaves were brewed to make a kind of tea, and the roots went into various concoctions. But the roots have served as a food, too; when cooked, they have a taste that is said to resemble that of chestnuts. The young shoots were also sometimes eaten. Candied sea holly roots are called "eryngo."

Common names and synonyms: Eringo, eryngo.

SEAKALE – A summer vegetable, seakale (*Crambe maritima*), which looks a bit like broccoli, grows wild along the coasts of western and northern Europe and has been cultivated in England and the United States. Despite its name, seakale is not related to the kale of the cabbage family. The stems and leaf tips are generally blanched, dipped into melted butter, and enjoyed like asparagus for their nutlike flavor.

SEA LETTUCE (*see also* **SEAWEED**) – Bright green seaweeds of the genus *Ulva* – especially *U. lactuca* – are collectively called "sea lettuce." These are gathered from rocks along seacoasts and added to soups, salads, and the like.

See in addition: "Algae," Part II, Section C, Chapter 1.

Sea moss – *see* **DULSE, SEAWEED**

Sea pickle – *see* **GLASSWORT**

SEA PURSLANE – Also called "seabeach sandwort," sea purslane (*Atriplex halimus* or *A. hastata*) has small edible leaves that are boiled and eaten as a vegetable. The plant is native to the Mediterranean, where its leaves have probably been consumed since the days of the hunter-gatherers.

Common names and synonyms: Seabeach sandwort.

Seaside plum – *see* **TALLOW WOOD PLUM**

Sea tangle – *see* **SEAWEED**

Sea vegetable(s) – *see* **SEAWEED**

Seaving – *see* **SOUARI NUT**

SEAWEED – Seaweeds – or more appetizingly, "sea vegetables" – consist of certain species of marine algae (belonging to genera like *Chondrus, Fucus, Macrocystis, Nereocystis, Laminaria,* and *Porphyra*) such as kelp, rockweed, gulfweed, and laver. When such algae are fresh, their taste is that of salty greens; when they are dried, however, the taste is just salty. Although (save for some people in the British Isles) Westerners from the time of the ancient Greeks have steadfastly ignored seaweed as a food, the Japanese have long appreciated it. They use kelp such as *nori* (in English, "laver" – *Porphyra laciniata, P. tenera,* and *P. umbilicalis*) for wrapping sushi; *kombu* (*Laminaria japonica* – known as giant sea kelp) for broths and stocks and for wrapping dried fish; *wakame* (*Undaria pinnatifida*) for soups and salads, and to sprinkle over rice dishes; *hijiki* (*Cystophyllum fusiforme*) for sautéing as well as deep-frying tempura; and agar as an agent for jelling. In the West, "Irish moss," or *carrageen*, is a seaweed that is the source of *carrageenin* and is instrumental in thickening salad oils, cottage cheese, and the like. Laver has been traditionally cooked into flatcakes (laverbread) by the Irish, and green laver is used as a cooked vegetable. In the past in the United States, one kind of edible kelp was called "bladder weed" because of its streamer-like leaves (or "giant bladder weed" when the streamers averaged 30 to 40 or more feet in length). Depending on the variety, seaweed can be high in beta-carotene and vitamin C, and all types are packed with a host of minerals.

Common names and synonyms: Agar, alga(e), bladder weed, carrageen moss, dulse, giant bladder weed, giant sea kelp, green laver, green sloke, gulfweed, *hijiki,* Irish moss, *karenga,* kelp, *kombu,* laver, *limu, nori,* rockweed, sea lettuce, sea moss, sea tangle, sea vegetable(s), *tecuitlatl, wakame.*

Seckel – *see* **PEAR**

SEDGE – Plants of the sedge family (Cyperaceae) and of the genus *Carex* are called "sedges"; they resemble grasses but have sharp stems that are solid rather than hollow. Various species are found worldwide, and their stems, corms, and grains have served as food for many thousands of years. Examples include the tender, whitish bases of the leaves of *C. aquatilis,* a plant that grows in North America and Europe and has long been consumed. The grains of an East Asian species (*C. kobomugi*) are also eaten.

Seje ungurahuay – *see* **PATAUA**

SÉMILLON (*see also* **GRAPES**) – This white grape (*Vitis vinifera*) is used to produce dry white wines, usually in combination with another grape such as Sauvignon. However, it is also used to make sweet Sauternes wines and is found mainly in the Graves and Sauternes regions of France.

See in addition: "Wine," Part III, Chapter 13.

Seminole bread – *see* **ZAMIA**

Sencha – *see* **TEA**

SENNA – Any of the various plants of the genus *Cassia* are called senna. The leaves of many of these, such as *C. angustifolia,* have been used medicinally especially in Asia. In North America the leaves, young shoots, and green pods of others, such as *C. occidentalis,* were used as food by Native Americans and settlers.

SENTUL – The fruit of a tall tree native to Indonesia, the sentul (*Sandoricum koetjape* formerly *indicum*) is round, yellow, 2 to 3 inches in diameter, and sweet and juicy. The fruit is generally eaten raw but is also made into jam. In addition, there is a red sentul – called *kechapi* – that is smaller and sour tasting.

Common names and synonyms: Kechapi.

SERENDIPITY BERRY – An edible red berry, the serendipity berry (*Dioscoreophyllum cumminsii*) is found in west-central Africa. It belongs to a large genus of mostly tropical fruits and is a relative of both the American black sapote and the Japanese persimmon.

Serpolet – *see* **THYME**

SERRANO (*see also* **CHILLI PEPPERS**) – A very popular pepper in Mexico and the southwestern United States, the serrano (meaning "mountain" or "highland"), a *Capsicum annuum,* is a very hot pepper, about 1 to 2 inches in length, with a torpedo-like shape. Serranos come in the colors green and red; both kinds are used interchangeably in salsas and other dishes. They are also canned, pickled, and packed in oil. When dried, serranos are called *chilli seco* or *serrano seco,* remain intensely hot, and are available both whole and in powdered form.

Common names and synonyms: Chilli seco, serrano seco.

See in addition: "Chilli Peppers," Part II, Section C, Chapter 4.

SERVICEBERRY (*see also* **BERRIES, ROWANBERRY**) – Growing in most of the world's temperate zones on a number of small trees and shrubs of the genus *Amelanchier,* the serviceberry is also known in North America as "shadbush" (because its white flowers appeared at about the same time that shad did in the rivers) and as "juneberry." The brownish or purple to black serviceberries were an important food for Native Americans such as the Chippewa. This was especially true of the fruits of *A. alnifolia* (a plant of North America called "Saskatoon" in the Cree language) and the western serviceberry, which resembles the blueberry more than do other serviceberries. Serviceberries were of particular significance in the American West, where they were sometimes the only food available to nourish the Mormons and other pioneers. Today, the fruits are sought for their "serviceability" in pies, jams, jellies, and sauces. Serviceberry is also a name sometimes applied to closely related berries of the mountain ash family. Equally confusing is the name bilberry, sometimes given to serviceberries.

Common names and synonyms: Juneberry, Saskatoon berry, Saskatoon serviceberry, shadblow, shadbush, western serviceberry.

Sesaban – *see* **SESBAN**

SESAME – A small seed with a nutty flavor that comes in a variety of colors (white, black, red, and brown), sesame (*Sesamum indicum*) is far more important in other parts of the world than it is in North America, where the white or black seed is used mostly atop breads and buns. The plant is alternatively said to be native to East Africa and to India (as the Latin name would have it), but there is no reason that it cannot have originated in both locations. Sesame is probably the oldest crop grown for its oil: It was cultivated in the Tigris and Euphrates valleys some 5,000 years ago and has competed with olive oil in the Mediterranean and India ever since its production began.

Sesame oil is also the oil for many in Asia: The seeds are a basic ingredient in the *tahina* of the Middle East and the *halvah* of Turkey, and in the Far East pastry cooks have long mixed sesame seeds with wheat flour. The seeds traveled in the holds of slave ships to reach the New World and today are commercially grown in South America. The darker, unhulled seeds (in contrast to the whitish, hulled seeds) are rich in calcium and iron.

Common names and synonyms: Benne, ben(n)iseed, gingelly, sim(-)sim, til(seed).

See also: "Sesame," Part II, Section E, Chapter 4; "Spices and Flavorings," Part II, Section F, Chapter 1.

SESBAN – Also known by numerous common names such as "sesaban," "sesnania," "white spinach," "West Indian pea," "corkwood tree," and "agati," sesban (*Sesbania grandiflora*) – now naturalized in the United States – is a small tree of Southeast Asia and Australia, where it is called the "Australian corkscrew tree." Its white wood is very soft, which lends it to the same uses as cork. The fruit is a green pod (growing up to 2 feet in length), which is cooked and eaten along with the leaves, the buds, and the very large, white flowers. In many cultures, the flower petals are battered and fried. The tree has provided nourishment for humans for thousands of years, and even today is cultivated in India as a food plant. A related North American plant is the "coffee weed" (*S. cavanillesii*), the roasted seeds of which have served Mexicans as a coffee substitute.

Common names and synonyms: Agati, Australian corkscrew tree, coffee weed, corkwood tree, sesaban, sesnania, West Indian pea, white spinach.

SHALLOT(S) – Shallots, once thought to be a species (*Allium ascalonicum*) distinct from the onion (although related to it [as for example, are chives and garlic, also members of the genus *Allium*]), are now considered to be a variety of the onion species (*A. cepa*). In fact, because shallots do not exist in a wild state, they may actually be a mutation of the onion.

The name "shallot" comes from the Greek name of a trading town in southern Palestine (*Askalon*) that was associated with the vegetable, which was carried to western Europe by returning Crusaders. A shallot is generally the size of a large head of garlic, grows in clove form, has a flavor more subtle than onion, and is less pungent than garlic. Chopped fine, shallots are indispensable in numerous classic sauces; sliced, they are an ingredient in many fine dishes; and they are roasted whole as an accompaniment for meats and poultry. In the Far East, shallots are pickled for use in salads, as a snack, and as a side dish. In Louisiana, scallions are frequently (and incorrectly) called shallots, doubtless because the French settlers there substituted scallions for the shallots of their homeland.

Common names and synonyms: White shallot.

SHEA TREE – A West African native, the shea tree (*Butyrospermum parkii*) has large seeds with kernels that yield a fat called "shea-butter." The fat is utilized locally in cooking and is also exported to Europe, where it is used to make margarine and employed as a cooking fat.
Common names and synonyms: Shea-butter.

Siberian hazel – *see* **HAZELNUT AND FILBERT**

SICHUAN PEPPERCORN (*see also* **PEPPERCORN**) – An ancient spice in China but not actually a peppercorn, the "Sichuan peppercorn" (*Zanthoxylum piperitum*) was in use (especially in the province of Sichuan) long before true peppercorns arrived. It is a small, aromatic, reddish brown seed from the prickly ash tree and, when ground, is frequently blended with salt to make pepper-salt – a fragrant dip for grilled and fried foods – and is also blended with other ingredients as in China's "five spices." In Japan, the leaves of the prickly ash tree (which have a peppery-lemon taste) serve as a garnish.

SILPHIUM – An extinct plant of the genus *Ferula,* silphium was well known to the ancient Greeks and utilized as a condiment by the Romans. It was grown in North Africa and was used as a medicine as well as in cooking. There are other plants of a genus now called *Silphium* that have been employed as foods. One such food is the sap of an eastern North American plant (*S. laciniatum*) called "rosinweed" or "compass plant." Another is the roots of *S. laeve* (also called "compass plant"), which reportedly were consumed by Native Americans. These peoples also used the sap of the cup plant (*S. perfoliatum*), but apparently mostly as a medicine.
Common names and synonyms: Compass plant, cup plant, rosinweed, silphion.
See also: "Spices and Flavorings," Part II, Section F, Chapter 1.

SILVANER (*see also* **GRAPES**) – A grape known as "sylvaner" in Austria and France, the Silvaner (*Vitis vinifera*) originated in eastern Europe and moved west to become well known in medieval Germany. It remained one of Germany's most important wine grapes until about the middle of the twentieth century but now accounts for only about 7 percent of that country's wine. It is regarded today as a specialty grape of Franken (Franconia) in western Germany, although it is also grown in Alsace.
Common names and synonyms: Sylvaner.

SKIRRET – A Eurasian herb, skirret (*Sium sisarum*) is a member of the parsley family. It was cultivated in the past for its small, sweet, fleshy, edible roots, which can be boiled and buttered and eaten like potatoes or parsnips.
Common names and synonyms: Skirret-root(s).

Skoke – *see* **POKEWEED**

SKUNK CABBAGE – An offensive-smelling, swamp-dwelling herb of eastern North America, "skunk cabbage" (*Symplocarpus foetidus*) has a host of less-than-elegant common names, such as "polecat weed," "swamp cabbage," and "stinking poke." Its purple flowers are among the first of the New Year to appear and announce the impending arrival of spring. Skunk cabbage has long been used medicinally and even – despite its rank smell – culinarily. Native Americans boiled its young shoots as a vegetable and also cooked the root, after which it could be dried and made into a flour.
Common names and synonyms: Polecat weed, stinking poke, swamp cabbage.

SLIPPERY ELM – A tree of eastern North America, the slippery elm (*Ulmus fulva* = *U. rubra*) has unappetizing leaves and a rough outer bark but a fragrant, mucilaginous inner bark. Native Americans ate the inner bark raw and boiled it as a vegetable in both fresh and dried form. The bark continues to be harvested and dried (generally under pressure so that it remains flat); when reconstituted, it is employed as a food for babies and for adults with digestive problems.

Sloak – *see* **LAVER**

SLOE (*see also* **PLUM**) – Also called "sloes," "black sloe," and "blackthorn," the sloe (*Prunus spinosa*) is a Eurasian and North African plum that is sometimes viewed as the ancestor of the Damson plum and other cultivated varieties. The fruit is berry sized, pale blue to black in color, and – as a rule – too astringent to be eaten raw. It is, however, made into juice, jellies, syrups, and preserves. Perhaps the most notable use of sloes is in the flavoring of liquors and liqueurs such as "sloe gin."

Common names and synonyms: Black sloe, blackthorn, sloes.

SMOOTH SUMAC – Also known as "mountain sumac," "upland sumac," and "vinegar tree" (among other common names), the smooth sumac (*Rhus glabra*) is a shrub of eastern North America. It is a relative of poison oak, poison ivy, and poison sumac, but it produces edible red berries that were dried and used as food by Native Americans.

Common names and synonyms: Mountain sumac, upland sumac, vinegar tree.

Snailseed – *see* **PIGEON PLUM**

Snake bean – *see* **WINGED BEAN**

Snake cucumber – *see* **ARMENIAN CUCUMBER, CUCUMBER, SNAKE GOURD**

SNAKE GOURD – Also called "snake melon," the snake gourd has long been thought of in terms of two species (*Trichosanthes anguina* and *T. cucumerina*), but it is now generally acknowledged that both names refer to the same species. Yet, as the two names remain, so do distinctions. *Trichosanthes anguina* is mostly intended to mean wild snake gourds, whereas *T. cucumerina* ("cucumber-like") refers to the cultivated vegetable. Unquestionably, the suggestion of a snake-like appearance seems appropriate – at least for the wild gourds, which can grow up to 5 or even 6 feet in length, sometimes remaining straight, sometimes curling, but in either case resembling a snake. The snake gourd is most appreciated in India and southeastern Asia, where the immature fruits, with a zucchini-like taste, are usually harvested at 10 to 12 inches in length and are boiled to be eaten whole or used in curries. The mature fruits, which become bitter, are cut into pieces for soups.

Common names and synonyms: Snake cucumber, snake melon.

Snake melon – *see* **ARMENIAN CUCUMBER, SNAKE GOURD**

Snapping hazel – *see* **WITCH-HAZEL**

Snow pea – *see* **PEA(S), SUGAR PEA**

SOAPBERRY – Any of several (mostly tropical) plants of the genus *Sapindus,* which produce berries that lather like soap in water, are called "soapberries," especially *S. saponaria* (the southern soapberry). Indeed, the berries contain sufficient saponin that they are sold as soap in some places. There are, however, other species, like *S. marginatus,* which Native Americans employed as food.

Common names and synonyms: Indian soap, southern soapberry.

SOLOMON'S-SEAL – Plants of the genus *Polygonatum* are called "Solomon's-seal" because of the resemblance of scars on their rootstocks to that mystical symbol of two interlaced triangles that make a six-pointed star. The plants are native to both Europe and North America, where their rhizomes have served humans as food for millennia. However, those rootstocks are toxic and consequently required processing. Native Americans sometimes dried them, then ground them into flour. In Europe, the rhizome was boiled and the starch made into a bread. The rootstocks and fresh shoots of some species are still consumed in East Asia.

SONCOYA – As its scientific name indicates, the soncoya (*Annona purpurea*) is a close relative of the cherimoya. The tree – a native of tropical and subtropical America – is relatively small (rarely reaching more than 22 feet in height), but the brown fruit is large. Its pulp is orange and sweet, and some have likened the taste to that of a papaw. The fruit is mostly eaten fresh.

SORB APPLE – The astringent fruit of the service tree, the "sorb apple" (*Sorbus domestica*) is a native of Asia Minor that was once fairly popular but is now uncommon. Like medlars, sorb apples are made edible by "bletting" (storage until they are on the verge of decomposing). A frost also helps to improve the texture and taste of these pear- and apple-shaped, brownish green fruits. Rowanberries and serviceberries are close relatives of the sorb apple, and their names are sometimes used interchangeably.

SORGHUM (*see also* **MILLET**) – There are several varieties of this Old World grass (*Sorghum vulgare* = *S. bicolor*) that are cultivated for grain, for forage, and as a source of syrup. Sorghum is native to East Africa, where it was being cultivated around 5,000 to 6,000 years ago. Sometime in the distant past (at least 2,000 years ago), the grain crossed the Indian Ocean to India and subsequently made its way to China. More recently, various sorghums reached the New World via the slave trade. Today, grain sorghums are grown extensively in Africa and Asia for use as human food and in the Americas as animal food.

Some sorghums in North America – like "Johnson grass" and "Mississippi chicken corn" – probably arrived as the seeds of important cultivars, only to escape from cultivation and become annoying weeds. The juices of sorghums have provided humans with syrup for sweetening, and in Asia and Africa the plant supplies malt, mash, and flavoring for alcoholic beverages, especially beers. Sorghum grains are made into flour (for unleavened breads) and into porridges, and they are also prepared and consumed much like rice. In addition, they can be popped in hot oil like popcorn. Despite these many uses, however, when available, the major grains like wheat, rice, and maize are chosen before sorghum, which means that its major role has been that of a famine food.

Common names and synonyms: Broomcorn, grain sorghum, great millet, Guinea corn, Johnson grass, Kaffir corn, Mississippi chicken corn, shattercane, sorgo, Sudan grass, sweet sorghum.

See also: "Sorghum," Part II, Section A, Chapter 9.

Sorgo – *see* **SORGHUM**

SORREL (*see also* **ROSELLE, WOOD SORREL**) – Species of the genus *Rumex* are called either sorrel or "dock." Garden sorrel (*R. acetosa*), also known as "sheep sorrel," and French sorrel (*R. scutatus*) are the two most important species that are cultivated for use as vegetables or herbs. Another type, *R. patientia,* known as "spinach dock," is less widely used. The name "sorrel" is derived from a Germanic word meaning "sour"; the plant's oxalic acid content contributes to its sour or bitter taste. Sorrel is related to rhubarb.

Many species of sorrel were native to Eurasia, and it was an herb used by the ancient Egyptians, Greeks, and Romans. These Old World species subsequently became naturalized in North America alongside native species that had been employed as food by Native Americans and were often cultivated as a vegetable. *Rumex articus* is an Arctic species that is still utilized by the Inuit, who boil and eat the leaves and also ferment them for later use. "Water dock" (*R. hydrolapathum*) and several other species are simply sorrels that grow in wet places.

