Depending on the severity of the poisoning, the affected person may have total or partial recovery. If the rescue effort comes too late, a patient may die of acute chemical or drug poisoning. For those affected by chronic exposure to environmental poisoning, recovery depends on the severity of the poisoning, the ability to stay away from the offending agent, and appropriate diagnosis and treatment. Total recovery can occur in many patients.

Prevention

Some strategies to avoid poisoning are:

- Avoid eating contaminated fish, especially that which comes from known contaminated areas or a lot of big fish, such as shark, swordfish, or tuna, which tend to contain higher amounts of mercury than smaller fish. Pregnant women should not consume more than 7 oz of tuna per week. Mercury can cause brain damage in the developing fetus.
- Do not paint or remodel a home while pregnant or when children are still small. Paint may contain chemicals that can harm a fetus and cause learning disabilities in small children.
- Limit use of chemicals inside the house as much as possible and instead use natural benign alternatives, such as baking soda (as cleaner, deodorizer), distilled white vinegar (as cleaner), essential oils (as fragrances), lemon juice (as cleaner), and liquid soaps (as detergents).
- Increase ventilation of the house.
- Consider installing tile or wood floors in new homes instead of new carpet.
- Have the house tested for radon.
- Eat organic foods. Otherwise, to better remove toxins, wash fruits and vegetables carefully before eating with a mild acid solution, such as diluted vinegar.

KEY TERMS

Antidote—A remedy to counteract a poison.

Cumulative—Increasing in effects or quantity by successive additions.

Detoxification—A structured program for removing stored toxins from the body.

Diazinon—A member of the organophosphate family of pesticides. This chemical causes nerve and reproductive damage.

Insecticides—Any substance used to kill insects.

Pesticides—Chemicals used to kill insects.

- Avoid toxic chemical exposure as much as possible if pregnant.
- Keep all medications, petroleum products, and cleaning products locked and away from small children. Install child-proof locks or gates to prevent children from finding poisons.
- Avoid mixing household cleaning products. Nontoxic chemicals when mixed together can release toxic gases or cause an explosion.
- Keep all chemicals in original containers, properly identified and stored away from foods.
- Only use chemicals in well-ventilated areas to avoid breathing in fumes. Use adequate skin, eye, and respiratory protection.
- Never put household chemicals in food or beverage containers.
- Avoid smoking or lighting a candle near household chemicals such as cleaning solutions, hair spray, paints or paint thinner, or pesticides.
- Dispose all hazardous chemicals properly according to the manufacturer's instructions.

Cherry bark

Description

Cherries are members of the botanical genus *Prunus*, which is a member of the *Rosaceae* (or rose) family. Cherries can be a shrub or a tree, and are believed to have originated in the Caucasus mountain region between Europe and Asia.

Cherries are divided into two broad groups: sweet (*Prunus avium*) and sour (*Prunus cerasus*). Varieties of the cherry are widely distributed throughout temperate regions of the world and have been cultivated for thousands of years. Roman historian Pliny reported that sour cherries were introduced to ancient Rome as part of a victory celebration after the defeat of the Parthians at a place called Cerasus.

From the simple division of sweet and sour cherries, classification of the various cherry types has grown increasingly complex through the years. Today, there are literally hundreds of varieties due to their long record of cultivation and crossbreeding.

Cherry trees have been used widely for their fruit, eaten fresh and used in cooking. Both the fermented fruit and the crushed pits are used in making the European liqueur, kirsch. The tree is also a source of wood used in making high-quality furniture. The stalks from some of these cherry varieties have been used medicinally as an astringent, however, it is widely accepted that the cherry tree bark used in herbal medicine comes from the wild cherry (listed now as *Prunus serotina*, but in nineteenth century herbal books is listed as *Prunus virginianus*).

The wild cherry is a native of North America. It is found in central and northern parts of the United States, as well as in cooler, nondesert parts of the Southwest. Wild cherry trees characteristically grow to a height of 50-80 ft (15.2-24.4 m), with a trunk width of 2-4 ft (0.6-1.2 m). The leaf of the wild cherry is oval, with a minutely serrated edge, and is more pointed toward the tip. Its leaves are approximately 3 in (7.6 cm) in length, dark green and shiny on top, and paler and fuzzy on the underside. Small, white, petaled flowers appear along the stems before the leaves in early spring. Pea-sized, purplish black fruits that are bitter develop and ripen by late summer.

The outer bark of the wild cherry tree is dark gray to black, very rough to the touch, and breaks away easily from the trunk. Even though the bark from the roots, trunk, and branches has medicinal properties, it is the root bark that is the most beneficial. Beneath a cherry root's dark outer covering, the interior is a dusky reddish color. It has an almond-like aroma that evaporates when dried, but re-emerges when the bark is crushed or dissolved. Its tastes astringent and bitter. Its chemical constituents include cyanogenic glycosides, starch, resin, tannin, gallic acid, fatty matter, lignin, red coloring material, as well as **calcium**, **potassium**, and **iron** salts.

Cherry bark. *(O.D. vande Veer / Alamy)*

General use

Wild cherry bark has a strong sedating effect on the **cough** reflex and is particularly useful to treat dry, nonproductive coughs in respiratory conditions. Because of its antispasmodic qualities, it has been used with other herbs to treat **asthma**. It is given for spasmodic cough to enhance **relaxation** and resting or at night to reduce cough and enhance sleep. Its astringent properties make it useful as a bitter, taken to stimulate sluggish digestion and the appetite. A cold infusion of wild cherry bark has been noted to soothe eye inflammation.

Preparations

Bark is collected in the autumn by carefully stripping away small sections. The outer wild cherry bark is then removed and the lighter colored, reddish interior cortex is dried, but not in direct sunlight. Once thoroughly dried, it must be stored in airtight containers away from light. Because it deteriorates so rapidly, it is more beneficial if used when still fresh and must be newly collected each year. The fragments of inner bark crush easily to make a powder. This powdered cherry bark can then be dissolved in either alcohol or water. A cough remedy is made by dissolving 4 oz (113 g) of the bark in 4 oz (120 ml) of water for several hours. The solution is then strained, and honey is added to sweeten to taste. Boiling cherry bark is not recommended since this decreases the medicinal properties. Cherry bark can also be used to make a tincture and lozenges.

Precautions

Coughing is a normal and helpful reaction to airway or lung irritation. It is designed to expel harmful substances (such as excess phlegm or irritants) from the lungs. Suppressing a cough, then, can actually prevent or postpone recovery. It is persistent coughing that needs treatment. It is also important for potential users to remember that a cough is merely a symptom of some other illness, as are digestive problems. Wild cherry bark preparations should not be taken for an extended period of time. They should only be used for temporary relief of symptoms. A doctor should be consulted for persistent cough or digestive problems.

KEY TERMS

Antispasmodic—An agent used to relieve muscle spasms.

Side effects

Wild cherry bark preparations can cause sedation, especially if recommended dosage is exceeded.

Interactions

None known.

Chickenpox

Definition

Chickenpox (varicella) is a common and extremely infectious childhood disease that also occasionally affects adults. It produces an itchy, blistery rash that typically lasts about a week and is sometimes accompanied by a **fever** or other symptoms.

Description

About four million Americans contract chickenpox each year, resulting in roughly 5,000-9,000 hospitalizations and 100 deaths. Chickenpox is caused by the varicella-zoster virus (a member of the herpes virus family), which is spread through the air or by direct contact with an infected person. Once someone has been infected with the virus, symptoms appear in about 10-21 days. The period during which infected people can spread the disease is believed to start one or two days before the rash appears until all the **blisters** have formed scabs, usually four to seven days after the rash breaks out. For this reason, doctors recommend keeping children with chickenpox away from school for about a week.

Child with chickenpox. *(© Janine Wiedel Photolibrary / Alamy)*

Chickenpox has been a typical part of growing up for most children in the industrialized world (although this may change because of the new varicella vaccine). The disease can strike at any age, but by ages nine or 10 about 80-90% of American children have already been infected. U.S. children living in rural areas and many foreign-born children are less likely to be immune. Because almost every case of chickenpox leads to lifelong protection, adults account for less than 5% of all cases in the United States. Study results reported by the Centers for Disease Control and Prevention (CDC) indicate that more than 90% of

American adults are immune to the chickenpox virus. Adults, however, are much more likely than children to suffer dangerous complications. More than half of all chickenpox deaths occur among adults.

Causes and symptoms

A case of chickenpox usually starts without warning or with only a mild fever and a slight feeling of unwellness. Within a few hours or days small red spots begin to appear on the scalp, neck, or upper half of the trunk. After a further 12-24 hours the spots typically become itchy, fluid-filled bumps called vesicles, which continue to appear for the next two to five days. In any area of skin, lesions of a variety of stages can be seen. These blisters can spread to cover much of the skin, and in some cases may also be found inside the mouth, nose, ears, vagina, or rectum. Some people develop only a few blisters, but in most cases the number reaches 250-500. The blisters soon begin to form scabs and fall off. Scarring usually does not occur unless the blisters have been scratched and become infected. Occasionally a minor and temporary darkening of the skin (called hyperpigmentation) is noticed around some of the blisters. The degree of itchiness can range from barely noticeable to extreme. Some chickenpox sufferers also have headaches, abdominal **pain**, or a fever. Full recovery usually takes five to 10 days after the first symptoms appear. The most severe cases of the disease tend to be found among older children and adults.

Some groups are at risk for developing complications, the most common of which are bacterial **infections** of the blisters, **pneumonia**, dehydration, encephalitis, and **hepatitis**. Immediate medical help should always be sought when anyone in these high-risk groups contracts the disease. These include:

- Infants. Complications occur much more often among children less than one year old than among older children. The threat is greatest to newborns, who are more at risk of death from chickenpox than any other group. Children born to mothers who contract chickenpox just prior to delivery face an increased possibility of dangerous consequences, including brain damage and death. If the infection occurs during early pregnancy, there is a small (less than 5%) risk of birth defects.
- Immunocompromised children. Children whose immune systems have been weakened by a genetic disorder, disease, or medical treatment usually experience the most severe symptoms of any group. They have the second-highest rate of death from chickenpox.
- Adults and children 15 and older. The typical symptoms of chickenpox tend to strike this group with greater force.

KEY TERMS

Dehydration—Excessive water loss by the body.

Immune system—A biochemical complex that protects the body against pathogenic organisms and other foreign bodies.

Immunocompromised—Having a damaged immune system.

Pus—A thick yellowish or greenish fluid containing inflammatory cells. Usually caused by bacterial infection.

Reye's syndrome—A rare but often fatal disease that involves the brain, liver, and kidneys.

Shingles—A disease (also called herpes zoster) that causes a rash and a very painful nerve inflammation.

Varicella-zoster immune globulin (VZIG)—A substance that can reduce the severity of chickenpox symptoms.

Varicella-zoster virus—The virus that causes chicken pox and shingles.

Varivax—A vaccine for the prevention of chicken pox.

Virus—A tiny particle that can cause infections by duplicating itself inside a cell using the cell's own machinery.

Diagnosis

Where children are concerned, especially those with recent exposure to the disease, diagnosis can usually be made at home, by a school nurse, or by a doctor over the telephone if the child's parent or caregiver is unsure that the disease is chickenpox. A doctor should be called immediately if:

- The child's fever goes above 102°F (38.9°C) or takes more than four days to disappear.
- The child's blisters appear infected. Signs of infection include pus drainage or excessive redness, warmth, tenderness, or swelling.
- The child seems nervous, confused, unresponsive, or unusually sleepy; complains of a stiff neck or severe headache; shows signs of poor balance or has trouble walking; finds bright lights hard to look at; is having breathing problems or is coughing a lot; is

complaining of chest pain; is vomiting repeatedly; or is having convulsions. These may be signs of Reye's syndrome or encephalitis, two rare but potentially very dangerous conditions.

Treatment

Treatment focuses on reducing symptoms of chickenpox. The patient should drink plenty of fluids and eat simple, nutritious foods. Soups (especially mung bean), herbal teas, and fruit juices are good choices.

Applying wet compresses or bathing the patient in cool or lukewarm water once a day can help the itch. Adding four to eight ounces of baking soda or one or two cups of oatmeal to the bath is helpful. Only mild soap should be used and patting, not rubbing, is recommended for drying the patient. The patient should not scratch the blisters as this can lead to infection or scarring. For babies, light mittens or socks on the hands can help guard against scratching. If mouth blisters are present, cold drinks and soft, bland foods can make eating less painful.

Supplements

Vitamin A may help to heal skin. **Vitamin C** and bioflavinoids help to reduce fever and stimulate the immune system. **Zinc** also stimulates the immune system and promotes healing, however, it can cause **nausea** and **vomiting**. **Calcium** and **magnesium** help to relieve restlessness and sleeping difficulties. Magnesium has a laxative effect at high doses.

Herbals and Chinese medicine

The following herbals are ingested to treat chickenpox:

- Echinacea and goldenseal (*Hydrastis canadensis*) support the immune system and soothe skin and mucous membranes. Echinacea is also an antiviral.
- Chamomile tea is a sleep aid.
- Chinese cucumber (*Trichosanthes kirilowii*) root tea is used to relieve symptoms of chickenpox.
- Elder flower, peppermint, and yarrow reduce fever.
- Garlic has antiviral activity.
- Mullein (*Verbascum thapsus*) treats chickenpox.
- Yin Qiao Jie Du Wan (Honeysuckle and Forsythia Pill).
- Ban Lan Gen Chong Ji (Isatis Infusion).

The following herbals are used externally to treat chickenpox:

- Aloe leaf, calendula, and plantain relieve the itching of the chickenpox rash.
- Turmeric powder mixed with lime juice treats chickenpox rash.
- Garlic clears skin infection.

Other remedies

Homeopathic remedies are selected on a case by case basis. Some common remedy choices are **apis**, aconitum, **belladonna**, **calendula**, antimonium tartaricum, pulsatilla, *Rhus toxicodendron*, and sulphur.

The **acupressure** points Four Gates, Large Intestine 11, Spleen 10, and Stomach 36 help alleviate symptoms associated with chickenpox.

Allopathic treatment

Treatment usually focuses on reducing discomfort and fever. Because chickenpox is a viral disease, antibiotics are ineffective. Antibiotics may be prescribed if the blisters become infected. Calamine lotion helps to reduce itchiness. Painful genital blisters can be treated with an anesthetic cream recommended by a doctor or pharmacist.

Fever and discomfort can be reduced by acetaminophen (Tylenol) or other medications that do not contain aspirin. *Aspirin (or any aspirin- containing medications) must not be used with chickenpox, because it increases the chances of developing Reye's syndrome*. The best idea is to consult a doctor or pharmacist if one is unsure about which medications are safe.

Immunocompromised chickenpox sufferers are sometimes given the antiviral drug acyclovir (Zovirax). Zovirax also lessens the symptoms of chickenpox in otherwise healthy children and adults.

Expected results

Most cases of chickenpox run their course within a week. The varicella-zoster virus lies dormant in the nerve cells, where it may be reactivated years later by disease or age-related weakening of the immune system. The result is **shingles** (herpes zoster), a very painful rash and nerve inflammation, that strikes about 20% of the population, particularly people 50 and older.

Prevention

A substance known as varicella-zoster immune globulin (VZIG), which reduces the severity of chickenpox symptoms, is available to treat persons at high risk of developing complications. It is administered by

injection within 96 hours of known or suspected exposure to the disease.

A vaccine for chickenpox (Varivax) has been found to prevent the disease in 70-90% of the vaccinated population, to reduce the severity of disease in the remaining cases. CDC and the American Academy of Pediatricians recommend vaccination of all children (with some exceptions) at 12-18 months of age. For older children, up to age 12, the CDC recommends vaccination when immunity cannot be confirmed. Vaccination is also recommended for any older child or adult considered susceptible to the disease, particularly those who face a greater likelihood of severe illness or transmitting infection. A single dose of the vaccine is sufficient for children up to age 12; older children and adults receive a second dose four to eight weeks later.

Chickweed

Description

Chickweed (*Stellaria media*) is a member of the Caryophyllaceae, or carnation, family. There are about 25 species of *Stellaria*, including some native varieties, growing abundantly in the wild in North America. Chickweed is a European native that has naturalized throughout the world in fertile, mineral-rich soil. It thrives in shady, moist locations in gardens, near human habitations, and on the edge of woods. The herb is often found growing under the shade of **oak** trees. Chickweed is a persistent annual. It self-seeds and may produce as many as five generations within one season.

The genus name *Stellaria* refers to chickweed's tiny, white, star-shaped flowers. The common name refers to the herb's appeal to birds and barnyard fowl, particularly young chickens. Other common names include Indian chickweed, stitchwort, starwort, white bird's eye, chick wittles, satin flower, adder's mouth, mouse ear, starweed, passerina, tongue grass, and winter weed. Chickweed has been used for centuries. The nutritious herb was fed to caged birds and rabbits. It was also traditionally prepared as an early spring tonic, eaten fresh or steamed, to cleanse the kidneys and liver. English physician Nicholas Culpeper described chickweed as "a fine soft pleasing herb under the dominion of the Moon."

Chickweed is a juicy, succulent, low-growing, and delicate herb which grows from a slender taproot. The straggly, weak stems may stretch along the ground for two feet or more forming dense mats only a few inches off the ground. The light-green, oval, and entire leaves grow in opposite pairs about an inch apart along the smooth and branching stem. A single line of fine white hairs grow along one side or the other of the thin stems, alternating at the node of each pair of leaves. Stems are slightly swollen at the joints. Leaves appear stalkless at the growing tip but the older leaves develop stalks at least as long as the attached leaf. At night the half-inch long leaves close in on each other to protect the developing buds. The tiny white flowers grow singly in the leaf axils of the upper leaves. The five petals are deeply incised, and smaller than the pointed green sepals. Blossoms open in the sun and close on cloudy, gray days and throughout the night hours. Minuscule seed capsules, with a barely-perceptible toothed edge, follow the blossoms. In damp weather the "teeth" swell, effectively closing the capsule to protect the ripening seed. The tiny yellow-orange seeds continue to ripen even after the herb is harvested. Chickweed self-seeds freely in cool, moist habitats.

General use

The entire chickweed plant is edible. The stems and leaves are used in medicinal preparations. Herbalists, however, disagree about the medicinal potency of chickweed. One writer, a professor of pharmacognosy, dismissed chickweed as a "worthless weed" and an "ineffective herb." Other writers and herbalists praise the diminutive herb for providing "optimum nutrition" and for its "unsurpassed" ability to cool fevers and **infections**. The English physician Nicholas Culpeper, writing in the seventeenth century, credited chickweed as beneficial for "all pains in the body that arise of heat." Taken as an infusion, chickweed acts internally to cool inflammation of the digestive and respiratory system. It has been used to treat **bronchitis**, **pleurisy**, **colitis**, **gastritis**, **asthma**, and **sore throat**. The herb's diuretic action helps eliminate toxins from the system and reduce retention of fluids. Chickweed contains mucilage, saponins, **silica**, coumarins, flavonoids (including glycoside rutin), triterpenoids, and carboxylic acids. The herb is rich in minerals, including **copper** and **iron**, and vitamins A, B, and C.

Gathered fresh, chickweed is beneficial in poultice form to ease rheumatic **pain** and to treat **boils** and abscesses. The herb can also be used to draw out splinters and the stingers of insects and to dissolve **warts**. Its vulnerary (wound-healing) action speeds the healing of **cuts** and **wounds**. Its emollient qualities soothe **itching** and irritation of **eczema** or **psoriasis**. An infusion of chickweed may be added to bath water for soothing relief of inflamed skin. Chickweed also provides relief to swollen and painful **hemorrhoids**.

Another species of chickweed, *S. dichotoma*, known as *yin chai hu* is used in Chinese medicine to stop nosebleed, to reduce heavy menstrual bleeding, and to bring down fevers. The species *S. alsine* is also used in Chinese medicine as a medicinal remedy for treating colds, snakebites, and even traumatic injury.

Preparations

Gather chickweed from young plants before or during flowering and throughout the year. Snipping the stems will encourage growth of new branches for later harvest. The freshly harvested herb will keep for several days if refrigerated. The fresh herb may be eaten in salads, or very lightly steamed as a potherb. Chickweed has a somewhat bland taste, so other edible greens may be added to the pot to enhance the flavor.

- Infusion: Place 2 oz of fresh chickweed leaves and stems in a warmed glass container. Bring 2.5 cups of fresh, nonchlorinated water to the boiling point and add it to the herbs. Cover and infuse the tea for about 10 minutes. Strain and drink warm. The prepared tea will store for about two days in a sealed container in the refrigerator. Chickweed tea may be enjoyed by the cupful up to three times a day. A strong infusion may be used as a skin wash or bath additive to soothe itching and inflamed skin.
- Poultice: Chop fresh chickweed leaves and stems in sufficient quantity to cover the area being treated. Sprinkle the herb with water and place over the area. Cover the herbal mass with a strip of wet cotton gauze to hold the poultice in place. When gathering the older, tougher plant, the herb may be simmered either in water alone or in a 50/50 mixture of water and vinegar for about five minutes. Apply to the skin after the mixture has sufficiently cooled.
- Tincture: Combine four ounces of finely-cut fresh or powdered dry herb with one pint of brandy, gin, or vodka, in a glass container. The alcohol should be enough to cover the plant parts. Place the mixture away from light for about two weeks, shaking several times each day. Strain and store in a tightly-capped, dark glass bottle. A standard dose is 1–4 ml of the tincture three times a day.

KEY TERMS

Diuretic—A substance which tends to increase the flow of urine.

Pleurisy—Inflammation of the pleura (lining of the chest cavity) usually caused by a lung infection.

Precautions

The wind-blown pollen of chickweed may aggravate **hay fever**. Chickweed is considered safe for all external applications. There was a report in 1980 of "temporary paralysis" after ingestion of large amounts of the infused herb, however there are no other documented reports of toxicity. The *PDR For Herbal Medicines* reports no health hazards when this herb is taken "with the proper administration of designated therapeutic dosages."

Side effects

None reported.

Interactions

None reported.

Chicory

Description

Chicory (*Cichorium intybus*) is an herb and root that has been known for its curative benefits since the first century A.D.. It is a member of the Asteraceae family. A scraggly plant with blue flower heads, chicory flourishes in the wild, as well as in gardens all over the world. It may be found in Europe, the Near East, northern and southern Africa, Australia, New Zealand, and North and South America.

The dried leaves and roots of the chicory plant are collected in autumn for medicinal purposes. When flowering, the whole plant is collected and dried. With a height that may reach up to 5 ft (1.5 m), chicory can be recognized by its oblong leaves that resemble a crosscut saw or slit, with numerous stiff hairs on the underside. Chicory, whose common names include succory, chicory root, chicory herb, blue sailors, wild chicory, or hendibeh, is well known for its bitter taste and use as a coffee substitute.

General use

The ancient Egyptians ate large amounts of chicory because it was believed that the plant could purify the blood and liver, while others have relied on the herb for its power to cure "passions of the heart." Chicory continues to be a popular herbal remedy due to its healing effects on several ailments.

KEY TERMS

Biodegradable—Capable of being broken down by the actions of living organisms. Inulin from chicory roots can be used to produce biodegradable substances used in industry.

Diuretic—A medicine or agent that increases the body's output of urine.

Infusion—A liquid extract of an herb or other plant prepared by steeping or soaking the plant material in water. Chicory can be taken at home as an infusion.

Inulin—A starchlike complex sugar obtained from chicory roots that is used to improve the texture of processed foods.

Prebiotic—A type of nondigestible substance found in chicory and some other plants that supports the growth and activity of beneficial bacteria in the colon.

Premenstrual syndrome (PMS)—A group of symptoms that occur several days prior to the beginning of menstruation, including irritability, emotional tension, anxiety, and mood changes such as depression, headache, breast tenderness with or without swelling, and water retention. Symptoms usually subside shortly after the onset of the flow.

Sedative—A drug or agent that calms or soothes. Chicory by itself has a sedative effect on the body.

Chicory is taken internally for the following disorders.

- jaundice
- spleen problems
- gallstones
- rheumatism
- gout
- loss of appetite

In addition, the leaves of chicory may also be used as compresses to be applied externally to ease skin inflammations and swellings.

According to folklore, chicory was recommended as a laxative for children, and it is also believed to increase the flow of bile. As a mild diuretic, it increases the elimination of fluid from the body, leading to its use as a treatment for rheumatism and **gout**.

Women who suffer from **premenstrual syndrome** (PMS) may find that regular use of chicory root as a bitter and a liver tonic may assist in maintaining

hormone balance and lessening the symptoms of PMS. In addition, altering the diet by eating a "bitter" salad that includes fresh **dandelion**, chicory, and sorrel is believed to strengthen the liver and discourage the growth of candida.

Chicory also supports the body's ability to absorb **calcium**, a nutrient that helps build and maintain strong teeth and bones. Raftilin inulin and raftilose oligofructose are fibers extracted from chicory root that cannot be digested by the small intestine. Instead, they are fermented by bacteria in the large intestine, leading to the increased absorption of calcium and other minerals. Oligofructose is an example of a prebiotic, or nondigestible food ingredient that benefits health by supporting the growth of one or several types of bacteria in the colon.

A study published in 2002 indicates that inulin appears to lower the risk of colon **cancer**. The precise nature of its protective effects is not yet known, however.

In addition to enhancing digestive processes, chicory helps to keep the liver healthy. The inclusion of chicory root supplements in the diet supports the proper metabolism of **cholesterol**.

Preparations

While the medicinal uses of chicory are numerous, the plant is also often used as a food additive, as a flavoring agent, and in meals. Inulin can be used to improve the texture of processed foods as well as sweeten them. It can also be used to make biodegradable nonfood substances with many industrial applications. This versatility is important to environmentalists because chicory is a renewable natural resource.

Wild and cultivated chicory leaves may be added to salads or sautéed and served alone. Moreover, the roasted and ground root of the plant is a common addition to coffee in Europe and in the United States.

Studies have shown that chicory complements coffee when it is used as a supplement due to its lactucin and lactucopicrin. These two substances are responsible for the bitter taste of chicory, and may serve to counteract the stimulating effects of **caffeine**. Chicory by itself actually has a sedative action on the central nervous system.

Chicory is available over the counter in bulk as green leaves and dried roots. To prepare the herb as a tea, also known as an infusion, for home use: steep 1 tsp (5 ml) rootstock or dried herb with 0.5 cup (4 fl oz) water and strain after 10 minutes. To treat **jaundice**, spleen problems, **gallstones**, or **gastritis**, drink 8-12 oz (225-350 ml) of chicory tea per day.

As a dietary supplement, 1 tsp (5 ml) of juice from chicory stems may be squeezed by hand and taken in milk or water three times a day.

Precautions

Chicory has shown to be safe for a variety of medicinal uses and as a food source. There are no necessary precautions to observe when including the herb in the diet.

Side effects

There are no known health hazards or side effects when chicory is added to the diet. The only possible minor side effect is skin irritation. If the hands become irritated after handling chicory, it is best to cover them with gloves and treat the affected area as needed.

Childbirth

Definition

Childbirth, or parturition, is the process of labor that dilates the cervix and includes the delivery of the baby and placenta through the birth canal.

Description

Most babies are born following approximately nine calendar months of **pregnancy**. Delivery between 37–42 weeks of gestation is considered normal and full-term. A baby born prior to 37 weeks of gestation is considered premature, or preterm. After 42 weeks, a baby is considered postterm. Both preterm and postterm deliveries are considered higher risk deliveries.

Labor occurs in three stages. The first is the dilation of the cervix, the second is the delivery of the baby, and the third is the expulsion of the placenta. Approximately 25 percent of babies born in the United States, however, are surgically delivered by Caesarean section. This procedure can be necessary and even life-saving, but many medical experts believe that Caesarean sections are performed too frequently and could be reduced through better management of labor and a more informed public.

At one time, "once a Caesarean, always a Caesarean" meant a woman could not deliver vaginally after having a Caesarean, but as of 2008 that is no longer true for everyone. Part of the reason is that the Caesarean surgery is performed differently, and women can heal from it sufficiently to have a subsequent birth vaginally. In fact, more and more women choose vaginal birth after Caesarean (VBAC). Having a sympathetic, informed caregiver and preparation helps achieve this goal for some women.

The first stage of labor is the time the cervix must reach full dilation. It includes latent (early), active, and transition phases. The latent phase of labor, when the cervix progresses from being closed to 3 cm open, may last for days or longer. For some women, latent labor is not a distinguishable phase, and for others it leads immediately into active labor. The latent phase is often exciting for the mother, who wonders if her baby is finally going to be born. Contractions during this phase are not very painful. Active labor ensues around the time the cervix reaches 3 cm dilation and continues until approximately 7 cm dilation. At this stage, labor contractions are powerful and require the mother's concentration. The length of this stage is also variable and is usually longer for first-time mothers than for those having subsequent babies. Active labor is followed by transition, the shortest and most intense stage of labor, when many women express feelings of despair or not being able to continue. At the end of transition, the cervix is fully dilated to 10 cm and pushing can begin.

The second stage of labor is pushing the baby out through the vagina (birth canal). Contractions are generally less frequent than in the first stage of labor but are very strong and long lasting. Many women find it a relief to be able to push. In the unmedicated mother, pushing is reflexive and instinctual. The pressure of the baby's head on stretch receptors in the maternal pelvis triggers the urge to push. First-time mothers generally push for about 60 minutes; subsequent births require an average of only 15 minutes.

The third stage of labor is the delivery of the placenta, which often goes unnoticed by the mother who is attending to her newborn. After the baby is delivered, the uterus should continue to contract in order to push out the placenta. The placenta functioned to bring the baby nourishment from the mother throughout the pregnancy and return the child's waste products to the mother to be excreted. If contractions become sluggish or stop before the placenta is delivered, breastfeeding the baby can trigger the release of the hormone oxytocin to stimulate the uterus to contract again. Alternatively, artificial oxytocin (pitocin) can be given by injection.

Causes and symptoms

The onset of spontaneous labor may be marked by irregular contractions, not very different from the Braxton-Hicks contractions that are common throughout late pregnancy. In approximately 10 percent of spontaneous labors, rupture of membranes ("water breaking") may occur before the onset of contractions. Since prolonged rupture of membranes prior to delivery presents a risk of infection, the care provider for the mother should be contacted regardless of whether she is experiencing contractions.

Even experienced mothers sometimes have difficulty recognizing when labor begins, as prelabor may occur on and off for days or longer before settling into a regular pattern. In general, the contractions associated with labor will gradually become more frequent, more regular, longer, and stronger. Walking or changing activity will not alter them. These contractions are effective at changing the cervix, which will become appreciably lower, thinner, and more dilated. By contrast, contractions of prelabor stay about the same intensity and frequency. A change of activity will often make them disappear. These contractions may

be uncomfortable and may even cause some mild cervical changes, but they do not change on an hourly basis.

Diagnosis

For women who choose to deliver in a hospital, a diagnosis of active labor is generally made if contractions are regular and strong, and the cervix is effacing and/or dilating noticeably on an hourly basis. A woman who arrives at the hospital reporting regular contractions who has no complicating factors is generally observed for at least an hour to see whether her labor will progress. Monitors that fit around the abdomen measure the fetal heart rate and the nature of the contractions. A nurse checks the position and station of the baby, as well as the effacement, dilation, and position of the mother's cervix. Admission is generally made regardless of progress if the water has broken (rupture of membranes) or if complications exist. These may include high maternal blood pressure, more than one fetus, fetal distress, abnormal fetal presentation, or excessive bleeding. Women delivering before 37 weeks or after 42 weeks of gestation are also well-advised to deliver in a hospital.

Treatment

For a routine, uncomplicated labor and delivery, the primary treatment required is assistance with comfort measures. What each mother finds comforting is individual. At some point during the pregnancy, it is a good idea to make a list of methods to try to relieve **pain** during labor, in the event that one or two favored techniques do not work: A mother who generally enjoys massage may suddenly discover that it is distracting to be touched during active labor, or a woman who plans to rely on medication could have an epidural that does not take or be laboring too quickly for it to be allowed. Having a list of comfort measures on hand is useful and reassuring for most laboring women. Reassurance is important, as relieving **stress** during labor allows it to progress more quickly and with less pain. Many women find it helpful to employ an experienced doula, or birth assistant, to provide comfort, reassurance, and information.

Fear of the unknown can certainly contribute to increased pain. Expectant parents should learn all they can about the process of childbirth. Many good reference books are available. Taking Lamaze classes lends a personal touch, and many couples enjoy the camaraderie of sharing the learning experience with other expectant families. Even though labor can take unexpected turns, being aware of the options at each stage lends some perception of control. Making a list of birth preferences can be helpful in defining what the parents desire at the birth, but flexibility is important to avoid disappointment if every expectation is not met.

Acupuncture

A skilled acupuncturist may be able to offer some relief of labor pain, particularly for women who have previously found **acupuncture** to be helpful with other types of pain.

Massage therapy

Some women find massage or **therapeutic touch** to be quite relaxing during labor. Contractions are sometimes felt intensely in the back, and a combination of massage and counterpressure can offer relief. Foot massage may also be comforting, both during pregnancy and during labor. Laboring women report a great temptation to tense the abdomen against a contraction. The contraction will be more effective and less painful with effleurage (light stroking) of the area, and a verbal reminder to let the abdomen hang heavy and relax. The jaw area is also frequently clenched and benefits from **relaxation**. Gentle touch and massage of any area that appears tense will help to relieve stress. This is a good technique to practice before labor begins.

Music

The sounds of a favorite piece of music can be an excellent aid to relaxation. Instrumentals are generally preferable to singing. Soothing sounds or tunes that evoke happy memories are helpful. Some women enjoy tapes of nature sounds.