The French employ *R. scutatus,* which is somewhat less acidic than garden sorrel, for their sorrel soup and famous *soupe aux herbes.* Other uses are in salads and egg dishes, and sorrel was a key ingredient in the old English green sour sauces that accompanied a roasted goose or pig. Last, sorrel leaves are often cooked and eaten like spinach, which they resemble. Sorrel is very high in vitamins A and C and is a good source of potassium.

Common names and synonyms: Dock, French sorrel, garden sorrel, round(-leaved) sorrel, sheep sorrel, sour(-)dock, sour grass, spinach dock, water dock, wild sorrel.

SORVA (*see also* **SERVICEBERRY**) – A tree of South America, sorva (*Couma utilis*) yields an edible, sweet fruit that is sold in local markets. Its main product, however, is a latex that serves as a substitute for chicle gum. "Sorva" is also a common name for the serviceberry.

SOTOL – Also known as the "spoonplant," "desert-spoon," and "cactus-spoon," the sotol (*Dasylirion wheeleri*) is a member of the agave family. Native Americans ate the heart and young stalks of the plant. Its head contains a sugary sap that when fermented becomes a potent beverage also called sotol.

Common names and synonyms: Cactus-spoon, desert-spoon, spoonplant.

SOUARI NUT – A native of Guiana, the souari nut (*Caryocar nuciferum* or *C. amygdaliferum* – also called "butternut") is an edible nut that grows on very tall trees that have been much used in shipbuilding. In addition to its consumption raw, the souari nut yields an oil used in cooking. This nut with white meat is seldom seen in North American markets.

Common names and synonyms: Achotillo, butternut, seaving.

Souchong – *see* **TEA**

SOUR CHERRY (*see also* **CHERRY**) – A member of the rose family, the sour cherry (*Prunus cerasus* = *Cerasus vulgaris*), a stone fruit, is mostly cultivated in North America but is said to be native to southwestern Asia. Its tree has been cultivated since antiquity. Indeed, there is a story that its Latin name refers to the city of Cerasus in Pontus, an ancient kingdom in the northeast of Asia Minor. After defeating its king, Mithradates, the Roman general Lucullus carried the tree back to Italy and called it *cerasus.*

The sour cherry tree is small and rarely reaches over 8 feet in height, but it is known to spread out quite a bit. Sour cherries, which are bright red to almost black in color, can be eaten raw and are often cooked in various dishes, most notably cherry pie. In addition, they yield a colorless juice, which can be used to advantage in certain culinary applications. There is also an Australian tree (*Eugenia corynantha*) with sour-tasting red fruits that are called "sour cherries." Both sour cherries are rich in vitamin C.

SOUR PLUM – *Ximenia caffra* is a small tree or shrub common in southern Africa. Its greenish blossoms are followed by oval orange to scarlet fruits that are about 1 inch in diameter. The fruit envelops a seed that yields an oil used in the tanning of leather. The pulp, rich in vitamin C and potassium, is made into jelly and marmalade.

Common names and synonyms: Emu apple, Natal plum.

SOURSOP – Native to the Caribbean region and now also grown in Madeira and the Canary Islands, the soursop (*Annona muricata*) is a spiny fruit with a white, tart, edible pulp. Also called "guanabana," it is a big fruit that can easily weigh 4 or 5 pounds. It is used for making syrups, it is often served as a frozen dessert resembling ice cream, and its juice is sold commercially as a soft drink. The soursop is a very close relative of the sweetsop (custard apple) and the cherimoya.

Common names and synonyms: Dutch durian, guanabana.

SOURWOOD – A tree of eastern North America, the sourwood (*Oxydendrum arboreum*) has longish and slightly sour-tasting leaves that, when young and tender, constituted one of the many wild foods gathered by Native Americans. Indigenous peoples also braved bees in seeking the honey made from the sourwood's small white flowers, which blossom in June and July.

SOUTHERNWOOD – A shrubby European wormwood sometimes called "old-man," southernwood (*Artemisia abrotanum*) has become naturalized in North America. In Europe, its leaves have been employed to flavor beers.

Common names and synonyms: Old-man, southern wormwood.

Southern wormwood – *see* **SOUTHERNWOOD**

Southwestern barrel cactus – *see* **BARREL CACTUS**

Sowfoot – *see* **COLTSFOOT**

SOW THISTLE – A number of coarse, often spiny herbs comprise the genus *Sonchus. Sonchus arvensis* (perennial sow thistle), *S. asper* (spiny sow thistle), and *S. oleraceus* (annual sow thistle) were known to the ancient Romans and doubtless to the hunter-gatherers who preceded them by thousands of years. Today, this plant, a native of Europe but now naturalized throughout the world, is a weed that grows best in cultivated soils. Its roots can be eaten raw or cooked, and the young shoots and leaves make a fine salad.

SOYBEAN (*see also* **BEANS, LEGUMES**) – Legumes are by far the best plant sources of protein, and soybeans (*Glycine max*) are the best of the legumes because they are the only plant food to contain a complete protein. Equally remarkable, the soybean is the most widely consumed plant in the world. According to legend, soybeans were under cultivation in China close to 5,000 years ago, and we know that the plant had emerged as a domesticate in the eastern part of northern China by about 3,000 years ago. The Chinese have had myriad uses for this green, pea-sized legume that comes in a hairy pod. It provides vegetable milk, vegetable oil, bean sprouts, meal, flour, paste, various sauces, a curd (tofu) that substitutes for meat, and the beans themselves, which are eaten both fresh and dried.

Many of these uses were expanded with the widening range of the plant. In the sixth century, soybeans accompanied Chinese Buddhist missionaries to Korea and Japan and became a staple food and a nutritional cornerstone for the teeming populations of these parts of East Asia. Soybeans were also introduced (by the migration of tribes, and by trade along the Silk Road and by sea) into Indonesia, the Philippines, Vietnam, Thailand, Malaysia, and northern India. Through Portuguese, Dutch, and (later) English traders and travelers, the West was made aware of soybeans, but, aside from acquisitions by botanical gardens, there was little interest in the plant. Indeed, this attitude persisted even after the turn of the eighteenth century, when Engelbert Kaempfer, a medical officer of the Dutch East India Company who had lived in Japan, published a book that explained the varied foodstuffs made possible by soybean cultivation.

In 1765 and again in 1803, soybeans were introduced in North America from England, and later on, after U.S. naval officer Matthew Perry had opened Japan to the West in 1854, germ plasm was acquired directly from Japan (as well as from China and Korea). However, those who grew the crop in the United States did so mostly for forage, and it was only in the late nineteenth and early twentieth centuries that soybeans began to receive scientific evaluation. In 1922, the first major soybean processing plant was built in Decatur, Illinois, and when enough such plants had come into being (about a decade later), the National Soybean Processors Association was formed.

During World War II, soybean oil was employed to replace imported fats and oils, and the meal found use as a feed to help expand the production of meat animals. After the war, soybeans played a major role in feeding the destitute population of Europe. Soybean production in the United States skyrocketed, and the nation quickly became the world's leading producer. Production in 1940 had been 78 million bushels, and in 1945 it was 193 million bushels. But by 1984, U.S. production had hit almost 2 billion bushels annually and was still climbing a decade later. Much of the U.S. crop is used for cattle feed, but soybean oil is also a mainstay of margarines, vegetable oils, salad dressings, and a host of processed foods. In addition, soy flour has many food-processing uses.

SPAGHETTI SQUASH (*see also* **SQUASH AND PUMPKIN**) – Also called "vegetable spaghetti," the spaghetti squash (*Cucurbita pepo*) is an exception to the rule that stringiness in squash is bad. This relatively new squash variety – the origin of which is uncertain – is so stringy that it can be baked (or "microwaved") and then its flesh raked with a fork into spaghetti-like strands that can be eaten like pasta. Moreover, spaghetti squash packs far fewer calories than pasta. Recipes abound combining this vegetable – spaghetti-like – with garlic, with vinaigrette dressing, with meat sauce, and with any of the other favorite pasta toppings.

Common names and synonyms: Vegetable spaghetti.

SPANISH BAYONET – There are several plants of the genus *Yucca* (and especially *Y. aloifolia* = *Y. elephantipes*) that are called "Spanish bayonet" because of the formidable appearance of their stiff, pointed leaves. The plants have a redeeming feature, however, in an edible pod-like fruit that ripens in clusters and is generally cooked rather than eaten raw. These fruits were among the many that sustained Native Americans in the southern part of North America.

SPANISH LIME – Also called "ginep," and *mamoncilla* in Cuba, the Spanish lime (*Melicoccus bijugatus*) is a popular tropical American green berry, about an inch in diameter and resembling a plum in appearance, with a grape-like taste. The fruit is eaten raw, although its pulp must be popped out of its tough skin; it is also made into drinks and cooked. In addition, Caribbean peoples roast the seeds of the Spanish lime and eat them like chestnuts. The tree is grown as far north as southern Florida.

Common names and synonyms: Genip, genipe, ginep, ginip, honeyberry, *mamoncilla.*

Spanish pine – *see* **AZAROLE**

SPANISH PLUM (*see also* **HOG PLUM, PLUM**) – Also called the "red mombin," the Spanish plum (*Spondias purpurea*) is a native of tropical America and a distant relative of cashews and pistachios. It is a red, edible fruit that is both eaten raw and employed in cooking. In addition, its stone is sometimes roasted and eaten like a chestnut.

Common names and synonyms: Red mombin.

Speedwell – *see* **BROOKLIME**

SPELT (*see also* **WHEAT**) – The place of origin of spelt (*Triticum spelta*), a hardy wheat, is a matter of some debate, with some experts suggesting Iran about 6000 to 5000 B.C.; others arguing for two independent sites, one in Iran and the second in southeastern Europe; and still others who would have spelt emerging only in Europe and at a later date. In any case, spelt was cultivated throughout the Near East, Europe, and the Balkans during the Bronze Age (4000 to 1000 B.C.) and, along with einkorn and emmer, it is another of the ancestors of modern wheat. Spelt was probably an important cereal of the ancient Egyptians and Greeks and seems to have been a staple of the Romans, in which case the latter people may have facilitated the grain's spread northward to Germany and Switzerland and westward to Spain, where it was still being grown at the beginning of the twentieth century.

Complicating the picture, however, are the finds of spelt remains dating from 3800 to 2800 B.C. in Neolithic sites in Spain, western Germany, the Netherlands, and Belgium – but whether these are the remains of domesticated spelt is another matter. Also confounding the problem is that invading Vandals have been credited with introducing spelt in Europe around the fifth century A.D.

But, whenever and wherever spelt was established, the grain became a major cereal crop in Europe and joined einkorn and emmer in sustaining multitudes during the Middle Ages. Around the middle of the nineteenth century (if not before), spelt was carried to North America, where production (much of it for fodder) peaked in the early decades of the twentieth century. Spelt is grown today on a small scale in isolated parts of Germany and Switzerland, and it seems to be making a comeback in the United States and Canada because of the health-food market.

Spice birch – *see* **SWEET BIRCH**

SPICEBUSH – "Spicebush" refers to a number of plants but the name is mostly intended to mean the eastern North American spicebush (*Lindera benzoin*). Also called the "Benjamin bush," it produces red or yellow berries. Native Americans dried and powdered the berries and used them as a spice. The bark from the roots and stems – along with the leaves – were employed to make a tea.

Common names and synonyms: Benjamin bush.

Spikenard – *see* **UDO**

SPINACH – A green leafy vegetable, spinach (*Spinacia oleracea*) is a native of southwestern Asia. The plant reached China as a gift from Nepal during the first years of the Tang dynasty (the early seventh century A.D.) and was introduced in Sicily in 827 by invading Saracens from North Africa – they having first encountered the plant in Persia. However, spinach seems to have been in no hurry to spread out over the rest of Europe, although it may well have done so without recorded mention during those centuries of the Middle Ages that food historian Reay Tannahill has called "The Silent Centuries." The vegetable probably reached Spain with the invading Moors, but it was not until the very end of the Middle Ages that spinach showed up in a cookbook published anonymously in Nuremberg in 1485. After this it caught on rather quickly on the Continent, probably in no small part because spinach made its appearance in early spring, when other fresh vegetables were still scarce yet human bodies were desperate for vitamin C after a winter of deprivation. Spinach was first planted in England in 1568, and within a century it had become one of the few vegetables that appeared on the tables of the wealthy. Presumably, the plant was carried to North America long before 1806, when seed catalogs mentioned three varieties. However, it was only after another century had elapsed that a food encyclopedia stated that the vegetable was becoming "increasingly popular."

Part of the difficulty in tracing the history of spinach is that there are so many spinach-like vegetables (such as the amaranth of India and Japan, the kang kong or water spinach of Southeast Asia, and New Zealand spinach) that one is not always certain which "spinach" is being confronted, and even "real" spinach comes in two basic types. The fresh spinach encountered in most markets is the crinkle-leafed Savoy kind, but there is also the flat, smooth-leafed variety that is generally employed for freezing or canning. In addition, there is a sort of "semi-Savoy" spinach that is a cross between the two basic types. Young, tender spinach leaves make fine salads. Sautéing and steaming are great ways to prepare the vegetable so that it does not become overcooked and develop a characteristic limp and washed-out appearance. Spinach also makes splendid soufflés; oysters, broiled on the half shell with a mixture of spinach, some other ingredients, and a sauce become "Oysters Rockefeller"; and when foods are served on a bed of spinach, they are known collectively as *florentine.*

With apologies to "Popeye the Sailor-Man" (whose appearance as a cartoon character in 1929 increased spinach consumption by 33 percent among children), spinach is not a "miracle food" – not even a particularly good source of iron. But it is rich in beta-carotene, calcium, folacin, and a number of important minerals.

Common names and synonyms: Savoy spinach.

SPRUCE – The young shoots as well as the inner bark of spruce trees (genus *Picea*) were eaten by Native Americans, and the shoots are still employed in Europe for various dishes. In addition, the shoots of some species have served to make "spruce beer" (at one time thought to be effective against scurvy), and the leaves can be made into a tea. Finally, spruce trees have been a source of balsam used as "chewing gum" since Paleolithic times.

Sqamash – *see* **CAMAS**

SQUASH AND PUMPKIN (*see also* **PUMPKIN, SQUASH FLOWERS**) – Squashes, pumpkins, and some gourds are all American natives and members of the Cucurbitaceae. However, further division can sometimes be confusing, especially when a common name embraces more than one species. There are five species of the genus *Cucurbita* that were domesticated in the Americas, four of which subsequently became good food for people the world over. But squashes are gourds, and domestication probably came about initially at the hands of those seeking hard shells to employ as containers and utensils. From that point on, however, it was only a matter of time until the seeds and, later on, the flesh of the various squashes began playing an important role in the Native American diet.

Moving from north to south, *C. pepo* may have been domesticated in what is now the eastern United States as well as in Mexico, where it has reportedly been grown for over 7,000 years. Most varieties of this species, such as zucchini, yellow straightneck, yellow crookneck, and pattypan (also called cymling or scallop), fall under the rubric of summer squash. The summer squash are eaten while still soft and immature, as are winter varieties of *C. pepo* (like the acorn squash and most pumpkins), which otherwise mature into hard, starchy fruits (the very large pumpkins, however, belong to *C. maxima*). Chayote, although thought of as a summer squash, is another plant entirely, albeit "squashlike."

The other species of *Cucurbita* provide winter varieties. *Cucurbita mixta* is the cushaw or calabaza – a pear- or crookneck-shaped squash – developed in an area extending from the U.S. Southwest to Costa Rica. The species that came into being at the intersection between the Northern and Southern Hemispheres is *C. moschata,* the major representative of which is the Butternut squash. *Cucurbita maxima* was apparently domesticated in Peru, and out of this emerged the Hubbard and banana squashes, as well as varieties developed outside the Americas, like the Australian Blue and the *Rouge Vif d'Étampes* squashes. Native Americans, who cultivated squashes and pumpkins, ate the vegetables roasted or boiled and preserved the flesh as *conservas* in syrup. They also ate the young shoots, leaves, flowers, and especially the seeds. Since the arrival of the Europeans, usage has been expanded to include employing the flesh in pies, in soups (especially in France), and even as pickles.

A species that was domesticated in the Americas but did not travel to other lands (although it was long thought to be a native of Asia) is *C. ficifolia,* sometimes known as the Malabar gourd or the fig-leafed gourd. Of all the cucurbits, this is the only species adapted to high altitudes, and it is a food for many in the highlands of Mexico and South America, where its fruits, appearing on the outside like small watermelons, can often be seen on rooftops, drying in the sun. In addition, there are wild cucurbits with flowers and seeds that served Native Americans as food; these include the buffalo gourd (*C. foetidissima*) and the coyote melon (*C. palmata*), and in southern Florida *C. okeechobeensis,* named for the lake, was consumed by Native Americans.

The yellow and orange flesh of winter squashes (especially the Hubbard and the Butternut) is rich in beta-carotene and not a bad source of vitamin C and folacin. Summer squashes are high in water content and, consequently, low in calories. They, too, are a fair source of vitamin C and folacin.

Common names and synonyms: Acorn squash, Australian Blue, banana squash, buffalo gourd, Butternut, calabaza, courge, courgette, coyote melon, crookneck, cushaw, cymling, fig-leafed gourd, gourd, Hubbard, Malabar gourd, pattypan squash, *pepo,* pumpkin, *Rouge Vif d'Étampes,* scallop squash, straight crookneck, summer squash, turban squash, vegetable marrow, winter squash, yellow crookneck, yellow straightneck, zucchini.

See in addition: "Squash," Part II, Section C, Chapter 8.

Squash blossom(s) – *see* **SQUASH FLOWER(S)**

SQUASH FLOWER(S) (*see also* **SQUASH AND PUMPKINS**) – The orangish yellow, mostly male flowers (so the vines will still bear fruit) that appear on summer squash (*Cucurbita pepo*) vines are frequently picked for consumption. They are edible and considered a delicacy by many. In fact, it is probably no coincidence that they are available in the markets of Mexico and are added most to the dishes of that land, where many, perhaps most, of the squashes originated. Squash flowers are sometimes added to *quesadillas* and sautéed, but they are generally battered and deep-fried. The flowers are a good source of beta-carotene and also – if the cooking is brief – of vitamin C.

Common names and synonyms: Squash blossom(s).

STAR-ANISE – Despite the names "star-anise" and "Chinese anise," *Illicium verum* is not, in fact, a member of the magnolia family and not related to true anise. Doubtless, the reason for the "anise" part of its name is that it has a licorice-like flavor, very similar to that of anise. As the rest of its name implies, star-anise has star-shaped yellow flowers, with each point of the star containing a shiny, oval seed. The leaves and seeds (which have a taste somewhat stronger than that of anise) are dried and added whole, broken, or ground to various dishes, especially in the cuisines of China and Vietnam. This spice has never been much used in the West, save as a flavoring for liquors such as anisette.

Common names and synonyms: Badian anise, Chinese anise.

STAR-APPLE (*see also* **CARAMBOLA**) – A tropical American fruit of the sapodilla family, and native to the West Indies and Central America, the star-apple (*Chrysophyllum cainito*) is a purple-brown, sweet fruit about the size of an apple. It grows on a large evergreen tree and fascinated early Spanish explorers, who discovered that when it was cut in two, it had a star shape in the middle.

STEVIA – An herb of South America (especially southern Brazil and Paraguay), stevia (*Stevia rebaudiana*) has leaves that have long been employed locally as a natural sweetener. Dried and ground, they are said to be infinitely sweeter than sucrose, and one suspects that we will hear more of this plant as a sugar substitute.

Common names and synonyms: Sugar-leaf, sweet-herb-of-Paraguay.

STONECROP – A number of species of the genus *Sedum* are collectively called "stonecrop." *Sedum roseum* of North America has fleshy roots that have served as food for millennia. In Europe, the young leaves and shoots of *Sedum reflexum* are eaten in soups and salads, especially by the Dutch. They may be consumed cooked or raw and have a slightly astringent taste. The sharp taste of *S. acre* is sometimes employed for seasoning in Asia. The plant is also known as "Jenny-stonecrop" and "ditch-stonecrop."

Common names and synonyms: Ditch-stonecrop, Jenny-stonecrop.

STRAWBERRY (*see also* **BERRIES, WILD STRAWBERRY**) – The garden strawberry (*Fragaria ananassa*) is probably the best known of the berries and certainly the most versatile. It is a hybrid – between the Chilean berry (*F. chiloensis*) and *F. virginiana* of eastern North America that is now cultivated worldwide. There are myriad other strawberry species, however, that grow wild in the Americas and Eurasia. Indeed, although strawberries have been planted in gardens since Roman times, berries gathered from the wild were generally the only kind available to most people until the fifteenth century, when Europeans began to cultivate them in earnest. Most of the European names for these berries poetically suggest their fragrance, although the English name comes from the layers of straw that were placed around the plants to keep the berries off the ground. Strawberries were probably also cultivated by the Indians of North and South America, which may account for the fact that two of the American species produce the largest fruits.

Strawberries are now available fresh most of the year, making it possible to avoid frozen strawberries, which tend to disintegrate when thawed. Strawberries are mostly eaten raw but are also made into jams, preserves, and pies and are used to flavor everything from ice cream to chewing gum. They contain more vitamin C than any other berry.

Common names and synonyms: European strawberry, garden strawberry, Virginia strawberry.

STRAWBERRY GUAVA – Also known as the "Cattley guava," the strawberry guava (*Psidium cattleianum*) grows on a bush that is much more resistant to cold and frost than the common guava. But the reddish fruits are much smaller and lack the common guava's flavor. They are generally used for jelly.

Common names and synonyms: Cattley guava, purple guava.

STRAWBERRY-RASPBERRY (*see also* **JAPANESE WINEBERRY**) – This real "strawberry-raspberry" (*Rubus illecebrosus*), which is sometimes confused with the Japanese wineberry, is a low bramble that is frequently used in Japan as a ground cover to hold the soil on the banks of rivers and streams. It also produces showy, red, edible fruits that are generally made into preserves.

Common names and synonyms: Balloonberry.

Strawberry tomato – *see* **CAPE GOOSEBERRY**

STRAWBERRY TREE – A native of the Mediterranean region, the strawberry tree (*Arbutus unedo*) is a small evergreen tree with fruits that are strawberry-like in appearance but not in taste. The tree was known to the ancient Greeks, but its fruits have never really been developed. The most common variety is the "Killarney strawberry tree," whose berries are made into liqueurs, sherbets, confections and the like but are not eaten raw.

Common names and synonyms: Killarney strawberry tree.

Straw mushroom – *see* **MUSHROOMS AND FUNGI**

STRIPED SCREW-PINE – A native of the tropics of the Old World, and an important food tree for Pacific Islanders, the striped screw-pine (*Pandanus veitchii*) is also known as the "Veitch screw-pine." It has fruits and nuts that are both edible.

Common names and synonyms: Veitch screw-pine.

SUDAN POTATO – Also called "Hausa potato" and "piasa," the Sudan potato (*Coleus tuberosus* = *C. parviflorus* = *Solenostemon rotundifolius*) is a tuber – probably a native of tropical Africa – that is grown and used like a white potato. It is still cultivated in Africa and also in Southeast Asia. As a rule, the tubers (and sometimes the leaves) are boiled for consumption.

Common names and synonyms: Hausa potato, piasa.

Sugar apple (tree) – *see* **CUSTARD APPLE, SWEETSOP**

Sugar beet – *see* **BEET, SUGARCANE**

Sugarberry – *see* **HACKBERRY**

SUGARCANE – There are several species of sugarcane (genus *Saccharum*) in Southeast Asia, which probably gave rise to cultivated cane (*S. officinarum*), with a juice or sap high in sugar. This giant grass was used as a medicine – and possibly to sweeten foods and beverages – in ancient India and China. Sugar became known to the Persians and probably to the Greeks around 500 B.C., when, during a foray into the Indus Valley, the Persian king Darius reported finding reeds that produced honey although there were no bees. A couple of centuries later, an emissary of Alexander the Great learned that the "honey" in question was actually cane juice evaporated by boiling, and sometime after that the Persians themselves began making sugar.

Sugarcane was introduced in southern Europe in the ninth and tenth centuries A.D. by the Arabs, who had captured Persia and revived its sugar industry. Venice became a "middleman" that imported sugar, then exported it again to central Europe and the Slavic countries, and plantations were established in the West by the Arabs around Valencia in Spain. Medieval Europeans called sugar "white salt" but never tasted it save in medications destined mostly for the wealthy. Yet demand was sufficient that in the fifteenth century, the Iberians transferred sugar cultivation to Madeira and the Canary Islands, and slaves were imported from nearby Africa to work in the fields – all a dreadful harbinger of things to come in the Americas in the wake of Christopher Columbus. By 1518, the Spaniards were operating a number of sugar plantations on Hispaniola, and in that year began the transatlantic slave trade.

Europe, however, was closer to the sugar of the Middle East than it was to that of the West Indies, and a voracious European demand for sugar (other than as a medicine) had to wait for the consumption of tea, coffee, and chocolate to become widespread, which it did during the course of the seventeenth and eighteenth centuries. The Dutch seized northeastern Brazil in 1635 and moved into the sugar industry there. After being driven out a few years later, they began providing the secrets of sugar production to English colonists on Barbados, along with the financing to help them switch from tobacco to sugar cultivation. Such behavior was hardly altruistic; the Dutch made great profits supplying Barbados with slaves from Africa and carrying the sugar away to Europe.

This activity at about the midpoint of the seventeenth century is generally viewed as the beginning of the "sugar revolution," during which on island after island in the Caribbean saw lands devoted to sugar monoculture and gathered into the hands of a relatively few whites, surrounded by huge black slave populations. The French island of Martinique was caught up in the sugar revolution in 1655 – the same year that the British seized Jamaica from Spain. By the end of the seventeenth century, Jamaica had emerged as a major sugar producer, but by the end of the following century French St. Domingue was producing about half of the world's sugar. The slave revolution in that country (which created the new nation of Haiti) and British abolition of first the slave trade and then slavery itself (during the first third of the nineteenth century) led next to the rise of Cuba as the Caribbean's biggest sugar grower and a competitor of Brazil for dominance of the world market – a competition that Cuba won because of the willingness of its planters to embrace railroads and other new technologies.

Meanwhile, in North America sugar had been grown in Louisiana by French colonists throughout most of the eighteenth century, albeit with little success until experts on the crop, fleeing from the revolution in Haiti, arrived to take a hand. By the time of the American Civil War, Louisiana sugar held a position of world importance that it would never regain after the war's end and the abolition of slavery.

Despite the avalanche of sugar from sugarcane that was reaching the Old World from the New, beet sugar had been experimented with, and during the Continental blockade around the turn of the nineteenth century, Napoleon ordered that thousands of hectares of French land be planted with sugar beets to avoid dependence on imports from the New World. Although French production faltered after the war in the face of resumed imports of cane sugar, beet-sugar production continued to constitute worrisome competition for cane-sugar producers, and by 1845 beet sugar had captured some 15 percent of the world market.

In the United States, sugar beets were being raised on a commercial scale in the last two decades of the nineteenth century but accounted for only a fraction of the country's sugar needs. It was at about this time (1878) that London sugar magnate Henry Tate introduced the sugar cube to the world. Its effect on demand is not known, but about a century later – during the last decades of the twentieth century – the world was producing more sugar than it could use, despite the heavy demands made by the food-processing and beverage industries. Thus, in addition to its use as a sweetener with myriad applications, its employment in raw form in many tropical countries, and its by-products, such as molasses, rums, and other cane spirits, there have been efforts to convert sugar into fuel for automobiles, and even into wax. In the face of health concerns as well as competition from artificial sweeteners (such as saccharin and aspartame, which are now in use, and a vast number of others on the horizon), the future of sugar, after four centuries or more of prosperity, seems uncertain.

Common names and synonyms: Noblecane, white salt.

SUGAR PEA (*see also* **LEGUMES, PEA**) – Peas were domesticated about 6000 B.C. in the Near East, but the sugar pea (*Pisum sativum* var. *macrocarpon*) has only been around since the sixteenth century. Also known as the "snow pea," *mange-tout,* and "edible pod pea," the sugar pea is often said to have originated in China, but there is some evidence to indicate that the plant was first cultivated in Europe and taken to China by the Dutch. Moreover, the extent to which the sugar pea is employed in Asian cuisine today appears to be a matter of contention (in India there is a similar flat legume called *papdi*), although there is no question of its prominence in Asian dishes served in the West.

"Snow pea" seems something of a misnomer because the plant grows no earlier in the season than other peas. But the name "sugar pea" is quite appropriate, as it is a sweet legume. It appears similar to a garden pea except that it has a skin so thin and delicate that the entire pod can be eaten. Or at least this is the case if the sugar pea is picked when the immature peas inside are only just discernible, but if it reaches maturity, the pod becomes tough, and the sugar content decreases. The sugar snap pea, which has recently been developed, is an interesting legume that permits large sweet peas to grow inside a pod that remains sweet and edible. Sugar peas are high in vitamin C and iron.

Common names and synonyms: Chinese pea, Chinese pea pod, Chinese snow pea, edible-podded pea, edible pod pea, *ho loan, mange-tout, papdi,* podded pea, snow pea, sugar snap pea.

Sumac – *see* **SMOOTH SUMAC, SUMAC BERRY**

SUMAC BERRY (*see also* **BERRIES**) – There are countless varieties of shrubs and trees of the genus *Rhus,* with one in particular – "Sicilian sumac" (*R. coriaria*) – noted for its red, slightly sour-tasting berries that can impart a cherry color to dishes. These are dried and used whole, ground for sauces, or combined with other spices to sprinkle on meat dishes. The Romans employed sumac berries for their fruity sourness before lemons reached Europe, and they remain popular in the Middle East. In Europe, however, they are no longer in common use. In North America, *R. typhina* produces a sumac berry that was doubtless used by Native Americans for flavoring foods and liquids. Also doubtless, Native Americans quickly learned to stay clear of some other members of the sumac family, such as poison sumac, poison ivy, ;and poison oak.

SUMPWEED – A plant with an interesting history and a harsh name, sumpweed (*Iva annua*) has also been more pleasingly called the "marsh-elder." It is a weed that inhabits the central United States, is generally around 2 or 3 feet in height, and yields an oily seed that is as nutritious as the seeds of its domesticated relative, the sunflower. In fact, archaeobotanists have discovered that sumpweed was also domesticated some 2,000 years ago. Yet by the time the Europeans arrived, the plant had returned to the wild. The most likely explanation for this is that sumpweed was displaced by the maize-beans-and-squash triumvirate that had moved northward from Mexico and then across all of North America by A.D. 1200 or so.

Common names and synonyms: Marsh-elder.

Sunberry – *see* **WONDERBERRY**

Sunchoke – *see* **JERUSALEM ARTICHOKE**

SUNFLOWER OIL AND SEED (*see also* **JERUSALEM ARTICHOKE**) – The sunflower (*Helianthus annuus*), with its daisy-like head bristling with oil-rich seeds, is North America's only native plant to become a major world crop (the second most important oilseed crop in the world). Wild sunflower seeds were an important food gathered by Native Americans that could be dried and used throughout the winter. But many tribes in the western and especially the southwestern parts of what is now the United States had gone beyond the gathering stage to domesticate and cultivate sunflowers long before the Europeans arrived. After that arrival, sunflowers – then thought of as a decorative plant – were carried to Europe around 1510, beginning what would be a world tour.

Two centuries later, the plants were being grown for their oil on a large scale in France and Bavaria, and following this development, they moved farther eastward into eastern Europe and especially Russia, where – as a previously unknown food – sunflower oil was not on the proscribed list for the many fasting days observed by the Orthodox church. As a result, today Russia is by far the world's largest producer of sunflower oil, accounting for about three-quarters of the total despite vast tracts of land given over to sunflowers in Argentina (which is a distant second), Uruguay, the United States, and some of the other eastern European countries. Turkey, Morocco, Tanzania, and Ethiopia are the most important producers in the tropics and subtropics.

With its low unsaturated-to-saturated fat ratio, sunflower oil has become ever more important as an oil for cooking, and the oilseeds (the black-shelled kind) are also popular as a feed for birds. Dried sunflower seeds make a fine snack that is high in protein, the B-vitamins, and calcium.

Common names and synonyms: Common sunflower, giant sunflower, prairie sunflower, single-headed sunflower.

SUNSAPOTE – Native to the lowland tropics of central-northern South America, the sunsapote (*Licania platypus*) is a tall wild or semicultivated tree that produces a large fruit of the same name. The pulp of the fruit is sweet and generally is eaten raw. The sunsapote can be important locally but is not really a commercial crop.

SUNSET HIBISCUS – Also called "edible hibiscus" and "aibika," the sunset hibiscus (*Abelmoschus manihot = Hibiscus manihot*) is a relative of okra and probably a native of China. It is widely cultivated for its leaves in the islands of the South Pacific and in areas of tropical Asia. The usually sweet leaves are harvested when fully developed and are eaten raw, cooked as greens, and used in stews.

Common names and synonyms: Aibika, edible hibiscus.

SWAMP CABBAGE (*see also* **HEART(S) OF PALM, SKUNK CABBAGE**) – Not to be confused with hearts of palm, which can also go by this name, this real swamp cabbage (*Ipomoea aquatica*) is a green-leafed vegetable and not a cabbage, grows in or near water, and is a member of the Convolvulaceae (sweet potato) family. "Kang kong" and "water spinach" are two common names for the plant, and both Africa and tropical Asia have been put forward as its place of origin. Swamp cabbage is grown throughout Southeast Asia, in some parts of Africa, and in Australia. A land form of the plant is grown in Indonesia. Both the water and land forms are raised for their tender stems and leaves, which are used in salads and cooked as a vegetable. The leaves are a good source of calcium and a fair source of vitamin C.

Common names and synonyms: Espinaca acquatica, kang(-)kong, karamta, kang kung, patate aquatique, swamp morning-glory, water convolvulus, water spinach.

SWEET BIRCH – A tree that is native to eastern North America, the sweet birch (*Betula lenta*) is known to many as the "black birch." Its inner bark was eaten by Native Americans, who consumed it fresh and also dried it for later use. The twigs and leaves of the sweet birch (along with the inner bark) contain an oil similar to wintergreen and were used to brew a tea; the sap of the tree was also drunk. Later, European settlers made "birch beer" by steeping the bark in water.

Common names and synonyms: Black birch, cherry birch, spice birch.

SWEET CLOVER – This biennial herb (*Melilotus officinalis*) is native to Europe, temperate Asia, and North Africa. It was introduced into North America around 1700 and is grown for erosion control and for fodder. In Europe, it is often used as an herb. In France, sweet clover is an ingredient in the stuffing for a cooked rabbit. In Switzerland, the flowers and seeds of the plant are used to flavor Gruyère and Sapsago cheeses. The roots are also edible, and in Iceland they are cooked and eaten like other root vegetables. In many places throughout Europe, the leaves and flowers of sweet clover flavor soups, stews, and marinades. Its flowers are also a good source of nectar for honey production.

Common names and synonyms: Melilot, melist, yellow melilot, yellow sweet clover.

Sweet-corm-root – *see* **GUINEA ARROWROOT**
Sweet cumin – *see* **ANISE**

SWEET DUMPLING (SQUASH) (*see also* **SQUASH AND PUMPKIN**) – Like the Delicata and the Golden Nugget, the Sweet Dumpling squash (*Cucurbita pepo*) is a small squash that serves only one person. It is generally light colored with green stripes, and its sweet flesh makes a good soup. The small cavity of the squash can also be hollowed out for stuffing.

See in addition: "Squash," Part II, Section C, Chapter 8.

SWEET FERN – A shrub that grows throughout eastern North America, the sweet fern (*Comptonia peregrina*) has a pleasing, sweet-scented odor. Its leaves have been steeped to make a tea, and the leaves and tops can be chopped and used as a condiment.

Common names and synonyms: Canada sweetgale, fernbush, ferngale, meadow fern, sweet bush.

SWEET FLAG – Also known as "calamus," sweet flag (*Acorus calamus*) grows in eastern North America in moist areas such as swamps, the shores of lakes, and riverbanks. It has fernlike foliage and an aromatic root with a sharp taste, which in the past, at least, was sometimes candied. The rhizome is also used for flavoring alcoholic beverages, including beer, and has been sold commercially as a breath freshener. Native Americans ate the young shoots of the plant both raw and after cooking.

Common names and synonyms: Calamus, calamus root, flag root, myrtle flag.

Sweet gale – *see* **BOG MYRTLE**
Sweet granadilla – *see* **PASSION FRUIT**

SWEET GUM – The hardy tree *Liquidambar styraciflua* is native to North and Central America. Also known as "red gum," "American sweet gum," and "bilsted," the tree yields a resin that is called American styrax or storax. The resin has been chewed both to freshen the breath and to clean the teeth. It has also been used to flavor tobacco and beverages.

Common names and synonyms: American storax, American styrax, American sweet gum, bilsted, red gum.

SWEET PEPPERS (*see also* **CHILLI PEPERS**) – These Capsicums (*C. annuum* var. *annuum*) are called sweet because they do not impart the heat that their more aggressive relatives are noted for (although the "Mexi-Bell" – a cross between a sweet bell pepper and a hot pepper – has a bit of a bite). Bell peppers, which constitute one category of sweet peppers, are so called because of their bell-like shape. Although most commonly found in the color green, bell peppers also come in variations of red, yellow, orange, and black. Such variety makes bell peppers a colorful ingredient in salads and any number of other dishes and sauces. They are also grilled, roasted, and in many cultures have traditionally been stuffed.

A large, dark, heart-shaped red pepper (although not actually a red bell pepper, with which it is often confused), grown in the U.S. South, in Spain, and in Hungary, is called variously a pimento (or pimiento), a *chilli pimiento,* a *pimiento dulce,* or a *pimiento morrón.* The flesh of this chilli is roasted to become pimento or pimiento (not allspice, which the Jamaicans call pimiento), which is packed in jars and can be used for decorating dishes such as paella. Its major uses, however, are in stuffing olives and the production of paprika. A similar pepper is the Hungarian sweet chilli, which is elongated in shape but fairly thick, crimson in color, and sweet, with a flavor quite like that of the pimento.

Cubanelle peppers (also called *chawa*) are also sweet and have more taste than bell peppers. They are relatively long (about 4 inches), tapered, and range in color from pale yellow to light green; in other words, they have the characteristics of the banana or Hungarian wax peppers, including just a touch of heat. Of the sweet peppers, which are all natives of the Americas, bell peppers are the most popular in the United States and are extensively grown in California and Mexico as well as in the Mediterranean countries, Hungary, and the Netherlands.

Holland peppers, grown hydroponically in the Netherlands for the Dutch export trade in specialty produce, come in all of the bell pepper's many colors and act as expensive substitutes. In addition, the "sweet purple pepper" is cultivated by the Dutch. Sweet peppers are a good source of vitamin C, and those that tend toward red in color are rich in beta-carotene.

Common names and synonyms: Bell pepper, *chawa, chile pimiento, chilli pimiento,* cubanelle pepper, green bell pepper, green pepper, Holland pepper, Hungarian sweet chilli, mango (pepper), Mexi-Bell, pimento, pimiento, *pimiento dulce, pimiento morrón,* red bell pepper, sweet purple pepper.

See in addition: "Chilli Peppers," Part II, Section C, Chapter 4.