Hydrotherapy

A warm tub or shower may be one of the most underestimated methods of relieving the pain of labor. Warmth encourages muscle relaxation, which in turn decreases **anxiety**. The water in a tub also supports the mother's body. In a jetted tub, position and water pressure can be adjusted to soothe areas that are cramping or painful. This may be particularly comforting for back labor. In a birthing pool or large tub, the mother is free to move around and find a position that optimizes her comfort. The relaxation brought on by water can make for a shorter, more comfortable labor.

Aromatherapy

Some **essential oils** are particularly recommended during birth for those women who enjoy the scents. They can be added to a diffuser or a crock-pot of water in the birthing area, emitted from a scented candle, or concentrated drops of the scent can be placed on the pillow and bed linens. Clary **sage** and **lavender** are popular choices, but any scent that is pleasant to the mother may be used.

Visualization

The use of visualization, or **guided imagery**, can be powerful to promote relaxation and the progress of labor. One exercise that can be practiced in advance of labor is choosing a place or image that the mother associates with comfort, security, and serenity. This place can be imagined and explored at any time to help relieve stress. If the details of this visualization are shared with someone who will be present during labor, that person can help to evoke those feelings during times of pain or stress. Another popular visualization is that of a flower blooming. The cervix can be envisioned as a flower bud that gradually opens to allow the baby to descend. Other scripts for guided imagery can be practiced to relieve stress and reduce pain.

Increasingly, women (not in high-risk pregnancies) desire a more low-tech approach to labor and choose a nurse midwife to assist them rather than a physician. For thousands of years, midwives have given women support and care through the birthing process. In 2004, a nurse-midwife rather than a physician attended about 8 percent of births, which is approximately twice the number in 1989. Nurse-midwives are committed to helping meet mothers' individual needs and to give them freedom of choice during birth. They work to provide a natural childbirth and to help the woman prevent complications before, during, and after the birth. Those wishing to use midwives should check with the obstetrician and also determine if the midwife is certified (CNM). More and more obstetrician practices also employ or work with nurse-midwives.

Allopathic treatment

Modern pain relief for childbirth generally involves the use of medication. Although medication has evolved from the days of mothers being put under so-called twilight sleep for a normal vaginal birth, the use of chemical pain relief is not without risk.

One of the most common pain relief methods during labor is the epidural. This technique involves the injection of anesthetic medication through a catheter into the epidural space in the back. Epidurals often provide excellent relief of pain from contractions, episiotomy, and perineal repair. They do not impair the mother's mental alertness, although she may sleep if labor to that point has been long and arduous. The disadvantages of epidurals include possible prolonging of labor, impaired ability to push, inability to move around, possible need for bladder catheterization and accompanying risk of infection or injury, maternal low blood pressure, maternal **fever**, spinal **headache** from inadvertent injection into the subdural space, and patchy or ineffective blocks. Low blood pressure can result in **nausea** and **dizziness**, as well as fetal distress. Supplemental oxygen may be given to the mother to alleviate this effect. Allergic reactions to the anesthetic agents occur rarely. The woman who wishes to have an epidural needs to have IV access, IV fluids in advance to help prevent low blood pressure, and fetal monitoring. The woman's inability to move around and change positions because of the tubes and wires can impede the progress of labor. If labor slows, it may be augmented by the injection of pitocin. Assisted delivery via forceps or vacuum extractor may be necessary if the mother finds herself unable to push effectively.

Injectable narcotic pain medications are also available. They can be given by either intramuscular (IM) or intravenous (IV) routes. When given intravenously, the effects are felt sooner and are shorter in duration. These medications are more likely to affect the fetus and are generally not given late in labor. Some women say that their pain is not greatly diminished but that they are better able to rest between contractions. Others experience side effects, such as nausea, **vomiting**, and dizziness that they feel negate any benefit that they get from the medication.

Prevention

Techniques that are used to prevent pregnancy are known as contraception. Some methods require a prescription, including those involving hormones, diaphragms, cervical caps, or intrauterine devices (IUDs). Hormonal birth control is available as a daily pill, an injection, a patch, a vaginal ring, or an implant. Consultation with a healthcare professional will determine the appropriateness of these methods. Conditions including clotting diseases, **breast cancer**, and liver disease will preclude hormonal forms of birth control. Significant side effects may occur even in women who are good candidates for these methods. Timing of taking the daily birth control pills is important, and

KEY TERMS

Braxton-Hicks—Mild, painless contractions of prelabor.

Episiotomy—Incision into the perineum to allow for easier passage of the baby.

Gestation—Time of development in the uterus.

Parturition—Childbirth.

back-up methods should be available if doses are missed. Diaphragms and caps are barriers used next to the cervix along with a spermicide. For diaphragms and caps, the typical pregnancy rate lies between 20 and 40 percent, according to the U.S. Food and Drug Administration (FDA). If these two methods are always used correctly, the pregnancy rates fall to 6 to 26 percent. The IUD is a uniquely long-term device. It is placed by a medical professional and, depending on the type, can retain effectiveness for as long as 10 years. It is not recommended for women who have ever had **pelvic inflammatory disease** or for those who are not in a mutually monogamous relationship. The pregnancy rate for IUD users is from 0.6 to 2 percent, according to the FDA.

Several popular forms of birth control are nonprescriptive. Barrier method materials, such as condoms, foam, and spermicides are available over the counter. Condoms have the distinction of being the only type designed for males. Used correctly, they are highly effective in preventing pregnancy. They have no side effects, and latex varieties have the additional advantage of providing some protection against sexually transmitted diseases. Average pregnancy rates are around 14 percent for typical users, but fall to 3 percent when they are always used correctly, according to the FDA.

Periodic abstinence, sometimes called natural family planning, requires training and attentiveness to physical signs. A variety of methods are available and may include monitoring of cycle days, basal body temperature, cervical mucus characteristics, and other symptoms related to the timing of ovulation. Effectiveness can be as great as 99 percent, according to the FDA, but it requires significant commitment for the couple to faithfully monitor signs and abstain from intercourse for at least one week of every cycle. Women with irregular cycles or unreliable signs have the most unplanned pregnancies with these methods.

Childhood nutrition

Definition

Childhood **nutrition** involves making sure that children eat healthy foods to help them grow and develop normally, as well as to prevent **obesity** and future disease.

The traditional or mainstream approach to good childhood nutrition is to follow suggestions based on dietary guidelines that are appropriate for a child's age and development level and that have been developed and recommended by government, research, and medical professionals. The guidelines include selections from different food groups to provide the vitamins and minerals young bodies need for natural growth and activity. The U.S. Department of Agriculture's (USDA's) Food Guide Pyramid recommends how many servings a day a child should eat of each food group, such as milk, vegetables, fruits, fats, and meats. The Food Guide Pyramid asserts that by sticking closely to the guidelines, parents can ensure their children get a well-balanced diet that supplies the vitamins, minerals and calories they need to support growing bodies and active lifestyles. However, in this age of what has been called "advanced medicine," there are those who seek to understand why so many among us, especially children, suffer from so much serious illness.

Minimum nutrient and calorie levels for school lunches

(school week averages)

	Preschool	Grades K–6	Grades 7–12
Calories	517	664	825
Total fat (percentage of total food energy)	*1	*1, 2	*2
Saturated fat (percentage of actual total food energy)	*1	*1, 3	*3
RDA for protein (g)	7	10	16
RDA for calcium (mg)	267	286	400
RDA for iron (mg)	3.3	3.5	4.5
RDA for vitamin A (RE)	150	224	300
RDA for vitamin C (mg)	14	15	18

*1 The Dietary Guidelines for Americans recommends that after 2 years of age, children should gradually adopt a diet, that by about 5 years of age, contains no more than 30 percent of calories from fat.

2 Not to exceed 30 percent over a school week

3 Less than 10 percent over a school week.

"RE" refers to "retinol equivalent," a measure of the vitamin A activity in foods.

(Illustration by GGS Information Services. Cengage Learning, Gale)

Origins

Humans, unlike plants, cannot manufacture the nutrients they need to function. Each culture over centuries has developed its own traditional diet. In modern-day western civilization, many of these **diets** have developed into convenient, fatty and sugary foods, leading to obesity even in children and teens.

Advice on nutritional choices predates recorded language, but the first science-based approach to a healthy diet probably began just over 100 years ago. W. O. Atwater, the first director of the Office of Experiment Stations in the U.S. Department of Agriculture (USDA) and a pioneer in the field of nutrition investigation, developed some of the components needed for a food guide. He created food tables with data on protein, fat, carbohydrate, mineral matter, and fuel value for common foods.

Food guides with food groups similar to those used today first appeared in USDA publications in 1916 and were developed by nutrition specialist Caroline L. Hunt. Interestingly, the first daily food guide was published under the title *Food for Young Children*. In the early 1930s, the Depression economic restraints on families and the USDA responded with advice on how to select affordable healthy foods. In 1941, the Food and Nutrition Board of the National Academy of Sciences released the first recommended dietary allowances (RDAs) for calories and essential nutrients. The nine nutrients included on the list were protein, **iron**, **calcium**, vitamins A, C, and D, thiamin, **riboflavin**, and **niacin**.

Throughout the years following the release of the first guidelines, recommendations were debated and revised. The new food guide was first presented in 1984 as a *food wheel*. The USDA first used a pyramid to represent the food groups in 1992 after intensive research on the most effective way to visually communicate healthy eating by portion and food choice. Although it has been modified over the years, the pyramid has continued to represent the food groups.

Annemarie Colbin was brought up on a European vegetarian diet before she came to the United States in 1961. In her search for optimum health and the ability to control how one feels by what one eats, she became a professional cook, lecturer, founder of the Natural Gourmet Cookery School in New York City, and author of best-selling books *Food and Healing, The Book of Whole Meals,* and *The Natural Gourmet,* as well as articles appearing in the *New York Times* and *Cosmopolitan*.

In Chapter One of *Food and Healing,* Colbin looks at the health of children and she points out that:

- A child born today can expect to live 26 years longer than a child born in 1900, but a person who has already reached 45 today can expect to live only four or five years longer than a person born in 1900.
- The following childhood problems that were rare in 1900 are now so prevalent that they are called "the new morbidity (an unsound, gruesome condition)": learning difficulties, behavioral disturbances, speech and hearing difficulties, faulty vision, serious dental misalignment.
- The average child loses three permanent teeth to decay by age 11, eight or nine by age 17, and 94% of adolescents have cavities in their permanent teeth.
- Among children, tuberculosis is on the rise
- By the mid-1980s, cancer as a killer of children and adolescents was surpassed by only accidents and violence.

Colbin cites statistics linking children to emotional disorders and violence, indicating that at any given time, as much as a quarter of our population is estimated to suffer from depression, **anxiety**, or other emotional disorders; that suicide is the ninth leading cause of death for all age groups; and that there may be as many as four million cases of child abuse every year, at least 2,000 of which result in death. She then states, "All this violence is no longer viewed as purely

Causes, risks, and prevention of childhood obesity

Causes

Increased consumption of sugary beverages with a decreased consumption of milk

Super-size portions in fast food restaurants

More meals eaten away from home and use of prepared foods in the home

Increased snacking between meals and fewer meals eaten together as a family

Heavy advertising of high-sugar high-fat foods to children

Decrease in children carrying their lunch to school from home

Poor eating habits such as skipping breakfast and later snacking on high fat, sugary foods

More time spent watching television or using the computer

Fewer children walking to school

Fewer physical education requirements at school and decreased recess in grades 1-5

Fear of crime, which limits outdoor activities of children

Increase in teen access to cars

Inherited tendency toward weight gain or having at least one obese parent

Eating in response to stress, boredom, and loneliness and/or poor sleeping habits

Medical conditions, such as Prader-Willi syndrome, hypothyroidism, mental illness, binge eating disorder, or taking certain medications

Risks

Type 2 diabetes

High blood pressure (hypertension)

Cardiovascular disease

Gallbladder disease

High cholesterol

Fat accumulation in the liver (fatty liver/liver disease)

Sleep apnea

Early puberty; early start of menstruation in girls

Eating disorders

Joint pain and degenerative joint disease

Sleep apnea

Depression

Increased anxiety and stress

Low self-esteem

Exposure to social prejudice and discrimination

Prevention

Serve a healthy variety of foods and keep healthy snacks on hand

Choose low-fat cooking methods such as broiling or baking

Eliminate junk snack food and sugary beverages from the house

Eat meals together as a family rather than grabbing something quick on the run

Limit visits to fast-food restaurants

Plan family activities that involve physical activity, such as hiking, biking, or swimming

Encourage children to become more active such as walking to school, biking to friends' houses, walking the dog or mowing the lawn

Limit television and computer time

Avoid using food as a reward

Pack healthy homemade lunches on school days

Encourage school officials to eliminate soda machines on campus, bake sales, and fundraising with candy and cookies

Set realistic goals for weight control and reward children's efforts

Model the eating behaviors and active lifestyle you would like your child to adopt

(Illustration by Corey Light. Cengage Learning, Gale)

Healthy snack foods for children

- Applesauce cups (unsweetened)
- Apples or pears and low-fat cheese
- Baby carrots and celery
- Bagels pizzas with tomato sauce and melted low-fat cheese
- Baked potato chips or tortilla chips with salsa
- Cereal, dry or with low-fat milk
- Cucumber or zucchini slices
- Dried fruits such as raisins, apple rings, or apricots
- Fresh fruit
- Fruit canned in juice or light syrup
- Fruit juice
- Fruit salad
- Frozen fruit bars
- Frozen grapes
- Low-fat chocolate milk
- Low-fat frozen yogurt with fresh berries
- Low-fat yogurt with fruit
- Nonfat cottage cheese with fruit
- Popcorn, air popped or low-fat microwave
- Pretzels (lightly salted or unsalted) and a glass of low-fat milk
- Raw vegetable sticks with low-fat yogurt dip, cottage cheese or hummus
- Rice cakes with peanut butter
- Smoothies with low-fat milk or yogurt and sliced bananas or strawberries
- String cheese and fruit (canned or fresh)
- Vanilla wafers, gingersnaps, graham crackers, animal crackers or fig bars and a glass of milk
- Whole-grain crackers or English muffin with peanut butter
- Whole-wheat crackers with cheese or peanut butter

(Illustration by GGS Information Services. Cengage Learning, Gale)

psychological. A growing body of research links mood, violent behavior, and even criminal behavior with various physiological imbalances: an over-active thyroid, an excess of testosterone (male hormones), **allergies**, low blood sugar. **Lead poisoning**, vitamin deficiencies, and of course alcohol and drugs all alter physiology as well as mood. Behavioral problems have even been associated with a lack of natural light, insofar as light plays a vital role in the metabolism of calcium, a mineral widely regarded as 'nature's tranquilizer.'"

Based on these statistics and many more that she cites, Colbin contends that proper nutrition plays a key role in disease prevention. She indicates that she sees three major errors in our contemporary assumptions about health and illness: the belief that physiological symptoms such as headaches, fevers, etc. are mistaken reactions of the body to normal stimuli; the belief that surgical intervention or chemical substances, natural or artificial in origin, can restore health by stopping the disease process; and the belief that dietary habits are unrelated to symptoms or illnesses. Although the last belief is slowly changing, it has a long way to go. For example, she points out, many people are still buying antacids for digestive distress without changing their diet.

Benefits

The Food Guide Pyramid and other healthy eating recommendations generally apply to children age two and older. When used as a starting point for planning family meals and snacks, applying these sensible recommendations to children's daily diets can encourage good eating habits at an early age. This will help children develop mentally and physically according to growth charts and other measurements set by pediatricians (physicians who specialize in caring for children) and will help prevent future problems with overeating or with eating disorders. Many nutritional experts agree that if children eat a balanced diet that includes all of the recommended food groups, they will not need to take vitamin/mineral supplements. Also, eating a balanced diet with a variety of foods will give children the energy they need to stay physically active, which is important to their growth and mental health, and in keeping obesity in check.

Description

In spite of recommendations, the diet quality of most children is not what it should be. The USDA surveyed American children ages two to nine in 1998 and found that up to 8% of them had a poor diet, while as many as 80% of those ages seven to nine had a diet that needed improvement. The Centers for Disease Control (CDC) defines childhood obesity at a level above the 95th percentile of body mass index for the child's age group. Body mass index (BMI) is a measurement system used to assess if a child (or adult) is underweight, overweight, or at risk for becoming overweight. Pediatricians use height and weight measurements taken at a child's regular checkup to determine his or her BMI. To help guide parents and others in making good nutritional choices, maintain a healthy BMI, and keep children healthy, the American Medical Association (AMA) suggests the following food choices for children based on the USDA guidelines.

Children two to five years of age

The AMA and USDA recommend food guidelines for young children similar to those for older children and adults, but with smaller portions. When looking at a range of portion sizes, parents and those who care for young children should choose smaller portion sizes for children age two or three, and slightly larger portions for children who are age four or five. Daily recommendations include:

- four to five servings of breads, cereals, rice, pasta
- two or more servings of vegetables
- two or more servings of fruit

- three to four servings of dairy products
- two or three servings of meat, fish, poultry, legumes (beans, lentils, peas)

After age two, a child needs less fat than an infant— about 30% of daily calories. After age three, fiber becomes more important in a child's diet and can impact future heart health.

Calcium requirements steadily increase as children get older, from 500 mg a day at age three to 800 mg a day at age four to eight. There is more calcium in the body than any other mineral. Calcium works together with **phosphorus** (two parts calcium to one part phosphorus) for healthy bones and teeth and works together with **magnesium** (two parts calcium to slightly over one part magnesium) to prevent cardiovascular (blood vessels of the heart) and other degenerative diseases. In order for calcium to be absorbed by the body, it must also have sufficient amounts of vitamins C, D and A. In addition to food sources, an hour of sunshine each day can also provide a child with his/her daily **vitamin D** requirement.

Children six to twelve years of age

By the time children reach age five or six, they begin to tell parents what foods they like. Parents and those who care for children can help select foods from each recommended group that a child will enjoy. Calorie requirements and portion sizes increase as children get older: between ages six and ten, boys and girls need between 1,600 and 2,400 calories each day. During puberty and adolescent growth between ages 10 and 12, girls need about 200 more calories a day. Boys will begin needing about 500 more calories a day after age 12. The following servings per day are recommended for children ages six to twelve:

- six to 11 servings of breads, cereals, rice, pasta
- three to five servings of vegetables
- two to four servings of fruit
- three or four servings of dairy products
- two or three servings of meat, fish, poultry, legumes

By age six, children still need only about 30% of calories from fat. Nutritionists say that by adding five to the child's age, parents can estimate the number of fiber grams a child needs each day. Calcium requirements continue to rise, from 800 mg a day at ages four to eight to 1,300 mg each day for children beginning at age nine.

Preparations

Getting children to eat the right foods is easy if they develop good eating habits at a young age and if they are offered a variety of healthy foods. Many books, magazines, and web sites offer tips on making healthy foods interesting. Some foods children like from each food group are suggested below.

- breads, cereals, and pastas including whole grain breads, unsweetened cereals, unrefined rice, whole grain crackers, cornbread, rice cakes
- vegetable servings from cooked or raw vegetables such as asparagus, beets, broccoli, carrots, corn, green and red peppers, green beans, kale, peas, pumpkin, squash, sweet potato, tomato, zucchini, or vegetable juice
- good fruit choices such as apples, applesauce, bananas, cantaloupe, apricots, peaches, unsweetened fruit cocktail, plums, grapefruit, kiwi, nectarines, strawberries, watermelon, and fresh fruit juices
- milk, low-fat yogurts and cheeses are good dairy sources, as are low-fat cottage cheese, custard, ice milk, and occasional ice cream servings
- meat, fish, poultry, and legume choices include lean meats, dried beans, peanut butter, shellfish, dried peas, lentils, tofu, and reduced-fat cold cuts

To reduce fat in a child's diet, parents can switch to low-fat or non-fat milk; remove skin from poultry or trim fat from red meat; reduce use of margarine and butter; use low-fat cooking methods such as baking, broiling, and steaming; and serve foods rich in fiber.

KEY TERMS

Anorexia—A serious and sometimes fatal eating disorder characterized by intense fear of being fat, and severe weight loss. It primarily affects young females. Sufferers may see themselves as fat even when they are underweight.

Bulimia—Sometimes called binge eating, this eating disorder consists of cravings for foods that often result in periods of continuous eating followed by purging (forced vomiting or diarrhea) and depression or food-deprivation, etc.

Gout—A metabolism defect resulting in overproduction of uric acid and pain in one or a few joints.

Hypoglycemia—A condition of abnormally low blood sugar.

Malnutrition—Any disorder of nutrition caused by insufficient or unbalanced diet that can result in impaired absorption or use of foods.

Seborrheic dermatitis—A skin condition characterized by loose, greasy, or dry white to yellowish scales with or without reddened skin.

Fresh salads can improve fiber in diet, as can adding oat or wheat bran to baked foods. Good, easy-to-assimilate sources of calcium for children, besides milk and cheeses, are tofu made with calcium sulfate; soup made with fish, fowl or beef bones and one tablespoon of wine vinegar to draw out the calcium into the broth; canned salmon and sardines with bones; sesame seeds and tahini (ground sesame seed butter); beans and nuts; calcium-fortified fresh orange juice; greens, especially broccoli, collards, kale, mustard, turnip tops, **parsley**, watercress and **dandelion**; and cooked sea vegetables if children like them.

In *Food and Healing,* Annemarie Colbin explains what sugar is and why it causes so much damage to the health of children and adults. White sugar, like white rice and white flour, goes through an industrial refining process: its juice is extracted from sugar cane, then filtered and boiled until it has been separated from all of its water, minerals, vitamins, protein and fiber, all of which the body needs to digest and metabolize the sugar. Because it lacks those nutrients, refined sugar becomes what Colbin calls a "naked carbohydrate," and so the body will draw them from other foods in the same meal or the body's tissues. Thus when refined white sugar is consumed, there is loss of stored B vitamins, calcium, phosphorus, iron, and other nutrients from the body. The loss of calcium stored in teeth weakens them and makes them more susceptible to bacterial attack/cavities. Also, this nutrient loss from refined sugar consumption can produce hunger for the missing nutrients and provoke great sugar-eating binges. On food labels, sugar is often identified as lactose, maltose, fructose, sucrose, and others. Glucose is the name of sugar found in the blood.

Colbin points out that if you eat meat, you need to digestively balance it with white sugar and vice versa, and that serious problems arise when the amount of sugar eaten is more than the amount needed to balance the meat. Sugar is as addictive as a drug because eating a small amount creates a desire for more sugar and because quitting sugar "cold turkey" brings on withdrawal symptoms that can last for an extended period of time. Typical withdrawal symptoms include strong cravings, **fatigue**, depression, mood swings, and sometimes headaches. Excessive sugar consumption is believed to be involved in such very common problems as **hypoglycemia** or hyperinsulinism, diabetes, **heart disease**, dental caries, high **cholesterol**, obesity, **indigestion**, **myopia** (nearsightedness), seborrheic **dermatitis**, **gout**, genetic narrowing of pelvic and jaw structures, crowding and malformation of teeth, hyperactivity, lack of concentration, depression, and anxiety. Colbin notes that these problems result when the sugar intake provides more "naked carbohydrates" than are needed to balance the animal protein intake. Since white flour also provides additional "naked carbohydrates," only a small amount of sugar can create an excess amount in the body.

It is important that children eat three meals a day and not skip breakfast. Studies have shown that children and teens who skip breakfast have more trouble concentrating, do not perform as well in school, and often later develop heart disease. Obesity is common in children who skip breakfast.

While the obesity problem in today's youth can be blamed on a number of factors, including larger food portions for adults and children, convenient salty and sugary snack foods, and cheap and convenient fast food, much attention has been focused on the role of the nation's schools. There are fewer physical education classes due to more emphasis on academic classes. Those gym classes that remain do not include enough activities that interest the children, say some experts. School lunches generally have not provided healthy or balanced nutrition but instead have consisted of highly refined, processed foods that are full of additives and simple carbohydrates, which do not provide good nutrition or energy. In addition, many schools also offer "snack bars" or vending machines with sodas and sugary, fatty, or salty snacks. Many children choose these snacks over prepared school lunches.

To counter this problem in schools, the Healthy Schools Summit was held in October 2002. It consisted of representatives from more than 30 national education, fitness, nutrition, and health organizations, as well as 450 school administrators, government leaders, food service directors, counselors, dietitians, nurses, and health and fitness teachers. Since that time, many school districts around the country have been working to improve their physical education programs and to remove or change the selections in vending machines and snack bars on school campuses. Parents can look into lunchtime option at their children's schools or pack healthy lunches from home with foods their children like to ensure they eat well while at school.

Children who are very active and participate in organized sports need a particularly healthy diet. For extended energy, they should eat many complex carbohydrates, such as unrefined rice, whole grain pasta and bread, and whole grain cereal. While all children need to drink plenty of water, those who participate in sports need to drink even more. Some experts say an

easy formula to remember is one cup of fluid for every one-half hour of physical activity.

At home, some parents choose convenient snack and fast foods because often, both parents work long hours. Today's youth eat bigger portions, spend more time in front of the television instead of engaged in physical activity, and are growing accustomed to less nutritional foods. Many experts say that getting children up off the couch and watching their snack choices helps. Also, many sources can help parents find healthier alternatives to fast food meals for their families. Suggestions include cooking healthy meals on weekends and freezing them for busy weekdays and looking for cookbooks or online sources of quick and healthy recipes. Simply cooking with less fat and using baking, roasting or poaching methods instead of frying makes meals healthier for everyone. Also, offering children healthy snacks to last them until mealtime will keep them from reaching for poor snack choices and make them less likely to overeat at the evening meal.

For a variety of reasons, some children follow vegetarian diets. Some people are concerned that a vegetarian diet is harmful for children, but generally, if a child aged two or older still follows the recommended Food Guide Pyramid and makes good food choices, a vegetarian diet can be healthy. In fact, 2% of children ages six to 17 never eat meat, fish, or poultry. If a vegetarian child needs a vitamin or mineral supplement, a physician or professional nutritionist can help determine the proper level of supplement needed.

Precautions

Parents are sometimes cautioned by nutritional experts not to turn mealtimes and eating into a battle of wills. Offering a variety of healthy choices allows children to select favorite foods from among those that are good for them and to balance foods containing a number of vitamins and minerals. Research in 2004 showed that taste for certain foods probably develops while people are still infants. In fact, infants in the study who had been exposed to the flavor of carrots through their mothers' breast milk later ate more of a carrot-flavored cereal that those who had not been exposed to carrots as infants. The researchers said that encouraging children to eat more fruits and vegetables as early as possible was helpful.

Many physicians and medical researchers have cautioned parents not to turn to fad diets for their children's weight problems. Many of the diets and diet products on the market have not been proven by clinical studies to be effective in the long term for adults and therefore they certainly have not been proven safe or effective as a solution to weight problems in children. The best solution for childhood obesity is a combination of activity, a balanced diet that follows the AMA/USDA guidelines for food groups and portions, and involvement of a physician, dietician, or other trained professional as needed. A further caution concerning dieting is the concern that as young children enter adolescence, too much worry about weight and appearance can cause social anxieties and lead to eating disorders such as anorexia and bulimia.

When changing a young child's diet, it should be done slowly, particularly when introducing fiber, and with the help of a physician, dietician, or nutritionist. Too much fiber can interfere with the body's absorption of vitamins and minerals.

Children who do not eat enough food and do not get enough nutrition suffer from severe undernourishment, or malnutrition. Each year, more than six million children under the age of five years die around the world as a result of hunger. Malnutrition can also make a child more susceptible to a number of diseases. Worldwide, it is estimated that food insecurity affects 815 million households, mostly in developing countries. However, in 2003, a report showed that at least 10% of U.S. households don't have enough food and about 3% report hunger at home. In this case, it is not the sort of hunger a person feels when they eat a late lunch but the kind of painful sensation someone gets from repeated or involuntary lack of food.

There are parents and health professionals, both traditional and alternative, who feel children should have vitamin/mineral supplements to stay healthy. However, there are also parents and health professionals who believe that when children eat a balanced diet of wholesome foods, they seldom need vitamin supplements; that individual vitamins and minerals should be taken, like medicine, when a deficiency has been created by a diet imbalance; and that when such a deficiency has been corrected, they should be discontinued.

If children are not eating a healthy diet and are being given a vitamin/mineral supplement, it is important to keep chewable vitamins out of reach of young children, as their appealing taste may be irresistible and dosage needs to be controlled according to directions. Children with poor appetites or erratic eating habits also may benefit from vitamins and minerals. It is best to check with a pediatrician, dietician or nutritionist for dosing.

Some parents and health professionals feel that vegetarian children may benefit from vitamin/mineral

supplementation because they may lack some iron and **zinc** normally obtained through meat products and/or fish. Other substantial sources of iron are eggs, whole-grain breads and cereals, leafy and other vegetables, potatoes, fruit and milk. Foods containing **vitamin C** (broccoli, Brussels sprouts, collards, kale, parsley, sweet peppers, strawberries, grapefruit, melons, tangerines, potatoes, and more) will increase absorption of iron in non-animal foods. Vegetarian sources of zinc are eggs, legumes, and whole grains. Zinc deficiency has been found in populations whose intake is derived solely from cereal sources, but in recent studies, vegetarians had adequate zinc levels. Those children who avoid dairy products, although it is difficult to get enough, may get calcium from broccoli, leafy green vegetables like kale, canned salmon and sardines including the bones, and soy products. If a child's physician or qualified nutritionist feels a supplement is necessary, he/she should recommend the dosage.

Children often don't recognize feelings of thirst and have to be encouraged to drink before becoming thirsty. If a child's urine is clear or the color of pale lemonade, he or she is drinking enough fluids. Dark urine the color of apple juice indicates too little fluid and the child is in danger of dehydration or heatstroke.

Side effects

Only the fat-soluble (capable of being dissolved in fat or oil) vitamins A, D, K and E have side effects that are potentially, though rarely, toxic (poisonous).

In their book *The Real Vitamin & Mineral Book,* Sheri Lieberman and Nancy Bruning state, "The facts are that only a few vitamins and minerals have any known toxicities, all of which are reversible, with the exception of vitamin D. Anything can be harmful if you take enough of it—even pure water. But vitamins and minerals are among the safest substances on earth. The amounts needed to become toxic are enormous." They add that being on medication or having a medical condition can influence vitamin/mineral requirements and indicate that when one's physician is not well-versed in nutrition, it is ideal to have him or her work with a qualified nutritionist.

With regard to vitamin D, they indicate, "According to several studies, up to 1,000 IU per day of vitamin D appears to be safe. Both the beneficial and adverse effects of exceeding this amount are controversial. Overdosing of vitamin D is *irreversible and may be fatal*. Symptoms of too much vitamin D are **nausea**, loss of appetite, **headache**, **diarrhea**, fatigue, restlessness, and calcification of the soft tissues (insoluble lime salts in tissue) of the lungs and the kidneys, as well as the bones." Vitamin D (400 IU) is usually sold with **vitamin A** (5,000 IU) in a tiny tablet or capsule.

Lieberman and Bruning say that active vitamin A from fish liver oil or synthetic palmitate is stored in the liver; that 15,000 IU would cause problems in infants; but that 100,000 IU of active vitamin A would have to be taken daily for months before any signs of toxicity (state of being poisonous) appear. Vitamin A in the form of beta-carotene can be taken without any risk of toxicity.

At doses of 800–1,200 IU per day, Lieberman and Bruning found no well-documented toxicity of **vitamin E**. At doses of over 1,200 IU per day, adverse effects such as flatulence, diarrhea, nausea, headache, heart palpitations, and fainting have been reported, but were completely reversible when dosage was reduced.

Vitamin K is easily obtained by the body from a healthy diet and deficiencies are rare, especially in children. It is given prophylactically to newborn infants to prevent hemorrhage and before surgery to people with blood-clotting problems. Lieberman and Bruning describe the major effect of too much vitamin K as an **anemia** where red blood cells die more quickly than usual and cannot be replaced by the body.

Some children have severe food allergies. It is important to watch for signs of allergies in very young children in particular, since they are eating many foods for the first time. Signs of food allergies can range from mild to severe. A child may, for instance, eat peanuts or shellfish and immediately show signs of a severe reaction, such as swelling and trouble breathing. Other food allergies may be less obvious but may occur from common foods found in many everyday products such as milk, eggs, wheat, or soy. If a child appears to have a severe reaction and has trouble breathing, the parent or caregiver should seek immediate medical attention, since the allergic reaction may be serious. If a child has ongoing problems such as **eczema** or other allergic reactions or signs of intolerance to foods, the parent may choose to seek help from a registered dietician and/or an allopathic physician who specializes in allergies. The allopathic physician may test the child first to determine the source of the allergies. The dietician will work with the family to help plan ways to meet nutritional needs while avoiding foods that cause allergic reaction or intolerance.

The parent of an allergic child can also choose to seek help from a homeopathic or naturopathic physician.

Andrew Weil, M.D., author of *Spontaneous Healing,* a *New York Times* number one bestseller that sold well over one million copies, believes that the body can heal itself and believes allergies are learned responses of the immune system to environmental agents that are not necessarily harmful. Weil says treatment should focus on calming an over-reactive immune system in order to alleviate allergy symptoms. Allergies can and are frequently "healed." However, traditional allergy medications tend to be "more or less" toxic to the body and can increase an allergic response over time.

To increase the likelihood of spontaneous healing, Dr. Weil made the following recommendations. Dietary modification to reduce allergic responses: following a low-protein diet; cutting down on animal protein in general; eliminating cow's milk and products made from it because they are known to irritate the immune system; and eating organically grown foods as much as possible to avoid agricultural chemicals that cause immune system reaction. Regular use of **quercetin**, a natural product from buckwheat and citrus fruits, that stabilizes cell membranes that release histamine, which is involved in many allergic reactions. Quercetin is a preventative and Dr. Weil recommends it be used regularly. The recommended dose is 400 mg twice a day between meals. For **hay fever**, the freeze-dried extract of the herb stinging **nettle**, one to two capsules every two to four hours as needed, he says will control symptoms with none of the toxicity of antihistamines or steroids. He also recommends a safe nasal spray, Nasalcrom, which works like quercetin. In the home, environmental methods like installing air filters can reduce allergic effects on and relieve the immune system. And finally, some allergic reactions indicate that high brain levels are involved in misdirected immune system response, and mind/body intervention is suggested.