SWEET POTATO (*see also* **BONIATO**) – Not to be confused with the potato of the genus *Solanum,* nor with the yam of the genus *Dioscorea,* the sweet potato (*Ipomoea batatas*), with the Caribbean Indian name *batata,* is a member of the morning-glory family and a native of tropical America (probably western South America but possibly also southern Mexico and Central America). It was cultivated in Peru some 5,000 years ago for its sweet and starchy tubers, while at the same time there were many other wild *Ipomoea* species whose tubers and leaves constituted gathered foods for other Native Americans in North, Central, and South America.

But the sweet potato did not confine its range to the Western Hemisphere. Rather, it wandered far and mysteriously – reaching Australia, New Zealand, and Polynesia long before (about 1,500 years before) the Europeans stepped ashore in the New World. By the time Christopher Columbus arrived, sweet potato cultivation had spread over much of the Americas and certainly across the Caribbean, and sweet potatoes were among the items he carried back to Spain at the end of his first voyage. A few years later, Hernando Cortés reintroduced sweet potatoes in Spain, and in 1564 John Hawkins is said to have taken the tubers from the Caribbean to England. Unlike the potato, which took a while to catch on, the sweet potato was received enthusiastically from the beginning by Europeans, who appreciated its sweet taste and were titillated by the reputation it quickly acquired as an aphrodisiac.

From the New World, sweet potatoes traveled on the Manila galleons of Spain to the Far East, while the Portuguese also spread the plant about as they tended their empires in Africa and the East Indies. The sweet potato was a staple for many in colonial America, including those soldiers in the War for Independence against Great Britain. Today, sweet potatoes are widely cultivated in the world's tropics and subtropics, especially in Latin America, the southern United States, Southeast and East Asia, and Oceania.

Sweet potatoes come in moist- and dry- (or mealy-) fleshed forms. The moist-fleshed variety is the one often (and wrongly) called a yam. Most people in the United States eat sweet potatoes only on the Thanksgiving and Christmas holidays, which means that save for these special occasions, they are depriving themselves of one of the most nutritious of the world's foods. Sweet potatoes are an excellent source of vitamin A, the B-vitamins, and vitamin C. They can be boiled, baked, and fried – indeed, they are used in the same ways as white potatoes, which includes starring in potato salad. Sweet potatoes come canned and frozen as well as fresh, but those that are canned and frozen suffer a substantial loss of nutrients.

Common names and synonyms: Batata, batata dulce, camote, common potato (archaic), *kumara,* wild sweet potato.

See in addition: "Sweet Potatoes and Yams," Part II, Section B, Chapter 5.

SWEET-SHOOT – Found in Southeast Asia, the sweet-shoot (*Sauropus androgynus*) has leaves that are used to flavor soups and stews. They are also consumed as a vegetable, act as a green dye in pastries, and as an ingredient in the alcoholic beverage "brem bali." The fruits of the plant are made into sweetmeats.

Common names and synonyms: Chekkurmanis, katook, katuk, sweet-leaf bush.

SWEETSOP – The sweetsop is a tropical American tree (*Annona squamosa* – sometimes called the "sugar apple tree") with a sweet, edible, yellowish green fruit about the size of a baseball (often called a "sugar apple"). The tree can reach upwards of 20 feet in height and (like its relative the papaw) belongs to the custard-apple family – so called because the taste of their fruits resembles that of custard. Although widely cultivated in warm regions, where it is used for making jellies and preserves, the sweetsop is quite perishable and thus is far from commonplace in northern markets.

Common names and synonyms: Anon, custard apple, sugar apple (tree).

Sweet wood – *see* **CINNAMON AND CASSIA**

SWISS CHARD (*see also* **BEET**) – Also called chard, "silver beet," and "spinach beet," Swiss chard (*Beta vulgaris* var. *cicla*) is a kind of beet, native to the shores of the Mediterranean (it may have originated in Sicily), that is grown for its greens rather than its roots. The leaves of both red (the leaf stalks and veins are red) and green Swiss chard are large and fleshy and are used in salads or prepared like spinach. The thick white or, occasionally, red stalks that can reach between 1 and 2 feet in length not only may be eaten but, in some countries of Europe, are viewed as the best part of the plant and a very satisfactory asparagus substitute. The small root, however, is not edible. Like other greens, Swiss chard is high in vitamin C, calcium, and especially vitamin A.

Common names and synonyms: Chard, green chard, green Swiss chard, leaf beet, red chard, red Swiss chard, seakale beet, silver beet, spinach beet, white beet.

Swiss-cheese plant – *see* **MONSTERA**

SWORD BEAN (*see also* **BEANS, JACKBEAN**) – Sometimes called the "wonder bean" or "Pearson bean" in the United States, and the "Babricorn bean" in the West Indies, the sword bean (*Canavalia gladiata*) is a native of tropical Asia and Africa but is now cultivated throughout the tropical world. It is very similar to the jackbean – so similar, in fact, that a common ancestor is suspected. The young pods and seeds are eaten as a cooked vegetable, and the seeds are also used in dried form.

Common names and synonyms: Babricorn bean, Pearson bean, wonder bean.

See in addition: "Beans, Peas, and Lentils," Part II, Section C, Chapter 3.

Sword fern – *see* **GIANT HOLLY FERN**

Sylvaner – *see* **SILVANER**

SYRAH (*see also* **GRAPES**) – Not to be confused with Petite Sirah, the Syrah (*Vitis vinifera*) is a grape with a pepper-like taste that has long been grown in the northern Rhône valley of France and more recently in Australia (where the popular wine it yields is called "Shiraz"). In California, Syrah is used to make spicy red wines.

Common names and synonyms: Shiraz.

See in addition: "Wine," Part III, Chapter 13.

TABASCO PEPPER (*see also* **CHILLI PEPPERS**) – In the aftermath of the American Civil War, a wild pepper from Mexico (presumably from the state of Tabasco) was brought to Avery Island, Louisiana, where it was put under cultivation to make the now-famous McIlhenny "Tabasco" brand sauce. This bright orange to red and very pungent variety of *Capsicum frutescens* (the species name means "brushy") is now grown commercially in Central America as well. In addition to serving as the base of "Tabasco" sauce, the dried tabasco goes well in stir-fries and makes a lively salsa.

See in addition: "Chilli Peppers," Part II, Section C, Chapter 4.

TACOUTTA – Known also as "wing sesame," tacoutta (*Sesamum alatum*) is a West African tree that yields oil-rich seeds. The oil is used in cooking, and the seeds are often ground into a flour.

Common names and synonyms: Wing sesame.

Tacu – *see* **ALGARROBO**

TAGAL MANGROVE – An evergreen tree of East Africa and South and Southeast Asia, the tagal mangrove (*Ceriops tagal*) provides a bark that has a multitude of uses in folk remedies. It also has a leathery, berry-like fruit that is edible if not very tasty.

TAILED PEPPER – Also called the "Java pepper" as well as "cubeb," the tailed pepper (*Piper cubeba*) is a native of the Indonesian islands, where it is grown mostly in Java. The "pepper" in question is a brownish berry that grows on a tree-like vine. The berry was a commodity in the early spice trade and became popular in the West as both a medicine and a spice (it substituted for the peppercorn) until about 1600. That popularity, however, began to dissipate as real peppercorns became more available, and today the tailed pepper is once more confined to its native habitat. A member of the same genus as the common black and white peppercorns, the tailed pepper does not have the same taste, but rather one more like that of allspice.

Common names and synonyms: Cubeb, Java pepper.

Taioba – *see* **COCOYAM**

Takenoko – *see* **BAMBOO SHOOT(S)**

TALINUM – One of the edible plants of the genus *Talinum* is the fameflower (*T. aurantiacum*), the roots of which were cooked and eaten by Native Americans in southwestern North America. Another (*T. triangulare*) is called both fameflower and waterleaf; although probably a tropical American native, it is also cultivated in tropical Asia and Africa. Its other common names, such as "Ceylon spinach" or "Philippine spinach," correctly suggest that the plant is grown for its leaves, which sometimes are cooked to be eaten alone as a vegetable but more frequently are added to soups and stews.

Common names and synonyms: Ceylon spinach, fameflower, Philippine spinach, waterleaf.

TALLOW WOOD PLUM – Also known as "false sandalwood," "seaside plum," and – somewhat contradictorily – "mountain plum," the tallow wood plum (*Ximenia americana*) is borne on a small, spiny, tropical tree or shrub. It grows in tropical and subtropical America but, despite its scientific name, seems to be a native of Africa. The "plums" in question are plumlike, edible, yellow to orange fruits, which are eaten both raw and cooked and sometimes pickled when unripe. Inside the fruit is a seed containing a nutlike kernel that is edible raw or roasted and also yields an oil sometimes used for cooking. The young leaves of this plant can be eaten as well, after cooking.

Common names and synonyms: False sandalwood, mountain plum, seaside plum.

Tamar – *see* **TAMARIND**

Tamar-hindi – *see* **TAMARIND**

TAMARILLO – Sometimes called the "tree tomato," the tamarillo (*Cyphomandra betacea*) is a member of the eggplant family. The fruit comes from an evergreen tree that was originally native to Peru or Brazil but has been grown commercially in Jamaica and is now cultivated mostly in New Zealand. The tamarillo is about the size of a small, oval-shaped tomato – and, in fact, is a very distant subtropical relative of the tomato – with a skin color ranging from yellowish to purple to crimson. Within the tough peel, which is not eaten, is an orange flesh and rows of purple seeds. The fruits, which tend to be sour, are generally stewed, although they can be eaten raw. The tamarillo tree is noted for the attractive fragrance of its foliage and flowers, and its fruit contains high amounts of vitamins A and C.

Common names and synonyms: Tomate de arbol, tree tomato.

TAMARIND – The tamarind, a basic ingredient in Worcestershire sauce, has a Latin name (*Tamarindus indica*) that certainly suggests an Indian origin, but East Africa also claims this plant. Its name, which comes from the Arabic *tamar-hindi,* means "Indian date." The tamarind has been cultivated since ancient times in India, where it retains a place in formal Hindu ceremonies. It must have reached Europe sometime before the Spaniards moved into the Americas, because they carried the plant to the West Indies and Mexico.

The tamarind is classified as a spice and looks like a fruit but is actually a "bean" that grows on a tree. Tamarinds can be acquired fresh, dried, and in concentrated and block form. Their sticky black pulp has a sour, acidic taste, is used in curries and chutneys, and is made into tamarind paste, which is much appreciated in the dishes of India. In addition, the flowers and leaves of the plant are eaten in salads, and the fruit pulp is sometimes made into a sherbet. The tamarind has a prominent place in many Caribbean and South American recipes as well.

Common names and synonyms: Indian date, *tamar, tamar-hindi.*

Tampala – *see* **CHINESE AMARANTH**

Tanaka – *see* **LOQUAT**

TANDOORI – Also called "ivy gourd," the tandoori (*Trichosanthes dioica*) seems to be native to South Asia. These vegetables look like miniature light or dark green cucumbers and are used in curries.

Common names and synonyms: Ivy gourd, pointed gourd, tindola, tindoori.

Tangelo – *see* **MANDARIN ORANGE, ORANGE**

Tangerine – *see* **MANDARIN ORANGE, ORANGE**

Tango – *see* **LETTUCE**

TANGOR (*see also* **CITRUS FRUITS**) – The most important American tangor is the "Temple" orange, which is a cross between the Mandarin orange (*Citrus reticulata*) and the sweet orange (*C. sinensis*). Tangors have segments that separate more easily than those of sweet oranges, which makes them an important hybrid.

Common names and synonyms: Temple orange.

Tania – *see* **MALANGA**

Tanjong tree – *see* **MIMUSOPS**

Tannia – *see* **MALANGA**

Tansey – *see* **TANSY**

TANSY – A wild-growing herb native to Europe, tansy (*Tanacetum vulgare*) has small, yellow flowers and very green, aromatic leaves with a bitter taste. Nonetheless, the leaves (always used fresh) can give a pleasant flavor to desserts and in the past were much used in confections. Tansy is also added sparingly to salads, omelettes, and ground meats.

Common names and synonyms: Bitter button(s), cow bitter(s), golden button(s), mugwort, tansey.

TANSY MUSTARD – Also called "mountain tansy mustard," this plant (*Descurainia pinnata*), a member of the mustard family, is found throughout the desert Southwest of the United States. It has bright yellow flowers and long, slender, seed-containing pods. Native Americans employed the seeds for making "pinole," a ground meal. Another species, *D. richardsonii,* was similarly used (and is also called "tansy mustard"); in addition, its leaves served Native Americans as a vegetable.

Common names and synonyms: Mountain tansy mustard.

Tansy ragwort – *see* **RAGWEED**

Tapèra – *see* **CAPER(S)**

TAPEREBÁ – Also known as cajá, taperebá (*Spondias lutea*) is a distant relative of cashews and pistachios and a very popular fruit in the Brazilian northeast. The pulp is generally sour, but it is readily turned into a sweetened juice of excellent flavor.

Common names and synonyms: Cajá.

Tapioca-plant – *see* **MANIOC**

Tara – *see* **TARO**

Tare vetch – *see* **VETCH**

TARO (*see also* **CALLALOO, COCOYAM, MALANGA**) – A tropical root, taro (*Colocasia esculenta* or *Colocasia antiquorum*) belongs to the arum family. It is a shaggy, large, brown-colored tuber that has a number of smaller (or side) tubers. The flesh is white and very starchy, with a nutty flavor, and is used much like that of potatoes. The origin of the plant was probably in South Asia, but it reached Egypt about 2,000 years ago. From there, taro was introduced into Europe, and the Spaniards carried it to the New World, and it probably reached West Africa from there. Meanwhile, taro had spread outward from India to the Pacific, and consequently this plant has long served as a common staple throughout much of Asia and the islands of the Pacific as well as in Africa and parts of the Americas. In Hawaii, taro is made into *poi,* a sticky, paste-like substance that has a lengthy tradition of use. In the West Indies, taro is known as "dasheen" or "eddo." Apparently, "dasheen" is a corruption of *de chine* ("from China") – the name deriving from the belief that the plant was imported from China into the West Indies to feed slaves. Taro remains important in many Chinese dishes, and in the West Indies taro leaves are called "callaloo." Given taro's plethora of names and geographic range, it is little wonder that it is frequently confused with malanga – and even with manioc. The so-called Egyptian taro (*C. antiquorum*), which is also apparently native to India, is regarded as inferior to other taro varieties.

Common names and synonyms: Callaloo, cocoyam, dasheen, eddo, eddoe, eddy root, Egyptian taro, elephant's-ear, *poi,* swamp taro, tara, tarro, tarrow, true taro.

See in addition: "Taro," Part II, Section B, Chapter 6.

Taro de chine – *see* **COCOYAM**

TARRAGON – French tarragon (*Artemisia dracunculus*) and Russian tarragon (*A. dracunculoides*) are two closely related forms of the same herb. Native to western Asia, tarragon reached Europe with Arab traders. The Arabs seem to have been the first to use the herb for cooking (in the thirteenth century), and by the fifteenth century it was in common use throughout Europe. Tarragon's scientific name, *dracunculus,* means "little dragon," and apparently the herb was so called because in the Middle Ages it was thought that tarragon was an antidote for the bites of poisonous snakes and insects. Like anise – and fennel, for that matter – tarragon has a licorice flavor; the French variety (now called "true tarragon") possesses the more delicate taste, whereas the Russian type is more pungent and bitter. In the West, most people prefer French tarragon, which makes a great contribution to flavoring vinegars, salad dressings, and cooked vegetables. The French use the herb to flavor numerous meat, egg, and fish dishes as well, not to mention classic sauces such as béarnaise.

Common names and synonyms: French tarragon, Russian tarragon, true tarragon.

TAWA BERRY – Native to New Zealand, the fruits and seeds of the evergreen tree *Beilschmiedia tawa* (much used for timber) are among the many "bush foods" that have long sustained the Maori.

TEA – Tea (*Camellia sinensis*) – the most commonly consumed drink in the world after water – is an ancient beverage that was enjoyed in China for at least 1,600 years before Europeans ever tasted it (Chinese legend would have it almost 4,500 years). But it was only about 1,000 years ago, during the Song dynasty, that tea drinking started to become widespread and the government began to supervise the production of tea, regulate its trade, and collect tea taxes. Buddhist monks, who were not permitted alcohol and needed stimulation to stay awake during meditation, are given much credit for helping to popularize the beverage, as well as for carrying tea culture to Korea and Japan.

The Portuguese reached the South China coast in 1514 and become the first Europeans to gain the right to trade with China and the first to drink tea. They were also the first to introduce tea in Europe, and in the following century tea became one of the prizes sought in the three-way tug-of-war between the Portuguese, Dutch, and English for control of the China trade.

Tea – along with coffee and cacao – caught on in Europe during the seventeenth century, which in turn increased demand for slave-grown sugar to sweeten the new beverages. In London, "coffeehouses" that served these beverages began to multiply, and some – such as that owned by Edward Lloyd, which served a specialized clientele (in this case, individuals concerned with maritime shipping and marine insurance) – blossomed into other businesses like Lloyd's of London. Others, such as "Tom's Coffee House," opened by Thomas Twining, became major tea importers.

Tea was a staple of the English colonists in North America and, because of a British tax, became one more source of friction between the thirteen colonies and Parliament, which ultimately resulted in the Boston Tea Party – one in a succession of steps that seem to have led inexorably to the American Revolution.

It was only in the nineteenth century that Europeans discovered the secrets of tea cultivation, thus dispelling an ignorance that until then had meant monopoly for China. It was during the first half of that century that the British established the great plantations of Assam and Ceylon in India, and the Dutch created tea plantations in their East Indian colonies. But China nonetheless continued to dominate the markets of the world, and Britain continued to buy huge amounts of Chinese tea, even though, as a rule, the tea had to be paid for in specie. The stubborn insistence by the Chinese that they needed nothing from the West but precious metals had always been a major irritant to the English, who now saw opium (grown in British India and smuggled into China) as a solution to the trade imbalance. The Chinese government became increasingly outraged at the wholesale addiction of its people, and its attempt to stop the traffic triggered the Opium Wars (1840–2), during which Britain triumphed militarily and effectively "opened" China to the trade of the world while wrangling huge territorial and trade concessions for itself.

The half century or so following the Opium Wars saw much competition in the China trade, and, with a Western public convinced that the fresher the tea the better, speed in transport became critical. For a few romantic decades, that speed was supplied by the famous clipper ships, which could rush tea from China to London or New York in 90 to 120 days instead of the earlier 6 to 9 months – effectively cutting the sailing time in half.

Tea reached the height of its popularity in the 1880s, but subsequent events served to sustain demand for the beverage. One was the introduction of iced tea to a thirsty crowd at the St. Louis World's Fair of 1904, which, although hardly constituting the invention of the drink (as has been claimed), certainly did help to popularize it. Another such event was the inadvertent invention of the "tea bag" by Thomas Sullivan in 1908. Sullivan was a tea merchant who began distributing his samples in hand-sewn silk bags rather than in tin boxes and was suddenly swamped with orders by customers who had discovered that they could brew the tea right in the bag.

It has been said that there are more kinds of tea in China than there are wines in France. To this it might be added that the classification of teas is every bit as complicated as that of wines. All tea starts as "green," and it must be rolled, withered, fired, and dried to deactivate an enzyme present in the leaves. If, however, the rolled and cut leaves are permitted to stand (and ferment) for one to three hours before heating, the tea becomes "black." If the leaves are semifermented, the tea is called "Oolong." Tea grading is by leaf size. Young, soft shoots make the best tea, and thus only the bud and the top leaves are plucked from the bush. With black tea, the leaf bud is called "pekoe tip"; the youngest fully opened leaf is "orange pekoe"; the next leaf is "pekoe," then "pekoe souchong"; and finally there is "souchong" – the largest leaves that are used. The corresponding green tea grades are "twanky" for the bud, then "gunpowder," "imperial," "young hyson," and "hyson." The very small pieces, called "dust," generally go into tea bags.

The most famous of China's black teas is Keemun (or Keemum), known for its winelike quality. Darjeeling tea, from the foothills of the Himalayas, is one of India's contributions to the ranks of rare and prestigious black teas. Assam tea (from the same region but a lower elevation) is another. The Ceylon teas, from Sri Lanka, run the gamut – from the mild Flowery Orange Pekoe to the full-bodied Broken Orange Pekoe Fannings. The highest-grade Oolongs and the smoky Lapsung Souchongs come mostly from Taiwan.

In truth, however, most commercial teas are blends of several of these individual teas. Green teas are consumed mostly in Japan and some of the Arab countries, whereas black teas constitute the overwhelming bulk of the tea drunk in the West.

Common names and synonyms: Assam, black tea, Broken Orange Pekoe Fannings, *ch'a,* Darjeeling, dust, Flowery Orange Pekoe, green tea, gunpowder, hyson, iced tea, imperial, Keemum, Keemun, Lapsung Souchong, leaf pekoe, Oolong, orange pekoe, pekoe souchong, pekoe tip, *sencha,* souchong, *tsocha,* twanky, women's-tobacco, young hyson.

TECUITLATL – A blue-green algae (*Spirulina geitleri*), *tecuitlatl* grew profusely in pre-Hispanic times on the surface of Lake Texcoco and was harvested and eaten by the residents of Tenochtitlan, the island capital of the Aztec empire. The Indians used fine nets to gather it, then spread it out to dry. After a few days, they cut it into loaves, which kept for up to a year. The Spanish naturalist Francisco Hernández described *tecuitlatl* as being like cheese "with a certain muddy smell." The Indians ate it on tortillas, often spiced with tomato-and-chilli sauce.

Tecuitlatl is 70 percent protein, with a blend of amino acids similar to that in a chicken egg, and is also an excellent source of the B-vitamin complex. Some scholars have speculated that the profuse growth of *tecuitlatl* indicates that the Mexicans dumped raw sewage into Lake Texcoco, and consequently would have suffered widespread gastrointestinal disease. Other sources, however, relate that wastes from the island city were carried by canoe to fertilize the raised-field *chinampas* of Lake Chalco-Xochimilco. Following the Spanish conquest, the lakes of the central valley were drained and *tecuitlatl* gradually declined. The algae was recently rediscovered on the shores of Lake Chad in central West Africa, where it was called *dihe* and was harvested and eaten in much the same manner as in pre-Hispanic Mexico.

Common names and synonyms: Dihe, dihé, douhé, tecuilatl.

TEF – Tef (*Eragrostis tef = E. abyssinica*), a plant native to Ethiopia, is an ancient grain that was cultivated long before recorded history. It is the basic ingredient in *injera,* the popular unleavened bread that is a major component of Ethiopian cuisine. *Injera* is a large, round, somewhat sour-tasting, spongy, flat bread from which pieces are torn to pick up mouthfuls of the stews that are generally the main course of the meal.

Both the bread and the grains from which it is made are cherished. But tef is costly, and thus only those with sufficient means can enjoy the bread regularly. Tef is also an important ingredient in *kita* (a sweet bread), in *muk* (a nutritious gruel), and in a number of homemade beverages. In addition, it can serve as a thickener for all sorts of foods. Nutritionally, tef is a superior cereal. It is a good source of protein and is rich in lysine, iron, calcium, potassium, and phosphorus; moreover, because the entire kernel is consumed, none of the important nutrients are lost. Free of gluten, tef provides an attractive alternative for persons allergic to wheat.

Despite its immense popularity in Ethiopia, *Eragrostis tef* has been a neglected crop in most other parts of the world. Exceptions are Yemen, Kenya, Malawi, and India, where it has been included in the traditional diet, and Australia and South Africa, where it has been cultivated as animal fodder. This is likely to change, however, as more and more people around the globe (particularly in Western cultures) come in contact with tef and enjoy it either as an exotic ethnic food or as a nutritious health food, or both. Because the plant is ideally suited to grow in arid regions and under conditions in which many other plants fail, it is not surprising that other countries, including the United States, have started production, albeit on a small scale.

Ten-months-yam – *see* **WATER YAM**

TEPARY BEAN (*see also* **BEANS**) – An annual twining bean, the tepary bean (*Phaseolus acutifolius*) is a native of the southwestern United States and Mexico. It has been cultivated since ancient times by Native Americans (especially the Papagos, who are known as the "bean people") and is now also grown by white farmers because of its adaptability to arid conditions. In the past, the green, immature pods were sometimes eaten raw or cooked as a vegetable, but the bean's main food use was as dried seeds that were ground or parched.

See in addition: "Beans, Peas, and Lentils," Part II, Section C, Chapter 3.

TEPÍN CHILLIES AND RELATIVES (*see also* **CHILLI PEPPERS**) – Present in the archaeological record of Mexico from some 8,000 years ago, the wild varieties of the *Tepín* chilli (*Capsicum annuum*) still exist in a region extending from the southern United States, through the West Indies and Central America, to northern South America, and they are still collected and sold in the markets of Central America, where they are called *chilli pequín.* These are tiny (about a quarter of an inch in diameter), orange-red, oval-shaped peppers, which pack a huge punch when used in salsas, soups, and other cooked dishes.

Chilli pequín is also the name of a cultivated pepper that looks like the wild variety but is somewhat elongated. A close relative is the Macho pepper, which is cultivated and, as the name implies, is extremely hot – indeed, it is a close second to the fiery Scotch Bonnet and Habanero in pungency. Machos are tiny like the *pequín,* are both green and red, are generally used fresh, and are grown almost exclusively in Mexico. Another type of *pequín* is the *tuxtla,* an orangish, pointed chilli that is slightly larger and slightly less hot than its fiery relatives. Collectively, these are also known as "bird peppers" because birds eat the fruits.

Common names and synonyms: Bird pepper, chilli pequeño, *chilli pequín,* Macho pepper, *pequín,* Tepín pepper, *tuxtla.*

THISTLE – There are many species of thistle (genus *Cirsium*) as well as plants of the genera *Carduus* and *Onorpordum,* some of which are natives of the New and others of the Old World. However, today, as the result of humans transporting them about, they are found mixed together all around the globe. Native Americans ate the boiled or roasted roots of many different kinds of these prickly plants, along with the stems, which were peeled and cooked like greens. Other species have been consumed in Asia and Europe since the days of the hunter-gatherers. The dried flowers are employed to curdle milk, and the seeds can be dried and roasted or ground into meal.

THOMPSON SEEDLESS (GRAPE) (*see also* **GRAPES**) – Originally a wine grape from Turkey called the "Sultana," and further named for William Thompson, the first person to grow Sultana grapes in California around the turn of the twentieth century, the Thompson Seedless (*Vitis vinifera*) has been giving ground to the French Colombard and Chenin Blanc grapes since 1983 and now is mostly a table grape. In the past, however, it was an important grape in the California wine industry.

Common names and synonyms: Sultana (grape).
See in addition: "Wine," Part III, Chapter 13.

THORNLESS RUKAM – The thornless rukam (*Flacourtia inermis*) is easier to work with than most trees of the genus *Flacourtia,* which are, as a rule, very thorny. It is a native of Malaysia (and perhaps also of India) that produces bright red fruits about the size of cherries. Although there are sweet varieties, most are sour and are used to make pies, jams, and chutneys.

Common names and synonyms: Lovi-lovi.

THYME – Thyme, a strongly flavored herb that comes in many varieties, has leaves that are used both fresh and dried. The three most important kinds of thyme are *Thymus vulgaris, T.* × *citriodorus,* and *T. serpyllum.* The first – common or garden thyme – grows as a bush and has tiny, dark green leaves. The second – lemon thyme – has a citrus-like aroma and flavor and spreads out by growing horizontally. The third kind – creeping thyme, also called *serpolet* – is a wild French thyme that flavors Provençal dishes.

Thyme is a Mediterranean plant that, like so many herbs, was put to use medicinally before it was employed for culinary purposes. The name comes from the Greek "to make a burnt offering," meaning presumably that the spice was burned as a fumigant. But oil of thyme has been used since antiquity for gargles and mouthwashes as well. In culinary usage, thyme is one of the requisite herbs for a bouquet garni, and it joins sage in poultry stuffings and basil and oregano in tomato sauces. Thyme is an important ingredient in the Creole cookery of Louisiana as well as in the liqueur Benedictine.

Common names and synonyms: Common thyme, European wild thyme, French thyme, garden thyme, lemon thyme, *serpolet.*

TOBACCO – An American herb, tobacco is a plant of the genus *Nicotiana,* now cultivated worldwide. Its leaves are dried and prepared for smoking, chewing, and "snuffing." Tobacco was used by the Indians of the Antilles when Christopher Columbus first reached them, and the word "tobacco" is probably from the Taino meaning a "roll of (tobacco) leaves." The name for the genus is in honor of Jean Nicot, who introduced tobacco plants at the French royal court. Tobacco use speeds up the metabolic processes and thus helps to hold down a person's weight, although at a considerable risk to health.

TOMATILLO – A member of the tomato family, the tomatillo (*Physalis ixocarpa*) is a large berry (about the size of a cherry tomato) native to Mexico and used in a number of Mexican dishes including *salsa verde* and guacamole. Also called the "husk tomato," the tomatillo (which means "little tomato" in Spanish) has a compact, green pulp covered by a dry, parchment-like skin that is easily removed. The tomatillo has been cultivated in Mexico for thousands of years. The Aztecs used the term *tomatl* (meaning something round and plump) for several fruits, including a number of tomatoes of the Solanaceae family, which today are regarded as true tomatoes. But it was the tomatillo that was preferred, even after the tomato (*Lycopersicon esculentum*) – a South American native – reached Mexico to fit nicely into a system of cultivation already long established for *Physalis ixocarpa.* Indeed, even today in the Mexican highlands, the tomatillo is preferred for cooking, but it has only recently traveled out of Mexico to find a place in the cuisines of other cultures. Tomatillos can be grown in most gardens and can be purchased fresh or canned. Canned tomatillos work about as well in sauces as fresh ones. They are high in vitamins A and C.

Common names and synonyms: Chinese lantern, *fresadilla,* green tomato, husk tomato, jamberry, Mexican green tomato, Mexican husk tomato, *miltomate, tomate de bolsa, tomate de cascara, tomatillo enteros,* tomatillo ground cherry, *tomatitos verdes, tomatl, tomatoe verde.*

Tomatitos verdes – *see* **TOMATILLO**

TOMATO – The tomato (*Lycopersicon esculentum*) is an American plant with an American name. In Nahuatl, the language of the Aztecs, *tomatl* indicates something round and plump, and this fruit (rather than vegetable) was almost certainly domesticated in Mexico, even though the presence of its numerous wild relatives (consisting of at least seven species) in South America suggests that it originated there. Apparently, however, tomatoes were not much used in the Andes region.

Meanwhile, to the north in Mexico, the tomatillo or "husk tomato" of the genus *Physalis,* which is also round and plump, was being cultivated, and as a consequence, there was already a cultivation tradition into which the newest round and plump fruit was fitted after its arrival. How the tomato made the voyage from South America to Mexico is not known with certainty, but it is probable that the seeds of wild tomatoes were carried by birds and that tomatoes began their career in Mexico as weeds in tomatillo fields. By the time Hernando Cortés reached Mexico in 1519, careful cultivation had brought forth a number of tomato varieties that were utilized for sauces, mixed with chillies, and eaten with beans along with numerous other dishes.

Before the sixteenth century was out, the tomato had been introduced in Europe, where its reception was far from enthusiastic. In part, this was because no one knew what it was or what to do with it, and nomenclature was such that no one could be certain that they were talking about the same plant. The sudden introduction of several American foods had left Europeans a bit confused about where all of these new items were coming from. As a rule, new foods had arrived from across the Mediterranean with the Moors. Thus, in a number of languages, the tomato became a *pomi di mori* ("apple of the Moors") or some variation thereof. In addition, there arose corruptions, such as the French *pomme d'amour* ("love apple") – although the tomato had no reputation as an aphrodisiac – and the Italian *pomodoro* ("golden apple"), which has wrongly been taken by some as an indication that the first tomatoes in Europe were of an orangish or yellowish variety. The Spanish, who continued to call the tomato a *tomate,* readily incorporated it into their diets and introduced it as well in their territories in Italy, where it was destined to make its largest impact.

However, tomatoes caught on more slowly elsewhere, probably in part because of the rank smell of the plant, in part because it was known to be a relative of "deadly nightshade," and partly because the tomato was adapted to warm climates, and new varieties were needed for northern climates. Thus, in Great Britain and the United States (even though Thomas Jefferson had grown tomatoes), the acceptance of the tomato was a late-nineteenth-century or even twentieth-century phenomenon. This was also the case in China and much of the East, even though tomatoes were introduced in Asia by the Spaniards and the Portuguese as early as the sixteenth century.

Tomatoes come in numerous varieties, ranging from bite-sized cherry tomatoes (used in salads and as appetizers); to egg-shaped plum tomatoes, also called Italian or Roma tomatoes (good for sauces, stews, and other cooked dishes); to round tomatoes (such as the "beefsteak" or "sunny") that are sliced and diced or left whole for everything from sandwiches to salads to stewing. Tomatoes are red or yellow in color when ripe but are also breaded when green for frying. In the past, tomatoes were stored in cellars to ripen for winter use.

In the United States, California produces most of the tomatoes (about 85 percent) to be used for processing. These are field grown and mechanically picked and result in catsup, salsa, juice, and any of the other tomato products, such as tomato paste, puree, sauce, and soup. Tomatoes destined for the table, however, are still picked by hand, and increasingly, those grown in greenhouses in either soil or water (hydroponically) have become available for home consumption. In addition, tomatoes are sun-dried, just as Native Americans processed them for storage centuries ago. Ripe tomatoes contain large quantities of vitamin C and respectable amounts of beta-carotene.

Common names and synonyms: Beefsteak tomato, cherry tomato, Italian tomato, plum tomato, *pomi di mori, pomme d'amour, pomodoro,* Roma tomato, sunny tomato, *tomate, tomatl.*

TONKA BEAN – Also called *cimaru,* which is the name of the mostly wild tropical American tree that it grows on, the tonka bean (*Dipteryx odorata*) has been cultivated to a limited extent in Venezuela and Trinidad. The bean is used mostly to flavor tobacco and in perfumery, but it is also employed to flavor liqueurs and to make artificial vanilla extracts.

Common names and synonyms: Cimaru.

TOOTHWORT (*see also* **COOLWORT**) – "Toothwort" is a common name for members of the genus *Dentaria.* These are wildflowers with edible tubers that are native to Europe, Asia, and eastern North America. In the latter region, the roots of *D. diphylla* (known as well as two-leaved toothwort, pepper-root, and crinkleroot) also served Native Americans as a spice. The roots have a horseradish-like flavor and are employed in salads and eaten raw like radishes. In addition, the leaves were eaten, both raw and cooked as a vegetable. This toothwort is not to be confused with a European plant, *Lathraea squamaria,* which is parasitic on hazel and beech trees.

Common names and synonyms: Crinkleroot, pepper-root, two-leaved toothwort.

TORCH GINGER – A perennial herb of the East Indies that probably originated in southern Asia, torch ginger (*Phaeomeria magnifica*) has thick stems that can reach 15 feet in height and are topped with red or pink flower heads in the shape of cones, all of which gives the impression of a cluster of "torches." The plant is cultivated for its young shoots, which are used to flavor curries in Indonesia and Malaysia, and for its edible buds, which are often shredded as a garnish and added to soups and salads.

Common names and synonyms: Ginger bud, pink ginger bud.

TREBBIANO (*see also* **GRAPES**) – Said to be the most widely planted of the white grapes in Italy, Trebbiano (*Vitis vinifera*) is used in the production of Italian white wines and is one of only two white grapes that can be used in making Chianti. Trebbiano is also blended into other wines of Italy.

TREE-FERN – The genus *Cyathea* encompasses a number of Australian and New Zealand tree-ferns with stems that yield a starch that has been consumed by aboriginal peoples for millennia. In New Zealand, one of these, the black tree-fern – also called the silver tree-fern – was heavily exploited by the Maori.

Common names and synonyms: Black-stemmed tree-fern, black tree-fern, sago fern, silver tree-fern.

TRIFOLIATE ORANGE (*see also* **CITRUS FRUITS**) – A native of central and northern China, the trifoliate orange tree (*Poncirus trifoliata*) is planted for its rootstock, which is used in grafting *Citrus* species. The tree produces small, intensely bitter fruits that cannot be eaten directly, but their rinds are employed to flavor beverages and desserts.

Trifoliate yam – *see* **BITTER YAM**

TRILLIUM – There are a number of plants of the genus *Trillium* that have served as food in the past, although the roots of most species have generally been employed medicinally. The roots of *T. pendulum,* for example, are known as "birthroots" and were used by Native Americans as an aid in childbirth. But these peoples also cooked the young leaves of *T. grandiflorum* as a vegetable. In addition, the reddish berries of some *Trillium* species were consumed in northwestern Asia. The many species of *Trillium* have an incredible number of common names, among them "wake-robin," "Indian balm," and "squawroot."

Common names and synonyms: Birthroot, Indian balm, squawroot, wake-robin.

TRITICALE – Triticale is a hybrid grain (*Triticum secale*), the result of cross-breeding wheat (genus *Triticum*) and rye (genus *Secale*). Such a cross was first attempted in 1875 by a Swedish botanist in an effort to develop a grain that would combine the baking qualities and high yield of wheat with the durability and protein content of rye. The few seeds that did germinate, however, were sterile, and it was only in the late 1930s that a fertile cross was achieved. This engineering of a brand new species that is hardier and more nutritious than both of its parent strains became part of the stimulus for the "Green Revolution." Triticale combines the taste of rye with the nutrition of wheat and has a better balance of amino acids than either of the two. It can be purchased cracked, in flakes, and as whole berries, most usually in health-food stores. The grain has not yet proven as useful or important as had been anticipated, and although it is increasingly employed in the baking industry, most triticale is used as livestock feed. It is a good source of the B-vitamins, thiamine, and folacin.

TRUFFLE(S) (*see also* **MUSHROOMS AND FUNGI**) – A number of fleshy subterranean fungi of the genus *Tuber* are called truffles, which today, depending on the kind, can cost between $800 and $1,500 a pound, ranking them among the most expensive food items in the world, and certainly making them the world's most expensive vegetable. Truffles are also among the oldest vegetables in the historical record. Food historian Reay Tannahill reports that they were known to the Babylonians and the Romans and that truffles were secured from the Arabian Desert in ancient times, just as today some of the richest truffle mines known are located in the Kalahari Desert.

Truffles gained European attention in fourteenth-century France, where they had developed a reputation as an aphrodisiac. In the late fifteenth century, their popularity as a flavoring agent was on the rise and by the seventeenth century, they were known in England. The late eightennth and nineteenth centuries saw truffles become something of a rage – with their desirability considerably enhanced by French gastronome Jean-Anthelme Brillat-Savarin's declaration in 1825 that without them there could be no truly gastronomic meal.

In France, the truffle of note (and the most famous variety) is the Périgord (*Tuber melanosporum*), a truffle that is black both inside and out, which Brillat-Savarin called a "black diamond." Another truffle – black on the outside but white on the inside – is the so-called cook's-truffle (*T. aestivum*). As the name implies, this fungus, found in the United Kingdom, is not as highly regarded. By contrast, the white truffle of the Italian Piedmont (*T. magnatum*) is a serious rival of the French Périgord, especially in the minds of the Italians. Spain, although not known for it, joins France and Italy as a major truffle producer, and in a given year any of the three countries may outproduce the other two.