Research and general acceptance

The AMA has based many of its food choices on the Dietary Guidelines for Americans, which were developed through research by the U.S. Department of Agriculture and the U.S. Department of Human Services. Input for the guidelines comes from a number of resources, including national surveys from the Centers for Disease Control (CDC).

As for children and the general public, accepting the importance of nutrition is another story. A 2003 study from the American Dietetic Association reported that preteens and their parents weren't concerned about preteens' weight being a health risk. Children and parents related obesity more to food than to physical activity and many overweight children said they didn't have much opportunity for physical activity.

Training and certification

Qualified dieticians and nutritionists may have a bachelor's, master's or a doctoral degree in nutrition and dietetics from an accredited college. They are also required to constantly update their knowledge with continuing education. Through the American Dietetic Association, these professionals can gain certification in their fields, including a certificate of training in childhood and adolescent weight management. Pediatricians obtain M.D. or D.O degrees and some specialize in childhood diseases and treatment. In the field of alternative medicine, parents may choose to seek treatment from naturopaths and homeopaths.

Andrew Weil, M.D. in *Spontaneous Healing* points out the benefits of **naturopathic medicine**. "Naturopathy comes from the old tradition of European health spas with their emphasis on hydro (water) therapy, massage, and nutritional and herbal treatment." Naturopaths are well trained in the sciences and have more experience with nutritional and herbal medicine than many allopathic physicians. Naturopathy is based on a general philosophy that focuses on the body's natural healing potential in an attempt to circumvent the use of drugs and surgery; however, naturopathic physicians may focus on different methods, using such therapies as **acupuncture**, bodywork, herbalism, and **homeopathy**. They are licensed in only a few states in the United States, mostly in the West. According to Dr. Weil, "Good naturopaths are worth consulting for childhood illnesses, recurrent upper respiratory **infections** and sinusitis, gynecological problems, and all ailments for which conventional doctors have only suppressive treatments. Naturopaths can be valuable as advisors to help people design healthy lifestyles." To find a naturopathic physician in their area, parents can contact the American Association of Naturopathic Physicians, 601 Valley Street, Suite 105, Seattle, Washington 98109, (206) 298-0126.

With regard to homeopathy, Dr. Weil also has positive feedback for the discipline. Homeopathy is a system that has a two hundred year old history. Homeopaths use diluted natural remedies to work on the body's energy field and encourage healing. Homeopathic physicians can be M.D.s, osteopaths, naturopaths, chiropractors, or lay persons. If a parent wishes to consult an alternative practitioner for homeopathic advice, the National Center for Homeopathy can be

contacted at 801 North Fairfax Street, Suite 306, Alexandria, Virginia 22314, (703) 548-7790.

Chili pepper *see* **Cayenne**

Chills

Definition

Chills is the common name for a feeling of coldness accompanied by shivering and possibly **fever**.

Causes and symptoms

Chills may occur for the following reasons:

- Exposure to extremely low outside temperature.
- Insufficient protection from cold temperature or weather.
- Age, as newborns and elders are intolerant of cold temperature.
- Anemia, particularly in women who frequently complain of cold intolerance. The condition is frequently found in females of reproductive age due to significant monthly blood loss during menses.
- Stress or poor health condition.
- Malnutrition. Poor diet and/or B-complex vitamin deficiency often makes a person more sensitive to cold temperature.
- Hypothyroidism. Hypothyroidism is one of the most common reasons for cold intolerance in women.
- Diabetes.
- Poor immune function as in AIDS or cancer patients. In these patients, chills and shivering may be signs of

infections (most likely), tumors, drug-induced fever, or malnutrition.

- Infections. Chills and fever are often caused by the common cold or viral infections. However, they may also be due to something more serious such as cystitis (bladder infection), septicemia (blood infections), pneumonia, meningitis, malaria or tuberculosis.
- Medications. Certain medications such as beta interferons can cause chills as side effect.
- Unknown infections or diseases.

Diagnosis

Those suffering from chills should investigate possible causes if the symptoms persist or are accompanied by fever and/or night sweat. They may be a sign or symptom of a serious condition and may require medical attention. A doctor can make accurate diagnosis of underlying diseases through detailed questioning about the chills, accompanying symptoms if any, patient's diet, daily **stress**, and lifestyle. In addition, doctors may order blood tests for **anemia**, **hypothyroidism**, or **infections** if these conditions are suspected.

KEY TERMS

Anemia—A condition in which there is a low number of red blood cells or hemoglobin resulting in paleness and weakness.

Hypothyroidism—Deficiency of thyroid gland activity. This is often due to low production of thyroxine, an inactive iodine continuing a hormone that aids in regulating metabolism. In its severe form, it may cause obesity, loss of hair, enlargement of the tongue, thickening of the skin, and physical and mental sluggishness.

Reye's syndrome—Acute and often fatal childhood syndrome marked by encephalopathy (brain disease), hepatitis (inflammation of the liver), and fatty accumulations in the viscera (many of the soft parts and internal organs). It may start as a mild illness with respiratory and gastrointestinal symptoms for a few days, terminating in rapid brain swelling, hepatomegaly (enlargement of the liver), and convulsions, even coma.

Treatment

Alternative treatment of chills includes protecting oneself from inclement weather conditions, drinking warm teas, and making appropriate dietary changes. Ayurvedic treatment might include fomenation therapy, called *svedana*, to aggravate the fatty tissue and force excess sweat out of the body. Svedana is used to relieve bodily stiffness, heaviness, and coldness.

In **traditional Chinese medicine**, those complaining of chills should follow a diet of "warming" foods and avoid "cold" foods. Reference to cold or warming does not mean the actual temperature of the food, but its internal effect. In general, the Chinese recommend cooked rather than cold, raw foods for this condition. The Ayurvedic formula for producing internal heat is *trikodu*, made of equal parts of **ginger**, black pepper, and long pepper (pippali, native to India and Java), and alleviating coldness and stagnation in the body.

Nutritional therapy

The following dietary changes are recommended to help prevent chills and cold intolerance:

- Limiting alcohol and caffeine intake and refraining from smoking tobacco products. These chemicals increase cold intolerance.
- Drinking warm tea with or without herbs such as ginger (a warming herb used in Chinese and Native American medicine) or chamomile.
- Taking daily multiple vitamin/mineral supplement or B-complex vitamins with C. People who are deficient of B-vitamins often are sensitive to cold temperature.

Allopathic treatment

Persons should consult their doctors if cold intolerance is severe or if chills are often followed by persistent fever or night sweats. They may be signs or symptoms of serious conditions or infections. Hypothyroidism or poor thyroid function should also be ruled out in women complaining of cold sensitivity.

If cold intolerance is accompanied by other signs and symptoms of thyroid deficiency such as lethargy, **obesity**, and **depression**, persons should consult their doctor for treatment of hypothyroidism. Thyroid supplement may be necessary.

Patients should also be concerned if chills frequently occur with fever. Fever may be the body's response to infections. Persistent chills, night sweat, fever, and rapid weight loss should be brought to a doctor's attention. They may be symptoms of **cancer** or infections such as **AIDS** or **tuberculosis**. Chills and fever in immunodeficient patients are often signs of infections that can be serious in patients with weakened immune systems.

Fever and chills can often be treated with over-the-counter medication such as acetaminophen or

ibuprofen. Aspirin should not be given to a child for fear of Reye's syndrome. Patients should be given soups, fruit juices, or water to replace fluid loss due to fever. If fever is high (more than 104°F [40°]), occurs in newborns (less than three months old) or lasts longer than 48 hours, a physician should be contacted.

Prevention

Wearing appropriate clothes for the weather, eating nutritious foods, and taking dietary supplements may help prevent chills in some people.

Chinese foxglove root

Description

Chinese **foxglove** root is a perennial herb found in northern China. It grows 6-8 in (15-20 cm) tall and has long oval leaves that are covered with fine hairs, fluted flowers that are reddish orange tinted with purple, and a round fruit. The root is thick and reddish yellow. Chinese foxglove root is collected in the fall. Its Latin name is *Rehmannia glutinosa* and it is also called *Rehmannia chinensis*.

General use

In China, Chinese foxglove root is used as a remedy for many different ailments: blurred vision, chronic **fever**, **constipation**, heart palpitations, hearing problems, **hot flashes**, **insomnia**, light-headedness, **low back pain**, menstrual irregularity and uterine bleeding (especially after **childbirth**), night sweats, restlessness, and stiff joints. It is also used to combat the effects of **aging**. Its effectiveness in treating these ailments has not been verified.

Preparations

Chinese foxglove root is washed and dried in the sun. It is sold in large, fleshy brownish-yellow chunks and tastes sweet and moist. The root is used in two stages of preparation: dried and cooked. To make dried Chinese foxglove root, called *sheng di huang* or dry Rehmannia, the fresh root is removed from the sand, washed well, then dried in the sun during the winter. Cooked Chinese foxglove root, called *shu di huang* or cooked Rehmannia, is prepared by steaming the fresh root until it is cooked, letting it dry, then steaming and drying it again several times. Cooking Chinese foxglove root is said to enhance the herb's properties as a blood tonic. To combat the effects of aging, the root is prepared with cardamon so that it is easier to digest and use as a tonic. The raw form of the root is a cooler herb and used for symptoms of heat. The cooked root is more of a blood tonic.

Chinese medicine practitioners also make special preparations of Chinese foxglove root for specific ailments. It can be mixed with gelatin for coughing and **vomiting** blood, **nosebleeds**, and bleeding from the uterus. It can be mixed with **cornus** and **Chinese yam** or freshwater turtle shell as a remedy for symptoms such as forgetfulness, insomnia, and lightheadedness. Rehmannia is the main ingredient in the Chinese six flavor Rehmannia tonic used for ailments and discomfort such as frequent urination, **infertility**, **impotence**, and weak and painful knees.

Both cooked Chinese foxglove root and the raw version are available in Chinese pharmacies, Asian markets, and some Western health food stores. There are no formal guidelines for recommended doses of Chinese foxglove root.

Precautions

People who have digestive problems, especially those who tend to have **gas** or become bloated, should use Chinese foxglove root with care; the cooked root can swell the belly and cause loose stools. There is no

KEY TERMS

Palpitation—A heartbeat that is irregular or too fast.

information available on what happens to people who take an overdose of Chinese foxglove root.

Side effects

The use of Chinese foxglove root can cause **diarrhea**, **nausea**, and abdominal **pain**. Many Chinese herbalists include **grains-of-paradise fruit**, a kind of cardamon, in their Chinese foxglove root preparations to prevent these side effects.

Interactions

No interactions due to use of Chinese foxglove root have been reported.

Chinese massage

Definition

Chinese massage is the name for a family of massage therapies practiced within **traditional Chinese medicine**. In traditional Chinese practice, massage is one of the fundamental treatment modalities, along with dietary regulation, herbal medicine, acupuncture/moxibustion, and therapeutic **exercise**.

Origins

The history of massage as a part of Chinese medical treatment dates back about 4,000 years. Written massage textbooks began to appear as early as the fourth century B.C., along with the earliest Chinese medical texts. Massage appears to have developed alongside both therapeutic exercise (**qigong**) and **acupuncture**, as it depends on the same understanding of the meridians and the flow of qi in the human body. The type of massage known as qi healing, or curing with external qi, was developed by master teachers of qigong.

Benefits

Chinese massage is not intended to be an experience of pampering or **relaxation**. It is a form of deep tissue therapy that conveys the following benefits:

- speeding the healing of injuries and clearing bruises
- stimulating blood circulation and regulating the nervous system
- removing scar tissue
- easing emotional distress
- curing some conditions affecting the internal organs
- increasing flexibility in the joints and improving posture
- relieving chronic pain
- maintaining wellness and functioning as a form of preventive care
- improving athletic performance
- strengthening the body's resistance to disease

The fact that some forms of Chinese massage do not require extensive training and can be used at home is another benefit of this modality.

Description

Theoretical background

The techniques of Chinese massage are inseparable from the philosophical belief system that underlies traditional Chinese medicine. Chinese massage is holistic in its orientation, which means that massage is understood to affect the patient's entire being, not just his or her physical body.

Several concepts are important in understanding all the major forms of Chinese massage, including *qi*, *jing luo*, *xue*, and *jin*.

Qi, sometimes spelled chi or ki, is the basic life energy animating the universe as well as human beings. The word can be translated into English as "breath" or "air." Qi can be transferred or transmuted. In humans, the digestive tract extracts the qi from food, whereas the lungs extract it from the air. When these two forms of qi meet in the bloodstream,

they form human qi, which then circulates throughout the body.

The meridians or channels (*jing luo*) are a network of energy pathways that link and balance the various organs. The meridians have four functions: to connect the internal organs with the exterior of the body and connect the person to the environment and the universe; to harmonize the yin and yang principles within the body's organs and Five Substances; to distribute qi within the body; and to protect the body against external imbalances related to weather. When the *jing luo* are blocked so that qi and blood cannot circulate, the person experiences physical **pain**.

The acupoints (*xue*) are locations on the body where qi tends to collect and can be manipulated or redirected. They are connected to different body organs through the meridians.

The soft and connective tissues (*jin*) and the joints all affect the flow of qi along the meridians. Thus, one function of Chinese massage is to relax the patient's *jin*.

In general, Chinese massage emphasizes movement and communication. The basic purpose of massage is to restore free movement to the patient's qi and blood. Chinese massage therapists use a range of techniques to accomplish this goal: they press, knuckle-roll, squeeze, knead, dig, drag, pluck, tweak, hammer, push, stretch, vibrate, knock, and even tread on the body with their feet. Massage accomplishes its purpose in three ways: it activates the activity of qi and blood, it regulates their movement and disperses stagnation, and it removes external causes of blockage (cold and damp). Since Chinese practitioners regard massage as affecting all dimensions of the patient's being, they think of it as involving communication between the therapist's qi and the patient's qi. In *Tui na* massage, the patient is allowed or even encouraged to talk while the therapist is working. This practice often helps the patient to release stored-up feelings.

Tui na massage

Tui na massage takes its name from two Chinese words that mean "push and pull." It requires the controlled use of very deep but constantly moving pressure, repeated hundreds of times. The practitioner pushes hard with the ball of the thumb then rubs lightly around the area being treated. A therapist using this form of massage might spend as much time on one of the patient's joints or limbs as a Western therapist would spend massaging the entire body. *Tui na* is used to treat a wide variety of conditions that would require a team of physiotherapists, chiropractors, and physicians specializing in sports medicine to treat in the West. One Chinese medical book lists over 140 conditions that can be treated with *Tui na*, including disorders of the internal organs as well as **sprains**, pulled muscles, arthritis, and **sciatica**, a pain in the lower back and back of the thighs.

Chinese pediatric massage

Chinese pediatric message, or *xiao er tui na*, is a form of *Tui na* massage adapted to the special needs of children from birth to 12 years of age. The Chinese believe that a child's energy system is different from an adult's because children have fewer physical and emotional barriers in place. Their qi is therefore more accessible to treatment. The acupoints and techniques used in pediatric massage are different from those used with adults. Massage oil, typically **sesame oil**, is often used with children. The sessions are much shorter than those for adults, usually only 15 to 20 minutes, but they may be repeated several times a day for children who are seriously ill. Pediatric massage is used to treat such chronic conditions as **asthma**, **bedwetting**, and nightmares as well as teething, **colic**, **nausea**, **fever**, **constipation**, and the **common cold**. Parents often learn the basic techniques of pediatric massage as preventive health care for their children or to treat minor illnesses.

An mo massage

An mo is a type of massage used for health maintenance and to restore vitality. Its name means "press and stroke" in Chinese. It can be used at home but is also part of **martial arts**, qigong, and athletic training. *An mo* differs from *Tui na* massage in that it is a full-body balanced treatment. *An mo* combines yang techniques to break up stagnant qi and activate its flow, followed by yin techniques to soothe and calm the body. *An mo* has a set pattern of movements and techniques that the therapist follows, but these can be adjusted to the patient's needs. A session of *An mo* massage may last as long as two hours, particularly if there is a strong qi communication between the therapist and the patient.

Dian xue massage (acupressure)

Dian xue, or "point press," is familiar to many Westerners as **acupressure**. It uses the same acupoints on the body as acupuncture but relies on pressure from the fingers rather than needles. *Dian xue* can be used by massage therapists to stimulate two different acupoints, one with each hand, while the area of the body between the points is stretched or twisted to maximize the flow of qi. *Dian xue* can be given in the home and is

sometimes used by acupuncturists when needles cannot be used.

Qi healing massage

The Chinese name of this form of massage is *wai qi liao fa*, or "curing with external qi." In qi healing, a qigong master who has practiced the art for many years transmits qi directly to the patient. Qi healing massage represents one strand of Chinese traditional practice in which healers passed on their own discoveries of the healing arts only to their closest disciples.

Preparations

Chinese massage is usually given with the patient lying on one side on a couch or seated on a chair or stool. The patient typically wears thin cotton clothing, particularly if the massage is being given in a public hospital or clinic. In smaller communities, the practitioner may work directly on the patient's skin. Touching the skin directly is thought to improve communication with the patient's qi; it also allows the application of herbal preparations to the skin.

Tui na massage is preceded by taking a full case history using the traditional four examinations of Chinese medicine (verbal interview; visual observation, which includes close examination of the tongue; listening to the patient's breathing and coughing; and touching, which includes taking twelve separate pulses). The massage therapist uses the information from the four examinations to identify the root complaint, the underlying pattern causing it, and the principles that will govern the treatment.

Precautions

Apart from giving a case history prior to receiving *Tui na* massage, no special precautions are necessary.

Side effects

Side effects are usually limited to some soreness, particularly after the first session of *Tui na* massage. This discomfort usually goes away after several more sessions. Pediatric massage is said to have few or no side effects. On rare occasions, patients have experienced headaches or mild stomach upset. These side effects are attributed to the imbalance or stagnation in the patient's qi prior to treatment.

Research and general acceptance

Between 1985 and 2005, Chinese massage became widely accepted in the West. A growing number of Western practitioners studied Chinese massage and obtained their training and certification from centers of traditional Chinese medical education. As of 2008, numerous alternative treatment centers in the United States offered Chinese massage along with Western forms of bodywork. Still another indication of the wider acceptance of Chinese forms of treatment is the emergence of hybrid massage therapies that combine Chinese techniques with those derived from other Oriental traditions of massage or from Western practices.

Training and certification

In China, massage is part of the curriculum of traditional Chinese schools of medicine, since it is an important aspect of primary health care. Graduates of these schools must pass rigorous examinations and government licensing procedures before setting up their practices. In addition, it is common for Chinese physicians to visit other practitioners as patients in order to learn about specialized techniques for treating specific conditions with massage. Last, many Chinese physicians come from families that have produced several generations of healers; younger practitioners often learn the techniques of massage from older family members. The master/apprentice model of teaching is still followed in traditional Chinese medical training in the twenty-first century.

In the United States, the Accreditation Commission for Acupuncture and Oriental Medicine (ACAOM) is the national accrediting agency, recognized by the U.S. Department of Education, that accredits acupuncture and Oriental medicine master degree level programs. The ACOM represents more than 50 schools and colleges with accredited or candidacy status.

The National Certification Commission for Acupuncture and Oriental Medicine (NCCAOM) is the only nationally recognized certification program available to qualified practitioners of acupuncture and Oriental medicine. NCCAOM certification is a requirement for licensure in most states. NCCAOM certifications are offered in acupuncture, Chinese herbology, Oriental medicine and Asian bodywork therapy.

The American Organization for the Bodywork Therapies of Asia (AOBTA) and the American Association of Acupuncture Oriental Medicine (AAAOM) are professional organizations that represent practitioners of Oriental medicine. These groups support appropriate credentialing, define scope of practice and educational standards, and provide training, professional development, and networking resources to their members.

KEY TERMS

Acupoint—A point or site on the body where qi tends to accumulate. Acupoints are pressed or manipulated in Chinese massage in order to activate or redirect the patient's qi.

An mo—A form of Chinese massage that treats the whole body and emphasizes balancing yin and yang techniques in the treatment. Its name means "press and stroke" in Chinese.

Dian xue—The Chinese name for acupressure. This form of massage can be done at home as well as by a trained therapist.

Qi—The Chinese word for life energy. Since traditional Chinese medicine understands pain to be the result of blocked or stagnant qi, all forms of Chinese massage are intended to restore free movement to the patient's qi and blood.

Tui na—A form of Chinese massage that focuses on a part of the patient's body in order to treat injuries and chronic pain. Its name literally means "push and pull" in Chinese.

Chinese system of food cures

Definition

The Chinese system of food cures regards dietary regulation as preventive medicine as well as a corrective measure to be undertaken when one falls ill. Diet is one of four major treatment modalities in **traditional Chinese medicine**, the other three being acupuncture/moxibustion, herbal medicine, and massage, plus remedial physical **exercise**.

Origins

The selection of foods in the diet as part of a lifelong program of health maintenance and treatment of illness has been a part of Chinese medicine from its beginnings. The first extensive written Chinese medical treatises (as the West understands the term) date from the Han dynasty (206 B.C.–A.D. 220), but the use of food as preventive medicine probably goes several thousand years further back. Legends says that tribal shamans and holy men who lived as hermits in the mountains of China as early as 3500 B.C. practiced what was called the "Way of Long Life." This regimen included a diet based on herbs and other plants, **qigong** exercises, and special breathing techniques that were thought to improve vitality and life expectancy.

After the Han dynasty, the next great age of Chinese medicine was under the Tang emperors, who ruled from A.D. 608 to A.D. 906. The first Tang emperor established China's first medical school in A.D. 629. This period produced China's earliest expert on dietary therapy, Sun Simiao. He specialized in the treatment of diseases caused by malnutrition and wrote several works on diet and health. Sun Simaio's principle of using diet and lifestyle changes as the first line of treatment for illness has governed traditional Chinese practice ever since. According to Sun Simaio, only when dietary treatment is not enough to cure the

patient should the doctor turn to **acupuncture** and herbal medicines.

Benefits

The benefits of traditional Chinese dietary treatment are many years of vigorous good health. According to the *Nei Jing*, China's oldest medical classic, the metaphor is that human beings are constituted to live for a hundred years, barring accidents or violence. Diet and good digestion are considered the most important ways to maintain physical strength and vitality.

Description

Chinese food cures are based on the philosophical principles of Taoism and its teachers' observations about nature. Some of its concepts are difficult for Westerners to understand because they rely on symbols and images rather than scientific measurements and theories. In general, Chinese medicine regards the human organism as an integrated entity within itself and as linked to the family, society, and the natural order by a pattern of symbolic connections.

The cosmic and natural order

In early Chinese philosophy, the Tao, or universal first principle, generated a duality of opposing principles that underlie all the patterns of nature. These principles, yin and yang, are mutually dependent as well as polar opposites. Yin represents everything that is cold, moist, dim, responsive, slow, heavy, and moving downward or inward; while yang represents heat, dryness, brightness, activity, rapidity, lightness, and upward or outward motion. The dynamic interaction of these two principles is reflected in the cycles of the seasons, the human life cycle, and other natural phenomena.

In addition to yin and yang, Taoist teachers also believed that the Tao produced a third force, primordial energy or chi (also spelled *qi* or *ki*, the Japanese term). The interplay between yin, yang, and chi gave rise to the Five Elements of water, wood, fire, earth, and metal. These entities are all reflected in the structure and functioning of the human body.

The human being

Traditional Chinese physicians did not learn about the structures of the human body from dissection (although they did perform some animal studies) because they thought that cutting open a body insulted the person's ancestors. Instead they built up an understanding of the location and functions of the major organs over centuries of observation, and then correlated them with the principles of yin, yang, chi, and the Five Elements. Thus wood is related to the liver (yin) and the gall bladder (yang); fire to the heart (yin) and the small intestine (yang); earth to the spleen (yin) and the stomach (yang); metal to the lungs (yin) and the large intestine (yang); and water to the kidneys (yin) and the bladder (yang). The Chinese also believed that the body contains Five Essential Substances, which include blood, spirit, vital essence (a principle of growth and development produced by the body from chi and blood), fluids (all body fluids other than blood, such as saliva, spinal fluid, sweat, etc.), and chi.

A unique feature of traditional Chinese medicine is the meridian system. Chinese doctors viewed the body as regulated by a network of energy pathways called meridians that link and balance the various organs. The meridians have four functions: to connect the internal organs with the exterior of the body, and connect the person to the environment and the universe; to harmonize the yin and yang principles within the body's organs and Five Substances; to distribute chi within the body; and to protect the body against external imbalances related to weather (wind, summer heat, dampness, dryness, cold, and fire).

KEY TERMS

Chi (Qi or Ki)—The universal life-force or energy. The quality, quantity, and balance of a person's chi determines his or her state of health and longevity.

Five Elements—The five basic substances (water, wood, fire, earth, and metal) that symbolize the fundamental qualities of the universe. In Chinese food cures, the five elements are correlated with the internal organs of the body and with the five basic food tastes.

Five Substances—The basic entities in the human body that serve its development and maintenance. They include chi, vital essence, spirit, blood, and fluids.

Meridians—Pathways of subtle energy that link and regulate the various structures, organs, and substances in the human body.

Taoism—The system of thought that looked at humans in relation to the whole universe. It had a significant influence on Chinese medicine.

Yin and yang—In Chinese thought, the two primordial opposing yet interdependent cosmic forces.

The composition and use of foods

Chinese food cures operate within this system of cosmic principles, symbolic correlation of internal organs with the five elements, and the meridian system. Food serves several functions in traditional Chinese medicine. It supplies nutritional energy to the body to replenish chi. It is also used by the body to produce vital essence and blood. Lastly, foods can be chosen to regulate the balance of yin and yang and the five elements within the body and to direct the flow of chi to different parts of the body.

Chinese medicine classifies foods according to four sets of categories:

- Temperature. Foods are classified as cold or cool (yin); or warm or hot (yang).
- Taste. There are five tastes correlated with the Five Elements: sour (wood); bitter (fire); sweet (earth); pungent (metal); and salty (water).
- Direction of action. Pungent, salty, and bland foods are thought to have an ascending or floating action that redirects chi upward, while sour, bitter, and sweet foods are thought to have a descending or sinking action that moves the chi downward.
- The organ or meridian affected by the food.

Chinese medicine uses foods to keep the body in internal harmony and in a state of balance with the external environment. In giving dietary advice, the Chinese physician takes into account the weather, the season, the geography of the area, and the patient's specific imbalances (including emotional upsets) in order to select foods that will counteract excesses or supply deficient elements. Basic preventive dietary care, for example, would recommend eating yin foods in the summer, which is a yang season. In the winter, by contrast, yang foods should be eaten to counteract the yin temperatures. In the case of illness, yin symptom patterns (**fatigue**, pale complexion, weak voice) would be treated with yang foods, while yang symptoms (flushed face, loud voice, restlessness) would be treated by yin foods. In addition, cravings for specific foods or flavors point to deficiencies to be remedied. Thus someone who wants a lot of hot drinks probably has a "cold" illness, while someone who refuses beverages has a "damp" disease.

Chinese medicine also uses food as therapy in combination with exercise and herbal preparations. One aspect of a balanced diet is maintaining a proper balance of rest and activity as well as selecting the right foods for the time of year and other circumstances. If a person does not get enough exercise, the body cannot transform food into chi and vital essence. If they are hyperactive, the body consumes too much of its own substance. With respect to herbal preparations, the Chinese used tonics taken as part of a meal before they began to use them as medicines. Herbs are used in Chinese cooking to give the food specific medicinal qualities as well as to flavor it. For example, **ginger** might be added to a fish dish to counteract the cold of the fish. Food and medical treatment are closely interrelated in traditional Chinese medicine. A classical Chinese meal seeks to balance not only flavors, aromas, textures, and colors in the different courses that are served, but also the energies provided for the body by the various ingredients.

Preparations

A traditional Chinese physician will examine a patient carefully before giving advice about diet. The diagnosis is based on four types of examination: visual observation, which includes examining the shape, color, and coating of the tongue as well as observing the complexion and taking the pulse; listening to the voice and breathing; inquiring about the patient's symptoms, food preferences, emotions, bowel habits, and sleeping patterns; and palpating (feeling) the patient's abdomen and key points along the meridians. The doctor will suggest changes in diet that will return the patient to inner balance and harmony with the environment according to the patterns he detects.

Precautions

The most important precaution for Westerners who are interested in Chinese food therapy is to consult an experienced practitioner of Chinese medicine. The system is complex and based on principles that differ from Western systems of thought. These factors make self-evaluation quite difficult.

Side effects

There are no known side effects from using the Chinese system of food cures as part of a wellness program under the guidance of an experienced practitioner.

Research and general acceptance

Research in the West has been largely confined to study of the herbs used in traditional Chinese medicine as distinct from food cures. Alternative practitioners in the West, however, have shown considerable interest in incorporating Chinese food cures into other systems, including **color therapy** and women's folk medicine. One school of color therapy classifies foods as yin or yang according to their color and recommends certain color combinations to correct energy imbalances in the body.

Training and certification

In contemporary China, traditional medicine is practiced alongside Western methods of diagnosis and treatment. Some Chinese medical schools still offer courses in Chinese medicine. Practitioners of traditional medicine must pass rigorous examinations and be licensed by the government. They usually obtain their clinical experience by serving apprenticeships under experienced doctors.

Chinese tea *see* **Green tea**

Chinese thoroughwax

Description

Chinese thoroughwax is an herb that is often called bupleurum, referring to the scientific naming of the species *Bupleurum chinense* and *Bupleurum falcatum*. Another name for the herb is hare's ear, and in **traditional Chinese medicine** the herb is called chai-hu.

Chinese thoroughwax (bupleurum) is a perennial flowering plant that grows from one to three feet tall. The leaves are long and slender, and the plant has yellow flowers in the summer months. It grows naturally in China, Japan, and Korea, and in other countries in northern Asia and northern Europe. The root of the plant is pale red, and is the part that is used medicinally. It tastes slightly bitter and pungent, and is believed to have cooling properties in the body.

One of the major herbs in traditional Chinese medicine, Chinese thoroughwax is used in several traditional formulas for liver problems, fevers, and inflammation. Chinese herbalists prescribe it for conditions that are associated with stagnation of qi, or chi (life energy), in the liver. Chinese thoroughwax is a major ingredient in a widely used Oriental medicinal formula called *shosaikoto* in Japanese, which also contains **Korean ginseng**, **licorice** root, **ginger** root, and other herbs. The Chinese name for the formula is *xiao chai hu tang*. This formula is almost 2,000 years old and is used in situations when someone gets a cold or flu but never completely recovers like some kinds of **chronic fatigue syndrome**.

Bupleurum has received attention most recently by researchers in China and Japan. Several studies that have shown significant findings have been translated into English. Professor Shibata of Tokyo University isolated a substance in Chinese thoroughwax he termed *saikogenin*, which is in a class of biologically active chemicals called saponins. In laboratory tests, saikogenin has shown potent anti-inflammatory properties, which recommend it for treating skin **infections** and other disorders in which inflammation and swelling are problematic. Saikogenin has been shown to increase the effectiveness of cortisone drugs, which are pharmaceutical steroids prescribed for arthritis, **asthma**, inflammation and other conditions. Bupleurum significantly increased the action of the cortisone drug prednisone in some laboratory tests. Another benefit of bupleurum is that it has been shown to protect the adrenal glands from the damaging effects of cortisone drugs.

Bupleurum extract has been shown in human studies to improve the symptoms of **hepatitis**, or viral infection of the liver. Other studies have pointed to its effectiveness as an antipyretic (fever-reducing agent), a mild tranquilizer, an antibiotic and antiviral agent, and as an immune system stimulant. A Japanese study published in 2002 suggests that bupleurum may be effective in the treatment of gastric ulcers. Chinese thoroughwax has also been shown to increase the efficiency of the chemotherapy drug 5-FU. It should be noted that Chinese thoroughwax has been generally most effective in tests when used in conjunction with other herbs in traditional Chinese herbal formulas.

General use

Traditional Chinese medicine recommends Chinese thoroughwax for chest congestion, respiratory problems, and for **chills** and fevers, including those associated with **malaria** and blackwater **fever**. It is used to treat fevers that have associated symptoms of

KEY TERMS

Interferon—A protein produced by animal cells that have been invaded by a virus, frequently used in the treatment of hepatitis. It has been reported to cause negative interactions with bupleurum.

Qi, or chi—Universal life energy, according to traditional Chinese medicine, that is found in the body, air, food, water, and sunlight.

Saikosaponins—Chemical compounds found in bupleurum that have anti-inflammatory effects.

Traditional Chinese medicine—Ancient Chinese healing system involving acupuncture, herbal remedies, dietary therapies, and other healing techniques.

bitter taste in the mouth, irritability, **nausea**, and abdominal pains, and is sometimes prescribed for **dizziness** and vertigo that occur with chest **pain**. Chinese thoroughwax is used in tonics to strengthen the lungs and sense organs, and to tone the leg muscles. Chinese thoroughwax is used to strengthen the liver and to treat liver problems, such as hepatitis and alcohol-related liver damage (**cirrhosis**).

For women, Chinese thoroughwax is used in formulas to regulate menstrual cycles in cases of **amenorrhea** (loss of menstrual cycle), to reduce the symptoms of PMS, and as a tonic for the female reproductive system. Chinese thoroughwax can be taken as an herbal supplement with corticosteroid drugs, to reduce the risks of damage to the adrenal glands. Some Chinese medicinal formulas containing Chinese thoroughwax (including xiao chai hu tang) are used for **cancer** treatment and as herbal support during chemotherapy.