"Mysterious" is a word often used in writings on truffles. Truffles vary in size from that of a walnut to that of a fist (belying the species name of the Piedmont truffle), are round shaped, and have a rough exterior. They live in clusters close to (and on) the roots of a host tree – especially the *truffier* or truffle oak – and, like mushrooms, they use spores to propagate. Truffles are gathered from October to late fall on the Continent (in the United Kingdom, the season is in late spring). Actually they are hunted, because they never break ground and thus must be smelled out, although a clue to their presence is that little else grows near the host tree – the truffles in providing their chosen tree with so much in the way of important nutrients from the soil discourage other growth. A sow, straining on a leash held by her owner, is a vivid portrait of a truffle-hunting team provided by art – the sow sniffing them out apparently because of a musky chemical exuded by truffles that mimics a sex hormone given off by hogs. Dogs (and other animals) are also used to hunt truffles but must be more rigorously trained for a task that the sow does happily.

The quarry is equally mysterious as a comestible. All truffles have a distinctive and powerful odor (something like garlic), which some find unpleasant and others think wonderful – and the Piedmont truffles have a garlicky taste. Yet somehow both aroma and taste transfer to whatever they are cooked with and enhance those foods in unbelievable fashion.

This quality helps to account for the cost of truffles. Another reason is scarcity. At the beginning of this century, the most costly truffles imported into the United States sold for upwards of $4 a pound – expensive in those days but nothing like the $1,000 or more charged today. This increase in cost reflects both the loss of forest lands and the overharvesting that make truffle production today only about 10 percent of what it was a century ago. In 1978, France harvested its first commercially cultivated truffles, but such production was fraught with so many difficulties that planned cultivation on a large scale remains a dream, and truffle prices continue to rise.

Because of the nearly prohibitive price of truffles (as well as the intense flavor they impart), they are used sparingly, frequently grated raw over hot foods (creamy fettuccine, for example) and employed to enliven the taste of pâté de foie gras. Truffles are also available canned and in tubes as a paste.

Common names and synonyms: Black diamond, cook's-truffle, Périgord, Piedmont truffle, white truffle.

TRUMPET TREE – Also known as "trumpetwood," the trumpet tree (*Cecropia peltata*) has large leaves with hollow stems. It is native to the Caribbean, where its young buds have served the people of the region as a cooked vegetable for millennia. The tree also produces a sweet, edible fruit.

Common names and synonyms: Trumpetwood.

Tucum – *see* **TUCUMA**

TUCUMA – *Astrocaryum* is a genus of chiefly Brazilian palm trees, many species of which are found in the Amazon region. Some, especially *A. tucuma,* produce fruits that yield an edible oil. The fruits are also eaten for their pulp, but the taste is reportedly bitter and not much appreciated by people from outside of the region.

Common names and synonyms: Tucum, tucum palm.

TUFTED VETCH – A species of *Vicia,* tufted vetch (*V. cracca*) is cultivated locally in Europe and Asia and is now naturalized in the eastern United States. Like many other vetches, the tufted vetch has edible seeds, pods, shoots, and leaves. In the past, the plant was cultivated in Europe for its seeds, whereas other, New World species of *Vicia* served as a gathered food for Native Americans.

Common names and synonyms: Bird vetch, boreal vetch, Canada pea, cow vetch, Gerrard vetch.

TURKEY FRUIT – Sometimes called the "bull-dog," this wild, edible fruit of Australia (*Grewia retusifolia*) is a drupe, and red to red-brown when ripe. *Grewia* is a large genus of Old World tropical shrubs that produce such fruits.

Common names and synonyms: Bull-dog.

TURMERIC – A major ingredient in curry powders, turmeric (*Curcuma longa*) is a member of the ginger family and, like ginger, is rhizomatous. Although it originated in India, the Chinese, Arabs, and Persians were all cultivating turmeric thousands of years ago. Turmeric was never very popular as a spice in western Europe, but its bright yellow color has been employed as a dye for clothing, margarine, and cheeses. Turmeric can be purchased whole or dried but – unlike ginger – is rarely available fresh. In addition to its use in curry powder, the spice goes well in chutneys, in rice and poultry dishes, and with cooked vegetables.

Common names and synonyms: Curcuma, Indian saffron, tumeric.

TURNIP AND TURNIP GREENS (*see also* **RUTABAGA**) – Members of the mustard family, wild turnips (*Brassica rapa*), which apparently are native to Asia Minor, were dug up and eaten by Old World hunter-gatherers millennia before such vegetables were cultivated – and they have been under cultivation in Eurasia for at least 4,000 years. Turnips, which are among the cruciferous vegetables, can grow in even poor soil and are so cheap to cultivate that they have often been grown for animal feed. Turnips were known to the Romans, became a staple of the European poor during the Middle Ages, and reached the Americas with colonists from both England and France. Turnip roots are generally white but can be other colors as well. They are used in stews and soups and are baked, fried, and boiled.

Perhaps more useful these days than turnip roots are the tops of turnips, eaten as a popular green, especially in Europe, the Orient, and the southern United States. They are tough and have very coarse leaves that are mostly light green, thin, and have a covering of hair. For tenderness and the best taste, turnip greens are harvested when they are very young. At one point in American history, this vegetable was a common part of the diet consumed by slaves and – consequently – today is a part of the cuisine called "soul food." Some varieties of turnips that are especially grown for their edible foliage are known as "Seven Top" and "Shogun."

Common names and synonyms: Seven Top, Shogun.

TURTLE BEAN (*see also* **BEANS**) – The turtle bean (*Phaseolus vulgaris*) is the small black bean that is the *frijol negro* of Mexico and of Cuba – indeed the main ingredient for the black-bean soup enjoyed by residents of that island and Cubans in Florida. Turtle beans are also much consumed in Brazil and are the foundation of that country's famous *feijoada.*

Common names and synonyms: Black bean, *Feijâo-prêto, frijol negro.*

TUTU BERRY – *Tutu* is a Maori word for a group of New Zealand shrubs or small trees of the genus *Coriaria.* Some, such as *C. ruscifolia,* produce a berry-like fruit that the Maori have made into a wine known as *tutu* or *tuhu.* Although the berries are edible, the rest of the parts of the tree (i.e., the shoots and seeds) are poisonous.

Common names and synonyms: Tuhu, wineberry.

U

UDO – A stout Japanese herb, udo (*Aralia cordata*) is a perennial that annually produces edible shoots from its roots. Cultivation generally involves keeping the young shoots totally covered with soil to blanch them. The result is an asparagus-like vegetable that is briefly boiled to remove a resin, then added to salads or cooked further in various dishes.

Common names and synonyms: Oudo, spikenard.

UGLI FRUIT (*see also* **CITRUS FRUITS**) – A far-from-handsome fruit, as its name might suggest, the ugli fruit, of the genus *Citrus,* is a cross between the tangerine and the grapefruit. Also known as "hoogly," the fruit was developed in Jamaica but is now grown commercially in Florida as well. Although the ugli looks like a badly mistreated grapefruit, it has a delicious, sweet, and juicy taste, which seems to combine the flavors of grapefruit, bitter orange, and tangerine. Moreover, because it has the loose skin of the tangerine, it is easy to peel, and the orange-yellow pulp is practically seedless. Like all citrus fruits, the ugli fruit is high in vitamin C.

Common names and synonyms: Hoogly.

ULLUCO (*see also* **OCA**) – Also known as *olluco* and *ullucu, ulluco* (*Ullucus tuberosus*) is another of the ancient Andean root crops that have been cultivated for their edible tubers. A staple of the Inca diet, these multicolored (white, yellow, green, magenta) tubers are still grown commercially today and, indeed, are increasing in importance and thus in their geographic range, which now extends from Venezuela to Chile and northwestern Argentina. The plants, which form tubers both above and below the ground, are frost resistant and, along with potatoes, generally constitute a major source of carbohydrates for those who consume them. The tubers, which are used like potatoes, can be eaten fresh or dehydrated.

Common names and synonyms: Melloco, *olluco, ullucu.*

Ullucu – *see* **ULLUCO**

UMBÚ – A native of the Brazilian Northeast, the *umbú* (*Spondias tuberosa*) grows on a medium-sized tree. When ripe, the oval fruit is about 10 inches in length and has a sweet flesh that is almost liquid in consistency. The umbú is eaten raw and made into preserves and into juice – the latter is often mixed with milk to become *imbuzada.* This drink of the Northeast has historically played an important role in the health of the people of the region.

UNICORN PLANT – Also called "martynia" and "devil's-claws," unicorn plants (*Proboscidea louisianica, P. parviflora,* and *P. fragrans*) are natives of the southern United States and Mexico. The elongated pods of these plants were eaten by Native Americans, and until recently people cultivated them in gardens and pickled the pods in much the same way as cucumbers are pickled.

Common names and synonyms: Devil's-claws, martynia, proboscis-flower, ram's-horn.

VALERIAN – A few plants of the genus *Valeriana* are called valerian. The "common valerian" (*V. officinalis*), a native of Europe and western Asia (and now naturalized in North America), has leaves that are used as greens and flowers that can flavor sauces. But its main use – and the reason for its cultivation in northern and eastern Europe – lies in its roots and rhizomes that have been used medicinally since the days of the Greeks. They contain an essential oil, which is employed mostly in the pharmaceutical industry but is also used to flavor beverages. Another valerian (this one a native of North America) called "tobacco-root" (*V. edulis*) has a large, fleshy, edible root, which was used as food by Native Americans.

Common names and synonyms: Bitterroot, common valerian, tobacco-root.

VANILLA (*see also* **CAROLINA VANILLA**) – Of the great number of orchid family members, *Vanilla planifolia* (= *V. fragrans*) is one of the few to be prized for something other than its flowers. The vanilla bean is the pod fruit of this climbing orchid, which is native to that part of the New World that also gave chocolate to the whole world. Indeed, when Hernando Cortés and his men first reached Mexico, the Aztecs offered them *chocolatl,* a chocolate drink flavored with *tlilxochitl* – the Aztec name for "vanilla" (the word "vanilla" itself is from the Spanish diminutive for *vaina,* which means "pod").

However, it was not the Aztecs who first discovered the secret of vanilla, which was one of nature's better-guarded secrets in that neither the vanilla flower nor its fruit have a telltale aroma that might have demanded further investigation. Rather, it was the Totonacs, in what has become the Mexican state of Vera Cruz, who discovered at least 1,000 years ago that if the initially tasteless beans were "sweated" in the sun for two or three weeks, and then slowly dried for several months, this process would force the development of *vanillin,* the major flavor component of the beans.

It is interesting to note that although the Totonacs were subsequently conquered by the Aztecs, they in turn joined forces with the newly arrived Spaniards to overturn the Aztec empire. And this meant that they continued to have a monopoly on vanilla. For although the Spaniards carried vanilla and chocolate back to Europe with them, and sugar produced in the New World became more and more plentiful (bringing on something of a revolution in beverages and desserts as well as baked goods), until the nineteenth century the Europeans were totally unsuccessful in growing vanilla elsewhere.

This was because of an intricate system of pollination involving hummingbirds, bees, ants, and butterflies within an ecosystem not found elsewhere in the world. But, during the eighteenth century, French colonists in Mexico cultivated vanilla, and in the nineteenth century the French introduced bees from Vera Cruz into their own tropical islands; combined with intensive hand-pollination techniques, this effort finally established vanilla production outside of Mexico. Recently, another plant (*V. tahitensis*) was promoted in French Polynesia to lessen reliance on the original vanilla orchid. And back in 1874, German chemists synthesized vanilla in an effort to free the flavor from the plant itself. Because of the high cost of real vanilla, there is plenty of false vanilla on the market today, although synthetic vanilla is easily detected because of a flat aroma and an unfortunate aftertaste. United States law insists that "vanilla extract" be true vanilla. In addition to extract, whole beans and powdered vanilla are available.

Common names and synonyms: Tlilxochitl.

One is a large East Indian tree – *D. indicum* – that is used for timber and produces a small fruit with a blackish, velvety rind and a sweet pulp that is eaten raw. The other (also called the "black tamarind") is a West African tree – *D. guineense* – that produces velvety black pods that have an acid pulp. They are chewed to relieve thirst and are soaked in water to make a beverage.

The most notable of the vetches is *V. faba* – the fava bean. Then there is the common vetch (*V. sativa*), native to the Mediterranean region and western Asia. Also known as "tare vetch" or "spring vetch," it is cultivated as a cover crop or for use as fodder. However, the young shoots as well as the pods and seeds of spring vetch, along with those of many other *Vicia* species, are edible. In North America, both *V. americana* and *V. gigantea* served as food for Native Americans.

It is grown nonetheless because it yields a fine wine, and indeed, two of the most famous (and expensive) wines of the Rhône Valley are made from Viognier grapes. The grape has recently been planted in California, where presumably it will prosper and add even more diversity to the California wine industry.

WALNUT – There are some 15 species of walnuts native to Asia, Europe, and the Americas, of which two – both with a green, leathery husk – are the best known. By far the most important of these commercially is the smooth-shelled and tan-colored Persian (or English, or Italian) walnut (*Juglans regia*), with its easy-to-crack shell. The Persian walnut was reportedly sent to ancient Greece by the Persians and found its way throughout Europe with the Romans. It is interesting to note that although one of its names is the English walnut, *wealhhnutu,* the Old English translation of the Latin *nux gallia,* means "Gaulish nut" or "foreigner's nut." Today, these nuts are grown in orchards and sold commercially, with California one of the leading producers. Historically, oil pressed from the Persian walnut has been highly prized. It was much used in the Middle Ages by those without a taste for – or access to – olive oil and was common in the cooking of central France until the middle of the nineteenth century. Today, some consider walnut oil to be one of the greatest salad oils because of its nutty flavor.

Another walnut is the black walnut (*J. nigra*), a North American native. It comes in a rough and very hard to crack shell but nonetheless is much used (in its native land, at least) in breads, cakes, candies, and ice cream. Still a third walnut is the little-known butternut (*J. cinerea*), another North American native, which many claim to be the best tasting of all nuts. Walnuts provide the consumer with some vitamin B_6 as well as iron, and the butternut has an incredibly high protein content – close to 30 percent.

Common names and synonyms: American black walnut, black walnut, butternut, California black walnut, Carpathian walnut, cordate walnut, demon walnut, eastern black walnut, English walnut, heartnut, Hind's walnut, Italian walnut, Juglans, *nux gallia,* oil nut, Persian walnut, Siebold walnut, walnut oil, *wealhhnutu.*

Wampee – *see* **WAMPI**

WAMPI – Native to southern China, the wampi (*Clausena lansium*) belongs to the family of plants that also includes oranges and lemons. Unlike these more familiar fruits, however, wampi are small and grow in clusters, much as grapes do. They are pale yellow and have a hard rind enclosing flesh with a consistency reminiscent of Jell-O. Their taste is sweet yet slightly acidic. Wampi are eaten as fresh fruit, made into preserves, used in desserts, and added to curries.

Common names and synonyms: Wampee.

Wapata – *see* **ARROWHEAD**

Wapato(o) – *see* **ARROWHEAD**

WASABI – A perennial crucifer, native to Japan and sometimes called "Japanese horseradish" or "mountain hollyhock," the wasabi plant (*Wasabia japonica*) has a gray-green-colored root that, when grated, becomes a searingly hot condiment used with dishes such as sushi and sashimi. A traditional but now very expensive seasoning in Japanese cuisine, wasabi is available fresh and in powdered form in most Asian markets. New Zealand now grows wasabi for the Japanese market and it is also cultivated in Oregon in the United States.

Common names and synonyms: Japanese horseradish, mountain hollyhock.

See also: "Spices and Flavorings," Part II, Section F, Chapter 1.

WATER BAMBOO – Also called Manchurian wild rice, water bamboo (*Zizania latifolia*) is a close relative of the wild rice (*Z. aquatica*) of North America. A gathered food in prehistoric times, water bamboo has been cultivated for its succulent stems since the beginnings of agriculture in paddy-like East Asian fields from Manchuria to Taiwan.

Common names and synonyms: Manchurian wild rice.

Water caltrop – *see* **WATER CHESTNUT**

WATER CHESTNUT – An Asian vegetable, the Chinese water chestnut (*Eleocharis dulcis*) is the edible bulb of a Chinese water plant that has been cultivated for thousands of years. The firm, white flesh is covered by a brown, shaggy coat that is not eaten. These bulbs are a paddy crop, grown in the mud, and require plenty of water. A similar but unrelated aquatic plant is the "caltrop" or European water chestnut (*Trapa natans*), which provided food for hunter–gatherer bands and has been fried, roasted, and made into flour in both Europe and Asia since antiquity. It is, however, the starchy and somewhat sweet Chinese water chestnut that provides crispness for so many Asian dishes.

Another vegetable called water chestnut is the water caltrop (*Trapa bicornis*), which is used like a water chestnut. Most water chestnuts available outside of Asia are canned, although they can be found fresh in some ethnic markets. There is also water-chestnut powder, available in many Chinese markets. Water chestnuts are a good source of carbohydrates as well as vitamin B_6 and riboflavin.

Common names and synonyms: Caltrop, Chinese water chestnut, European water chestnut, Jesuit nut, *trapa* nut, water caltrop, waternut.

WATERCRESS – Native to Eurasia, watercress (*Nasturtium officinale*) is a cruciferous vegetable that now grows wild in freshwater ponds and streams the world over. But watercress is also produced commercially and is available in bunches in the produce sections of U.S. supermarkets as well as in the markets of Europe. The pungent, deep green leaves make a wonderful garnish and give a peppery taste to salads and sandwiches. Watercress is high in vitamin C and calcium.

WATERLEAF (*see also* **TALINUM**) – Any North American plant of the genus *Hydrophyllum* is called a waterleaf and is identifiable by its clusters of white or purplish flowers. The roots, leaves, and shoots of *H. canadense* served as food for Native Americans (and, later, white settlers) in the eastern part of the continent, whereas *H. occidentale* was similarly exploited in the West.

Water lily – *see* **LOTUS**

WATERMELON (*see also* **MELON**) – A native of Africa, this ground-hugging vine (*Citrullus lanatus* = *C. vulgaris*), cultivated for its melons, managed early on to get around the globe with a great deal of agility. It reached the Middle East, India, and what is now Russia in prehistoric times, was consumed in Egypt and ancient Persia some 6,000 years ago, and was later cultivated by the ancient Greeks and Romans. The Chinese were growing the fruit by the tenth century A.D.; it entered Europe through Spain with the Moors and reached the Americas via the slave trade.

Wild watermelons, which grow throughout Africa around water holes in the savannas and oases in the deserts, are not much larger than apples. Those that are cultivated (there are some 50 varieties) grow larger, ranging from "icebox" varieties that fit in the refrigerator to the "picnic" sizes that can be large enough to feed a crowd. Watermelons are cultivated worldwide in subtropical, tropical, and temperate climates; in the United States, they have flourished in the warm soils of the southern states as well as those of New Jersey. Most watermelons have red flesh, but some are orange and yellow fleshed, and all contain about 90 percent water and about 10 percent sugar. Watermelon rinds – especially those that are white inside – have traditionally been turned into sweet pickles. Juice from the fruit is bottled commercially and drunk fresh as well as reduced to syrup or sugar. Another use is as watermelon wine.

Watermelon seeds are consumed by humans after drying, roasting, and salting. In Iran and China, such snacks are thought to control hypertension. The seeds are 30 to 40 percent protein, are rich in the enzyme urease, and yield an edible oil (20 to 45 percent) that is used for cooking and illumination. Livestock animals are fed the expressed oilseed cakes and benefit from the high protein content. Like nuts, however, watermelon seeds are high in fat, whereas the flesh is low in calories. Seedless varieties have been developed and are very popular, although more expensive than the traditional seeded varieties. Watermelons provide their consumers with some vitamin C.

Common names and synonyms: American watermelon, Jubilee, seeded watermelon, seedless watermelon.