Preparations

Chinese thoroughwax is available as dried root and capsules in herb stores, health food stores, and Chinese markets. It is also available in several formulated Chinese medicines. To prepare a daily serving of tea, 3–12 g of the dried root can be simmered for over an hour in a quart of water. For more extreme cases of fever and hepatitis, two servings of the tea can be drunk daily.

Side effects

Chinese thoroughwax can cause nausea, dizziness, sweating, and intestinal discomfort when taken in excessively high dosages.

Interactions

Chinese thoroughwax is frequently prescribed with licorice root and Korean ginseng. In the traditional and often used Oriental medicine called *shosaikoto* in Japanese or *xiao chai hu tang* in Chinese, Chinese thoroughwax is blended with licorice, jujube fruit, ginger root, Korean ginseng, Chinese **skullcap** root, and half summer root (*Pinellia ternata*). Herbalists often recommend that Chinese thoroughwax be combined with lycii berries to counteract its drying effects in the body. For cases of vertigo and chest pain, and as a liver tonic, bupleurum can be taken with **white peony root**, bitter orange fruit, and licorice. For **menstruation** problems, bupleurum may be combined with white peony and mint.

Bupleurum has been reported to have negative interactions with interferon, which is a protein produced by animal cells when they are invaded by a virus. Interferon is frequently used to treat hepatitis, and patients who are receiving interferon for this disease should not take herbal formulations containing bupleurum.

Chinese yam

Description

Chinese yam (*Dioscorea opposita*) is a root that is used in **traditional Chinese medicine**. The Chinese pharmaceutical name for this herbal is *Rhizoma dioscoreae*. Other names for Chinese yam include dioscorea and shan yao. Chinese yam is native to China, Japan, Korea, and Taiwan, where it can be found growing wild on hill slopes and in valleys. It is also propagated for medicinal and dietary uses.

The genus name *Dioscorea* is dedicated to the Greek physician and naturalist, Diosorides. There are between 600 and 800 different species of *Dioscorea*, making it one of the largest genera of the plant kingdom. Many species in this genus are grown and collected for their medicinal properties. Sweet potatoes are often called yams, although they are different plants.

The Chinese yam plant is a climbing vine that supports itself by coiling around the branches of other vegetation. The plant can be 9.75 ft (3 m) high and 5 ft (1.5 m) wide. Chinese yam has heart-shaped leaves and it produces small white flowers which have a cinnamon-like aroma. Small tubers (called tubercles) form in the axials (the angles between the leaves and the stem). These pea-sized tubercles are harvested in the late summer or early fall and are used to propagate the plant.

Chinese yam plants take three or four years to reach maturity, although fairly large roots may be harvested from well developed plants after the first year. Chinese yam is a spindle-shaped, thick, hard root or tuber that is white on the inside. However, cultivated forms from China or Japan may have different root shapes. The yam may be up to 3 ft (about 1 m) in length. Chinese yam is dug up in the winter. After the rough bark is removed, the root is washed and allowed to dry in either the shade or the sun. The dried root is rehydrated in water and then cut into slices.

Chinese yam contains large amounts of mucilage. Mucilage is a thick, slimy substance produced by plants. It has a soothing effect on mucous membranes, such as the tissues that line the respiratory passages. This may explain why Chinese yam is effective at relieving **cough**.

General use

Traditional Chinese medicine classifies Chinese yam as neutral and sweet. It serves to tonify and augment the spleen and stomach; augment the lung yin and tonify the lung qi; and stabilize, tonify, and bind the kidneys. Chinese yam enters through the spleen, lung, and kidney channels (meridians). It is used as a tonic (restores tone to tissues). Chinese yam is used to treat weak digestion with **fatigue** and **diarrhea**, general weakness, frequent urination, decreased appetite, leukorrhagia (excessive vaginal discharge), premature ejaculation, the symptoms associated with diabetes, and chronic **wheezing** (whistling sound caused by breathing difficulty) and coughing.

Chinese yam should not be taken if the patient's symptoms include abdominal swelling and **pain**.

KEY TERMS

Mucilage—A thick, slimy, adhesive substance produced by certain plants. It consists of gum that is dissolved in the plant's juices.

Tonic—An agent that restores normal tone to tissues. Tonics are used to treat indigestion, general debility, and other disorders.

Traditional Chinese medicine—The medicine practiced in China since ancient times which utilizes herbal remedies, acupuncture, cupping, and other treatment modalities.

Tubercles—Small, pea-sized tubers that grow on *Dioscorea* plants in the angles between the leaves and the stem. They are used in the cultivation of Chinese yam.

Preparations

Chinese yam may be found in dried or fresh form or as a powder. It is available in Asian food stores, Chinese pharmacies, and may be found in certain health food stores.

Chinese yam is taken by mouth for all indications. A tea (infusion) may be prepared by steeping slices of the root in boiling-hot water. The dosage is 10–30 g of root or 6–10 g of powder.

Combinations

It is common in traditional Chinese medicine to mix herbs to treat specific sets of symptoms. Chinese yam may be combined with the following to treat certain symptoms as shown:

- poria and white atractylodes for loose, watery stools.
- codonopsis root for general weakness, fatigue, and poor appetite.

- Chinese foxglove root and cornus for lightheadedness, forgetfulness, insomnia, and related symptoms.
- ginseng (ren shen), white atractylodes rhizome (bai zhu), and poria (fuling) for weakness of the spleen and stomach characterized by poor appetite, lassitude (exhaustion, weakness), and diarrhea.
- white atractylodes rhizome, poria, and euryale seed (qian shi) for excessive dampness because of deficiency of the spleen characterized by white leukorrhagia and lassitude.
- phellodendron bark (huang bai) and plantain seed (che qian zi) for excessive dampness changing into heat characterized by yellow vaginal discharge.
- dogwood fruit (shan zhu yu) and dodder seed (tu si zi) for deficient kidneys characterized by lower back pain and leukorrhagia.
- astragalus root (huang qi), trichosanthes root (tian hua fen), pueraria root (ge gen), and fresh rehmannia root (sheng di huang) for the thirst, excessive drinking and eating, lassitude, and frequent urination associated with diabetes.
- dogwood fruit and prepared rehmannia root (shu di huang) for frequent nighttime urination because of deficient kidneys.
- bitter cardamon (yi zhi ren) and mantis egg case (sang piao xiao) for frequent urination because of deficient kidneys.
- glehnia root (sha shen), schisandra fruit (wu wei zi), and ophiopogon root (mai dong) for deficient lungs characterized by chronic cough

Precautions

Species of *Dioscorea* that are edible have opposite leaves (leaves on the stem are directly across from one another), whereas species that are poisonous have alternate leaves (leaves on the stem are not directly across from one another).

Women who are pregnant or lactating should consult with a physician before using Chinese yam.

Side effects

There are no side effects associated with the use of Chinese yam.

Interactions

Chinese yam should not be taken with kan-sui root. As of mid-2000, there were no indications of any interactions between Chinese yam and any drug or other herbal medicine.

Chiropractic

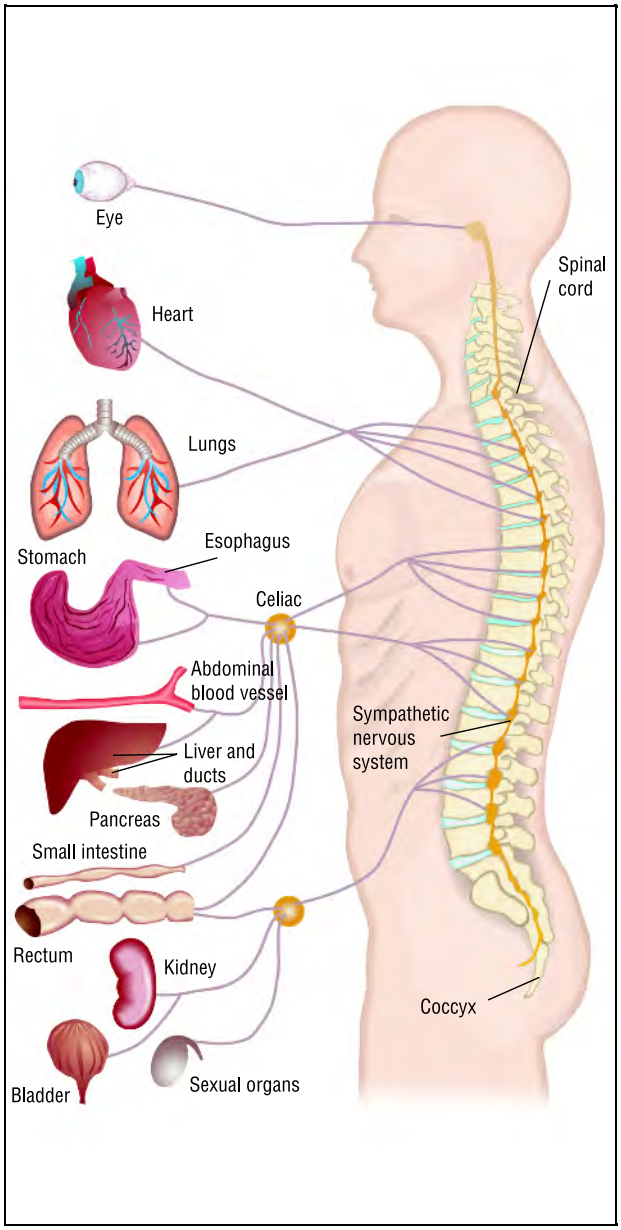
Definition

The term chiropractic is from Greek words *cheir* meaning hand and *praxis* meaning action. Chiropractic is a system of treatment grounded in the principal that the body can heal itself when the skeletal system is correctly aligned and the nervous system is functioning properly. To achieve this proper function and alignment, practitioners uses their hands or an adjusting tool to perform specific manipulations, most commonly of the spine. When the bones of the spine are not correctly articulated, resulting in a condition known as subluxation, the theory is that nerve transmission is disrupted and causes **pain** and illness manifested in the back as well as other areas of the body.

Chiropractic is one of the most popular alternative therapies currently available. According to the National Institutes of Health's National Center for Complementary and Alternative Medicine, about 20% of Americans report having used chiropractic care at least once. Chiropractic treatment is covered by many insurance plans, including Medicare. The most common reason for seeking chiropractic care is for pain in the lower back. According to the American Chiropractic Association, lower back pain accounts for about 43% of chiropractic visits. In addition, many people seek chiropractic care for a variety of other problems, including ear **infections**, dysmenorrheal, infant **colic**, migraine headaches. Patients also visit chiropractors with complaints of pain or injury to the neck, middle back, arms, or legs.

Origins

Spinal manipulation has a long history in many cultures. However, Daniel D. Palmer (1845–1913)



Points on the spine that correspond to various organs and their functions according to chiropractic medicine. *(Illustration by GGS Information Services, Inc. Cengage Learning, Gale)*

founded modern chiropractic theory in the 1890s. A grocer and self-taught magnetic healer, Palmer applied his knowledge of the nervous system and manual therapies to unusual situations. One renowned story concerns Harvey Lillard, a janitor in the office where Palmer worked. The man had been deaf for 17 years, ever since he had sustained an injury to his upper spine. Palmer performed an adjustment on a painful vertebra in the region of the injury and Lillard's hearing was reportedly restored. Palmer theorized that all communication from the brain to the rest of the body passes through the spinal canal and areas that are poorly aligned or under **stress** can cause physical symptoms both in the spine and in other areas of the body. Thus, the body has the innate intelligence to heal itself when unencumbered by spinal irregularities causing nerve interference. After his success with Lillard, other patients began coming to Palmer for care and responded well to adjustments. This success resulted in Palmer's further study of the relationship between an optimally functional spine and normal health.

Palmer founded the first chiropractic college in 1897. His son, B. J. Palmer, continued to develop chiropractic philosophy and practice after his father's death. B. J. and other faculty members were divided over the role of subluxation in disease. B. J. saw it as the cause of all disease. The others disagreed and sought a more rational way of thinking, thus broadening the base of chiropractic education. From 1910 to 1920, many other chiropractic colleges were established. Other innovators, including John Howard, Carl Cleveland, Earl Homewood, Joseph Janse, Herbert Lee, and Claude Watkins also helped to advance the profession.

The theories first developed by the Palmers received somewhat broader interpretation in the late 2000s. Many chiropractors believe that back pain can be relieved and health restored through chiropractic treatment even in patients who do not have demonstrable subluxations. Scientific development and research of chiropractic is gaining momentum, with controlled, scientific studies of chiropractic techniques becoming increasingly common. The National Center for Complementary and Alternative Medicine has even targeted funding to help increase the number of chiropractors participating in research.

Many people besides the Palmers have contributed to the development of chiropractic theory and technique. Some have gone on to create a variety of procedures and related types of therapy that have their roots in chiropractic, including McTimoney-Corley chiropractic, craniosacral manipulation, naprapathy, and **applied kinesiology**. **Osteopathy** is a related holistic discipline that utilizes spinal and musculoskeletal manipulation as a part of treatment, but osteopathic training is more similar in scope to that of a medical doctor.

Benefits

Many people experience back pain at some time in their lives. Depending on the cause and severity of the condition, options for treatment may include physical

therapy, rest, medications, surgery, or chiropractic care. Chiropractic is not believed to carry the risks of surgical or pharmacologic treatment. Practitioners use a holistic approach to health, which is appreciated by many patients. The goal is not merely to relieve the present ailment, but to analyze the cause and recommend appropriate changes of lifestyle to prevent the problem from recurring. Chiropractors generally believe in performing a risk/benefit analysis before use of any intervention. The odds of an adverse outcome are extremely low. Chiropractic is often less expensive than many more traditional treatment methods such as outpatient physical therapy. Relief from some neuromuscular problems is immediate, although a series of treatments is likely to be required to maintain the improvement. Spinal manipulation is often considered an excellent option for acute lower back pain and may also relieve **neck pain** and other musculoskeletal pain. Although many instances of back pain subside eventually with no treatment at all, chiropractic treatment can significantly shorten the time required for improvement. Some types of **headache** can also be successfully treated by chiropractic.

Description

Initial visit

An initial chiropractic exam often includes a history and a physical. The patient is asked about the current complaint, about any chronic health problems, about family history of disease, dietary habits, medical care received, and any medications currently being taken. Further, the chiropractor asks how long the patient has had the problem, how it has progressed, and whether it resulted from an injury or occurred spontaneously. The chiropractor also asks for details of how the injury occurred. The physical exam evaluates by observation and palpation whether the painful area has evidence of inflammation or poor alignment. Range of motion may also be assessed. In the spine, either hypomobility (fixation) or hypermobility may be a problem. Laboratory analysis is helpful in some cases to rule out serious infection or other health issues that may require referral for another type of treatment. Many practitioners also take x rays during the initial evaluation

Manipulation

When spinal manipulation is employed, it is generally done with the hands, although some practitioners may use an adjusting tool. A classic adjustment involves a high velocity, low amplitude thrust that produces a usually painless popping noise and improves the range of motion of the joint that was treated. The patient may lie on a specially designed, padded table that helps the practitioner achieve the proper positions for treatment. Some adjustments involve manipulating the entire spine, or large portions of it, as a unit; others are small movements designed to affect a single joint. Stretching, traction, and slow manipulation are other techniques that can be employed to restore structural integrity and relieve nerve interference.

Length of treatment

The number of chiropractic treatments required varies depending on several factors. Generally longer-term treatment is needed for conditions that are chronic, severe, or occur in conjunction with another health problem. Patients who are not in overall good health may also have longer healing times. Some injuries will inherently require more treatments than others. Care is usually given in three stages. Initially, appointments are more frequent with the goal of relieving immediate pain. Next, the patient moves into a rehabilitative stage to continue the healing process and help to prevent a relapse. Finally, the patient may elect periodic maintenance, or wellness treatments, along with lifestyle changes if needed in order to stay in good health.

Follow-up care

Discharge and follow-up therapy are important. If an injury occurred as a result of poor fitness or health, a program of **exercise** or **nutrition** should be prescribed. Home therapy may also be recommended, involving such treatments as anti-inflammatory medication and applications of heat or ice packs. Conscious attention to posture may help some patients avoid sustaining a similar injury in the future, and the chiropractor is be able to advise the patient of any poor postural habits that require correction.

Types of practitioners

Some practitioners use spinal manipulation to the exclusion of all other modalities and are known as straight chiropractors. Others integrate various types of therapy such as massage, nutritional intervention, or treatment with vitamins, herbs, or homeopathic remedies. They may also embrace ideas from other health care traditions. This group is known as mixers. The vast majority of chiropractors, perhaps 85%, fall in this second category.

Preparations

Patients should enter the chiropractic clinic with an open mind, which will help to achieve maximum results.

Precautions

Chiropractic is not an appropriate therapy for all problems. Many diseases and conditions require medication or surgery. Although there are many conditions of the spine that are amenable to manipulative treatment, it is not appropriate for **fractures**. The chiropractor should be informed in advance if the patient is taking anticoagulants or has **osteoporosis** or any other condition that may weaken the bones. Other circumstances that contraindicate chiropractic care are detected in the history and physical exam. Down syndrome, some congenital defects, some types of **cancer**, and a variety of other diseases and conditions may preclude spinal manipulation. On rare occasions, a fracture or dislocation may occur during manipulation. There is also a risk of a **stroke** occurring as a result of spinal manipulation, although this risk is extremely low. Estimates put the risk at no more than 2.5 occurrences per one million treatments.

Side effects

It is not uncommon to have local discomfort in the form of aches, pains, or spasms for a few days following a chiropractic treatment. Some patients may also experience mild headache or **fatigue** that resolves quickly.

Research and general acceptance

As recently as the 1970s, the American Medical Association (a national group of medical doctors) was quite hostile toward chiropractic. AMA members were advised that it was unethical to be associated with chiropractors. Later that changed and as of 2008, many allopathic or traditionally trained physicians enjoyed cordial referral relationships with chiropractors. There remained, however, strong debate over which diseases and conditions can be successfully treated using chiropractic.

Although some members of the medical community continue to have reservations about chiropractic, it seems to be favored by a significant section of the general population. A study published in the October 2007 volume of the *Journal of Occupational & Environmental Medicine* found that 89% of workers experiencing occupational **low back pain** began visiting a chiropractor within 30 days after the onset of pain.

KEY TERMS

Adjustment—A specific type of manipulation of the spine designed to return it to proper structural and functional form.

Allopathic—Conventional practice of medicine generally associated with medical doctors.

Dysmenorrhea—Painful menstruation.

Osteoporosis—A condition of decreased bone density, causing increased bone fragility, which is most common in elderly women.

Subluxation—Misalignment between vertebrae that structurally and functionally impairs nerve function.

Although studies such as this one show how popular chiropractic care is with the general population, scientists and medical researchers continue to conduct studies to determine which treatments are really effective.

A July 2006 study took 235 subjects who were seeking care for low back pain and randomly assigned them to either chiropractic care or to physical therapy. The study found that, in general, those who received chiropractic care had a larger reduction in pain. The study did find, however, certain subgroups, such as those with recurrent pain, improved more with physical therapy. This type of complexity may help to explain why some studies find that chiropractic intervention has a very high success rate in treating low back pain, and other studies find that it is not effective.

In addition to treating low back pain, there is some anecdotal evidence that recommends chiropractic treatment for ailments unrelated to musculoskeletal problems, but as of 2008 there was not enough research-based data to support this. By contrast, a chiropractor may be able to treat problems and diseases unrelated to the skeletal structure by employing therapies other than spinal manipulation.

Although many chiropractors limit their practice to spine and joint problems, others claim to treat disorders that are not closely related to the back or musculoskeletal system. These include **asthma**, bedwetting, **bronchitis**, coughs, **dizziness**, **dysmenorrhea**, **earache**, fainting, headache, hyperactivity, **indigestion**, **infertility**, migraine, **pneumonia**, and issues related to **pregnancy**. There is not a significant body of scientific evidence showing that chiropractic care is successful in treating these conditions. There are, however, at least three explanations sometimes given for why chiropractic may be successful in treating these

DANIEL PALMER (1845–1913)

Chiropractic inventor, Daniel David Palmer, was born on March 7, 1845, in Toronto, Ontario. He was one of five siblings, the children of a shoemaker and his wife, Thomas and Katherine Palmer. Daniel Palmer and his older brother left Canada with a tiny cash reserve in April 1865. They immigrated to the United States on foot, walking for 30 days before arriving in Buffalo, New York. They traveled by boat through the St. Lawrence Seaway to Detroit, Michigan. There they survived by working odd jobs and sleeping on the dock. Daniel Palmer settled in What Cheer, Iowa, where he supported himself and his first wife as a grocer and fish peddler in the early 1880s. He later moved to Davenport, Iowa, where he raised three daughters and one son.

Palmer was a man of high curiosity. He investigated a variety of disciplines of medical science during his life time, many of which were in their infancy. He was intrigued by phrenology and assorted spiritual cults, and for nine years he investigated the relationship between magnetism and disease. Palmer felt that there was one thing that caused disease. He was intent upon discovering this one thing, or as he called it: the great secret.

In September 1895, Palmer purported to have cured a deaf man by placing pressure on the man's displaced vertebra. Shortly afterward Palmer claimed to cure another patient of heart trouble, again by adjusting a displaced vertebra. The double coincidence led Palmer to theorize that human disease might be the result of dislocated or luxated bones, as Palmer called them. That same year he established the Palmer School of Chiropractic where he taught a three month course in the simple fundamentals of medicine and spinal adjustment.

Palmer, who was married six times during his life, died in California in 1913; he was destitute. His son, Bartlett Joshua Palmer, successfully commercialized the practice of chiropractic.

conditions. One is that the problem could be linked to a nerve impingement, as may be possible with bed-wetting, dizziness, fainting, and headache. In a second group, chiropractic treatment may offer some relief from complicating pain and spasms caused by the disease process, as with asthma, bronchitis, coughs, and pneumonia. The discomforts of pregnancy may also be relieved with gentle chiropractic therapy. A third possibility is that manipulation or use of soft-tissue techniques may directly promote improvement of some conditions. One particular procedure, known as the endonasal technique, is thought to help the eustachian tube to open and thus improve drainage of the middle ear. The tube is sometimes blocked off due to exudates or inflammatory processes, which can cause earaches. Some headaches also fall in this category, as skilled use of soft tissue techniques and adjustment may relieve the muscle tension that may initiate some headaches.

Dysmenorrhea, hyperactivity, indigestion, and infertility are said to be relieved as a result of improved flow of blood and nerve energy following treatment. Evidence for this is anecdotal at best, but manipulation is unlikely to be harmful if causes treatable by other modalities have been ruled out.

For conditions such as cancer, fractures, infectious diseases, neurological disease processes, and any condition that may cause increased orthopedic fragility, chiropractic treatment alone is not an effective therapy and may even be harmful in some cases. Chiropractic treatment should never be sought to the complete exclusion of traditional medical therapies. Those who have known circulatory problems, especially with a history of thrombosis, should not have spinal manipulation.

Training and certification

Chiropractors are licensed by the state in which they practice. Matriculation at a certified school of chiropractic requires at least two years of science-based undergraduate work, and most applicants have completed a bachelor's degree. Chiropractic college is an additional four-year program and graduates receive a DC (doctor of chiropractic) degree. Chiropractic education emphasizes anatomy, physiology, diagnostic skills, neurology, and radiology. As of the year 2008, there were 18 chiropractic colleges in the United States. Following graduation, the doctors must pass both national board and state board exams in order to be licensed. A minimum number of continuing education hours per year may be required in some states to maintain licensure. Practitioners may also opt for a program to become a diplomate of a more specialized group. Requirements for these groups vary considerably, from a program similar to a traditional residency down to some that require a minimal number of hours of continuing education. Some of the specialties offered are radiology, orthopedics, sports injuries, nutrition, neurology, and internal medicine. Most chiropractors do not specialize.

Chlamydia

Definition

Chlamydia is the most common sexually transmitted disease in the United States. More than a million new cases of the diseases were reported in 2007, the most ever for a sexually transmitted disease in the United States. The disease is caused by a bacterium called *Chlamydia trachomatis*. The following areas in the body can be affected:

- cervix
- fallopian tubes, which carry ova (eggs) from the ovaries to the uterus
- urethra, which carries urine from the bladder to outside the body
- epididymis, a small organ attached to the testicles that is responsible for sperm production
- prostate gland, a gland at the base of the penis that provides nutrients for sperm
- anus
- throat
- eyes

In addition, *Chlamydia trachomatis* also causes lung and eye **infections** in newborns whose mothers have a chlamydial infection during the last part of their **pregnancy**.

Description

Chlamydia is most often found in sexually active adolescents aged 15 to 19. Data gathered by the Centers for Disease Control (CDC) suggest that sexually active girls in this age group may account for up to 40% of chlamydial infections.

According to the CDC, approximately 40% of women infected with chlamydia develop **pelvic inflammatory disease** (PID). If untreated, 18% of women with PID have chronic inflammatory **pain**. In addition, chlamydia may cause extensive damage to the fallopian tubes. Scarring can block the tube and prevent the egg from being fertilized. As a result, one of every five women with PID is unable to conceive. Tube scarring may also cause the fertilized egg to be trapped inside the tube, unable to reach the uterus. When the fertilized egg develops inside the tube rather than in the uterus, the condition is called tubal pregnancy. The condition is potentially fatal if the tube ruptures. In the United States, tubal pregnancy is the number one cause of death of women in early pregnancy.

Causes and symptoms

Cause

Chlamydia is caused by a bacterial parasite called *Chlamydia trachomatis*. The organism lives inside humans, who act as hosts. It is dependent on humans for energy because it is unable to produce energy for itself. *C. trachomatis* often causes genital and urinary tract infections in sexually active men and women.

Mode of transmission

A person can become infected with *C. trachomatis* in the following ways:

- having sex (oral, genital, or anal) with an infected partner
- sharing infected sex toys

- passing through the infected birth canal of a mother who has chlamydia
- experiencing an episode of sexual abuse (in children)

Risk factors

The following are risk factors for contracting chlamydia infections:

- Age. Young sexually active people aged 15 to 19 are most frequently affected.
- Race. Blacks contract this disease more often than whites or Hispanics.
- Marital status. Chlamydia is most often found in single women. Married women have the lowest risk.
- Behavioral factors. Douching increases risk of chlamydial infections. Smoking also increases one's risk of contracting this disease. Those who have sex with many different partners or with strangers are at high risk. Also at increased risk are those who have unprotected sex with partners of unknown disease status. Previous induced abortions also increase a woman's chance of getting this disease.
- Socio-economic status. Poor, uneducated women living in big cities are more often affected by this disease.
- Postpartum period. Increased risk of contracting chlamydia is observed during the period immediately after giving birth or undergoing an induced abortion. This risk arises because the cervix is not entirely closed, allowing a greater chance for infection.

Symptoms

Approximately 75% of women do not have symptoms. If a woman has symptoms, they typically develop one to three weeks after she is infected. Her symptoms may include:

- burning pain during urination
- more frequent urination
- abnormal vaginal discharge
- dull pelvic pain
- bleeding between periods and after sexual intercourse
- menstrual bleeding that is heavier than usual
- more painful periods

Chlamydia infection in men may develop in the urethra, epididymis, and/or the prostate. Approximately 50% of infected men do not have any symptoms. If a man has symptoms, they tend to develop one to three weeks after he is infected. His symptoms may include:

- burning pain during urination
- more frequent urination
- white or yellow discharge from the penis
- redness at the tip of the penis
- itchy or irritated urethra (urethritis)
- pain and swelling in the testicles (epididymitis)
- pain between the scrotum and anal area and difficult and frequent urination (prostatitis)

On rare occasions, chlamydia infection in men and women can develop outside the genital areas. These patients may have infections at the following sites:

- eyes (due to a contaminated hand touching the eyes): itching, redness and itching of the eyelids
- throat (following oral sex with infected men): throat irritation or no symptoms
- anus (following anal intercourse with infected men): rectal bleeding, mucous rectal discharge, diarrhea, and pain with bowel movement.

Diagnosis

Diagnosis is based on patients' history, laboratory testing for *C. trachomatis*, and physical examination for men and pelvic examination for women to determine if the patient is infected and/or the extent of infection.

There are several tests available for chlamydial infection. They often require swipes from the infected site or urine samples. Tests for chlamydia include:

- Cell culture test. This old test is reliable but requires 48 to 72 hours to complete. In the early 2000s, it was being replaced by faster and more convenient tests. In 2001, the U.S. Food and Drug Administration (FDA) recommended routine screening for chlamydia among sexually active young women. One year later, the administration approved a test called ThinPrep, a new type of Pap smear that allows doctors to screen for chlamydia, gonorrhea, and the human papillomavirus at the same time women have annual pap exams for cervical cancer.
- Direct fluorescent antibody (DFA) staining. This test is faster than the traditional culture test.
- Enzyme immunoassay (EIA). This test is easy to perform and faster than the traditional culture test but is not as accurate.
- DNA probe. This test is expensive but is more specific and convenient than culture, EIA, or DFA tests. Genital swipe samples are not necessary. Urine tests can provide accurate results.
- Nucleic acid amplification (PCR and LCR) tests. These tests look for genetic material of the organism. These are the tests of choice because they are the

most sensitive (more than 90% accurate) and the most specific. They are also convenient because they can be performed on urine samples and do not require a pelvic exam.

Treatment

Alternative therapy should be complementary to antibiotic therapy. Because of the potentially serious nature of this disease, patients should first consult an allopathic physician to start antibiotic treatment for infections. Traditional medicine is better equipped to quickly eradicate the infection while alternative treatments can help the body fight the disease and relieve symptoms associated with this disease. Some alternative treatments include nutritional therapy, herbal remedies, **traditional Chinese medicine**, and **homeopathy**.

Nutritional therapy

The following dietary changes may be helpful:

- Following a low-fat, high-fiber diet. The diet should include a variety of fresh fruits and vegetables. These foods contain high amounts of phytonutrients and essential vitamins that help keep the body strong and stimulate the immune system to fight infections.
- Limited intake of fat, sugar, highly processed foods, caffeine, and alcohol, which depresses the immune function.
- Taking a multivitamin/mineral supplement daily.
- Drinking cranberry juice. Cranberry juice helps prevent urinary tract infections.
- Taking acidophilus pills to prevent yeast infections while on antibiotics.
- Eating fresh garlic or taking garlic pills to help fight infection.

Herbal treatment

Echinacea and berberine-containing herbs such as **saw palmetto** (*Serenoa repens*) and **goldenseal** are natural antibiotics. These herbs can assist the action of prescription antibiotics.

Traditional Chinese medicine

An experienced Chinese herbalist typically prepares an herbal mixture based on a patient's specific condition and symptoms.

Homeopathy

A homeopathic practitioner may prescribe a patient-specific remedy to help reduce some of the symptoms associated with disease. Remedies for chlamydial symptoms include *Cannabis sativa*, *Cantharis*, and *Salidago virga*.

Allopathic treatment

Once detected, chlamydia can be easily treated with antibiotics. However, if not detected early enough, scarring of fallopian tubes (and resulting **infertility**) may not be preventable. The two most commonly used drugs are azithromycin and doxycycline. Azithromycin is more expensive but much more convenient to administer. Only one dose is needed to treat the disease. Doxycycline is cheaper but needs to be taken twice a day for more than seven days. Because patients tend to stop taking drugs after a few days, doxycycline is not as effective as azithromycin. Therefore, many doctors prefer to give azithromycin. Patients are advised to refrain from sex for a full week after taking azithromycin or until they finish doxycycline treatment.

An infected person should contact all partners within the last two months so that they can be tested for chlamydia.

Infected pregnant women should be given erythromycin for seven days, instead of other drugs, because this drug is safer during pregnancy.

Follow-up testing is done four weeks after drug treatment to see if the infection is eradicated. If tests continue to be positive, the patient is given another course of antibiotics.

Expected results

A woman's prognosis depends on the duration of infection, whether the infection has spread through the uterus and the fallopian tubes, and the number of previous chlamydial infections. If detected early, the disease can be completely cured with antibiotic treatment in seven days. However, if left untreated, chlamydia can spread through the uterus to the fallopian tubes and cause chronic pelvic inflammatory disease. Infertility may occur as a result of serious damage to the female reproductive tract. Potentially fatal tubal pregnancy is also a risk.

Prevention

Prevention is the most important means of stopping the spread of this disease. The following practices are recommended to prevent the spread of this and other sexually transmitted diseases:

- Abstinence. Abstinence is the only sure way to prevent chlamydia and other STD infections.

KEY TERMS

Abstinence—Choosing not to engage in a certain action, such as sex.

Infertility—Inability to have children, which may occur as a result of pelvic infections.

Nongonococcal urethritis (NGU)—A sexually transmitted urethral infection that is not gonorrhea.

Pelvic Inflammatory Disease (PID)—An infection of the uterus, fallopian tubes, and/or ovaries.

Tubal pregnancy—A fertilized egg that implants in the fallopian tube instead of inside the uterus, which often occurs as a result of sexually transmitted infections such as Chlamydia; also known as ectopic pregnancy.

- Monogamy. Having a mutually monogamous relationship with an uninfected partner reduces the chance of getting STD infections.
- Avoiding a sexual relationship with an unknown partner or a partner whose infection status is unknown.
- In having sex with an unknown partner, using a barrier contraceptive such as a condom (for men) or diaphragm (for women) is recommended. However, condoms (or diaphragms) are not 100% effective against chlamydia or other STDs.
- Refraining from douching.
- Avoiding sex soon after giving birth or undergoing an induced abortion.
- Getting tested for chlamydia at yearly pelvic examinations.

Chlorella

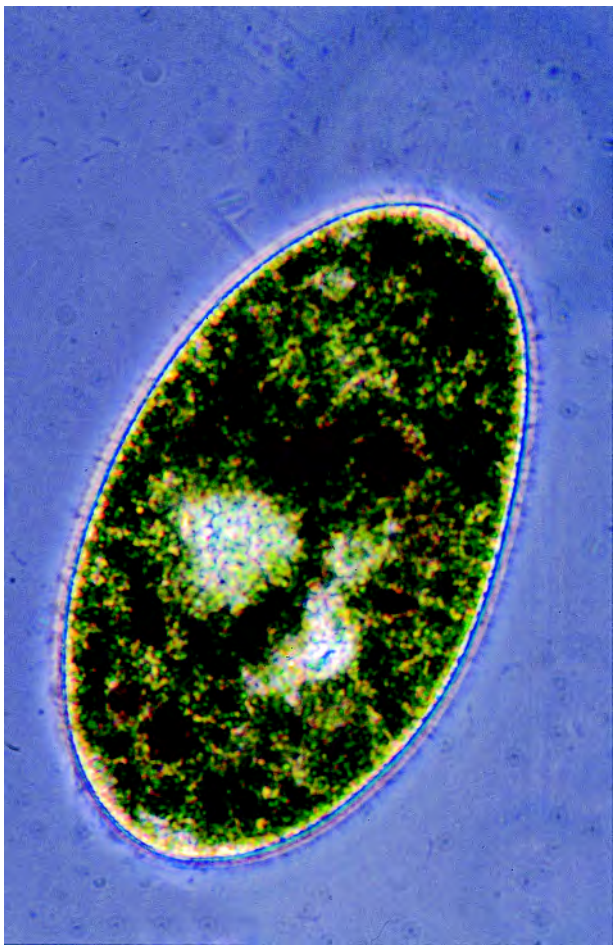
Description

Chlorella is a type of single-cell green algae. It is a major component of phytoplankton, which are very small free-floating aquatic plants found in plankton. Chlorella is a popular food supplement, especially in Japan, and is sold as a nutritional supplement in the United States, Canada, and other parts of the world. There are several species of chlorella, but those most commonly found in supplements are *Chlorella vulgaris* and *Chlorella pyrenoidosa*.

General use

Chlorella contains high levels of chlorophyll, protein, **iron**, vitamins C and B_{12}, **beta carotene**, and 19 **amino acids**.

Several studies have indicated that chlorella may be effective in treating some types of **cancer**, high **cholesterol**, **hypertension** (high blood pressure), and **fibromyalgia** syndrome, and in boosting the immune



This ciliate protozoan Paramecium bursaria, a green slipper animalcule, gets its color from symbiotic algae Chlorella. *(PHOTOTAKE Inc. / Alamy)*

system and detoxifying the body. As is often the case with alternative therapies, there are several studies that dispute the effectiveness of chlorella in treating these medical conditions.

The ability of chlorella to fight cancer cells has been shown in several scientific studies, although the exact mechanisms by which it works were not known as of 2008. Several scientists believe chlorella stimulates the activity of T-cells—important components of the immune system—and macrophages, which are large cells that protect against infection by removing waste products, harmful microorganisms, and other toxins from the bloodstream. Increasing the production of T-cells and macrophages increases interferon levels in the body, enhancing the immune system's ability to fight invading substances such as viruses, bacteria, and chemicals. Interferon is an immune-related protein produced by the body that performs antiviral and anti-tumor activities.

Studies in laboratory animals suggest some substances in chlorella may reduce bone marrow suppression in patients taking the anticancer drug fluorouracil. In this interaction, chlorella may increase the white blood cell and platelet counts, which reduces the risk of infection and bleeding, respectively.

Studies have also shown chlorella can significantly reduce cholesterol levels in laboratory animals. As of 2008 studies were underway to determine if chlorella has the same effect on human cholesterol levels.

Chlorella may help reduce blood pressure in some people with hypertension (high blood pressure). A study reported in the March 2003 issue of *Original Internist* indicated that treatment with 10 grams of chlorella daily for three months significantly improved blood pressure in 25% of the patients involved.

In a 2000 study, patients with fibromyalgia syndrome (a disorder that causes muscle aches, **fatigue**, and **sleep disorders**) were treated with high doses of chlorella. After two months, the study found significant benefits from chlorella treatment.

Clinical studies of laboratory animals have also shown that chlorella can protect against gamma radiation and other toxic drugs and chemicals, including dioxin. In the intestines, it can deactivate heavy metals such as cadmium, lead, and mercury.

The benefits of chlorella have been disputed. According to an equivocal article about chlorella on the American Cancer Society Web site, there is no scientific evidence showing chlorella's effectiveness against cancer or any other disease. Limited laboratory and animal research suggests that the algae may have some anticancer properties. One investigation concluded that a protein extract from one type of chlorella prevented the spread of cancer cells in mice. Another study of mice suggested that the extract decreased the side effects of chemotherapy treatment without affecting the potency of anticancer medications.

Preparations

Chlorella is available in various forms, including capsule, tablet, softgel, powder, and liquid. It is found as a supplement alone or in a combination with other green food extracts such as wheat grass, **barley grass**, and **spirulina** (a nutritionally rich microorganism). Capsules and tablets are available in doses of 200 to 500 milligrams (mg). There is no standard dosage, but some herbalists recommend 3 grams (g) per day.

KEY TERMS

Algae—A mainly waterborne organism that produces energy from light and chlorophyll.

Amino acids—A group of organic compounds that are vital to living cells.

Cadmium—A heavy metal.

Chlorophyll—A green plant pigment found in plants, algae, and some bacteria. Chlorophyll is responsible for capturing the light energy needed for photosynthesis.

Cholesterol—A compound found in animal tissue, blood, and fats, high levels of which in the blood are linked to clogged arteries, heart disease, and gallstones.

Diabetes—A metabolic disorder in which the body produces insufficient insulin or is unable to effectively use normal amounts because of insulin resistance. Type 1 diabetes typically manifests in children as a pancreatic deficiency; Type 2 (adult onset diabetes) is usually a consequence of chronic blood sugar dysregulation.

Dioxin—A toxic chemical produced in the manufacture of some pesticides and herbicides.

Fibromyalgia syndrome—Also called fibromyalgia, a disorder that causes muscle aches, fatigue, and sleep disorders.

Fluorouracil—An anticancer drug.

Gamma radiation—High energy electromagnetic waves emitted in some nuclear reactions.

Hypertension—High blood pressure.

Insulin—A hormone that helps muscle and fat cells take up and sugars, starches, and other foods for conversion into energy the body needs.

Interferon—An immune protein produced by cells in the body to fight viral infections.

Macrophages—Large cells that protect against infection by removing waste products, harmful microorganisms, and other toxins from the bloodstream.

Phytoplankton—Very small free-floating aquatic plants found in plankton.

Plankton—A mass of tiny animals and plants floating in the sea or in lakes, usually near the surface.

Platelet—The smallest kind of blood cell, usually found in large quantities, that plays an important part in blood clotting. Also called thrombocytes.

Spirulina—A nutritionally valuable organism that is rich in vitamins, minerals, essential fatty acids, and antioxidants.

T-cells—A type of white blood cell that plays an important role in the immune system and in combating viral infections and cancers.

Ulcerative colitis—An inflammation in the walls of the bowel that causes internal sores, called ulcers, on the lining of the bowel.

Warfarin—A blood-thinning drug, known by the brand name Coumadin.

Precautions

Pregnant and breastfeeding women are advised to use caution and follow the advice of their healthcare professional, since the effects of chlorella have not been studied for these two groups. Caution may also be advised for persons known to be sensitive or allergic to **iodine**.

Side effects

Although chlorella appears to be safe, no research as of 2008 in humans had been conducted to determine if the supplement causes any negative side effects. Also, no studies had been done regarding the consequences of long-term use. Mild side effects that have been reported include bloating and **nausea**, which usually disappear after a few days of use. Some people using chlorella have had allergic reactions and adverse reactions to sunlight. Allergic reaction symptoms include difficulty breathing, chest **pain**, **hives**, rash, and itchy or swollen skin. If any of these reactions occurs, the person should seek medical care immediately.

Interactions

Persons taking the blood-thinning drug warfarin (Coumadin) are advised to completely avoid chlorella or use caution and follow the advice of their healthcare professional because some chlorella supplements contain high amounts of **vitamin K** that may affect the inhibition of **blood clots**.

Cholesterol

Definition

Cholesterol, a fatty substance found in animal tissue, is an important component of the human body. It is manufactured in the liver and carried throughout the body in the bloodstream. Problems can occur when excess cholesterol causes accumulation of plaque on blood vessel walls, which impedes blood flow to the heart and other organs. The highest cholesterol content is found in meat, poultry, shellfish, and dairy products.

Description

Cholesterol has both good effects and bad effects. It is necessary for digesting fats, making hormones, building cell walls, and it participates in other processes for maintaining a healthy body. The body contains two forms of cholesterol: high-density cholesterol (HDL), the so-called good cholesterol, and low-density cholesterol (LDL), the so-called bad cholesterol. The total amount of HDL and LDL is called the total cholesterol. A third type of fatty material found in the body, triglycerides, is a simple form of fat with health effects related to those of cholesterol.

The American Heart Association estimated in 2008 that 106.7 million American adults, roughly one-half of the adult population, have elevated cholesterol levels. High LDL is a major contributing factor for **heart disease**. The cholesterol forms plaque in the heart's blood vessels that restricts or blocks the supply of blood to the heart and causes **atherosclerosis**, which can lead to a **heart attack**, resulting in damage to the heart and possibly death.

The U.S. population as a whole is at some risk of developing high LDL cholesterol. Specific risk factors include a family history of high cholesterol, **obesity**, heart attack or **stroke**, **alcoholism**, and lack of regular **exercise**. The chances of developing high cholesterol increase after the age of 45. One of the primary causes of high LDL cholesterol is too much fat or sugar in the diet, a problem especially prevalent in the United States. Cholesterol is also produced naturally in the liver and overproduction may occur even in people who limit their intake of high cholesterol food. Low HDL and high triglyceride levels also are risk factors for atherosclerosis.

Types of cholesterol

Types	Levels (mg/dl)
Total cholesterol:	
Desirable	<200
Borderline	200 to 240
Undesirable	>240
HDL cholesterol:	
Desirable	>45
Borderline	35 to 45
Undesirable	<35
LDL cholesterol:	
Desirable	<130
Borderline	130 to 160
Undesirable	>160
Ratio of total cholesterol to HDL cholesterol:	
Desirable	<3
Borderline	3 to 4
Undesirable	>4

Causes and symptoms

There are no readily apparent symptoms that indicate high LDL or triglycerides, or low HDL. A simple blood test can reveal a problem. However, one general indication of high cholesterol is obesity. Another is a high-fat diet. Research has shown that both genetic factors and diet contribute to cholesterol levels.

Diagnosis

High cholesterol is often diagnosed and treated by general practitioners or family practice physicians. In some cases, the condition is treated by an endocrinologist or cardiologist. Total cholesterol, LDL, HDL, and triglyceride levels as well as the cholesterol to HDL ratio are measured by a blood test called a lipid panel. The cost of a lipid panel is typically covered by health insurance and HMO plans, including Medicare, providing there is an appropriate reason for the test. Home cholesterol testing kits are available over the counter, but these test only for total cholesterol. The results should be used only as a guide, and if the total cholesterol level is high or low, a lipid panel should be performed by a physician. In most adults the recommended levels, measured by milligrams per deciliter (mg/dL) of blood, are: total cholesterol, less than 200; LDL, less than 130; HDL, more than 40; triglycerides, less than 200; and cholesterol to HDL ratio, four to one. However, the recommended cholesterol levels may vary, depending on other risk factors such as **hypertension**, a family history of heart disease, diabetes, age, alcoholism, and **smoking**.

Doctors wonder why some people develop heart disease whereas others with identical HDL and LDL levels do not. Some studies indicate it may be due to the size of the cholesterol particles in the bloodstream. A test called a nuclear magnetic resonance (NMR) LipoProfile exposes a blood sample to a magnetic field to determine the size of the cholesterol particles. Particle size also can be determined by a centrifugation test, in which blood samples are spun to allow particles to separate and move at different distances. The smaller the particles, the greater the chance of developing heart disease. This test allows physicians to treat patients who have normal or close to normal results from a lipid panel but abnormal particle size.

Treatment

U.S. guidelines in the late 2000s for management of cholesterol levels were established in a 2004 report of the National Cholesterol Education Program of the National Heart, Lung, and Blood Institute, American College of Cardiology Foundation, and American Heart Association. According to that report, the primary goal of cholesterol treatment is to lower LDL to under 160 mg/dL in people without heart disease and who are at lower risk of developing it. The goal in people with higher risk factors for heart disease is less than 130 mg/dL. In patients who already have heart disease, the goal is under 100 mg/dL. Also, since low HDL levels increase the risks of heart disease, the goal for all patients is an HDL level of more than 35 mg/dL.

In both alternative and conventional treatment of high cholesterol, the first-line treatment options are exercise, diet, weight loss, and stopping smoking. Other alternative treatments include high doses of **niacin**, **soy protein**, **garlic**, algae, and the Chinese medicine supplement Cholestin (a red yeast fermented with rice).

Diet and exercise

Since a large number of people with high cholesterol are overweight, a healthy diet and regular exercise are probably the most beneficial natural ways to control cholesterol levels. In general, the goal is to substantially reduce or eliminate foods high in animal fat. These foods include meat, shellfish, eggs, and dairy products. Several specific diet options are

beneficial. One is the vegetarian diet. Vegetarians typically get up to 100% more fiber and up to 50% less cholesterol from their food than non-vegetarians. The vegetarian low-cholesterol diet consists of at least six servings of whole grain foods, three or more servings of green leafy vegetables, two to four servings of fruit, two to four servings of legumes, and one or two servings of non-fat dairy products daily.

A second diet is the Asian diet, with brown rice being the staple food. Other permitted foods include fish; vegetables, such as bok choy and bean sprouts; and black beans. This diet includes one weekly serving of meat and very few dairy products. The food is flavored with traditional Asian spices and condiments, such as **ginger**, chilies, **turmeric**, and soy sauce.

Another regimen is the low glycemic or diabetic diet, which may raise the HDL (good cholesterol) level by as much as 20% in three weeks. Low glycemic foods promote a slow but steady rise in blood sugar levels following a meal, which increases the level of HDL. They also lower total cholesterol and triglycerides. Low glycemic foods include certain fruits, vegetables, beans, and whole grains. Processed and refined foods and sugars are avoided.

Exercise is an extremely important part of lowering bad cholesterol and raising good cholesterol. It should consist of 20 to 30 minutes of vigorous aerobic exercise at least three times a week. Exercises that cause the heart to beat faster include fast walking, bicycling, jogging, roller skating, swimming, and walking up stairs. Various aerobic programs are available at gyms or on videocassette.

Garlic

A number of clinical studies have indicated that garlic can offer modest reductions in cholesterol. A 2006 summary of those studies concluded that garlic appears to have the potential for reducing the level of substances such as LDL associated with heart disease but that further studies were needed to confirm this relationship.

Cholestin

Cholestin first became available in the over-the-counter market in 1997 as a cholesterol-lowering dietary supplement. It is a processed form of red yeast fermented with rice, a traditional herbal remedy used for centuries by the Chinese. Two studies released in 1998 showed Cholestin lowered LDL cholesterol by 20 to 30%. It also appeared to raise HDL and lower triglyceride levels. Although the supplement contains hundreds of compounds, the major active LDL-lowering ingredient is lovastatin, a chemical also found in the prescription drug Mevacor. The FDA banned Cholestin in early 1998 but a federal district court judge lifted the ban a year later, ruling the product was a dietary supplement, not a drug. As of 2008, it remained unclear how the substance works. Patients may want to consult with their physician before taking Cholestin. No serious side effects have been reported, but minor side effects, including bloating and **heartburn**, have been reported. As of 2008, the FDA had not approved the use of Cholestin for any disease, and many questions remained about its efficacy in treating coronary problems.

Other treatments

A study released in 1999 indicated that blue-green algae contains polyunsaturated fatty acids that lower cholesterol levels. The algae, known as alga *Aphanizomenon flos-aquae* (AFA) is available as an over-the-counter dietary supplement. As of 2008, only one study had confirmed the results of the initial 1999 research, and questions remained as to the value of AFA in treating cholesterol problems. Niacin, also known as nicotinic acid or vitamin B_3, has been shown to reduce LDL levels by 10 to 20% and to raise HDL levels by 15 to 35%. It can also reduce triglyceride levels. But because an extremely high dose of niacin (2–3 grams) is needed to treat cholesterol problems, it should be taken only under a doctor's supervision so that in monitoring use, he or she can watch for possible toxic side effects. Niacin can also cause flushing when taken in high doses. Soy protein with high levels of isoflavones has been shown to reduce bad cholesterol by up to 10%. A daily diet that contains 62 mg of isoflavones in soy protein is recommended and can be incorporated into other diet regimens, including vegetarian, Asian, and low glycemic.

Allopathic treatment

Various prescription medicines are available to treat cholesterol problems. These include statins such as lovastatin (Mevacor), fluvastatin (Lescol), pravastatin (Pravachol), simvastatin (Zocor), cervastatin (Baycol), and atorvastatin (Lipitor) to lower LDL. A group of drugs called fibric acid derivatives are used to lower triglycerides and raise HDL. These include gemfibrozil (Lopid), clofibrate (Atromid-S), and fenofibrate (Tricor).

A new class of drugs was identified late in 2001 that work differently from the statin drugs. These drugs rely on compounds that bind to a sterol that regulates protein (called SCAP) and speeds up removal of cholesterol from the plasma (the fluid

KEY TERMS

Atherosclerosis—A buildup of fatty substances in the inner layers of the arteries.

Estrogen—A hormone that stimulates development of female secondary sex characteristics.

Glycemic—The presence of glucose in the blood.

Hypertension—Abnormally high blood pressure.

Legumes—A family of plants that bear edible seeds in pods, including beans and peas.

Lipid—Any of a variety of substances that, along with proteins and carbohydrates, make up the main structural components of living cells.

Polyunsaturated fats—Non-animal oils or fatty acids rich in unsaturated chemical bonds not associated with the formation of cholesterol in the blood.

part of the blood). Doctors decide which drug to use based on the severity of the cholesterol problem, side effects, and cost.

Expected results

High cholesterol is one of the key risk factors for heart disease. Left untreated, too much bad cholesterol can clog the blood vessels, leading to chest **pain** (**angina**), **blood clots**, and heart attacks. Heart disease is the number one killer of men and women in the United States. By reducing LDL, people with heart disease can prevent further heart attacks and strokes, prolong and improve the quality of their lives, and slow or reverse cholesterol buildup in the arteries. In people without heart disease, lowering LDL can decrease the risk of a first heart attack or stroke.

Prevention

The best way to prevent cholesterol problems is through a combination of healthy lifestyle activities, a primarily low-fat and **high-fiber diet**, regular aerobic exercise, not smoking, and maintaining an optimal weight. But for people with high risk factors for heart disease, such as a family history of heart disease, diabetes, and being over the age of 45, these measures may not be enough to prevent high cholesterol. In the late 2000s research continued on the effectiveness of existing anti-cholesterol drugs for controlling cholesterol levels in people who do not meet the criteria for high cholesterol, but no definitive results were yet available.

Choline

Description

Choline is an organic compound that functions as an important nutrient. It is found in many animal tissues, either by itself or combined with **lecithin**. In 1998, the United States Food and **Nutrition** board, a part of the Institute of Medicine, declared choline an essential nutrient. Choline is found naturally in meats, egg yolks, dairy foods, and soy products. Lecithin is a source of choline.

A study published by the United States Department of Agriculture in 2001 found that the human

body needs both folate and choline in order to continue to produce sufficient quantities of choline. A balanced diet rich in meats and vegetable products is recommended to help obtain sufficient amounts of choline.

General use

Choline has multiple important roles in the body. Choline is used to treat high **cholesterol**, improve memory, and safeguard the liver. It aids in the absorption and use of fats. Without choline, fat accumulates within the liver, damaging the organ. Choline also serves as an essential component in the making of acetylcholine. The latter is necessary for muscle control, storage of memory, and other neurological activities. Choline has gained popularity among body builders and athletes. According to a 2003 article in *Psychology Today*, choline reduced **fatigue** in long-distance runners and improved speed in a 20-mile run.

In 2003, scientists from the Massachusetts Institute of Technology released a study showing the positive effect of choline on boosting memory when laboratory rats took in a CDP-choline supplement. Choline is also important in the formation of DNA and other genetic compounds. A study released in 2006 found that a diet deficient in choline was linked with DNA damage. Choline is involved in the conversion of homocystine into **methionine**. This is an important physiological function because an accumulation of homocystine can increase risk for **heart disease** or **stroke**.

In 1999, the National Institutes for Health estimated that one percent of the United States population suffered from a genetic disorder that resulted in a fishy **body odor** due to a build-up of trimethylamine. A diet restricted in choline was suggested as a potential aide for these individuals.

Newborns require large amounts of choline to help their tiny organs undergo rapid growth and to achieve membrane biosynthesis. Choline and compounds containing choline are found in human breast milk and, in varying degrees, in infant formula.

A study released in 2007 found that supplements containing choline were beneficial for children with cystic fibrosis. A 2001 study involving rats found that pre- and postnatal supplementary choline prevented a loss of memory function associated with status epilepticus. As of 2008 more study in this area was needed.

Preparations

The recommended dose of choline, set by the Food and Nutrition Board of the National Academies of Science, is 425 mg per day for women and 550 mg per day for men. Choline is available in capsules, tablets, and liquid form.

KEY TERMS

Biosynthesis—A process that produces chemical compounds from simpler components.

Folate—A vitamin used to treat a number of medical conditions.

Homocysteine—An amino acid found in the body. High levels raise the risk for heart disease and stroke.

Lecithin—A fatty substance found in plant and animal material, particularly egg yolk.

Methionine—An amino acid that provides benefits for the liver, as well as for conditions such as osteoarthritis, depression, fibromyalgia, and a host of other medical issues.

Trimethylamine—A product of decomposition associated with a fishy odor. Its build-up can result from excessive choline.

Precautions

Prior to taking choline, individuals should inform their physician if they are pregnant, breastfeeding, or if they have a chronic illness. A study released in 2007 found a potential link between ingestion of choline and increased risk of colon polyps in women. Its role in the formation of such polyps may be related to its ability to help form the outer shell of the polyps. However, researchers noted that other factors in the study, such as intake of red meat, may also be related to the rise in colon polyps. Scientists cautioned that more information is needed before conclusions can be drawn about choline intake and the development of colon polyps. A study involving men was planned.

Side Effects

In general, choline is considered to be a well tolerated supplement. Individuals who experience the following side effects should stop taking choline and report right away to their physician because they may be experiencing an allergic reaction:

- Problems breathing or tightness in the throat or chest
- Pain in the chest
- Rash, hives, itchiness, or swelling of the skin

Other side effects include:

- Stomach pains or upset stomach
- Increased saliva

- Decreased appetite
- Sweating
- A fishy body odor

Interactions

As of 2008, there were no known negative interactions. Choline works in conjunction with other compounds, such as folate. Choline is a precursor to *betaine*.

Chondroitin

Description

Chondroitin is a substance found in human and animal cartilage that is used to treat several physical disorders, most importantly arthritis, **psoriasis**, and **cancer**. It is the most plentiful type of glycosaminoglycan (GAG) found in cartilage. Glycosaminoglycans (GAGs) are complex carbohydrates that are found in the various types of connective tissue in the body. GAGs account for 5–20% of cartilage tissue. Chondroitin occurs in connective tissue as a sulfate composed of repeating disaccharide units; the first unit is either **glucosamine** or galactosamine; the other unit is glucuronic acid.

General use

Chondroitin has been studied in humans since about 1975 as a treatment for psoriasis, cancer, and arthritis. It is also used by veterinarians to treat animals for arthritis. These different applications are derived from different properties of chondroitin. In the early 2000s, chondroitin has been used in conjunction with another dietary supplement called glucosamine to help treat joint **pain** caused by **osteoarthritis** and to help stop cartilage loss in patients with the disease.

Psoriasis

Studies have been conducted in the United States since 1990 to determine whether chondroitin from shark cartilage can speed wound healing in psoriasis and related conditions. No conclusive findings had been reported as of early 2008.

Cancer

The use of cartilage products to treat cancer is based on the popular belief that cartilaginous fish (sharks, skates, and rays) do not get cancer. Samples of these fish indicate, however, that they do in fact develop a variety of tumors, mostly soft-tissue cancers.

There are several theories as to why chondroitin and cartilage products containing it may be useful in treating cancer. One theory is that they slow or stop the formation of blood vessels that supply the cancer with oxygen and nutrients. Another theory is that chondroitin blocks the formation of certain enzymes that tumors produce to invade surrounding tissue. The third theory suggests that cartilage products stimulate the immune system. As of late 1999 the National Cancer Institute was conducting a multicenter clinical trial of liquid cartilage extract.

Osteoarthritis

An estimated 20 million Americans suffer from joint-related disease and about 15 million of these people suffer from osteoarthritis. Chondroitin is best known to the general public as a remedy for osteoarthritis, which is a form of arthritis caused by wearing

away or degeneration of the cartilage that cushions the ends of bones. In particular, it is thought that the drying of cartilage tissue in osteoarthritis is a major cause of tissue destruction. Chondroitin sulfate is given together with glucosamine, a building block of GAGs. The chondroitin helps to attract and hold fluid within cartilage tissue. Tissue fluid keeps cartilage healthy in two ways: it acts as a shock absorber within the joints of the body, thus protecting cartilage from being worn away by the bones; and it carries nutrients to the cartilage. The cartilage in the joints of the human body has no blood vessels, so it must receive its nutrients from tissue fluid.

In addition to drawing tissue fluid into cartilage, chondroitin is also thought to protect cartilage in the following ways:

- Acting as an anti-inflammatory activity.
- Inhibiting the activity of enzymes that break down cartilage.
- Counteracting enzymes that interfere with the transport of nutrients to the cartilage.
- Stimulating the production of proteoglycans, glycosaminoglycans, and collagen. These complex molecules are the building blocks of new cartilage.

Results of several European studies demonstrated that oral as well as injected chondroitin helps to increase joint mobility and reduce pain. A landmark 2001 study showed that combining glucosamine and chondroitin worked better than either worked alone in preventing cartilage damage and that both supplements worked well when taken orally. However, the Glucosamine/chondroitin Arthritis Intervention Trial reported in 2006 that glucosamine and chondroitin did not effectively reduce pain in people with osteoarthritis of the knee. Nearly 1,600 patients with osteoarthritis of the knee took part in the study conducted at 16 centers across the United States. Not all of the news from the study was discouraging, however. Among study participants who reported moderate to severe pain, as opposed to mild pain, 79% reported significant pain reduction when taking glucosamine and chondroitin supplementation. The study lasted for six months and a majority of the participants said they suffered from mild osteoarthritis of the knee. An ancillary study lasting an additional 18 months was conducted to see if glucosamine and chondroitin can reduce overall osteoarthritis pain if taken longer than six months. The results were expected in early 2008.

Preparations

The normal (non-vegetarian) adult diet already contains a certain amount of chondroitin; it is found in most animal tissues, particularly the gristle attached to bones.

Chondroitin sulfate can be taken orally as a pill, powder, or liquid. It can also be administered by injection. Oral preparations of chondroitin, alone or in combination with glucosamine, are available in the United States as over-the-counter (OTC) dietary supplements. They can be purchased over the Internet, at pharmacies, health food stores, and some grocery stores. Because they are marketed as dietary supplements, they do not require testing or approval by the Food and Drug Administration (FDA). As of 2008, there were no specific quality control requirements or clear manufacturing process (GMP) standards for these products.

There are, as of 2008, no standard patterns for administration of chondroitin as a treatment for psoriasis or cancer. When chondroitin is used together with glucosamine as a treatment for osteoarthritis, the daily dosage is based on the patient's weight. Suggested dosages are: 1,000 mg glucosamine + 800 mg chondroitin sulfate for 120 lbs or less; 1,500 mg glucosamine + 1,200 mg chondroitin sulfate for 120-200 lbs; and 2,000 mg glucosamine + 1,600 mg chondroitin sulfate for heavier than 200 lbs.

For maximum effectiveness, patients are advised to divide their daily dosage into 2 to 4 doses and take them throughout the day with food. They are also encouraged to take **vitamin C** and **manganese** supplements since these substances appear to increase the effectiveness of the chondroitin.

Precautions

There are two important precautions regarding chondroitin as a dietary supplement for osteoarthritis. The first is to avoid self-diagnosing and self-medicating. Persons with stiff or sore joints should consult a medical doctor (M.D.), osteopathic physician (D.O.), or naturopathic physician (N.D.) for an evaluation to determine if the problem is indeed osteoarthritis. **Gout**, **bursitis**, **rheumatoid arthritis**, **fibromyalgia**, and several other conditions can also cause pain and stiffness in the joints. These conditions are not helped by chondroitin. The supplement has not been studied in children or in pregnant or nursing women.

The second precaution is to purchase chondroitin made by a reliable manufacturer. The lack of government regulation of products sold as dietary supplements means that that there is no guarantee that claims made on the label are accurate. Thus a product that claims to contain chondroitin may not actually contain it, may not contain the amount that it claims

KEY TERMS

Cartilage—A firm, whitish elastic connective tissue found in humans and other animals. Chondroitin is an important component of cartilage.

Glucosamine—A complex carbohydrate composed of glucose and an amino acid called glutamine. It is an important building block of cartilage and is often taken together with chondroitin as a treatment for osteoarthritis.

Osteoarthritis—A degenerative disease of the joints, characterized by pain and stiffness related to loss or destruction of the cartilage in the joints.

Psoriasis—An inflammatory disorder of the skin characterized by scaly patches. Chondroitin may be a possible treatment for psoriasis.

to, or may not be free from contamination and safe to use. One helpful guideline is to look for the words *pharmaceutical grade* on the label. This standard ensures that the product is pure and that it contains the stated amount of chondroitin.

With regard to potential overdose problems, chondroitin sulfate appears to be nontoxic. One six-year study of people taking doses of 1.5-10 grams per day of chondroitin found no toxicity in the subjects.

Side effects

Chondroitin sulfate has no known significant side effects. Some people report having a bad taste in the mouth or mild **nausea** when taking large doses of oral chondroitin on an empty stomach. **Gas** or bloating has also been reported. A few people who have received chondroitin by injection report a mild soreness around the injection site.

Interactions

Chondroitin sulfate is not known to cause any significant interactions with other medications. A paper presented at the 1999 annual meeting of the American Academy of Orthopaedic Surgeons, however, stated that because the chondroitin sulfate molecule is similar to the heparin molecule, its use together with anticoagulant drugs is questionable.

Christian Science healing

Definition

Christian Science healing is a method of spiritual healing based on the beliefs of the Christian Science, or Church of Christ, Scientist, church. The church's

KEY TERMS

Psychosomatic illness—A condition in which unresolved emotional distress manifests as physical symptoms of illness.

healing practices are based on the divine healing work of Jesus. Adherents hold that the material world is a false reality and that health is a condition of mind, God, and truth. Thus, Christian scientists believe that ill health can be cured by spiritual education, understanding of the truth, and **prayer**.

Origins

Mary Baker Eddy, the founder of Christian Science, was born Mary Baker in Bow, New Hampshire, on July 16, 1821, into a family of strict Christian practice and Puritan values. Baker was ill for much of her childhood and early adult life. She explored medical therapies popular in her time, including **homeopathy**, and found no relief for her chronic illness.

Between 1862 and 1865 Baker was a patient of a charismatic healer named Phineas Parkhurst Quimby. A former hypnotist, Quimby developed a philosophy of mental healing based on the belief that he had rediscovered the secret of Jesus' ability to heal the sick. It is thought that Quimby's ideas may have influenced Baker in the development of her philosophy of Christian Science healing, although she herself denied it.

In 1866, the same year that Phineas Quimby died, Baker suffered a spinal injury from a fall. This proved to be a critical turning point in her life. Seeking strength in the Bible to sustain her through the injury, Baker read a New Testament account of Jesus' healing. While she was reading, she experienced a sudden insight into how Jesus' healing was accomplished, and as she read, she found herself suddenly released from her injury and restored to health.

This transformation inspired Baker to spend the next three years studying the scriptures and codifying her discoveries about healing. She called her discoveries Christian Science, and believed that she had found the one and only "truth." She put her principles into action by healing others, including those who had illnesses declared by medical practitioners of the day to be incurable.

As Baker studied the Bible and practiced healing, she came to believe that she could teach others to heal following God's truth as she had discovered it. In 1870 in Lynn, Massachusetts, she taught her first class and began to develop a following that shared her belief in Christian Science healing.

In 1875, while still living in Lynn, Mary Baker published *Science and Health*, later renamed *Science and Health with Key to the Scriptures*. This book, revised by Baker Eddy over the next 35 years, is the fundamental document explaining the doctrine of Christian Science healing.

In 1877 Mary Baker married fellow Christian Scientist Asa Gilbert Eddy and by 1879 had established enough of a following to found the first Church of Christ, Scientist in Boston, Massachusetts. This church became her headquarters and is known as the Mother Church. The regulatory structure of the denomination was set forth in her book *The Manual of the Mother Church* published in 1895.

Throughout the late 1800s, Christian Science continued to attract converts. Most of these conversions were brought about by demonstrations of Christian Science healing. Eddy also established the Massachusetts Metaphysical College to teach Christian Science healing. It is estimated that by 1895 there were about 250 Christian Science congregations, mainly in New England.

Mary Baker Eddy died on December 3, 1910. At the time of her death, there were about 1,200 Christian Scientist congregations in the United States. By the 1930s the number had increased to about 2,400. The United States Bureau of the Census in 1936 estimated church membership in the United States at about 269,000. Meanwhile congregations were also being established overseas.

After World War II, the number of Christian Science congregations began to decline. Beginning in the 1980s the church had to deal with negative publicity from court cases alleging that the failure of Christian Science parents to seek conventional medical treatment for children who had illnesses considered treatable by mainstream medicine constituted child endangerment. Convictions, many of which were overturned on appeal, further hurt church membership. The number of Christian Scientist practitioners, as those people whom the Church of Christ, Scientist officially recognizes as spiritual healers are called, dropped from about 8,000 in 1960 to about 2,000 in 1998.