WATER YAM (*see also* **YAMS**) – Also called "white yam," "greater yam," "Asiatic yam," and "winged yam" (among numerous other common names), the water yam (*Dioscorea alata*) is a native of Southeast Asia but is now grown throughout the tropical regions of the world, including the Caribbean and especially Australia and Polynesia. The plant is a climbing vine usually planted at the beginning of the rainy season, and its tubers are generally mature by the season's end. The large tubers, with a fine white flesh, are baked or boiled as a vegetable or cooked with coconut milk, although they can also be roasted and fried.

Common names and synonyms: Asiatic yam, greater yam, ten-months-yam, white yam, winged yam.

WAX PEPPERS (*see also* **CHILLI PEPPERS, SWEET PEPPERS**) – Also known generically as banana chillies (and in Spanish as *güero* – meaning "blond"), wax peppers (genus *Capsicum*) include the banana pepper, the Hungarian yellow wax pepper, and the Santa Fe Grande. They are all relatively large – about 3 to 5 inches in length and about an inch and a half in diameter. As a rule, the banana pepper is sweet with a generally mild taste; Hungarian wax peppers are hotter; and the Santa Fe Grande has just a touch of heat. A problem is that all three may be generically labeled "yellow wax" in supermarkets, which gives no clue as to the degree of heat they might deliver. Another pepper with the characteristics and color of waxed peppers is the Chawa, which is found mostly in stores in California. Wax peppers go well in salads, are pickled, and are used to make yellow mole sauces.

Common names and synonyms: Banana chilli, banana pepper, Chawa, *güero,* Hungarian wax pepper, Hungarian yellow wax pepper, Santa Fe Grande, yellow wax pepper.

Actually a kind of scallion, with dark green, hollow, cylindrical leaves and a white end that does not develop a bulb, the Welsh onion is widely used in stir-fries.

Common names and synonyms: Chinese onion, Japanese bunching, spring onion.

WHEAT (*see also* **EINKORN, EMMER, KAMUT, SPELT**) – The wheat now growing in vast fields stretching across the Great Plains of North America had its beginnings in the eastern Mediterranean region, where the wild grass *Triticum aestivum* originated to become one of the first of the domesticated grains and ultimately one of the world's two most important superfoods. Wheat was probably first domesticated in the Middle East many thousands of years ago. The ancient Egyptians made bread from it, but only later did the Greeks adopt wheat in preference to emmer. Later still, one of the reasons for the expansion of Rome was the need for wheat, and the Romans turned Egypt into a wheat-growing breadbasket for their empire.

Wheat reached northern China later than it reached the West, and in eastern Asia it joined millet as a major crop. The plant does poorly in warm and humid climates because it is very susceptible to disease. But although it likes cool climates, it does not grow as far north as do rye and oats. In Europe, wheat lost ground to other grains (such as barley and rye) after the fall of the Roman Empire and did not regain its prominence until the nineteenth century. The grain reached the Americas in the early seventeenth century with the Spaniards and was first planted on the Great Plains at about the time of the American Civil War.

Wheat comes in some 30,000 varieties, which in part is testimony to its longevity as a domesticated plant which people tinkered with. The varieties, however, can be fitted into a relatively few classifications, such as "hard red spring," "hard red winter," "soft red winter," "durum," and "white" wheat. The hard varieties (hardness measured according to the strength of the kernel) provide more protein and are most valued for the production of all-purpose and baking flours. The even harder durum wheat is employed for making semolina and pasta, whereas the soft wheats are preferred for flours utilized to bake pastries.

As a grain, wheat has a special characteristic that provides humankind with raised breads: When it is ground and combined with water, its protein forms gluten – a sticky, adhesive mass that can be rolled and pummeled yet still holds together and expands to contain rather than release the gases produced by yeast. Bulgur is made by steaming and drying whole wheat kernels, then cracking them. The coarsest wheat grains are used for pilafs, the medium for cereals, and the finest for the various forms of tabbouleh – a cold grain salad. Farina (also called "Cream of Wheat"), which has most of the bran and germ removed, usually comes as a breakfast cereal. Wheat can also be purchased as whole "berries," as cracked wheat, as rolled wheat, and as wheat flakes.

Common names and synonyms: Alaska wheat, bearded wheat, bread wheat, bulgur, common wheat, cone wheat, cracked wheat, durum wheat, English wheat, farina, hard wheat, macaroni wheat, Mediterranean wheat, non-bearded wheat, Poulard wheat, red wheat, river wheat, rivet wheat, rolled wheat, soft wheat, spring wheat, wheat flakes, white wheat, wild wheat, winter wheat.

WHITE CINNAMON – An aromatic tree, the white cinnamon (*Canella alba* or *C. winteriana*) is native to southern Florida and the West Indies. It is also known as the wild cinnamon tree, and its bark, which is marketed rolled up in tubes, is referred to as "canella," "Bahama whitewood," and "white cinnamon," as well as "wild cinnamon." The bark's aromatic qualities make it useful as a spice. It is also employed to flavor tobacco and for medicinal purposes.

Common names and synonyms: Bahama whitewood, canella, wild cinnamon (tree).

See also: "Spices and Flavorings," Part II, Section F, Chapter 1.

WHITE PINE – Also known as the northern pine and the Weymouth pine, the white pine (*Pinus strobus*) – along with other species of *Pinus* – provides an inner bark that served as food for Native Americans of eastern North America. The bark was eaten fresh and was also dried over a fire, whereupon it was fashioned into cakes.

Common names and synonyms: Northern pine, Weymouth pine.

WHITE POTATO – An enlarged tip of an underground stem that stores energy in the form of starch, the potato (*Solanum tuberosum*) may have been domesticated in the highlands of Peru as many as 10,000 years ago. Certainly it was a well-established crop some 5,000 to 6,000 years ago and, along with other tubers, maize, and quinoa, served as the foundation of the Andean diet. There were hundreds of varieties – some sweet, some bitter, some red, some blue, and some black – that were baked, boiled, used in soups and porridges, and even eaten for dessert. In addition, the ancient Peruvians discovered how to preserve potatoes by a process of freezing and drying, with the resulting product called *chuño.*

Outside of the Andean region there were and are a great number of species of wild potatoes, the tubers and leaves of which served as food for other Native Americans from North through Central to South America. But apparently it was only in the Andes that the potato was domesticated, and the Spaniards reaching Peru in the 1530s who had never seen one before thought at first that potatoes were truffles. The Incas called the potato a *papa,* a name the Spanish adopted. However, because they also adopted the Caribbean Indian name for the sweet potato, *batata,* sufficient confusion ensued that the potato (*papa*) was eventually given the name of the sweet potato (*batata*).

Potatoes were carried back to Spain in 1539 by returning conquistadors and followed the same route as the tomato to reach Spanish territory in Italy, where a hungry peasantry quickly embraced them. They reached the British Isles more circuitously, bringing about even more semantic confusion in the process. The story is that the confusion began when Francis Drake in 1586 picked up some potatoes at Cartegena in the Caribbean, then went to Virginia before returning to England. This created the impression that the potato had originated in Virginia. It also gave rise to the name "Virginia potato," which received "scientific" blessing in John Gerard's *Herbal* of 1597, and neither the impression nor the name was fully dispelled until the 1930s work of Russian geneticist Nikolai Vavilov established or reestablished an American origin for the potato.

Hardy and easy to grow, potatoes were therefore an inexpensive food that caught on quickly enough that the poor of Ireland were planting them in "lazybeds" by the early 1640s. The timing was fortunate, because at the end of that decade the English, under Oliver Cromwell, began killing and transporting thousands of Irish, and those who survived the English depredations did so on potatoes. Potatoes were also planted for the poor relatively early on in England but were not much appreciated there. On the Continent, potatoes were regarded with even less enthusiasm because they were thought to cause leprosy – a suspicion that lingered on in France until well into the eighteenth century. Moreover, potatoes were denounced by religious fundamentalists because the vegetable had not been mentioned in the Bible. Nonetheless, beginning in about 1650, potatoes started to gain acceptance in the Netherlands and then became widespread throughout the Low Countries by the middle of the following century.

Elsewhere, in Germany and Russia, rulers compelled the peasantry to plant potatoes, sometimes at gunpoint, and by the end of the eighteenth century even the French were eating them. Resistance to the tubers, however, continued well into the nineteenth century in Russia, where (in the aftermath of two famines) they were at last uniformly adopted. By the beginning of the twentieth century, Russia was among the leading potato-producing countries of the world, with a good bit of that production becoming vodka.

Meanwhile, the peripatetic potato, which had left the New World to become the "Virginia potato" in the British Isles, returned to the Americas as the "Irish potato," reaching Boston in 1718 with Irish immigrants. The following year, potatoes were planted in New Hampshire, although another century elapsed before they really caught on in North America. Elsewhere, the Spaniards and Portuguese had carried potatoes to Africa and disseminated them throughout the East. By the middle of the seventeenth century they were grown in even the most remote regions of China and, along with sweet potatoes, were helping to fuel a population explosion. Because potatoes produce far more calories per acre than cereal crops, they were also to some immeasurable extent responsible for the population explosion in Europe during the eighteenth and nineteenth centuries.

The Irish potato famine – which began in 1845 with the loss of half the potato crop and saw its total loss in 1846, causing the death or migration of millions – was, in retrospect, inevitable. The Irish potato crop had failed numerous times during the previous 100 years, each time encouraging tenant farmers to select potato varieties that were the highest yielding. But in so doing, they narrowed the genetic base and bred potatoes with little resistance to fungal diseases. Perhaps ironically, the fungus (*Phytophthora infestans*) that caused the potato famine reached Ireland from North America, probably on potatoes imported for breeding purposes.

The devastating blight that killed one million persons was a stark reminder of the dangers of too much reliance on a single crop, yet at the same time it galvanized plant breeders to develop potatoes that not only were disease resistant but also stored and shipped well. Unfortunately, their product has turned out to be not particularly tasty. The relatively few potato varieties available outside of the Andean region are often divided into the dry and mealy kinds, such as Idaho or russet potatoes, utilized for baking and mashing, and the moist and waxy kinds (new potatoes, for example), which are scalloped and made into potato salads.

In addition to these uses, there are french fries, born in the mid-nineteenth century on the streets of Paris, where they were peddled by pushcart vendors. Beginning in 1864, french fries were increasingly united with fried fish, on sale in London streets since the seventeenth century, to become the famous English "fish and chips." It is interesting to note that as U.S.-based restaurant chains such as McDonald's and Burger King have become worldwide operations, french fries are now known in many places as "American fries."

Potato chips, however, are the true American fries. They are said to have been invented in 1852 in Saratoga Springs by a chef mischievously responding with humor to a customer's complaint that his french fries were too thick. In 1925, an automatic potato-peeling machine was introduced, allowing potato-chip production on a massive scale, which in turn permits Americans to consume a per capita average of 6 pounds of potato chips annually. Other breakthroughs have seen potatoes dehydrated for "instant" products, and french fries, hash browns, and even mashed potatoes are now frozen. Consequently, almost 65 percent of the potatoes grown in the United States are used for these processed products, including, of course, potato chips.

Potatoes constitute the fourth most important crop in the world – after rice, wheat, and maize – and are by far the healthiest. Potatoes are a good source of vitamin C (in fact, they are a leading source in the American diet because of the vast quantities consumed), potassium, niacin, vitamin B_6, and iron.

Common names and synonyms: American fry (fries), common potato, European potato, french fry (fries), Idaho potato, Irish potato, new potato, *papa,* potato chip(s), red potato, round potato, Russet Burbank, russet potato, Virginia potato.

WHITE SAPOTE – The white sapote (*Casimiroa edulis*), a native of Central America and Mexico, is now cultivated in California (since the nineteenth century), Florida, Hawaii, and Puerto Rico. It is about the size of an orange with a green to yellow skin and white pulp. This fruit's sweet yet simultaneously bitter taste is not appreciated by some, which helps to explain why the white sapote has been a somewhat neglected fruit.

WHITE WILLOW – A large tree of Eurasia and North Africa, the white willow (*Salix alba*) was long ago introduced into North America. Its inner bark is edible, as are its young shoots, leaves, and flower clusters. The leaves, which are rich in vitamin C, were doubtless discovered to be a scurvy preventive sometime in the distant past.

Whitewood – *see* **AMERICAN LINDEN**

WHITE YAM (*see also* **YAMS**) – One of several yams that long ago lured West Africans into the forests to cultivate the tubers in clearings, the white yam (*Dioscorea rotundata*) has other common names, such as "Guinea yam" and "Eboe yam," which speak to its West African origin. The white yam is considered by many to be the premier yam grown in the region, and it is this yam that generally is used to make "foo-foo," the famous West African dish.

Common names and synonyms: Eboe yam, Guinea yam, white Guinea yam.

WILD BARLEY – Barley (*Hordeum vulgare*) – a Middle Eastern native – was domesticated in early Neolithic times. But many other species of the genus *Hordeum* continued to grow wild. In the Americas, one of these wild species was "little barley" (*H. pusillum*), which was widespread in western and southern North America as well as tropical America. Another was "foxtail barley" or "squirrel-tail barley" (*H. jubatum*). Both provided food for Native Americans.

Common names and synonyms: Foxtail barley, little barley, squirrel-tail barley.

WILD CUSTARD APPLE – Native to West Africa, the wild custard apple (*Annona senegalensis*) now enjoys a wide distribution across all of that continent's tropical regions. Although it does well even in poor, sandy soils of those hot climates, the small tree (or shrub) prefers low, moist places, such as along a stream or in a boggy wooded area. With such optimal conditions, it may grow to a height of 19 feet. The leaves, lush and green year-round, are enjoyed by monkeys and bushpigs. The tree bears fruits that are barely 2 inches in diameter. When young, they are green with light spots and, depending on the variety, turn yellow or red when ripe.

Opinions on their flavor range from "limited appeal" to "the best indigenous fruit in parts of tropical Africa." Some have likened their taste to that of an apricot and their aroma to that of a pineapple. Their sweet pulp is consumed fresh and the fruits are also pickled.

WILD GINGER – The reference here is not to the wild form (*Zingiber zerumbet*) of the Old World's common ginger (*Z. officinale*). Rather, it is to two species of the genus *Asarum* that are called "wild ginger." By far the best known is Canada wild ginger (*A. canadense*), which is also named "Canada snakeroot," "Vermont snakeroot," "heart snakeroot," and so forth. It is a small plant with kidney- or heart-shaped leaves and is found in the forests of and along roadsides in eastern North America. The other "wild ginger," *A. caudatum,* is a lesser-known denizen of western North America. Both have a fragrant, spicy-tasting rootstock – with a flavor somewhat reminiscent of ginger – that is used either fresh or dried and powdered as a spice. Native Americans made a tea from the roots. There is also a perennial Australian plant, *Alpinia coerulea,* which grows wild and is related to the common ginger.

Common names and synonyms: Black snakeroot, Canada ginger, Canada snakeroot, Canada wild ginger, heart snakeroot, Vermont snakeroot.

WILD GOOSEBERRY (*see also* **BERRIES**) – Also known as the "native gooseberry" – although it is not a true gooseberry (genus *Ribes*) at all – the wild gooseberry (*Physalis minima*) is an edible berry of Australia and one of the many foods that were gathered by the aboriginal populations.

Common names and synonyms: Native gooseberry.

Wild grape – *see* **FOX GRAPE**

WILD GUAVA (*see also* **GUAVA**) – Also known as the "Costa Rican guava," the wild guava (*Psidium friedrichsthalianum*) is a tree of Central America that produces greenish (or yellowish) fruit. As with other guavas, the flesh of the fruit (in this case, white in color) is good to eat raw if one does not mind the numerous hard seeds. The latter can, however, be ground into an edible paste. A refreshing beverage is derived from the juice of the fruit, and jellies and jams are made from it as well.

Common names and synonyms: Costa Rican guava.

Wild hyacinth – *see* **CAMAS**

Wild hyssop – *see* **BLUE VERVAIN**

WILD LEEK(S) (*see also* **ONION**) – Actually not a leek but rather a North American wild onion, the "wild leek" (*Allium tricoccum*) is one of about 500 members of the genus *Allium.* This plant – frequently called a ramp – resembles the leek, in that it has a long stalk and flat tapering leaves. But unlike the leek, which has a mild taste, the wild leek is noted for its strong, garlic-like flavor. Native Americans gathered ramps, and they are still eagerly sought out by many in springtime.

Common names and synonyms: Ramp.

WILD PEACH – The "wild peach" (*Landolphia kirkii*) is a member of the Apocynaceae family of mainly tropical trees, shrubs, and herbs. The fruit, highly esteemed by the Zulu people, grows on shrubs or woody climbers in southern Africa and matures between November and March. Rich in carbohydrates, it lends itself to the preparation of refreshing drinks and delicious jams.

WILD RICE – This tall, annual, grain-producing aquatic grass (*Zizania aquatica*) is actually not a rice at all. Rather, it is a native of the northern Great Lakes region of North America, where it grows in the shallow water of marshes and lakes and along riverbanks. It has been harvested by Native Americans from their canoes for millennia. They used the ripened, dark brown grains – now considered a delicacy – as a staple food. Recently, however, commercial producers have begun growing "wild rice" in paddies and employing mechanical harvesters – making the grain considerably less wild, although (so far at least) not less expensive.

Common names and synonyms: Indian rice, water oat(s).

Wild Roman chicory – *see* **PUNTARELLE**

WILD STRAWBERRY (*see also* **BERRIES, STRAWBERRIES**) – Wild strawberries (*Fragaria vesca* and numerous other species) have been an important food collected by humans since the days of the hunter-gatherers. One of these fruits is the "alpine strawberry" (*F. vesca* var. *monophylla*), which grows in the northern latitudes of Asia, Europe, and North America right up to the Arctic Circle. The *hautbois* (*F. moschata*), a native of central Europe, is another important wild strawberry, as were several American species (such as *F. vesca* var. *americana,* the "woodland strawberry"; and *F. chiloensis*) that provided vitamins A, B, C, and E for Native Americans. Today, wild strawberries are gathered mostly for making jams and jellies.

Common names and synonyms: Alpine strawberry, *hautbois,* woodland strawberry.

Wild tamarind – *see* **LEUCAENA**

WILD TRIGA – Also called "intermediate wheatgrass" when used as a forage crop, wild triga (*Agropyron intermedium* × *A. trichophorum* or *Elytrigia intermedia* ssp. *barbulata*) is an Old World perennial grain that can be cooked whole as a cereal or ground into flour for baking. It is a relative of wheat and may have been a staple crop in western Asia in ancient times. Today, wild triga is grown commercially in North America and elsewhere for hay and forage.

Common names and synonyms: Intermediate wheatgrass.

Wild water lemon – *see* **PASSION FRUIT**

WILD YAM (*see also* **YAMS**) – Also known as the "native potato," "devil's-bones," "rheumatism root," and "colicroot," the wild yam (*Dioscorea villosa*) grows throughout what is now the eastern and central United States. The rootstock was usually gathered in the fall and was one of the many foods that carried Native Americans through the winter. It is probably not the case (as has been suggested) that the plant's various common names, indicating pain, were occasioned by the backbreaking pain involved in digging up these slender tubers because the plant was also used medicinally.

Common names and synonyms: Colicroot, devil's-bones, native potato, rheumatism root.

See in addition: "Sweet Potatoes and Yams," Part II, Section B, Chapter 5.

Wild yam bean – *see* **AFRICAN YAM BEAN**

WILLOW – The majority of the 300 species of the genus *Salix* have practical uses and are planted for erosion control, windbreaking, or ornamental purposes, or are grown for their flexible branches, which can be woven into baskets and employed in light construction. But in the culinary realm, the leaves of the white willow (*S. alba*) are edible raw and are used as a tea substitute, whereas the inner bark and the young shoots of some Alaskan species are consumed raw or with seal oil by Eskimos. The leaves contain a fair measure of vitamin C.

Windberry – *see* **BILBERRY**

Windsor bean – *see* **FAVA BEAN**

Wineberry – *see* **JAPANESE WINEBERRY, TUTU BERRY**

WINE PALM – "Wine palm" refers to any of the various palm trees that yield sap or juice from which wine is made. Mostly, however, the name is intended to mean *Borassus flabellifer,* which has other common names such as "toddy palm," "lontar palm," and "palmyra." The wine palm also serves as a source of sugar in the drier portions of tropical areas where it grows best, especially in parts of India. In addition to providing sugar and toddy, the nuts of this palm contain a liquid that makes a refreshing drink, and the kernel of the fruit is eaten as a vegetable.

Common names and synonyms: Borassus palm, lontar palm, palmyra, toddy palm.

WINGED BEAN (*see also* **BEANS, LEGUMES**) – An annual herb, with names like "winged pea," "four-angled bean," "asparagus bean," "Goa bean," and "Manila bean" among its many aliases, the winged bean (*Psophocarpus tetragonolobus*) is a very close relative of the cowpea. It is usually said to have originated in tropical Asia – probably in India, although China may have been another center of origin. But some believe the winged bean to be an African plant because it grows wild in many parts of that continent. One explanation for this, however, is that it originally reached Africa from the East as a cultivated food crop but some plants managed a return to the wild.

The winged bean is now cultivated in all of the world's tropics, including those of South America and the Caribbean, which it presumably reached via the slave trade. The leaves, pods, seeds, shoots, and tubers of the plant are all edible and high in protein. The young and tender pods, which grow to a much greater length than string beans, are usually green, are eaten like string beans, and are known for their asparagus-like flavor as well as for their four longitudinal wings.

Once the seeds of the winged bean have reached maturity, they are either dried or eaten after roasting. In many places, the flowers of the winged bean are fried and yield a taste similar to that of mushrooms. Winged beans are very important in the cuisines of many peoples of Southeast Asia and southern China. The vegetable not only is a good source of protein but also provides some calcium, iron, and a fair amount of the vitamin-B complex. Today, in addition to the uses already mentioned, parts of the winged bean plant can be dried and used as a cereal and as feed for livestock, and the oily seeds make a cooking oil.

Common names and synonyms: Asparagus bean, asparagus pea, four-angled bean, Goa bean, long bean, long-podded cowpea, Manila bean, princess pea, snake bean, vegetable cowpea, winged pea.

See in addition: "Beans, Peas, and Lentils," Part II, Section C, Chapter 3.

WINTERBERRY – Like yaupon, the winterberry is a member of the holly family (genus *Ilex*). The leaves of this evergreen shrub are widely used for tea. Common winterberry is comprised of the species *I. verticillata* and *I. glabra.* The former is also called black alder, dogberry, and fever bush; the latter is called gallberry, bitter gallberry, inkberry, and Appalachian tea. In addition to the use of the leaves for tea, the flowers of *I. glabra* are a good source of nectar, which, after the bees finish their work, becomes honey.

Common names and synonyms: Appalachian tea, bitter gallberry, black alder, common winterberry, dogberry, fever bush, gallberry, inkberry.

Winter cherry – *see* **CAPE GOOSEBERRY**

Winter cress – *see* **YELLOW ROCKET**

WINTERGREEN – A native of eastern North America, wintergreen (*Gaultheria procumbens*) has aromatic leaves and spicy, edible, red berries. Oil of wintergreen is extracted from the leaves for flavoring a variety of foods, candies, chewing gum, and drugs. The berry is also called "checkerberry" and "teaberry" and it exudes the wintergreen aroma as well.

Common names and synonyms: Checkerberry, teaberry.

WITCH-HAZEL – This tall shrub (which can reach 25 feet in height) is a native of eastern North America. Historically, it has been known as the plant that provided witch-hazel extract to relieve the itching bites of insects, other skin irritations caused by plants, and even burns. But witch-hazel (*Hamamelis virginiana*) also has culinary uses. Its small, shiny, black seeds – contained in a seed capsule that bursts open – were reportedly eaten by Native Americans, who also used the leaves of the witch-hazel plant to make a tea.

Common names and synonyms: Snapping hazel, spotted alder, wych-hazel.

WONDERBERRY (*see also* **BERRIES**) – Also known as "garden huckleberry," "sunberry," "morella," and "black nightshade," the wonderberry (*Solanum nigrum*) is closely related to the poisonous nightshades. Nonetheless, the leaves of the plant – which is probably Eurasian in origin – are cooked and eaten in Asia and southern Europe. The fruits – ripe black berries – can be eaten raw but are more often used in pies and preserves. Wonderberries grow mostly wild (in Africa and the states of the U.S. South as well as Europe and Asia), although they have been cultivated on occasion.

Common names and synonyms: Black nightshade, garden huckleberry, morella, sunberry.

WONGAY – Also called the "wild prune," the wongay (*Pouteria sericea*) is an Australian fruit that grows wild and was one of many gathered foods of the Aboriginal population.

Common names and synonyms: Wild prune.

Wong bok – *see* **CHINESE CABBAGE**

Wood ear – *see* **CLOUD EAR, MUSHROOMS AND FUNGI**

Woodland strawberry – *see* **WILD STRAWBERRY**

WOODRUFF – Several plants of the genus *Asperula,* and especially *A. odorata* (= *Galium odoratum*), are called woodruff, *Waldmeister,* and sweet woodruff. Although a native of Eurasia, woodruff is naturalized in North America. It has small, white flowers with an aroma when dried that is used for flavoring May wine, other drinks, and in Europe a variety of foodstuffs as well.

Common names and synonyms: Sweet woodruff, *Waldmeister.*

WOOD SORREL – Any of the approximately 850 species of the genus *Oxalis* may be labeled "wood sorrel," although the term is technically limited to *O. acetosella* and *O. violacea.* A perennial herb found in Europe and North America, *O. acetosella* – also known as "European wood sorrel" or "Irish shamrock" – bears leaves that have been eaten as a vegetable. *Oxalis violacea,* also a perennial herb, and sometimes called "violet wood sorrel," is another American plant that was eaten by Native Americans.

Common names and synonyms: European wood sorrel, Irish shamrock, violet wood sorrel.

Wormseed – *see* **EPAZOTE**

WORMWOOD – There are a number of plants of the genus *Artemisia* called wormwood, especially *A. absinthium.* The latter is a native of Europe and is now naturalized in North America. Its leaves were employed in Europe in centuries past for flavoring sauces. The plant also yields a bitter extract used for flavoring vermouth. It was employed in making absinthe, which has been outlawed in many countries since World War I because the combination of wormwood's essential oil and alcohol was not only highly addictive but could and did produce hallucinations and convulsions that sometimes led to death.

X

XICALLI (*see also* **CALABASH**) – *Xicalli* is the Nahuatl name for a gourd of the tree *Crescentia cujete;* in Spanish, the gourd became *jicara* and the tree became *jicaro.* When the Spaniards first reached the New World, *xicalli* was used by the Aztecs to fashion vessels for drinking chocolate and bailing out canoes. Doubtless in the process of making such cups and pails, the seeds of the gourd were sometimes retained to be roasted, and perhaps even the pulp was consumed. It is probably the case, however, that these squashes were initially cultivated for the manufacture of liquid containers, and only later were the edible seeds and flesh exploited.

Common names and synonyms: Güiro, higüero, jicara, jicaro.

Xuxu – *see* **CHAYOTE**

Ya – *see* **COCOYAM**

Ya bené – *see* **COCOYAM**

YACÓN – Also called "leafcup," yacón (*Polymnia sonchifolia*) – like ajipa – is often confused with jícama and, in fact, is called jícama in parts of South America. The plant originated in the Andes, was domesticated long before the Europeans reached the New World, and today is cultivated from Venezuela to northeastern Argentina and in New Zealand and the United States as well. The plant's purple roots (which are orange colored on the inside) are sweet tasting and generally eaten raw, but only after several days of exposure to the sun, so that the peel shrivels.

Common names and synonyms: Leafcup.

YAM(S) (*see also* **AIR POTATO, BITTER YAM, BONIATO, CHINESE YAM, CUSH-CUSH YAM, LESSER YAM, WATER YAM, WHITE YAM, WILD YAM, YELLOW YAM**) – There are several species of yams (genus *Dioscorea*) grown in the world's tropical and subtropical regions, some of which are used solely for medicinal purposes. Among the most common edible species are the water yam or greater yam (*D. alata*), a native of Southeast Asia, and the yellow yam (*D.* × *cayenensis*) and white yam (*D. rotundata*), both of which are natives of Africa. In the New World, the major species is *D. trifida,* with common names such as Barbados yam, yampie, *ñame,* and cush-cush.

Yams evolved separately in Asia, Africa, and the Americas, and although they may have been cultivated as many as 10,000 years ago in Asia, for most who ate them they were a gathered food for many more years than that. Indeed, until relatively recently, the wild yam was a valued food for some Native American groups in North America. Yams are cultivated for their tubers, which are between 15 and 40 percent starch. These can reach upwards of 100 pounds in weight, and many average some 30 pounds, although most are about the size of the sweet potatoes they resemble.

Depending on the kind, flesh color can range from white to orange to orange-red to purple. Some Old World yams contain a poisonous alkaloid and must be carefully peeled and then boiled to be safe. In addition to use in stews and soups, yams are baked, fried, and boiled like potatoes. In Japan, yams are also battered and deep-fried.

See in addition: "Sweet Potatoes and Yams," Part II, Section B, Chapter 5.

Yam bean – *see* **AFRICAN YAM BEAN, AJIPA, JÍCAMA**

YAM DAISY – With daisy-like flowers aboveground and yam-like tubers below, it is not difficult to understand how the yam daisy (*Microseris lanceolata,* formerly *M. scapigera,* and also called *murnong*) got its name. The tubers constituted an important food of the southeastern Australian Aborigines, whose women dug up the roots with digging sticks, then roasted them in baskets in earth ovens. The appearance of the plant's flowers was the signal to the gatherers that the roots were fully developed. Other important flowering plants with roots that were dug and consumed by the Aborigines were the "bulbine lily" (*Bulbine bulbosa*), the "vanilla lily" (*Arthropodium milleflorum*), and the "milkmaid" (*Burchardia umbellata*).

Common names and synonyms: Bulbine lily, milkmaid, *murnong,* vanilla lily.

YARROW – Known as "milfoil" in Europe, yarrow (*Achillea millefolium*) is a pungent Eurasian herb now widely naturalized in North America. Its strongly flavored leaves enliven salads and soups; a tisane is also made from the plant, and it has been employed to flavor beer. Yarrow's genus is named for Achilles, who was said to have discovered its healing powers, and its medicinal uses have subsequently been myriad. A variety called western yarrow (*A. millefolium* var. *lanulosa*), which grows in the desert Southwest of North America, was much used by Native Americans.

Common names and synonyms: Milfoil.

YAUPON – Also known as cassina, the "Christmas tea-bush," and the "Carolina tea-tree," this holly (*Ilex vomitoria*) is found throughout the southeastern United States. The plant is a woody shrub that reaches 5 to 10 feet in height, with gray bark, dark green leaves, and yellow or orange berries. Native Americans made a ceremonial tea from the leaves by first toasting and then boiling them. This was the "black drink," the consumption of which might be followed by vomiting. The Muskogee (Creek) Indians as well as the related Seminoles of Florida were enthusiastic users, and indeed, the name of the Seminole war chief Osceola (1804?–38), which translates as "black water," was given to him because of his ritual position in the black-drink ceremony. Europeans who drank the black drink, however, experienced no emetic effect, and tests done in the twentieth century have established that yaupon is not an emetic. Thus, the vomiting seems to have been the result of a cultural practice. But yaupon *is* a natural source of caffeine, similar to *Ilex paraguariensis,* the yerba-maté tea of South America. The white residents of North Carolina's Outer Banks continued to drink yaupon until the twentieth century, as did residents of Charleston, South Carolina. The Europeans who first encountered the tea sent some of the leaves back to Europe, but this and subsequent efforts to establish yaupon tea as a commercial product have met with no success.

Common names and synonyms: Black drink, Carolina tea-tree, cassina, Christmas tea-bush.

Yautía – *see* **MALANGA**

YEHIB – Native to the arid regions near the Horn of Africa, this evergreen shrub (*Cordeauxia edulis*) is now an endangered species. It produces pods embracing a seed that weighs between 2 and 3 grams. Rich in starch and sugars, the pleasant-tasting nut is used by nomads in the region as a staple food.

YELLOW MOMBIN – A native of northern South America and Central America, the yellow mombin (*Spondias mombin*) is now grown throughout most lowlands of tropical America, although not with much enthusiasm, and it is not highly commercialized. The fruits are oblong, average about 10 inches in length, and vary greatly in taste, with some sweet but others harsh and unpleasant. They are consumed raw, made into preserves, and used as a flavoring.

Yellow nutsedge – *see* **CHUFA**

YELLOW ROCKET – Although considered a weed by some, this biennial herb (*Barbarea vulgaris*) has leaves that, when young, have occasionally been used in salads, whereas older leaves have been cooked as a vegetable. Native to Europe, the plant can now be found in North Africa, Asia, North America, New Zealand, and Australia. It is also known as "rocket," "upland cress," and "winter cress" and is rich in vitamins A and C.

Common names and synonyms: Rocket, upland cress, winter cress.

Yellowroot – *see* **GOLDTHREAD**

Yellow salsify – *see* **MOONFLOWER**

Yellow turnip – *see* **RUTABAGA**

YELLOW WILD-INDIGO – An herb with countless common names, ranging from "American indigo" to "rattlebush," yellow wild-indigo (*Baptisia tinctoria*) is found across eastern and central North America, its native territory. Its young shoots were cooked and eaten by Native Americans.

Common names and synonyms: American indigo, rattlebush.

YELLOW YAM (*see also* **YAMS**) – Also known as "Guinea yam" and "yellow Guinea yam," the yellow yam (*Dioscorea* × *cayenensis*) is a West African native that was carried to the West Indies via the early-sixteenth-century slave trade. It continues to be widely cultivated in West Africa, where it is perhaps the most important yam species. It is of much less importance in the Caribbean and is not grown in other tropical regions of the world. The yellow yam is one of those yams used to make the famous West African "foo-foo," and is also roasted, boiled, and fried.

Common names and synonyms: Guinea yam, twelve-months yam, yellow Guinea yam.

See in addition: "Sweet Potatoes and Yams," Part II, Section B, Chapter 5.

Yerba de conejo – *see* **QUELITES**

YERBA MATÉ – Also called maté and Paraguay(an) tea, yerba maté is a tea made from the dried leaves and young shoots of the evergreen tree *Ilex paraguariensis.* It is mildly stimulative and was being consumed throughout the day and evening by males in what is now Paraguay and Brazil long before the Spaniards and Portuguese ever arrived in the New World. Most likely, then as now, the natives were drinking the tea out of dried gourds – actually sucking it through a tube called a *bombilla* with a strainer attached.

Common names and synonyms: Maté, Paraguay(an) tea.

YERBA SANTA – Common along the Pacific coast from Oregon to California, yerba santa (*Eriodictyon californicum*) is an evergreen shrub with leaves that are covered with a fragrant resin. They have long been chewed to alleviate thirst and also are made into a tea.

Common names and synonyms: Bear's-weed, gum-plant, mountain balm.

YOUNGBERRY (*see also* **BERRIES**) – Developed by B. M. Young, a twentieth-century fruit grower, the youngberry (genus *Rubus*) is a hybrid between a blackberry and a dewberry. A juicy and very large berry, the youngberry is mostly cultivated and available in the western United States.

YUCCA – There are various members of the genus *Yucca* with white flowers that in the American Southwest are sometimes added to salads. *Yucca filamentosa* has been a perennial favorite of the region and was exploited by Native Americans, who boiled or roasted its flower stalks and buds and ate its plumlike fruits.

Common names and synonyms: Adam's-needle, spoonleaf yucca.

YUZU – A golden yellow citron, the yuzu (*Citrus medica*) is about the size of a small orange. It is a very sour Japanese fruit, which is cultivated for its aromatic rind. The Japanese carve the rind into traditional shapes and use it as a garnish. The yuzu can sometimes be found in Asian markets in the United States.

Z

Zahidi date – *see* **DATE**

ZAMIA – Of the cycad family (and looking something like palm trees except for their fern-like as well as palmlike leaves), these tropical American members of the genus *Zamia* (including *Z. integrifolia* in southeastern North America) have underground roots that Native Americans of the West Indies and southern North America pounded, grated, dried, ground, boiled, mashed, washed with plenty of water, and drained and dried (again) to obtain starch for making bread and porridges. These rigorous methods were necessary to render the vegetable safe; without such efforts, the roots are toxic – even deadly. The seeds from the cone-like fruits, as well as the zamia stems, are also toxic and must be cooked or otherwise processed before they become edible. Almost from the time they reached the island of Hispaniola, Columbus and his men began dining on zamia bread prepared by the Taino Indians.

Common names and synonyms: Coontie, cycad, Florida arrowroot, Florida sago, Seminole bread, starchy breadroot.

ZINFANDEL (*see also* **GRAPES**) – This red wine grape (*Vitis vinifera*) has been something of a surprise in California, where it was earlier employed to make "jug" wines. In the past two decades, however, it has been developed into one of the best of the red varietal grapes and is the most widely grown grape in the state. Although the Zinfandel is of obscure European origin, it has become known as "California's grape," in part because it has been grown in that state since the late nineteenth century, and Zinfandel wines have been a major American contribution to the world of wine. There are both red and white Zinfandels (actually, the "white zinfandel" is a "blush" wine, and one only recently made available), or "Zins," as they are popularly known.

See in addition: "Wine," Part III, Chapter 13.

ZUCCHINI (*see also* **SQUASH AND PUMPKIN**) – Although winter squashes do not enjoy the popularity they once did, the same is not true for summer squashes, and especially not for the versatile zucchini. An American summer squash, the zucchini (*Cucurbita pepo*) bears an Italian name that is the diminutive of *zucca,* meaning "gourd." As a rule, this vegetable has a smooth, shiny, green, very thin rind – reminiscent of that of its cousin, the cucumber. But the flesh is firmer. The zucchini also comes with a deep yellow skin – this is called a "golden zucchini" – and there is another variety called "Italian squash" or *cocozelle.* Zucchini goes well with tomato sauce and is worked into numerous main and side dishes. On its own it can be steamed, fried, boiled, broiled, simmered, stuffed, and eaten raw as an appetizer and in salads.

Common names and synonyms: Cocozelle, courgette, golden zucchini, Italian squash, vegetable marrow.

See in addition: "Squash," Part II, Section C, Chapter 8.

ZULU MILKBERRY – A southern African tree or shrub, *Manilkara concolor* varies in height from 9 to 23 feet and bears Zulu milkberries – egg-shaped fruits that range from yellow to bright red in color. Deliciously sweet, the fruits are good when eaten fresh but also are fermented to make alcoholic beverages. Zulu milkberries are highly prized and are frequently reserved for village chiefs.

Subject Index

About This Index

All plant and animal species appear under both their common name and their scientific (Latin) name. For example, the common pea is listed under *pea(s)* as well as *Pisum sativum.* The page citations given under the common names are for the major discussions of the food. Detailed subentries are found under the common name only and generally will not be duplicated under the scientific name.

The common name for any one species, such as *pea*, may also refer to many other species that are not *Pisum sativum.* In these cases the species most widely known by the common name is indicated by the subheading *common* before the Latin name. For example, under the main entry *pea(s)* are also such subheadings as *beach* (*Lathryus maritimus*), *blackeyed* (*Vigna* spp.), as well as the *common* (*Pisum sativum*).

In addition, the index subsumes entries under both individual countries and geographical regions. Thus, there are entries for Italy as well as for Europe, southern. Regions may also sometimes overlap, such as *Oceania*, *Pacific Islands*, and *Hawaiian Islands*. This is because of differences in the way the various essays discussed geographical regions and also because of changes in the names and boundaries of geographical regions over time.