Today Mary Baker Eddy is recognized both as a mind-body healer and as a pioneer in the area of equality for women. In the Church of Christ, Scientist, men and women function equally as leaders and

healers, an idea that was revolutionary in Eddy's lifetime. In 1995 she was elected to the National Women's Hall of Fame in recognition of being the only American woman to found an internationally established religion.

In addition to its practices of spiritual healing, Christian Science is best known today for its publishing activities, spearheaded by the international newspaper the *Christian Science Monitor* founded by Eddy in 1908. Each congregation also provides a public Christian Science Reading Room where the public may read Christian Science literature and ponder spiritual matters.

Benefits

For believers, Christian Science healing brings both spiritual and physical well being to those who are ill. Its healing practices make no distinction among different types of illnesses. It uses no material methods or laying on of hands to restore people to health and can be practiced in almost any setting.

Description

To understand Christian Science healing one must also understand Christian Science theology, because the two are inextricably linked. On the first page of *Science and Health with Key to the Scriptures* Eddy writes, "The prayer that reforms the sinner and heals the sick is an absolute faith that all things are possible to God . . . and a spiritual understanding of Him, an unselfed love . . . Prayer, watching, and working, combined with self-immolation, are God's gracious means for accomplishing whatever has been successfully done for the Christianization and health of mankind."

Christian Science teaches that the ordinary physical world that we perceive is a misconception. Matter is not created by God, but appears because of man's limited perception. Jesus, Eddy explains, was able to heal the sick, the blind, and the lame, because he saw beyond their material form and saw the spirit essence of the person.

In writing on the human body in *Science and Health with Key to the Scriptures*, Eddy states, "To measure intellectual capacity by the size of the brain and strength by the **exercise** of muscle, is to subjugate intelligence, to make the mind mortal, and to place this so-called mind at the mercy of material organization and non-intelligent matter. Obedience to the so-called physical laws of health has not checked sickness. Diseases have multiplied since man-made material theories took the place of spiritual truth. You say that **indigestion**, **fatigue**, sleeplessness, cause distressed stomachs and aching heads. Then you consult your brain in order to remember what has hurt you, when your remedy lies in forgetting the whole thing; for matter has no sensation of its own and the human mind is all that can produce pain."

For believers, Christian Science healing is the triumph of mind over matter and the spiritual over the material world. Ill health is simply an illusion. Good health occurs when the mind achieves awareness of itself, which is synonymous with awareness of God. The goal of healing is not to remove physical suffering, but to lead the ill person to Christ and transform the consciousness into a more pure and spiritual state that knows God. Healing is seen as a measure of the depth of one's sincerity and belief.

Since health does not reside in the body, and is not controlled by physical laws, Christian Science healing cannot occur when a person is in a state of moral sinfulness or lack of belief. The basis of disease is fear, ignorance, or sin. Health is a spiritual fact to be demonstrated.

Christian Science teaches that all believers can be taught to heal. Those people officially sanctioned as healers by the Church of Christ, Scientist are called Christian Science practitioners. Practitioners may be either male or female. These people must pledge to devote themselves to the practice of healing full time. They may be paid by their patients for their work. In 2000 there were about 2,000 officially recognized Christian Science practitioners in the United States, and that number is declining.

Practitioners do not use any material props or even touch to heal their patients; only prayer is used. The practitioner approaches the patient with a clear conviction of the omnipotence of God and the firm belief that God is good and produces only good things. Practitioners who hold false beliefs, or error, even unwitting error, blended with the truth, have weak healing abilities and may be guilty of malpractice. If the healer realizes the truth, it will free his patient from symptoms of disease, discord, and disharmony and lead the patient to Christ. This is said to leave the patient feeling calm, refreshed, and healthy.

Many converts come to Christian Science through the demonstration of its power to heal. Traditionally, Wednesday night meetings are given over to healing testimony and witnessing of the healing power of God's truth.

Preparations

The purpose of Christian Science healing is not to free the body from disease, but to lead the patient to a

higher spiritual understanding of God. Patients are best served if they are receptive to Christian Science beliefs and practices prior to the start of a healing session.

Precautions

There are no reasons other than disbelief or spiritual unreadiness not to participate in Christian Science healing. However, patients that do this must understand that they may be exacerbating their health problems by denying themselves access to traditional medical care.

Side effects

No side effects are reported from practicing Christian Science healing. There is, as noted above, danger posed by replacing traditional medical care with Christian Science practices in the case of serious illness.

Research and general acceptance

Christian Science healing is seen by the traditional medical community as quackery, since it denies any relationship between the physical universe and illness. It rejects the concepts of germs, contagion, and healing through the application of drugs.

All "proof" of the effectiveness of Christian Science healing is anecdotal. Many physicians believe that in certain cases of psychosomatic illness Christian Science healing may indeed bring about improvement in symptoms, but in diseases with a clear physical origin, it is ineffective.

Training and certification

The Church of Christ, Scientist recognizes some of its healers as official practitioners whose full-time job is healing. About 2,000 were in practice in the United States in 2000.

Chromium

Description

Chromium is a mineral that is essential to humans. It is found naturally in a variety of foods, and supplements are available in capsules or tablets. Supplements are prepared using a number of formulas, including chromium (III), chromium aspartate, chromium chloride, chromium citrate, chromium nicotinate, chromium picolinate, GTF chromium, and trivalent chromium.

General use

Chromium supports the normal function of insulin, which is a hormone secreted by the pancreas. Insulin helps transport glucose from the bloodstream into liver, muscle, and fat cells. Once it is inside these cells, the sugar is metabolized into a source of energy. Insulin is also involved in regulating protein, fat, and catalytic enzyme processes. People with diabetes do not produce insulin (or produce very little) or their bodies cannot properly use the insulin that is produced. As a result, sugar builds up in the bloodstream, causing serious health effects. Numerous scientific studies have shown that chromium is useful in treating **insulin resistance** (metabolic syndrome) and diabetes. Diabetic **peripheral neuropathy**, a form of nerve damage that is a direct result of diabetes, is indirectly related to a lack of sufficient chromium.

Several studies have shown that chromium supplements may improve insulin sensitivity and lower blood glucose and elevated body fat. In February 2004, the University of Pennsylvania School of Medicine began a comprehensive study of chromium as a therapy for insulin resistance. This condition occurs when the body fails to respond properly to the insulin it already produces. People who are insulin resistant may have the ability to overcome this problem by producing more insulin. However, if the body cannot produce sufficient amounts of insulin, glucose levels in the bloodstream rise, and type 2 diabetes ultimately occurs. It is estimated that up to 80 million Americans have insulin resistance.

Adequate intake of chromium

Age	mcg/day
Children 0-6 mos.	0.2
Children 7-12 mos.	5.5
Children 1-3 yrs.	11
Children 4-8 yrs.	15
Boys 9-13 yrs.	25
Girls 9-13 yrs.	21
Boys 14-18 yrs.	35
Girls 14-18 yrs.	24
Men 19-50 yrs.	35
Women 19-50 yrs.	25
Men > 50 yrs.	30
Women > 50 yrs.	20
Pregnant women ≤ 18 yrs.	29
Breastfeeding women ≤ 18 yrs.	44
Pregnant women ≥ 19 yrs.	30
Breastfeeding women ≥ 19 yrs.	45

Foods that contain chromium	mcg
Broccoli, 1/2 cup	11
Grape juice, 1 cup	8
English muffin, whole wheat, 1	4
Garlic, dried, 1 tsp.	3
Potatoes, mashed, 1 cup	3
Basil, dried, 1 tbsp.	2
Beef cubes, 3 oz.	2
Orange juice, 1 cup	2
Turkey breast, 3 oz.	2
Whole wheat bread, 2 slices	2
Red wine, 5 oz.	1-13
Apple, unpeeled, 1 med.	1
Banana, 1 med.	1
Green beans, 1/2 cup	1

mcg = microgram

(Illustration by GGS Information Services. Cengage Learning, Gale)

A study conducted by Isala Clinics and University Hospital Groningen in the Netherlands, released in 2003, showed that a daily dose of 1,000 micrograms of chromium significantly reduced blood sugar levels in people with poorly controlled type 2 diabetes who use insulin. However, a subsequent study, conducted by Louisiana State University in Baton Rouge, indicated that the response to chromium supplementation by diabetics may be in part genetically mediated, so not all patients respond to chromium.

Chromium has also been used as an effective treatment for polycystic ovarian syndrome (PCOS), a hormonal condition affecting about two million American women. The condition can lead to **infertility** if untreated and is associated with insulin resistance and type 2 diabetes. A study released in 2003 by the State University of New York at Stony Brook showed that insulin sensitivity increased an average of 35 percent after two months of daily treatment with 1,000 micrograms (mcg) of chromium.

Through its involvement with insulin function, chromium plays an indirect role in lowering blood lipids. Studies suggest, but as of the early 2000s had not proven, that chromium supplementation can reduce the risk of cardiovascular (heart) disease in men and may decrease total **cholesterol** and triglyceride levels. However, several studies contradict these claims. Studies in animals suggest chromium supplementation may reduce **hypertension** (high blood pressure). Lipid reduction is secondary to insulin regulation and control; therefore, persons whose insulin is well regulated and controlled may not achieve reduced **heart disease** risk by taking chromium supplements.

Chromium supplements in high doses—1,000 mcg or more a day—are sometimes used in weight loss and muscle development. However, a number of scientific studies have found that chromium supplements are not effective in these areas. In fact, precautions warn against chromium doses exceeding 1,000 mcg per day. Weight loss and muscle development are secondary to insulin regulation and control. Therefore, when insulin is well regulated and controlled, chromium may not impact weight loss or muscle development. A controlled study by the United States Department of Agriculture in which 83 women were fed a controlled diet but received either chromium piccolinate, piccolinic acid, or placebo, failed to demonstrate any changes in body composition between the three groups.

Preparations

A complete lack of chromium is rare, and the United States Food and Drug Administration (FDA) has not established recommended dietary allowances (RDA) for the mineral. However, national statistics on the prevalence of diabetes, heart disease, and **obesity** suggest that chromium deficiencies may be common. Chromium occurs naturally in meat, seafood, dairy products, eggs, whole grains, black pepper, and almonds. According to *The PDR Family Guide to Natural Medicines and Healing Therapies*, the usual chromium supplement dose for children ages seven and older and adults is 50–200 mcg a day in tablets or capsules. For persons with type 2 diabetes who are not taking insulin, doses from 200–1,000 mcg daily may be taken. However, persons should only take doses at these levels after consulting with a physician. Chromium should not be taken in doses exceeding

KEY TERMS

Calcium carbonate—A salt that is used in many antacids.

Diabetes—Several metabolic disorders in which the body produces insufficient insulin.

Glucose—Sugar.

Hypertension—High blood pressure, which, if untreated, can lead to heart disease and stroke.

Insomnia—The inability to sleep.

Insulin—A hormone that helps liver, muscle, and fat cells take up sugars, starches, and other foods for conversion into energy the body needs.

Insulin resistance—Also called metabolic syndrome, a condition in which the body fails to properly respond to the insulin it produces.

Polycystic ovarian syndrome—PCOS, a hormonal condition in women that if untreated can lead to the inability to have children.

1,000 mcg a day. The cost of a bottle of 100 tablets or capsules (200 mcg) of chromium piccolinate ranges from $5 to $10 for a generic or house brand preparation.

Precautions

Doses of 200–1,000 mcg of chromium should be taken only after consultation with a physician. Pregnant or breastfeeding women are advised to consult a physician before taking chromium supplements. Chromium should not be taken in doses exceeding 1,000 mcg a day. Increased dietary sugar may be associated with higher urinary excretion of chromium.

Side effects

Several studies have noted occasional reports of irregular heartbeats with chromium use. Infrequently, chromium has been reported to cause such sleep pattern changes as **insomnia** and increased dream activity. Irritability has also been reported. In rare instances, persons may be allergic to a chromium formula. The symptoms of an allergic reaction include difficulty breathing, chest **pain**, **hives**, rash, and itchy or swollen skin. If any of these symptoms occur, the patient is advised to seek medical care immediately. High doses may also cause liver and kidney damage or gastric irritation, although these side effects are rare.

Interactions

Persons who are taking antacids are advised to talk with a physician before taking chromium supplements. Studies in animals suggest that antacids, especially those containing **calcium** carbonate, may reduce the body's ability to absorb chromium. Studies have shown that chromium may enhance the effectiveness of drugs taken by people who have type 2 diabetes or insulin resistance. These drugs include glimepiride, glipizide, glyburide, insulin, and metformin. Individuals taking these drugs should discuss chromium supplementation with a physician because improved insulin function may necessitate medication dosage changes.

Sam Uretsky, PharmD

Chronic fatigue syndrome

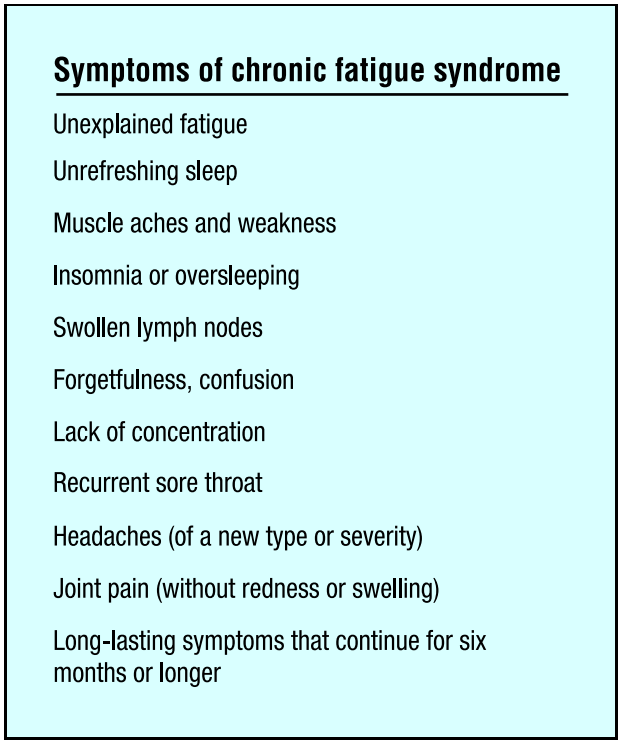
Definition

Chronic **fatigue** syndrome (CFS) is a condition that causes extreme tiredness. People with CFS have debilitating fatigue that lasts for six months or longer. CFS does not have a known cause, but it appears to result from a combination of factors.

Description

CFS is the most common name for this disorder, but it also has been called chronic fatigue and immune disorder syndrome (CFIDS), myalgic encephalomyelitis, low natural killer cell disease, post-viral fatigue syndrome, Epstein-Barr disease, and yuppie flu. Reports of a CFS-like syndrome called neurasthenia date back to 1869. Subsequently, people with similar symptoms were said to have **fibromyalgia** because one of the main symptoms is myalgia, or muscle **pain**. Because of the similarity of symptoms, fibromyalgia and CFS are considered to be overlapping syndromes.

In the early to mid-1980s, there were outbreaks of CFS in some areas of the United States. Although many CFS patients had high levels of antibodies to



(Illustration by Corey Light. Cengage Learning, Gale)

the Epstein-Barr virus (EBV), which causes **mononucleosis**, many healthy people also had high levels of EBV antibodies. Scientists also found high levels of other viral antibodies in the blood of CFS patients. These findings led many scientists to believe that a virus or combination of viruses may trigger CFS.

Although CFS can affect people of any gender, age, race, or socioeconomic group, most patients diagnosed with CFS are 25 to 45 years old and female. Estimates of how many people are afflicted with CFS vary due to the similarity of CFS symptoms to other diseases and the difficulty in identifying it. The Centers for Disease Control and Prevention (CDC) has estimated that about one million people in the United States have CFS.

Causes and symptoms

There is no single known cause for CFS. Studies have pointed to several different conditions that might be responsible. These include:

- viral infections
- chemical toxins
- allergies
- immune abnormalities
- psychological disorders

Many doctors and researchers think that CFS may not be a single illness but a group of symptoms caused by several conditions. One theory is that a microorganism, such as a virus, or a chemical injures the body and damages the immune system, allowing dormant viruses to become active. When these viruses start growing again, the immune system may overreact and produce chemicals called cytokines that can cause flu-like symptoms. Immune abnormalities have been found in studies of people with CFS, although the same abnormalities are also found in people with **allergies**, autoimmune diseases, **cancer**, and other disorders.

In late 2001, a panel of experts concluded that a virus or bacteria acting on the immune system may indeed cause CFS; the experts agreed that the published evidence was substantial enough to prove that the immune system is involved in CFS. They stated that **infections** may also play a role in the condition, but they did not identify one single agent common to all patients with CFS. Further research was recommended. The panel also concluded that reproductive hormones may play a role in the condition, which might explain the higher prevalence among women. In spite of these findings, the CDC continued as of 2008 to report that the causes for CFS had yet to be identified.

The role of psychological problems in CFS is controversial. Because many people with CFS are diagnosed with **depression** and other psychiatric disorders, some experts concluded that the symptoms of CFS are psychological. However, many people with CFS do not have psychological disorders before getting the illness. Many doctors think that patients become depressed or anxious because of the effects of the symptoms of their CFS. One study concluded that depression was the result of CFS, not its cause.

People with CFS have severe fatigue that keeps them from performing their normal daily activities. They may have sleep disturbances that keep them from getting enough rest or they may sleep too much. When they **exercise** or try to be active in spite of their fatigue, people with CFS experience debilitating exhaustion that can confine them to bed for days.

Other symptoms of CFS include:

- muscle pain (myalgia)
- joint pain (arthralgia)
- sore throat
- headache
- fever and chills
- tender lymph nodes
- trouble concentrating
- memory loss

One study at Johns Hopkins University found an abnormality in blood pressure regulation in 22 of 23 patients with CFS. This abnormality, called neurally mediated hypotension, causes a sudden drop in blood pressure when a person has been standing, exercising, or exposed to heat for a while. When this response occurs, patients feel lightheaded and may faint. They often are exhausted for hours to days after one of these episodes. When treated with salt and medications to stabilize blood pressure, many patients in the study had marked improvements in their CFS symptoms. Follow-up research on this topic was limited as of 2008.

Diagnosis

CFS is diagnosed by evaluating symptoms and eliminating other causes of fatigue. Doctors carefully question patients about their symptoms, any other illnesses they have had, and medications they are taking. They also conduct a physical examination, neurological examination, and laboratory tests to identify any underlying disorders or other diseases that cause fatigue. In the United States, many doctors use the CDC case definition to determine if a patient has CFS.

To be diagnosed with CFS, patients must meet both of the following criteria:

- Unexplained continuing or recurring chronic fatigue for at least six months that is of new or definite onset, is not the result of ongoing exertion, and is not mainly relieved by rest, and causes occupational, educational, social, or personal activities to be greatly reduced.
- Four or more of the following symptoms: loss of short-term memory or ability to concentrate; sore throat; tender lymph nodes; muscle pain; multijoint pain without swelling or redness; headaches of a new type, pattern, or severity; nonrefreshing sleep; and post-exertional malaise (a vague feeling of discomfort or tiredness following exercise or other physical or mental activity) lasting more than 24 hours. These symptoms must have continued or recurred during six or more consecutive months of illness and must not have started before the fatigue began.

Treatment

There is no specific cure for CFS, but many treatments are available to help relieve the symptoms. Treatments usually are individualized to each person's particular symptoms and needs. The first treatment recommended is a combination of rest, exercise, and a balanced diet. Prioritizing activities, avoiding overexertion, and resting when needed are key to maintaining existing energy reserves. Treatment of airborne allergies is an important facet in the treatment of CFS.

Diet

Drinking eight to 12 glasses of water daily helps fight fatigue. Food allergies can worsen CFS symptoms. Common food allergies include milk, wheat, eggs, citrus, alcohol, chocolate, and coffee. An extract from shiitake mushrooms (LEM) has been shown in Japanese studies to benefit CFS patients.

Ayurvedic medicine stresses that energy is derived from food. Energy-producing foods include: fresh fruits and vegetables, whole milk, wheat and wheat products, rice, barley, honey, olive oil, mung bean soup, raisins, dates, figs, almonds, clarified butter, and yogurt. Foods that deplete energy include: red meat, aged or fermented foods, onions, **garlic**, mushrooms, potatoes, sugar, alcohol, and coffee.

Ayurvedic medicine dictates that complete digestion of food is necessary to obtain the maximum amount of energy. The following measures can be taken to optimize digestion:

- eating in a quiet place
- following established mealtimes
- sitting while eating
- not eating while upset
- eating only until satiety (fullness)
- avoiding ice cold foods and drinks
- not talking while chewing
- eating at a moderate pace

Supplements

The following supplements have been used in treating CFS.

- Vitamin B_{12} deficiency causes fatigue, muscle aches, confusion, poor memory, and arm and leg numbness.
- Magnesium helps muscles to relax. Persons with kidney or heart disease should not take magnesium.
- Iron treats anemia, which can cause tiredness and improve mental clarity. This supplement should be taken only if a physician has diagnosed an iron deficiency.
- Manganese works with the supplements above to relieve CFS symptoms.
- Copper deficiency can cause inflammation. Maximum recommended daily dose for adults is 2 to 3

mg. Pregnant women should consult a physician before taking copper supplements.

- Zinc may boost the immune system.
- Coenzyme Q10 can increase immune health.
- NADH may lead to improvement in energy, cognitive ability, sleep patterns, headaches, and depression.
- Carnitine helps to better utilize fats for energy production. The recommended daily dose is 500 to 3,000 mg.
- Alpha lipoic acid enhances energy.
- 5-HTP helps to regulate sleep patterns.
- DHEA deficiency causes fatigue in females and low sex drive in males. It should be taken only under the direction of a physician.

Fluoride is a potentially toxic substance and should be avoided.

Other treatment options

Chinese medicine, including **acupuncture** and **cupping**, works to bring the body back into balance. Herbals that may help relieve symptoms of CFS include:

- astragalus (huang chi) to increase energy
- licorice (gan t'sao) for stomach and liver problems, adrenal exhaustion, and blood pressure warming
- ginger root for digestion
- turmeric for inflammation
- linden flowers for the heart
- echinacea for stimulating the immune system but taken for no more than 10 to 14 consecutive days
- Siberian ginseng (*Eleutherococcus senticosus*) to increase resistance to stress and boost the immune system
- ginkgo to increase blood flow through the brain but also thin the blood
- evening primrose (*Oenothera biennis*) oil to increase energy levels
- borage seed (*Borago officinales*) oil
- quercetin
- flaxseed oil

Some CFS patients use **fasting** only under the direction of a healthcare practitioner. **Probiotics** using *Lactobacillus acidophilus* can restore a normal balance to the intestinal bacterial.

Chiropractic adjustments may help relieve symptoms of CFS. **Osteopathy** helps some CFS patients. Osteopaths developed the craniosacral method that involves manipulation of the bones and membrane attachments of the head. Naturopathic physicians routinely treat CFS patients. Components of Ayurvedic treatment of CFS include **stress** reduction, daily oil massage, improving sleep, improving bowel function, and light to moderate exercise.

Psychological and spiritual counseling are important facets of CFS treatment. Cognitive behavior therapy helps patients manage activity levels to reduce fatigue. The type of **psychotherapy** employed is less important than having good rapport with the therapist.

For patients who are employed, modifications to the workplace are essential to maintaining good health. Vocational rehabilitation counseling allows the patient to maximize his or her work potential.

Exercise and physical therapy can have a dramatic impact on the health of CFS patients. Stretching exercises and moderate aerobic activity are beneficial. Too much exercise can worsen fatigue and other CFS symptoms. Exercise programs such as physical therapy, **t'ai chi**, **yoga**, chi kung, the **Alexander technique**, and muscle balance and function development (MBF) are all options.

There is a lengthy list of therapies used by CFS patients to find relief. These are not cures, and many have not been tested in clinical studies. CFS patients may find relief, if only temporarily, in the following:

- sessions with a spiritual healer
- yoga
- reflexology
- hydrotherapy
- sound therapy
- chocolate therapy
- magnet therapy
- meditation
- visualization
- spiritual cleansing rituals
- biofeedback

A 2002 report noted a study that showed some results from **homeopathy** for CFS patients. For the study, patients underwent six months of treatment chosen by one of four homeopaths and changed as needed. Sixty-five percent of patients reported some improvement, feeling fitter, more rested, and less tired. A 2002 review of research on the effectiveness of homeopathy in the treatment of CFS found mixed results, however. Authors of the review pointed out that the studies they examined were often poorly done, producing results that were difficult to interpret.

KEY TERMS

Alexander technique—A movement therapy that identifies and changes poor physical habits that may cause fatigue. The body is put into a state of relaxation and balance through the use of simple movements.

Arthralgia—Joint pain.

Depression—A psychological condition, with feelings of sadness, sleep disturbance, fatigue, and inability to concentrate.

Epstein-Barr virus (EBV)—A virus in the herpes family that causes mononucleosis.

Fibromyalgia—A disorder closely related to CFS. Symptoms include pain, tenderness, and muscle stiffness.

Lymphocytes—White blood cells that are involved in the immune system.

Mononucleosis—A flu-like illness caused by the Epstein-Barr virus.

Muscle balance and function development (MBF)—A movement therapy that strives to realign body posture through a series of exercises.

Myalgia—Muscle pain.

Natural killer (NK) cell—A lymphocyte that acts as a primary immune defense against infection.

Neurally mediated hypotension—A rapid fall in blood pressure that causes dizziness, blurred vision, and fainting, and is often followed by prolonged fatigue.

Neurasthenia—Nervous exhaustion. A disorder with symptoms of irritability and weakness, commonly diagnosed in the late 1800s.

Allopathic treatment

Drugs

Nonsteroidal anti-inflammatory drugs (NSAIDs), such as ibuprofen and naproxen, may be used to relieve pain and reduce **fever**. Another medication that is prescribed to relieve pain and **muscle spasms** is cyclobenzaprine (Flexeril).

Many doctors prescribe low dosages of antidepressants for their sedative effects and to relieve symptoms of depression. Antianxiety drugs, such as benzodiazepines or buspirone, may be prescribed for excessive **anxiety** that has lasted for at least six months.

Other medications that have been tested or were being tested as of 2008 for treatment of CFS are:

- Fludrocortisone (Florinef), a synthetic steroid, has helped some CFS patients who have neurally mediated hypotension.
- Beta-adrenergic blocking drugs, including atenolol (Tenoretic, Tenormin) and propranolol (Inderal), are sometimes prescribed for neurally mediated hypotension.
- Gamma globulin, which contains human antibodies, has been used experimentally to boost immune function in CFS patients.
- Ampligen, a drug which stimulates the immune system and has antiviral activity, improved mental function in some CFS patients.

Expected results

The course of CFS varies widely for different people. Some get progressively worse over time, while others gradually improve. Some persons have periods of illness that alternate with periods of good health. While some people with CFS do fully regain their health, those who do not find relief from symptoms and adapt to the demands of the disorder by carefully following a treatment plan combining adequate rest, **nutrition**, exercise, and other therapies.

Prevention

Because the cause of CFS is not known, there are no recommendations for preventing the disorder.

Chronic pain *see* **Pain**

Chrysanthemum flower

Description

The chrysanthemum, of which there are many varieties, has been known by a host of common names throughout history. Some of the chrysanthemum's common names include pellitory, **feverfew**, ox-eye daisy, and sunflower among others. It is a flower that has grown in gardens all around the world as far back as any records can tell, and seems to have been employed everywhere at some time or another as a cure for a host of complaints.

Chinese chrysanthemum flower

The Latin name for Chinese chrysanthemum flower is *Chrysanthemum indicum*, and it is known in China as Ju Jua. The plant grows profusely throughout China and is both an emblem to the Chinese and greatly prized for its medicinal properties, particularly as an anti-inflammatory.

The best flowers for medicinal purposes are considered to be the yellow fragrant ones. They are classified as being acrid, bitter, and slightly cold in the Chinese pharmacopoeia. Traditionally, they are harvested in the fall, when they are in full bloom.

The herb is taken internally for headaches, **dizziness**, and hearing disorders. It is also useful as a treatment for high blood pressure (**hypertension**). It is used as a compress or eye wash for inflammation of the eyes and for other eye problems such as dry-eye, blurred vision, and spots before the eyes. The herb can also be taken internally as an infusion and is combined with **honeysuckle** for the treatment of colds, the flu, and infected sores. It has a calming effect and can also be good for **stress**. Chrysanthemum is known to be a powerful antiseptic and antibiotic. However, people suffering from **diarrhea** should take it with caution.

Dalmatian pellitory

There are many plants that go by the name of pellitory, but this one is also a member of the chrysanthemum family. Its botanical name is *Chrysanthemum cinerariafolium*, and it originated in Dalmatia. It is cultivated in both Dalmatia and California. Previously, Persian pellitory was the most widely used, but it has been superceded by Dalmatian pellitory in practical use due to ease of cultivation.

Feverfew

The variety of chrysanthemum that is perhaps the most useful as far as herbal medicine is concerned, is feverfew, or *Chrysanthemum parthenium*. Most species of chrysanthemum are tall daisy-like flowers and feverfew is no exception. It is commonly found in England and the United States, and is similar to **chamomile** in appearance. Feverfew differs from chamomile in that it is larger and the white petals are arranged around a flat yellow center, as opposed to conical, which is the case with chamomile. The hairy stems of feverfew grow to about 2 ft (61 cm) tall, and the leaves are serrated and downy. Feverfew is also known by other common names, including featherfew, featherfoil, flirtwort, bachelor's buttons, and wild chamomile.

KEY TERMS

Decoction—These are made to be taken immediately (not for storage): simmer herbs for half an hour and strain, in the same way as for syrup, but sweetened to taste only.

Fluid extract—Made by simmering a plant and reducing the water until the mixture is thickened. This resulting liquid has a concentrated form of the active constituents of a plant. Alcohol, glycerin, or tincture of Benzoin may be added as a preservative.

Infusion—This is made in the same way that one would make tea, i.e., adding boiling water to the dried herb and allowing it to stand for a while.

Syrup—An herbal preparation that is made generally by boiling the herb with water, adding sugar as a preservative, and boiling until it thickens. The syrup may be stored.

Tincture—Herbs that are not soluble in water are bruised and steeped in alcohol. This liquid is placed in a bottle and may be filtered with coffee filters. The same procedure may be followed using vinegar instead of alcohol.

Ox-eye daisy

The botanical name for the ox-eye daisy is *Chrysanthemum leucanthemum*. It is a common sight in Britain, where it is known as dun daisy or maudlinwort. It is common throughout Europe, Russia, and Asia. Again, it is a yellow-centered flower with white petals. It grows to a height of 1-2 ft (30-61 cm) and has small leaves with serrated edges.

Sunflower

The sunflower is a native of Mexico and Peru, and is commonly grown in the United States and many other areas of the world. This is the largest of the chrysanthemum family, and there are several subspecies, varying slightly in size. Generally it grows to a height of 3-12 ft (91-366 cm), with flower heads that may measure more than 6 in (15 cm) across. The leaves are serrated and rough.

General use

The Flower Essence Society (FES) of California has a chrysanthemum essence that they recommend for those seeking spiritual growth.

According to many herbalists, species of chrysanthemum have many medicinal uses.

Dalmatian pellitory

This is commonly known as insect powder due to its insecticide properties. An advantage is that the powder is completely harmless to humans, and so does not have side effects (as is the case with all chemical insecticides), and can be used as a lotion and applied to the skin as an insect repellant. If the flowers are burned, the smoke that is given off can be valuable in exterminating insects.

Feverfew

Feverfew is chiefly regarded for its ability to treat fevers, reduce swelling, and for its analgesic properties; it is an excellent cure for a **headache** or any other **pain**. It is also used to promote menstrual flow, as an antidote to **depression** and nervous disorders, and as a general tonic. In addition, feverfew can be used to help in cases of difficult breathing, particularly associated with **asthma**, and chest **infections**. It has been used as a treatment for insect **bites** and even rat bites. In the past, feverfew was recommended for planting around dwellings because of its antiseptic properties. It wards off disease and prevents pests and diseases from attacking other plants. Similar to Dalmatian pellitory, it also has a repellant effect on insects. It can be used externally for flatulence and **colic**.

Ox-eye daisy

The herb has a soothing effect and is recommended for night sweats, especially those associated with **tuberculosis**. It is recommended for use in cases of **whooping cough**, asthma, and nervous tension. Generally its action can be compared to that of chamomile. It is useful for relieving chronic coughs and bronchial catarrh. Externally, it can be used as a lotion for **wounds**, **bruises**, and some skin conditions. In this regard, some herbalists recommend it as an ointment for treating swellings and it is also known for treating **gout**. Others recommend it for treating **jaundice** and also as a diuretic and tonic.

Sunflower

The sunflower is chiefly grown for its seeds which produce an oil, similar to olive oil, that is both cheap to produce and a valuable source of fatty acids. In many parts of the world, the sunflower provides much needed **nutrition** in poorer areas. The seeds can be used medicinally for treatment of bronchial complaints. A tincture of the seed has been used successfully in areas such as Russia, Turkey, and Persia for fevers (even **malaria**), where it has been found to be

free of the complications sometimes associated with the use of quinine.

Preparations

Dalmatian pellitory

PARTS USED: FLOWERS. The chief use for Dalmatian pellitory is as an insecticide, or as an ointment to ward off insects. It is mainly dried and ground to a powder to this end.

Feverfew

PARTS USED: BARK, FLOWERS, AND LEAVES. For coughs it is generally made up into a syrup (decoction) with sugar or honey. The herb, when bruised and added to a little oil, can be used as an external application for flatulence and colic. For swellings and bites, it can be made up into a tincture, two teaspoonfuls of which should be mixed with half a pint of cold water and applied. As an infusion, made with boiling water and allowed to cool, feverfew will soothe pain of any kind, (muscular, nerve-related, rheumatic or intestinal). Chewing the leaves (one to four per day) can be effective in the case of migraine. It has also been used in this way to treat cases of **worms**.

Ox-eye daisy

PARTS USED: FLOWERS, ROOTS, AND LEAVES. This plant is mainly employed as an infusion. But in the case of tuberculosis, 15–60 drops of the fluid-extract should be taken in water. The flowers boiled with the leaves and stalks and sweetened with a little honey are a treatment for chest complaints.

Sunflower

PARTS USED: SEEDS AND LEAVES. Chest complaints: boil two ounces of the seeds in one quart of water until the water is reduced to 12 oz. Strain and add six ounces of Holland gin and six ounces of sugar. The dose is one to two teaspoonfuls of the mixture three times a day. Roasting the seeds and making an infusion is recommended for whooping **cough**.

Precautions

As with any herbal preparations, all of the above should be used with care and preferably under the supervision of an herbal practitioner.

Side effects

Feverfew should not be used for migraine that is a result of some kind of deficiency in the body (whether nutritional or otherwise). It is possible that feverfew may cause **dermatitis**, allergic reactions, or sores in the mouth in susceptible individuals. It should not be taken by pregnant women due to its ability to stimulate the uterus.

Interactions

Feverfew has been known to interfere with blood-clotting ability, and so a doctor should be consulted before it is used in conjunction with anticoagulants.

Patricia Skinner

Chymotrypsin

Description

Chymotrypsin is a digestive enzyme that breaks down proteins (i.e., it is a proteolytic enzyme; it can also be referred to as a protease). It is naturally produced by the pancreas in the human body. However, it can also be taken as an enzyme supplement to improve health and digestion and aid in the treatment of various diseases.

The pancreas, which produces chymotrypsin and other **digestive enzymes**, is a digestive organ in the abdomen that is located just below the stomach. Its primary job is to produce enzymes required for the digestion and absorption of food. Each day the pancreas secrets about 1.5 qt (1.4 L) of pancreatic juice, consisting of enzymes, water, and electrolytes (primarily bicarbonate) into the small intestine. The enzymes are secreted in an inactive form (as proenzymes) so that they will not digest the pancreas. The pancreas secretes an inhibitor to ensure that the enzymes are not activated too early. When the pancreatic juice reaches the small intestine, the enzymes become activated. The small intestine is not digested because it contains a protective mucous lining. However, self-digestion

can occur if the pancreatic duct becomes blocked or if the pancreas is damaged. The proenzymes can overwhelm the inhibitor, causing the enzymes to become active while in the pancreas. This condition, called acute **pancreatitis**, can result in a lifetime of pancreatic insufficiency.

The enzymes secreted by the pancreas break down food by breaking the chemical bonds that hold food molecules together. Enzymes secreted include **lipase**, which, along with bile, digests fat; amylases, which break down starch molecules into smaller sugars; and protease, which breaks protein molecules into dipeptides and some single **amino acids**. In addition to chymotrypsin, other protease enzymes secreted by the pancreas include trypsin and carboxypeptidase.

Chymotrypsin, as a hydrolase type of enzyme (which means it adds a water molecule during the breakdown process) acts by catalyzing the hydrolysis of peptide bonds of proteins in the small intestine. It is selective for peptide bonds with aromatic or large hydrophobic side chains on the carboxyl side of this bond. Chymotrypsin also catalyzes the hydrolysis of ester bonds. Chymotrypsin does not digest blood proteins because of protective factors in the blood that block the enzyme.

KEY TERMS

Ecchymosis (plural, ecchymoses)—The medical term for a bruise, or skin discoloration caused by blood seeping from broken capillaries under the skin.

Enzyme—Any of a group of complex proteins that originate in living cells and help to break down organic compounds into simpler molecules.

Enzyme therapy—An alternative approach to the treatment of digestive disorders and other illnesses related to nutritional problems. Enzyme therapy emphasizes the use of animal- or plant-derived digestive enzymes as dietary supplements.

Pancreas—A tongue-shaped gland located in the upper abdomen behind the stomach. It secretes digestive enzymes into the small intestine, and glucagon and insulin into the bloodstream.

Scleroderma—A chronic autoimmune disorder in which connective tissue anywhere in the body becomes hard and rigid.

General use

Generally, the primary uses of chymotrypsin are as a digestive aid and as an anti-inflammatory agent. The presence and amount of chymotrypsin in a person's stool is sometimes measured for diagnostic purposes as a test of pancreatic function. Testing for fecal chymotrypsin is noninvasive, unlike some other tests of pancreatic function.

Chymotrypsin, along with the other pancreatic enzymes, is most often used in the treatment of pancreatic insufficiency. Pancreatic insufficiency is characterized by impaired digestion, malabsorption and passing of undigested food into the stool, nutrient deficiencies, **gas**, and abdominal bloating and discomfort. Pancreatic deficiency also occurs in persons with cystic fibrosis, a rare inherited disorder. It may also occur in those with chronic pancreatitis, as well as in the elderly. Other conditions that could result in chymotrypsin deficiency include physical injuries, chemotherapy, and chronic **stress**.

Starch and fat digestion can be accomplished without the help of pancreatic enzymes; however, the protease enzymes (i.e., chymotrypsin, trypsin, and carboxypeptidase) are required for proper protein digestion. Incomplete digestion of proteins may result in the development of **allergies** and the formation of toxic substances produced by putrefaction, the breakdown of protein materials by bacteria. Protease enzymes and other intestinal secretions are also required to keep the small intestine free from parasites such as bacteria, yeast, protozoa, and intestinal **worms**. A laboratory analysis of a stool sample along with physical symptoms are used to assess pancreatic function.

As an anti-inflammatory agent, the chymotrypsin and the other protease enzymes prevent tissue damage during inflammation and the formation of fibrin clots. Protease enzymes participate in the breakdown of fibrin in a process called fibrinolysis. Fibrin causes a wall to form around an area of inflammation, resulting in the blockage of blood and lymph vessels, which leads to swelling. Fibrin can also cause the development of **blood clots**. In autoimmune diseases, the protease enzymes aid in the breakdown of immune complexes, which are antibodies produced by the immune system associated with the compounds they bind to (antigens). High levels of immune complexes in the blood are associated with autoimmune diseases.

Specifically, chymotrypsin is used to:

- Aid in digestion.
- Treat inflammation and reduce swelling (i.e., soft tissue injuries, acute traumatic injuries, sprains, contusions, hematomas, ecchymoses, infections, edema

of the eyelids and genitalia, muscle cramps, and sports injuries).
- Treat arthritis and such other autoimmune diseases as lupus, scleroderma, and multiple sclerosis.
- Treat ulcerations and abscesses.
- Liquefy mucus secretions.
- Treat enterozoic worms and other parasites in the digestive tract.
- Treat cancer (a controversial use that requires much more scientific study, though chymotrypsin may be helpful in alleviating effects of radiation treatment or chemotherapy).
- Treat shingles and acne.
- Decrease effects of sun damage and age spots.

Preparations

Chymotrypsin is produced from fresh hog, beef, or oxen pancreas. It can be taken orally, topically, or by injection (by injection only by a physician in severe life-threatening situations), but is commonly taken orally in tablet form. As a tablet, it may be uncoated, microencapsulated, or enterically coated (to prevent digestion in the stomach so that the enzyme will be released in the small intestine). Other forms include coated granules, powder, capsules, and liquids. Creams and ointments are used to break down proteins and debride dead tissue resulting from **burns**, **wounds**, and abscesses. The enzyme preparation should be stored in a tight container with a moisture-proof liner in a dry, cool place. An opened container stored properly should maintain enzyme activity for about two to three months.

Usually chymotrypsin is included in a combination with other enzymes. A typical formulation may include: chymotrypsin (0.5–1 mg), **bromelain** (a plant protease) (25–45 mg), pancreatin (a mixture of many pancreatic enzymes) (100 mg), papain (a plant protease similar in action to chymotrypsin) (25–60 mg), and trypsin (a pancreatic protease) (24 mg). Formulations may also include vitamins, herbs, phytochemicals, and other nutrients to enhance the activity of the enzyme supplement.

Enzyme activity should be considered when a supplement is selected. Activity is usually indicated in units; however there is no one standard for enzyme activity level. Recognized guidelines for measuring enzyme activity include Food Chemicals Codex (FCC), United States Pharmacopoeia (USP), Federation Internationale du Pharmaceutiques (FIP), British Pharmacopoeia (BP), and Japanese Pharmacopoeia (JP). For example, the United States Pharmacopoeia has set a strict definition for level of activity that must be reported in a enzyme supplement. A 1X chymotrypsin product must contain not less than 25 USP units for chymotrypsin activity. A preparation of higher potency is given a whole number multiple indicating its strength. For example, a full-strength undiluted extract that is 10 times stronger than the USP standard would be referred to as 10X USP. A consumer can compare enzyme activity levels among enzyme products within a single guideline system, but unfortunately the information is not interchangeable among guideline systems.

The dose required will vary on the quantity (amount in mg) and the quality (activity level) of the enzyme in the preparation, which is usually tablet form. The dose will also depend on the condition being treated. In most cases, for oral ingestion and for topical application, the directions on the bottle or tube label can be followed. Enterically coated tablets should be swallowed and not chewed or ground up. Tablets should also be taken with at least 8 oz of water to help activate the enzyme. Chymotrypsin taken to enhance digestion is usually taken just before, during, or just after meals, or before going to bed at night. With proper dosages, improvements in digestion should be noted within a few hours.

For inflammatory or chronic conditions, chymotrypsin should be taken on an empty stomach, either one hour before meals or at least two hours after meals. When chymotrypsin is taken for an inflammatory condition, some improvement may be noted within three to seven days. Those with chronic conditions such as arthritis may require one to three months or more to notice a change in conditions.

Precautions

Chymotrypsin is generally well tolerated and not associated with any significant side effects. However, since a safe dose has not been established, it should only be used when there is apparent need.

People who should not use **enzyme therapy** include those with hereditary clotting disorders such as hemophilia, those suffering from coagulation disturbances, those who are just about to or have undergone surgery, those on anticoagulant therapy, anyone suffering from protein allergies, and pregnant women or those breast-feeding. Since there is not much known about the effects of enzyme therapy on children, it would be prudent to avoid giving enzyme supplements to children.

When protective mechanisms against self-digestion in the body break down, chymotrypsin should not be

used. For example, if a patient has stomach ulcers, chymotrypsin therapy should be discontinued.

Side effects

There do not appear to be any long-term side effects from chymotrypsin therapy if precautions for its use are followed. Studies have shown that at recommended doses, enzymes cannot be detected in blood analysis after 24–48 hours. Temporary side effects that may occur (but that should disappear when therapy is discontinued or dosage is reduced) include changes in the color, consistency, and odor of the stool. Some individuals may experience gastrointestinal disturbances, such as flatulence, a feeling of fullness, **diarrhea**, **constipation**, or **nausea**. With high doses, minor allergic reactions such as reddening of the skin may occur.

Interactions

Chymotrypsin is most often used in combination with other enzymes to enhance its treatment potential. In addition, a well-balanced diet or the use of vitamin and mineral supplements are recommended to stimulate chymotrypsin activity.

Some types of seeds, including jojoba and wild soja seeds, have been found to contain proteins that inhibit the activity of chymotrypsin. These proteins can be inactivated by boiling the seeds.

Chymotrypsin should not be used together with acetylcysteine, a drug used to thin mucus in the lungs. It should also not be used together with anticoagulant (blood thinning) drugs, as it increases their effects. Chloramphenicol, a medication used to treat eye **infections**, may counteract the effectiveness of chymotrypsin ophthalmic solutions.

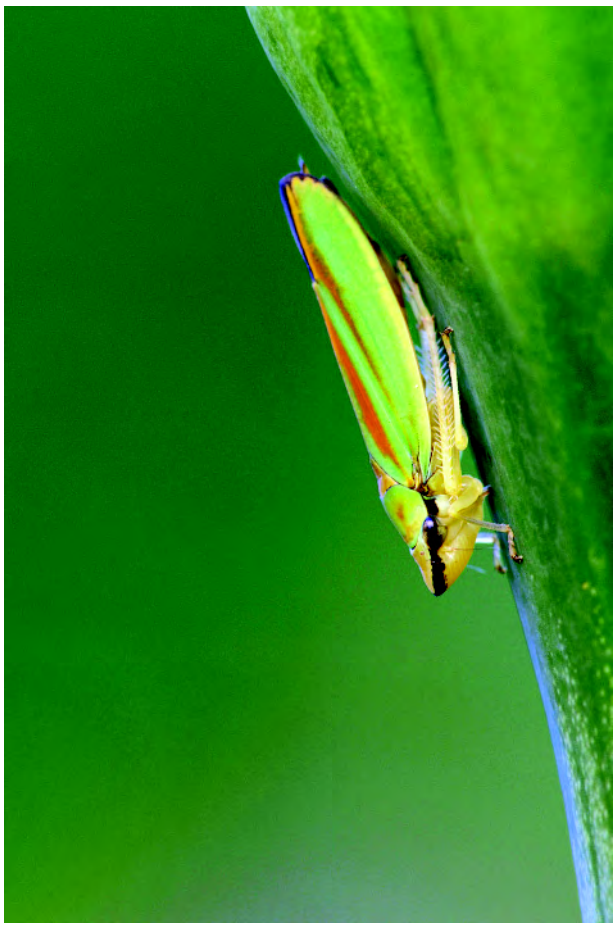
Cicada

Description

Cicada is an animal-derived substance used in **traditional Chinese medicine** (TCM). It is extracted from or prepared by grinding the empty shell shed every seven years by the cicada, (*Cryptotympana atrata* or *Cryptotympana pustulata*), which is a winged insect that makes a distinctive chirping sound and belongs to the Cicadidae family.

Cicadas are commonly found in mainland China, Taiwan, and Japan. They had religious significance in ancient China and symbolized reincarnation or immortality, as the Chinese compared the cicada's periodic molting of its shell with a person's leaving the physical body behind at the time of death. Bronze vessels as old as 1500 B.C. ornamented with cicadas have been found in Chinese tombs, along with white pottery and jewelry featuring cicada designs. During the Han dynasty (202 B.C. to A.D. 220), the Chinese carved small cicadas out of precious jade and placed them in the mouths of the dead.

The pharmaceutical name of the substance made from this insect is *Periostracum cicadae*, or *chan tui* in Chinese. It is prepared from the exuvium, or cast-off



Cicada is an animal-derived substance used in traditional Chinese medicine extracted from or prepared by grinding the empty shell shed every seven years by the cicada, shown here. *(© Arco Images / Alamy)*

shell of the nymph form of the insect. The empty shell is shiny, translucent, and yellow-brown in color. As it would appear in a living cicada, the shell has three portions: head (with two eyes), chest (with wings and a crossed gap), and abdomen (with three pairs of feet).

General use

The medicinal uses of cicada include treatment of **fever** and associated seizures; skin **rashes**; and such eye disorders as **conjunctivitis**, **cataracts**, and blurred vision.

Due to its antipyretic effect, cicada-containing preparations are often used to treat high fevers, such as those associated with the **common cold** or **influenza**. Western news media reported in April 2003 that the Chinese were using combinations of cicada and silkworm droppings to treat the fever associated with SARS. In addition to reducing fever, cicada is also used in TCM to treat other symptoms of colds and flu, including **laryngitis**, **headache**, restless sleep, or nightmares.

Cicada is said to be effective in relieving itchy rashes and **eczema**. Its special use is for the treatment of rashes or skin eruptions that occur in the early stages of **measles** or chicken pox. According to traditional Chinese medicine, the sooner the rashes appear, the shorter and less severe these diseases will be. Therefore, a Chinese herbalist may suggest cicada preparations to hasten the eruption of the rash.

Cicada is said to prevent or reduce **muscle spasms** by reducing the tension of the striated muscles. It may also delay transmission of nerve signals at the neuromuscular junction, thereby reducing muscle spasms. Its actions may be similar to those of Western barbiturates, sedatives, and anticonvulsants (antiseizure medications).

Cicada has also been used in TCM to treat eye diseases associated with wind and heat, including blurred vision and conjunctivitis (inflammation of the membrane that lines the eyelids). It is usually mixed with chrysanthemum flowers (*Chrysanthemum morifolium*, or *ju hua* in Chinese) when used to treat cataracts.

Preparations

The usual dosage of cicada when taken alone is 3–9 grams per day. As of 2004, whole cicadas cost about 10 cents per gram when purchased in bulk from suppliers of Chinese medicinal herbs. Cicada may be prepared as a decoction, which means that the insect

KEY TERMS

Anticonvulsant—A medication given to prevent or treat seizures.

Antipyretic—A medication or preparation given to bring down fever. Cicada is thought to have antipyretic properties.

Decoction—A medicine or herbal preparation prepared by boiling. Cicada is usually taken in the form of a decoction.

Exuvium—A cast-off shell of an insect or crustacean. Cicada in traditional Chinese medicine is made from the molted shell of a cicada.

Febrile—Characteristic of fever.

Qi—The Chinese term for life force or vital energy. It is sometimes spelled *chi* or *ki*.

shells are boiled down to a concentrated broth or tea to be taken internally. Other forms of cicada preparations include ground powder and water and alcohol extracts.

Precautions

A general precaution when using herbs or other alternative medicines is to purchase them only from reputable sources. In the case of traditional Chinese remedies, this precaution is particularly important because many of them are imported from countries without strict production or labeling standards. In the case of cicada, the United States Food and Drug Administration (FDA) reported in June 2003 that a shipment described as "Cicada Molting Herbal Food Supplement" from Taiwan was refused entry into the United States and considered dangerous. In this instance, the FDA defined "dangerous" in these terms: "The article appears to be dangerous to health when used in the dosage or manner, or with the frequency or duration, prescribed, recommended, or suggested in the labeling thereof."

Practitioners of TCM state that pregnant women should not use cicada because of the risk of miscarriage.

Side effects

No side effects from cicada preparations have been reported in the United States as of early 2008.

Interactions

As of 2008, cicada decoctions have not been reported to interact with any Western prescription medications.

Cinnamon bark

Description

Cinnamon bark (*Cinnamomum verum, C. zeylanicum, C. cassica*) is harvested from a variety of evergreen tree that is native to Sri Lanka, China, and India. The tree has thick, reddish brown bark, small yellow flowers, and its leathery leaves have a spicy smell. It grows to a height of approximately 20–60 ft (8–18 m) and is found primarily in tropical forests. Cinnamon bark belongs to the Lauraceae family. Related species are *Cinnamomum cassia* and *Cinnamomum saigonicum* (Saigon Cinnamon).

Cinnamon bark is cultivated in such tropical regions as the Philippines and the West Indies. It is not grown in the United States. Every two years the trees are cut to just above ground level. The bark is harvested from the new shoots, then dried. The outer bark is stripped away, leaving the inner bark, which is the main medicinal part of the herb.

The use of cinnamon dates back thousands of years to at least 2700 B.C. Chinese herbals from that time mentioned it as a treatment for **fever**, **diarrhea**, and menstrual problems. Indian Ayurvedic healers used it in a similar manner. Cinnamon was introduced around 500 B.C. to the Egyptians, who then added it to their embalming mixtures. Hebrews, Greeks, and Romans used it as a spice, perfume, and for **indigestion**. Moses is said to have included cinnamon in an anointing oil that he used. By the seventeenth century, cinnamon was considered a culinary spice by Europeans. American nineteenth-century physicians prescribed cinnamon as a treatment for stomach cramps, **nausea**, **vomiting**, diarrhea, **colic**, and uterine problems.

General use

Cinnamon bark is a common ingredient in many products such as toothpaste, mouthwash, perfume, soap, lipstick, chewing gum, **cough** syrup, nasal sprays, and cola drinks. A popular food flavoring, it is valued as one of the world's most important spices. It is also valuable in the treatment of various ailments. Modern herbalists prescribe cinnamon bark as a remedy for nausea, vomiting, diarrhea, and indigestion. Chinese herbalists recommend it for **asthma** brought on by cold, some digestive problems, backache, and menstrual problems.

The medicinal value of the herb is attributed to the oil extracted from the inner bark and leaves. The cinnamon bark harvested from the young branches is primarily used for culinary purposes. In fact, the cinnamon sticks commonly used in cooking are actually pieces of rolled outer bark.

The active ingredients of the bark have antibacterial, antiseptic, antiviral, antispasmodic, and antifungal properties. A study published in 2002 indicated that oil from cinnamon bark inhibits the production of listeriolysin, a protein released by *Listeria* bacteria that destroys healthy cells. Japanese research has shown cinnamaldehyde, one of the constituents of cinnamon bark, to be a sedative and analgesic. Eugenol, another component, contains pain-relieving qualities.

Cinnamon bark is helpful in strengthening and supporting a weak digestive system. Research indicates that cinnamon bark breaks down fats in the digestive system, making it a valuable digestive aid. It is used to treat nausea, vomiting, diarrhea, stomach ulcers, acid indigestion, **heartburn**, lack of appetite, and abdominal disorders.

A traditional stimulant in Chinese medicine, cinnamon bark has a warming effect on the body and is used for conditions caused by coldness. The twigs of cinnamon enhance circulation, especially to the fingers and toes.

Cinnamon bark contains antiseptic properties that help to prevent infection by killing decay-causing bacteria, fungi, and viruses. One German study showed that the use of cinnamon bark suppressed the cause of most urinary tract **infections** and the fungus responsible for vaginal yeast infections. It is also helpful in relieving **athlete's foot**.

Cinnamon bark is a frequent ingredient in toothpaste, mouthwash, and other oral hygiene products because it helps kill the bacteria that causes tooth decay and **gum disease**. Inflammations of the throat and pharynx may be relieved through its use.

Cinnamon bark is also known to control blood sugar levels in diabetics. United States Department of Agriculture (USDA) researchers found that cinnamon bark may reduce the amount of insulin required for glucose metabolism. A dose of 1/8 to 1/4 tsp of ground cinnamon per meal for diabetic patients may help to regulate their blood sugar levels. Several studies in the early 2000s produced mixed results on the effectiveness of cinnamon in treating type 1 and type 2 diabetes. All of the studies were on small groups of participants.

Cinnamon is believed to have strong antioxidant properties and to enhance the activity of insulin in diabetics. A 2003 study in Pakistan, published in the December 2003 issue of *Diabetes Care*, reported that daily consumption of 1, 3, or 6 grams of cinnamon significantly reduced blood glucose, LDL (bad) **cholesterol**, total cholesterol, and triglycerides in people with type 2 diabetes. A study by the University of Connecticut School of Pharmacy, published in the January 2008 issue of *Diabetes Care*, analyzed five previous studies and concluded that cinnamon did not significantly improve A1C, **fasting** blood glucose, or cholesterol levels in patients with type 1 or type 2 diabetes. A1C is a test that measures a diabetic's average blood sugar (glucose) levels over two to three months. The Connecticut study is contrasted by a 2007 European study that reported 3 grams of cinnamon extract taken daily lowered fasting blood sugar levels by 10% among diabetics after four months.

The spice has also garnered quite a reputation as an aphrodisiac. A study at the Smell and Taste Research Foundation in Chicago tested medical students' reactions to various aromas by attaching measurement devices to the students' penises. The smell of hot cinnamon buns generated the most blood flow of all the scents.

Cinnamon bark promotes **menstruation**. It has been used to treat menstrual **pain** and **infertility**. Women in India take it as a contraceptive after **childbirth**.

Other conditions in which cinnamon bark may be helpful include fevers and colds, coughs and **bronchitis**, infection and wound healing, some forms of asthma, and blood pressure reduction.

Cinnamon bark has been shown to be an effective natural snake repellent that is safer to use than synthetic pest management chemicals.

KEY TERMS

A1C—A test that measures a diabetic's average blood sugar (glucose) levels over two to three months.

Analgesic—A pain-relieving substance.

Antispasmodic—A substance that relieves muscle spasms or cramping.

Aphrodisiac—A drug or other substance that arouses or is thought to arouse sexual desire.

Essential oil—A concentrated oil that has been distilled from a plant.

Sedative—A drug or herb that has a calming and relaxing effect. Sedatives are used to aid sleep and ease pain and are often given as mild tranquilizers.

Preparations

Cinnamon bark is available in several forms from Chinese pharmacists, Asian grocery stores, and health food stores: fresh or dried bulk, pill, tincture, and as an essential oil.

Dosage

In Chinese medicine, cinnamon is usually taken in combination with other herbs. Below are some typical dosages for cinnamon alone.

- Tincture: Take up to 4 ml with water three times daily.
- Tea: Take 1 cup 2–3 times daily at mealtimes.
- Crushed: Take 1/2 tsp (2–4 g) daily.

Precautions

- Cinnamon bark may cause an allergic reaction in some individuals.
- Cinnamon bark is not recommended for pregnant or nursing women.
- Essential oil of cinnamon bark ought not to be taken internally unless under professional supervision. Internal ingestion may cause nausea, vomiting, and possible kidney damage.
- Essential oil of cinnamon bark is one of the most hazardous essential oils and should not be used on the skin. External application of the oil may cause redness and burning of skin.
- Cinnamon bark should not be given to children under two years of age.
- Cinnamon bark is considered toxic if taken in excess.
- Cinnamon bark should not be given to persons with inflammatory liver disease; in large quantities, it can irritate the liver.

Side effects

Mild side effects include stomach upset, sweating, and diarrhea. Large doses can cause changes in breathing, dilation of blood vessels, sleepiness, **depression**, or convulsions. Excessive use of cinnamon bark may cause red, tender gums; mouth ulcers; inflamed taste buds; and a severe burning sensation in the mouth.

Interactions

Some interactions with other medications have been reported. Cinnamon oil may cause skin irritation if applied to the skin together with **acne** medications that contain retinoic acid. Cinnamon bark has also been reported to intensify the effects of medications given to lower blood pressure. Persons taking cinnamon bark should discontinue its use two weeks before any surgery requiring general anesthesia because of the herb's tendency to lower blood pressure.

Cirrhosis

Definition

Cirrhosis refers to various types of chronic degenerative disease of the liver in which normal liver cells are damaged and then replaced by scar tissue.

Description

Cirrhosis changes the structure of the liver and the blood vessels that nourish it. The disease reduces the liver's ability to manufacture proteins, complex carbohydrates, fats, **cholesterol**, and to process hormones, nutrients, medications, and poisons. Cirrhosis worsens over time and can be life-threatening.

Cirrhosis is the seventh leading cause of disease-related death in the United States. It is the third most common cause of death in adults between the ages of 45 and 65. It is twice as common in men as in women. The disease occurs in more than half of all malnourished chronic alcoholics. Some authorities estimate that cirrhosis and related complications are responsible for the deaths of more than 40,000 people a year in the United States with direct healthcare costs of more than $1 billion. In Asia and Africa, however, most deaths from cirrhosis are due to chronic **hepatitis** B.

Types of cirrhosis

There are several typs of cirrhosis:

- Portal, or nutritional cirrhosis, the most common form of the disease in the United States. About 30 to 50% of all cases of cirrhosis are this type. Nine out of every 10 people who have nutritional cirrhosis have a history of alcoholism. Portal cirrhosis is also called Laënnec's cirrhosis.
- Biliary cirrhosis, caused by liver bile-duct diseases that impede bile flow. Bile is formed in the liver and carried via ducts to the intestines. Bile then helps digest fats in the intestines. Biliary cirrhosis can result in the scarring or blockage of these ducts. It accounts for 15 to 20% of all cases of cirrhosis.
- Postnecrotic cirrhosis. Caused by chronic infections, this form of the disease affects up to 40% of all patients who have cirrhosis.
- Pigment cirrhosis (hemochromatosis). Disorders such as the inability to metabolize iron and similar disorders may cause pigment cirrhosis, which accounts for 5 to 10% of all instances of the disease.

Causes and symptoms

Causes and risk factors

Long-term **alcoholism** is the primary cause of cirrhosis in the United States. Men and women respond differently to alcohol. Although most men can safely consume two to five drinks a day, one to two drinks a day can cause liver damage in women. Individual tolerance to alcohol varies, but people who drink more and drink more often have a higher risk of developing cirrhosis. In some people, one drink a day can eventually cause liver scarring.

Chronic liver **infections**, such as hepatitis B and particularly hepatitis C, are commonly linked to cirrhosis. People at high risk of contracting hepatitis B include those exposed to the virus through contact with blood and body fluids. This group includes healthcare workers and intravenous (IV) drug users. In the past, people have contracted hepatitis C through blood transfusions. As of 2003, cirrhosis resulting from chronic hepatitis has emerged as a

leading cause of death among HIV-positive patients; in Europe, about 30% of HIV-positive patients are coinfected with a hepatitis virus.

Liver injury, reactions to prescription medications, certain autoimmune disorders, exposure to toxic substances, and repeated episodes of heart failure with liver congestion can cause cirrhosis. A family history of diseases can genetically predispose a person to develop cirrhosis. These genetic problems include:

- a lack of a specific liver enzyme (alpha$_1$-antitrypsin deficiency)
- the absence of a milk-digesting enzyme (galactosemia)
- an inability to convert sugars to energy (glycogen storage disease)
- an absorption deficit in which excess iron is deposited in the liver, pancreas, heart, and other organs
- a disorder characterized by accumulations of copper in the liver, brain, kidneys, and corneas (Wilson's disease)

In the 2000s **obesity** was recognized as a risk factor in nonalcoholic hepatitis and cirrhosis. Some surgeons recommend that patients scheduled for weight-reduction surgery have a liver biopsy to evaluate the possibility of liver damage.

Symptoms

Symptoms of cirrhosis are usually caused by the loss of functioning liver cells or organ swelling due to scarring. The liver enlarges during the early stages of illness. Patients may experience one or more of the following symptoms:

- anemia
- bleeding gums
- constipation
- decreased interest in sex
- diarrhea
- dull abdominal pain
- extremely dry skin and intense itching
- fatigue
- fever
- fluid in the lungs
- hallucinations
- indigestion
- lethargy
- lightheadedness
- loss of appetite
- muscle weakness
- musty breath
- nausea
- painful nerve inflammation (neuritis)
- portal hypertension (This type of hypertension can be life threatening; it can cause veins to enlarge in the stomach and esophagus; the enlarged veins, called varices, can rupture and bleed massively.)
- redness of the palms of the hands
- slurred speech
- tremors
- dark yellow or brown urine and black or bloody stools
- vomiting
- weakness
- weight loss
- yellowish whites of the eyes and skin, indicating the development of jaundice

As the disease progresses, other symptoms usually appear:

- spleen enlarges and fluid collects in the abdomen (ascites) and legs (edema)
- spider-like blood vessels appear on the chest and shoulders and bruising becomes common
- men sometimes lose chest hair; their breasts may grow and their testicles may shrink
- women may have menstrual irregularities

If the liver loses its ability to remove toxins from the brain, the patient may have additional symptoms. The patient may become forgetful and unresponsive, neglect personal care, have trouble concentrating, and acquire new sleeping habits. These symptoms are related to ammonia intoxication and the failure of the liver to convert ammonia to urea. High protein intake in these patients can also lead to these symptoms.

Cirrhosis worsens over time and can become potentially life-threatening. This disease can cause:

- excessive bleeding (hemorrhage)
- impotence
- liver cancer
- coma due to accumulated ammonia and body wastes (liver failure)
- sepsis (blood poisoning)
- death

Diagnosis

A patient's medical history can reveal illnesses or a lifestyle likely to lead to cirrhosis. Liver changes can be seen during a physical examination. A doctor who suspects cirrhosis may order blood and urine tests to measure liver function. Because only a small number

of healthy cells are needed to carry out essential liver functions, test results may be normal even when cirrhosis is present.

In about 10% of all patients, the cause of cirrhosis cannot be determined. Many people who have cirrhosis do not have any symptoms (often called compensated cirrhosis). Their disease is detected during a routine physical examination or when tests for an unrelated medical problem are performed. This type of cirrhosis can also be detected when complications occur (decompensated cirrhosis).

Computed tomography scans (CT), ultrasound, and other imaging techniques can be used during diagnosis. They can help determine the size of the liver, indicate healthy and scarred areas of the organ, and detect **gallstones**. Cirrhosis is sometimes diagnosed during surgery or by examining the liver with a laparoscope. This viewing device is inserted into the patient's body through a tiny incision in the abdomen.

Liver biopsy is usually needed to confirm a diagnosis of cirrhosis. In this procedure, a tissue sample is removed from the liver and examined under a microscope in order to learn more about the organ's condition and to properly diagnose any liver disease.

A newer and less invasive test involves the measurement of hyaluronic acid in the patient's blood serum. As of 2008 the test was often used to monitor the progress of liver disease and to indicate when a liver biopsy may be necessary. The test for hyaluronic acid was not anticipated to completely replace liver biopsy in the diagnosis of cirrhosis.

Treatment

Before starting on any alternative treatment program, patients should consult their doctor regarding monitoring side effects and estimating effectiveness of treatment. Any nutritional changes should be discussed with the primary care provider. Alternative treatments that may be of help to cirrhotic patients include nutritional and juice therapy, Western herbal therapy, **traditional Chinese medicine**, and **homeopathy**.

Nutritional therapy

To support liver function and slow disease progression, a naturopath may recommend the following:

- Avoid liver toxins. Cirrhotic patients must completely avoid alcohol. Alcohol accelerates liver failure and hastens death in cirrhotic patients. In addition, even over-the-counter drugs, such as acetaminophen (Tylenol), should be avoided because they can be toxic in cirrhotic patients.
- Juice therapy helps the liver detoxify the body. Patients should mix one part of pure juice with one part of water before drinking.
- Eat smaller meals. To avoid overworking the liver, five or six smaller, lighter meals per day are recommended.
- Avoid fatty foods, especially those prepared with animal fats or hydrogenated oils and all processed foods. These types of foods put additional demands on the liver.
- Eat only meals containing lean proteins (containing no fats) and in limited amounts. Vegetable proteins, such as those found in legumes or tofu, and whole grains are preferred. High protein intake causes increases in ammonia levels in the blood, possibly resulting in mental confusion, and in severe cases, coma. However, individuals ought not to limit severely their protein intake, as this may cause protein deficiency and impair the healing process.
- Increase consumption of fruits and steamed vegetables. Fruits and vegetables are easy to digest, thus less work for the liver. In addition, they are good sources of vitamins, minerals, and antioxidants that help the liver detoxify and heal.
- Practice intermittent fasting.
- Take supplements that can improve digestion and help the liver heal and prevent further injury to the liver. These include pancreatic enzymes, milk thistle (*Silybum marianum*), lipotropic agents such as vitamin B_6, vitamin B_{12}, folic acid, choline, alpha lipoic acid, betaine, and methionine.

Many health practitioners have long recommended the use of **milk thistle** in treating cirrhosis and other liver diseases. The active component in milk thistle, silymarin, promotes liver protein synthesis. The National Center for Complementary and Alternative Medicine (NCCAM) selected milk thistle as one of the alternative treatments to study in more detail. As of 2008, the center had found mixed results from the studies it had reviewed and inconclusive evidence to support claims for milk thistle use. In 2008 NCCAM was supporting research on the possible health benefits of using milk thistle to treat liver diseases, **cancer**, and HIV disease.

Other therapies

Other types of therapies the patient may want to consider are naturopathic **hydrotherapy** and treatments that may improve immune function, including **stress** reduction, **guided imagery**, and massage.

Traditional Chinese medicine

Depending on a patient's specific condition, an expert Chinese herbalist may prescribe herbal remedies that may help improve liver function. Animal studies have shown that the following Chinese herbs may have protective effects on the liver:

- Propolis
- *Bupleurum chinense,* a frequently used herb for a variety of liver diseases
- *Phellodendron wilsonii*
- *Clementis chinensis*
- *Solanum incanum*
- *Ixeris chinensis*
- *Gardenia jasminoides*

Western herbal therapy

Patients should consult an experienced herbalist for specific herbal treatments.

Homeopathy

For homeopathic therapy, patients should consult a homeopathic physician who may prescribe specific remedies based on knowledge of the underlying cause.

Allopathic treatment

The goal of treatment is to cure or reduce the condition causing cirrhosis, prevent or delay disease progression, and prevent or treat complications.

Salt and fluid intake is often limited, and physical activity is encouraged. A diet high in calories and moderately high in protein can benefit some patients. Tube feedings or vitamin supplements may be prescribed if the liver continues to deteriorate. Patients must not consume alcohol.

Medication

Iron supplements, diuretics, and antibiotics may be used for **anemia**, fluid retention, and ammonia accumulation associated with cirrhosis. Vasoconstrictors are sometimes needed to stop internal bleeding and antiemetics may be prescribed to control **nausea**.

Laxatives help the body absorb toxins and accelerate their removal from the digestive tract. Beta-blockers may be prescribed to control cirrhosis-induced portal **hypertension**. Interferon medicines may be used by patients with chronic hepatitis B and hepatitis C to prevent post-hepatic cirrhosis.

Surgery

Medication that causes scarring can be injected directly into veins to control bleeding from varices in the stomach or esophagus. Varices may require a special surgical procedure called balloon tamponade ligation to stop the bleeding. Surgery may be required to repair disease-related throat damage. It is sometimes necessary to remove diseased portions of the spleen and other organs.

In the 2000s the incidence of liver cancer related to cirrhosis in the United States had increased 75% since the early 1990s. Partial surgical removal of the liver in patients with early-stage cancer of the liver appeared to be as successful as transplantation, in terms of the 5-year survival rate.

Liver transplants can benefit patients with advanced cirrhosis. However, the new liver will eventually become diseased unless the underlying cause of cirrhosis (such as alcoholism) is removed.

Supportive measures

A balanced diet promotes regeneration of healthy liver cells. Eating five or six small meals throughout the day should prevent the sick or bloated feeling patients with cirrhosis often have after eating. Alcohol and **caffeine**, which destroy liver cells, should be avoided, as should any other foods that upset the stomach. Patients with brain disease associated with cirrhosis should avoid excessive amounts of protein in the diet.

A patient can keep a food diary that describes what was eaten, when it was eaten, and how the patient felt afterwards. This diary can be useful in identifying foods that are hard to digest and in scheduling meals to coincide with the times the patient is most hungry.

Patients who have cirrhosis should weigh themselves every day and notify their doctor of a sudden gain of 5 lb (2 kg) or more within a one to two week period. A doctor should also be notified if symptoms of cirrhosis appear in anyone who has not been diagnosed with the disease. A doctor should be notified if a patient diagnosed with cirrhosis experiences the following:

- vomits blood
- passes black stools
- seems confused or unresponsive
- shows signs of infection (redness, swelling, tenderness, pain)

KEY TERMS

Compensated cirrhosis—Asymptomatic cirrhosis of the liver.

Edema—An excessive accumulation of fluid in body tissue.

Portal hypertension—A type of hypertension that can be life threatening; veins enlarge in the stomach and esophagus, and the enlarged veins, called varices, can rupture and bleed massively.

Sepsis—Blood poisoning.

Expected results

Cirrhosis-related liver damage cannot be reversed, but further damage can be prevented by patients who do the following:

- eat properly
- get enough rest
- do not consume alcohol
- remain free of infection

If the underlying cause of cirrhosis cannot be corrected or removed, scarring will continue. As scarring continues, the liver will fail, and the patient will probably die within five years. Patients who stop drinking after being diagnosed with cirrhosis can increase their likelihood of living more than a few years from 40% to 60-70%.

Prevention

Eliminating alcohol abuse could prevent 75 to 80% of all cases of cirrhosis.

Other preventive measures include:

- maintaining a healthy diet that includes whole foods and grains, vegetable, and fruits
- obtaining counseling or other treatment for alcoholism
- taking precautions (practicing safe sex, avoiding dirty needles) to prevent hepatitis
- getting immunizations against hepatitis if a person is in a high-risk group
- receiving appropriate medical treatment quickly when diagnosed with hepatitis B or hepatitis C
- having blood drawn at regular intervals to rid the body of excess iron from hemochromatosis
- using medicines (chelating agents) to rid the body of excess copper from Wilson's disease
- wearing protective clothing and following product directions when using toxic chemicals at work, at home, or in the garden

Club moss

Definition

Club moss is the common name for the approximately 200 species of plants that make up the genus *Lycopodium*. This genus is a member of the order Lycopodiales, the only extant order of the class Lycopodiopsida in the plant kingdom. A second order, Drepanophycales, is now extinct, having flourished during the late Silurian to late Devonian periods (about 450 million to 350 million years ago). Members of the two orders are very different from each other,

Club moss. *(© tbkmedia.de / Alamy)*

with the earlier plants growing to the size of trees with stems several millimeters to centimeters in diameter. Their decayed remains have become constituents of coal deposits found throughout the world.

Description

Modern club mosses look like true mosses, but are structurally very different in that they are vascular plants. They tend to be epiphytic (that is, subsisting on other plants without causing them harm) or terrestrial with extended, creeping stems. They are lacking in flowers and have abundant masses of tiny scale- or needle-like leaves. They produce sexually in two stages, one of which occurs beneath ground, by the production and distribution of spores.

Uses

Yellow spores collected from certain species of club moss, especially *Lycopodium clavatum*, are used for a variety of purposes, including fingerprint identification, fireworks displays, and coatings for pills. Spore preparations are commonly known as **lycopodium** powder or vegetable **sulfur**. In **traditional Chinese medicine**, the spores have been dried and ground into a powder for use in the treatment of **fever** and inflammation. In this form the material is usually called Chinese club moss, or *qian ceng ta*.

Recent research has focused on one of the components of qian ceng ta, the alkaloid known as huperzine A. The substance has been found to be effective in treating the **dementia** associated with a number of neurological disorders, such as **Alzheimer's disease**. Huperzine A apparently interferes with the enzyme acetylcholinesterase, which breaks down the neurotransmitter acetylcholine in the central nervous system. Reduced levels of acetylcholine are thought to be related to the development of dementia. Other studies have suggested that huperzine A may be effective in treating the symptoms of myasthenia gravis and poisoning from a class of compounds known as the organophosphates. Results are preliminary, however, and experts point out that further studies are needed to confirm the therapeutic effects of huperzine A.

Some researchers suggest that the beneficial effects of club moss for the treatment of fever and **pain** may be the consequence of its dehydrative effects on cells. As cells lose water, they tend to contract, causing less pressure on nerves with which they may be associated. Definitive evidence for this hypothesis is, however, not yet available.

Side effects

The most serious side effect of using Chinese club moss is arrhythmia, irregular heart beat. With people who have a history of seizure, arrhythmia may increase the likelihood of additional, more serious seizures. Less serious side effects associated with use of the drug include:

- nausea
- diarrhea
- dizziness
- drooling
- excessive sweating
- blurred vision
- stomach cramps

Interactions

Chinese club moss and related drugs may interact with a variety of prescription drugs that inhibit the

KEY TERMS

Acetylcholine—A neurotransmitter that operates in the central nervous system.

Acetylcholinesterase—An enzyme that interferes with the function of acetylcholine.

Neurotransmitter—A chemical that carries a message between two neurons (nerve cells) in the body

Spore—A reproductive cell produced by simple organisms, such as fungi and ferns.

action of acetylcholine, so-called anticholinergic drugs, such as:

- atropine
- propantheline
- glycopyrrolate
- dicyclomine (Bentyl®)
- hyoscyamine sulfate (Levsin®)

Cnidium seeds

Description

A variety of carrot unknown to most Americans, *Cnidium monnieri* is a leafy annual with flowers that grow in clusters. The herb has been a popular remedy in Asian folk medicine for millennia, being first described about 2,000 years ago in the Chinese herbal classic *Shen Nong Ben Cao Jing*. Cnidium's reputation for treating itchy skin conditions persists to this day. Only the seeds and essential oil of *Cnidium monnieri*, which belongs to the Apiaceae family, are used as a drug.

The seeds, which are also referred as *she chuang zi* or *she chuang dze*, are somewhat yellow in color and have a sweet smell. They are believed to have several important therapeutic properties, including antibacterial, antifungal, and astringent effects. Some of these claims have been supported by animal and laboratory studies. In one test tube investigation, published in the Chinese journal *Chung Kuo Chung Yao Tsa Chih* in 1991, researchers demonstrated that *Cnidium monnieri* was effective against several **strains** of bacteria and fungi. *Cnidium monnieri* also appears to have antipruritic activity, meaning that the herb may help to alleviate **itching**. In a study of mice, published in the Japanese journal *Biological & Pharmaceutical Bulletin* in 2000, cnidium was shown to significantly reduce the itch-scratch response in rodents.

In the somewhat ethereal parlance of Chinese folk medicine—in which diseases are often believed to occur due to disruptions in the flow of bodily energy—cnidium seeds are considered warm, bitter, and acrid. The **essential oils** derived from the seeds include camphene, borneol, pinene, and terpineol.

General use

While not approved by the FDA, cnidium seeds have been reported to have several beneficial effects. Because the seeds have not been extensively studied in people, their effectiveness is based mainly on animal studies and their ancient reputation as a folk remedy in China. In modern times, the herb is primarily used to treat skin conditions such as **scabies**, **eczema**, ringworm, and itchy, oozing skin lesions. It is also thought to be helpful in the treatment of **vaginitis** and vaginal discharge. Cnidium is used externally for all the purposes mentioned above. The seeds may also be taken internally to treat **impotence** as well as **infertility** in both sexes.

KEY TERMS

Astringent—An agent that helps to contract tissue and prevent the secretion of internal body fluids such as blood or mucus. Astringents are typically used to treat external wounds or to prevent bleeding from the nose or throat.

Eczema—A condition characterized by inflamed, itchy skin. Eczema may also involve oozing, crusting, and scaling.

Essential oil—A term describing a wide variety of concentrated plant-derived oils. They are often used to make soaps and perfumes, as well as being used extensively in natural medical remedies.

Osteoporosis—An age-related disease in which bones become fragile and prone to debilitating fractures.

Ringworm—A fungal skin infection that predominantly affects children. The condition is characterized by reddish, scaly rings on the skin.

Scabies—A contagious rash caused by the *Sarcoptes scabiei* mite, which burrows into the upper layer of the skin in order to lay eggs. Scabies is characterized by intense itching.

Vaginitis—An inflammation of the mucous membrane that lines the interior of the vagina. It often results from a *Candida* or other fungal infection, and is accompanied by pain, itching, and discharge.

Cnidium has shown some intriguing activity against **asthma** and **osteoporosis** in animal studies, though the clinical implications of these findings are not yet known. In one investigation, published in the Chinese journal *Chung-kuo Chung Ya Yao Tsa Chih* in 1990, chemicals in *Cnidium monnieri* called coumarins appeared to protect guinea pigs from the effects of bronchial asthma, which the animals experienced after inhaling histamine. The researchers also demonstrated that the coumarins can relax the tracheal muscles of guinea pigs in test tube experiments. A possible link between cnidium and osteoporosis was examined in two rodent studies published in the Chinese journal *Chung-kuo Yao Li Hsueh Pao* in 1994 and 1997. Both studies suggest that cnidium can help to prevent osteoporosis induced by glucocorticoid drugs.

Preparations

The optimum dosage of cnidium seeds has not been established with any certainty. Dosage may range from 3-12 g. Because cnidium seeds have been recommended for a variety of purposes, and can be used internally and externally, consumers are advised to consult a doctor experienced in the use of alternative remedies or Chinese medicine to determine proper dosage.

To treat skin conditions, the herb is usually applied to the skin in the form of a solution or ointment. Vaginitis and vaginal discharge are treated with a douche prepared from the seeds.

In Chinese folk medicine, cnidium seeds are often combined with other herbs or minerals. When used externally, the seeds may be mixed with stemona and sophora for itchy, oozing skin lesions or with calomel for scabies and eczema (including genital eczema). Taken internally, cnidium seeds are often combined with **schisandra** or **cuscuta** to treat impotence or infertility.

Cnidium seeds are generally available in bulk or in combination products (such as powders or pills) that contain several different herbs.

Precautions

Cnidium seeds are not known to be harmful when taken in recommended dosages, though it is important to remember that the long-term effects of taking the seeds (in any amount) have not been investigated. Due to lack of sufficient medical study, cnidium seeds should be used with caution in children, women who are pregnant or breast-feeding, and people with liver or kidney disease.

Cnidium seeds should not be applied to skin that is hot, dry, and sore.

Do not confuse cnidium seeds with the essential oil derived from them. While the seeds may be taken internally, the essential oil should not be ingested except under the supervision of a doctor.

While cnidium has shown some activity against bronchial asthma and osteoporosis in animal studies, it is not yet recommended for either of these conditions. Both diseases are potentially serious and require a doctor's care.

Side effects

When taken in recommended dosages, cnidium seeds are not associated with any bothersome or significant side effects.

Interactions

Cnidium seeds should not be used at the same time as croton seeds, **fritillaria**, or peony root, according to

practitioners of Chinese folk medicine. When used externally, cnidium seeds have been combined with stemona, sophora, and calomel without apparent harm. When used internally, the seeds have been safely mixed with schisandra and cuscuta.

Codonopsis root

Description

Codonopsis is the fresh or dried root of the plant *Codonopsis pilosula*. Codonopsis is a small perennial native to Asia. It is especially abundant in the Shanxi and Szechuan provinces of China. Codonopsis grows to a height of about 5 ft (1.5 m) in dense brushy thickets and at the edges of woods where the soil remains moist. Codonopsis is well known in Chinese herbalism. Its Chinese name is *tang shen*. The plant is also cultivated in many other parts of the world, including the United States, because of its distinctive bell-shaped greenish-purple flowers. Other names for codonopsis include bastard ginseng and bonnet bellflower.

General use

Codonopsis, or *tang shen*, has been used in China for more than 2,000 years. It is one of the best-known and most widely used herbs in Chinese medicine. In the Chinese system of health, the *yin* aspects of nature, which have to do with cold, moisture, dark, and passivity, must be kept in balance with the *yang* aspects, which have to do with heat, dryness, light, and activity. Ill health occurs when the energies and elements of the body are out of balance with nature or in interior disharmony. Health is restored by taking herbs and treatments that restore this balance. In **traditional Chinese medicine**, codonopsis is said to have a neutral nature and a sweet taste. It is used as a tonic for the lungs and spleen and to strengthen and nourish the blood and balance metabolic function.

Like ginseng, codonopsis is an adaptogen. Adaptogens are substances that non-specifically enhance and regulate the body's ability to withstand **stress**. They increase the body's general performance in ways that help the whole body resist disease. Codonopsis is thought to benefit the entire body by boosting strength, increasing stamina and alertness, rejuvenating the body, strengthening the immune system, aiding recovery from chronic illness, reducing stress, and stimulating the appetite. It belongs to a class of herbs called stomachics, which means that they tonify the stomach to improve digestive functions.

Codonopsis is sometimes called the "poor man's ginseng." It is often substituted in Chinese herbal formulas for ginseng, although it has a milder action that lasts for a shorter time. Scientists have shown that the actions of ginseng and codonopsis, although similar, are caused by very different chemical compounds. This type of substitution based on function rather than chemical structure, however, is considered acceptable in Chinese medicine.

In addition to the whole-body effects of codonopsis, the herb is used for a number of other specific conditions. It can be taken internally, in various combinations with other herbs, for **anemia**; **asthma**; **cancer**; **diarrhea**; headaches, especially tension

KEY TERMS

Adaptogen—A substance that regulates a body system, either stimulating or suppressing it to bring it back within its normal range.

Decoction—An extract of a plant made by boiling it, then straining the solid material out. The resulting liquid is the decoction.

Galactogogue—A substance or medication that increases the flow of breast milk in nursing mothers.

Stomachic—A substance or medication that tonifies the stomach to improve digestive functions.

Tincture—A plant extract prepared in a solution of alcohol and water.

Yang aspects—In traditional Chinese medicine, yang aspects are qualities of nature such as warmth, activity, light, and dryness.

Yin aspects—Yin aspects are the opposite of yang aspects and are represented by qualities such as cold, moisture, darkness, and passivity.

headaches; **hemorrhoids**; high blood pressure; mucus in the lungs and shortness of breath; **nausea** and **vomiting**; neck tension; and a prolapsed (collapsed) uterus. Codonopsis can also be taken internally as a galactogogue, which means that it increases the supply of breast milk in nursing mothers.

University and medical researchers only became interested in codonopsis in the 1980s. Most of the research work has been done in China. Overall research findings suggest that codonopsis is relatively effective and safe. Most of this work has been done in test tubes and on small laboratory animals. Large-scale controlled human studies have yet to be done.

In many studies, scientists have found that extract of codonopsis root helps mice withstand stress, whether that stress comes from swimming, high temperatures, or oxygen deprivation. Other studies show that codonopsis boosts the immune system. In research done in China in 1997, codonopsis was shown to protect laboratory animals against gastric ulcers.

Other research has shown that codonopsis can increase the number of red blood cells and hemoglobin in animals. It also improves the production of antibodies. Studies are being done to determine if codonopsis would be useful in treating HIV infection; such autoimmune diseases as **systemic lupus erythematosus** (SLE), or immune systems that have been weakened by chemotherapy. Although the results are promising, definitive answers cannot be obtained until controlled studies on humans are performed.

Preparations

Codonopsis root comes in different grades. Roots at least three years old are harvested in the autumn after the leaves of the plant have died back. The best quality roots are large, clean, and dry on the surface, but moist inside when chewed. Codonopsis has a pleasant taste when eaten raw. Poor quality codonopsis is almost tasteless and may be dry and dirty.

Although codonopsis is sometimes eaten raw, the dried root is usually made into a decoction, which is an extract of the plant made by boiling. Tinctures, which are solutions of alcohol and water containing plant matter, are used in the West but not in traditional Chinese medicine. Commercially produced tablets, capsules, and tinctures of codonopsis are available. Dosage varies with the condition being treated. Codonopsis is often used in Chinese preparations, and may replace ginseng in almost any formula.

Precautions

Years of use in China suggest that codonopsis is not toxic and can be used by almost everyone. In China, babies are sometimes given pieces of codonopsis root to teethe on. It is given to children to help them grow strong, and breast-feeding women use it as a tonic to increase the quantity of milk they produce.

Side effects

No unwanted side effects are reported with the use of codonopsis.

Interactions

There are few, if any, studies of how codonopsis interacts with traditional Western medicines. It has been used for many years in combination with other Chinese herbs without incident.

Coenzyme Q_{10}

Description

Coenzyme Q_{10} is a fat-soluble nutrient also known as CoQ_{10}, vitamin Q_{10}, ubidecarenone, or ubiquinone. It is a natural product of the human body that is primarily found in the mitochondria, which are the cellular organelles that produce energy. It occurs in most tissues of the human body; however, the highest concentrations are found in the heart, liver, kidneys, and pancreas. Ubiquinone takes its name from a combination of the word ubiquitous, meaning something that is found everywhere, and quinone 10. Quinones are substances found in all plants and animals. The variety found in humans has a 10-unit side chain in its molecular structure. Apart from the important process that provides energy, CoQ_{10} also stabilizes cell membranes and acts as an antioxidant. In this capacity, it destroys free radicals, which are unstable molecules that can damage normal cells.

KEY TERMS

Angina—Symptoms of pressure or burning in the chest that result from inadequate oxygen in the heart, generally due to coronary artery spasm or blockage.

Antioxidant—An enzyme or other substance that is capable of countering the damaging effects of oxidation in the body's tissues. Coenzyme Q_{10} performs antioxidant activity.

Cardiomyopathy—A condition of damaged, diseased, thickened, or stretched heart muscle, resulting in weakness of the heart. Cardiomyopathy often occurs following heart attacks due to scarring, but may also have an infectious or nutritional origin.

Friedreich's ataxia—An inherited disease that usually manifests in childhood or adolescence, characterized by loss of muscular coordination (ataxia), curvature of the spine, impaired speech, and cardiomyopathy.

Huntington's disease—A fatal inherited disorder characterized by progressive neurologic symptoms including loss of motor and cognitive function.

General use

CoQ_{10} is used extensively in Canada, Western Europe, Japan, and Russia to treat congestive heart failure. It is available as a prescription medication almost everywhere it is sold, although it is sold over-the-counter as a nutritional supplement in the United States. Some studies have shown it to be effective for as many as 70% of patients with congestive heart failure. It appears to improve patient health and well-being, and to increase cardiac efficiency. The dosage generally recommended for this condition is 100–300 mg a day, preferably in divided doses. According to Dr. Karl Folkers in *Prevention's Healing with Vitamins*, it takes one to three months to achieve desired results from supplementation, and as long as six months to attain maximum benefit.

CoQ_{10} may also help people with some forms of cardiomyopathy. Patients should consult their physician about the possible benefits of supplementation for this condition.

The usefulness of CoQ_{10} in lowering blood pressure is not well documented. One study suggests that the supplement is helpful for **hypertension**, but the results are in question as it was not a double-blind, controlled research project. The dose recommended is 200–250 mg a day, with results taking several months to appear. It is possible that some patients with essential hypertension who are initially low in CoQ_{10} may eventually be able to decrease the amount of their other blood pressure medications. This must be done under the care of a health care provider.

Oral supplementation of CoQ_{10} has been shown to improve periodontal disease, as it decreases the size of abnormally deep pockets in the gums, and also reduces the extent of bacterial contamination. Other possible benefits of CoQ_{10} are to decrease **angina** symptoms, improve immune function in patients with **AIDS** and other immune deficiencies, improve control of blood sugar, lower **cholesterol**, improve physical stamina, and help people with muscular dystrophy and Huntington's disease. A group of researchers at the University of California at San Diego reported in 2002 that coenzyme Q_{10} appears to slow the progress of **Parkinson's disease**, Friedreich's ataxia, and other conditions marked by degeneration of the central nervous system. The supplement can also reduce the toxicity of some types of chemotherapy. Doxorubicin, a chemotherapeutic agent, is known to sometimes damage the heart. Concomitant supplementation seems to reduce this toxic effect. The possible benefits of CoQ_{10} should be discussed with a nutritionally-oriented health care provider.

Since 1961, when it was first noticed that **cancer** patients in Sweden and the United States had low levels of the enzyme, coenzyme Q_{10} has been studied

as a possible cancer treatment. Researchers believe that coenzyme Q_{10} may protect against cancer by stimulating the immune system, and functioning as an antioxidant. Although animal studies have been conducted, as of 2008 no report of a randomized clinical trial involving human subjects whose survival times were lengthened by using coenzyme Q_{10} in addition to a traditional cancer treatment has been reported in a peer-reviewed medical journal.

Deficiency

Patients with certain conditions tend to have lower levels of CoQ_{10}, and may benefit from supplements. Some diseases that are associated with decreased amounts of this nutrient are AIDS, chronic **fatigue**, congestive heart failure, cardiomyopathy, and inflammatory **gum disease**. Levels of CoQ_{10} tend to decrease with age; tests for its presence in the body are not widely available. Adverse effects from this supplement are rare and mild, so anyone suffering from one of the listed conditions should consider discussing supplementation with a health care provider.

Preparations

Natural sources

Food products are a good source of CoQ_{10}, and provide approximately half of the body's requirement. Cold-water fish such as mackerel, salmon, sardines, and tuna are particularly high in CoQ_{10}. Vegetable oils and meats also provide good sources. The liver manufactures adequate amounts to fulfill the need not met in the diet. People who are deficient in B vitamins, **selenium**, **vitamin C**, and **vitamin E** may not be able to make as much CoQ_{10} as they need because these nutrients are required for production. Consumption of foods rich in CoQ_{10} and production of the nutrient in the liver will not provide the amounts needed to treat heart failure and other conditions that may contribute to a deficiency of this nutrient. In those cases, supplements are required.

Supplemental sources

Supplements of CoQ_{10} are widely available; however, its cost varies considerably. In 2004, it was available in the United States, ranging in price from $7.79 for a bottle of 40 30-mg capsules to $38.95 for a bottle of 60 100-mg capsules. It is found in various forms including capsules, gelcaps, liquids, and tablets. The latter may be the best choice, as this form generally includes a source of fat that improves absorption. Vitamin E is a helpful stabilizing additive as well. Most of the CoQ_{10} products currently available on the market are manufactured in Japan. Like other supplements, Co_{10} is best kept in a cool, dry place, out of direct light, and out of the reach of children.

Precautions

As of 2008, the safety of CoQ_{10} for pregnant or breast-feeding women has not been established, and its use is not recommended under these conditions. It is also not recommended for young children. People diagnosed with heart failure, diabetes, kidney problems, or liver disease should use particular care with this supplement, as the dosage of other medications may require adjustment. These individuals should consult a physician before taking coenzyme Q_{10}.

Side effects

Reported adverse effects related to supplemental CoQ_{10} use include **diarrhea**, irritation of the stomach, poor appetite, and **nausea**. These effects are rarely reported and are mild. CoQ_{10} is considered extremely safe for most people. If doses over 300 mg per day are taken, liver enzyme levels may be affected, and may need monitoring.

Interactions

It is possible that CoQ_{10} decreases the action of **sodium** warfarin (known by the brand name, Coumadin), which is prescribed to prevent the formation of **blood clots** in patients at risk of **heart attack** or **stroke**. Some oral diabetes medications may also interfere with the action of CoQ_{10}. Cholesterol-lowering drugs in the statin group may have this effect as well.

Coix

Description

Coix is a grain plant whose botanical name is *Coix lacryma-jobi*. It belongs to the Gramineae (or Poaceae) family. Coix is used in **traditional Chinese medicine**, where it is called *yi yi ren*. In English it is also known as Job's tears. Coix is also a food. In addition, the seeds are used to make jewelry and items such as rosaries and **prayer** beads.

Coix is an annual plant that grows wild to a height of about 3 ft (1 m) in sunny but moist grasslands. It is also cultivated in many parts of Asia. Coix may have originated in East Asia, but it is now found throughout East India, China, Japan, the Philippines, northern Africa, the Caribbean, Central America, northern South America, and the United States. The plant has narrow, ribbon-like leaves. The seed with the husk removed is used medicinally. In some areas, coix is cultivated as a food grain. The seeds contain about 52% starch, 18% protein, and 7% fat, giving them a higher protein-to-carbohydrate ratio than other cereal grains.

General use

Coix is used as both a healing herb and a food. It was used in folk medicine to treat conditions ranging from arthritis and **halitosis** (bad breath) to rheumatism and **worms**. The seeds, with the husks removed, are important in traditional Chinese medicine. These are said to have a cool nature and a sweet, bland taste. In traditional Chinese medicine, coix seed is used to treat internal dampness and damp-heat conditions, especially disorders of the spleen, stomach, lungs, and large intestine.

Chinese herbalists use coix to improve water flow through the body. It is used to promote urination and as a diuretic to treat **edema**. It can be used to reduce **pain** and spasms in the legs when there is also swelling of the legs. Coix is also used to treat such conditions of the gastrointestinal system as **diarrhea**, poor digestion, and abdominal bloating.

Other claims are also made for coix seed. It is said that a tea made from the boiled seeds will help to cure **warts**. Coix is thought to be beneficial for the skin, helping to nourish and soften it so that skin looks smooth and healthy.

Coix is often used in formulas that treat arthritis and rheumatism, conditions believed to be caused by excess dampness according to traditional Chinese medicine. Chinese herbalists also use it to treat appendicitis, lung disease, lung abscesses, beriberi, and **cancer**.

The seeds of coix are said to have anti-inflammatory, antiseptic, and fever-reducing properties. It is claimed that they can prevent spasms, lower blood sugar, and act as a sedative. The coix root has been used to treat menstrual disorders.

There is no doubt that coix also has value as a food grain, although the seed coat is hard to remove, making it difficult to produce flour. Coix can be cooked like barley or rice, however, and the flour can be used to make bread. Parched coix seeds are used to make tea, and a coffee substitute can be made from the roasted seeds of some Chinese subspecies.

With so many claims made for coix, scientific interest in the plant was quite high in the 2000s.

Coix (Coix lacryma-jobi). *(© blickwinkel / Alamy)*

Agricultural scientists were investigating the genetics of coix with an eye toward growing it as a food crop, and medical researchers were looking at its healing properties. Kanglaite, a compound obtained from the coix seed, had been studied in Asia as a treatment for conditions, including cancer. As of 2008, research included Phase II clinical trials studying people with non-small-cell **lung cancer**, according to the University of Texas M. D. Anderson Cancer Center.

Although coix may be proven effective in treating medical conditions, the American Cancer Society cautioned that many studies involving Chinese herbs were written in Chinese. Some journal articles about clinical trials did not include details such as how studies were conducted, information needed to compare the results with research performed in the United States.

The society's assessment paralleled the results of a February 2008 review of publications accessed through *PubMed* (http://www.ncbi.nlm.nih.gov/PubMed), an online service of the U.S. National Library of Medicine and the National Institutes of Health. A literature search for studies of kanglaite (KLT) produced five English-language abstracts (summaries) of articles originally written in Chinese or Russian.

The October 2005 issue of *Zhongguo Zhongyao Zazhi* (*China Journal of Chinese Materia Medica*) contained an article titled "Effect of Kanglaite Injection Oncyclooxygenase Activity in Lung Carcinoma A549 Cell." Few details were provided in the article, which was written in Chinese.

An article in the November 2004 issue of *Hepatobiliary and Pancreatic Diseases International* described a study involving 40 rats. Although KLT appeared to be effective in the treatment of liver tumors, researchers concluded that it was less effective than ethanol in terms of liver function, according to the article titled, "Efficacy of Intra-Tumor Injection of Kang-Lai-Te in Treating Transplanted Hepatoma in Rats."

Preparations

Coix seeds are harvested when the plant ripens in the autumn. The husks are removed and the seed is used fresh, boiled, roasted, or fermented. In traditional Chinese medicine, liquor fermented from coix seeds may be given for rheumatism. Coix is also used

in combination with other herbs in rheumatism and arthritis formulas such as ginseng and **atractylodes** formula. When coix is used for medicinal purposes, the usual daily dose is 10–30 g.

Combination treatments include a remedy for arthritis. The combination consists of 30 g of coix combined with cinnamon twig tea. The mixture is cooked with rice and consumed.

Coix may be eaten as nourishment. That makes it different from other herbs, which are given in limited doses. Puffed coix, similar to puffed wheat or puffed rice cereals, is sold in health food stores and in markets that sell Asian food.

Precautions

Traditional Chinese herbalists suggest that pregnant women not use coix.

Furthermore, the United States Food and Drug Administration does not regulate herbal remedies such as coix, which means that the remedies have not proven to be safe or effective. The safety of coix has not been established for use by children, pregnant women, and nursing mothers. In addition, ingredients are not standardized to comply with federal regulations.

As of 2008, there was limited information about research claims into the effectiveness of coix as a remedy. The lack of information raises questions such as how coix would interact with other medications and herbs. In addition, the lack of detailed information about product ingredients drew cautions from organizations, including the American Cancer Society. After the California Department of Health tested Chinese herbal remedies, the tests revealed that close to 33% contained prescription drugs or were contaminated with toxic metals such as mercury, arsenic, and lead, according to the society.

Side effects

In traditional Chinese medicine, coix has been used without any undesirable side effects. Although there were no known side effects as of 2008, there were indications that people who eat large amounts of coix as a food may become dehydrated.

Interactions

Coix has been used for thousands of years in conjunction with other herbs with no reported interactions. Since coix is used almost exclusively in Chinese medicine, there were no studies of its interactions with Western pharmaceuticals as of 2008.

KEY TERMS

Beriberi—A serious disease caused by a deficiency in vitamin B1 and characterized by a slow degeneration of the nerves of the digestive system and heart.

Diuretic—Any substance that increases the production of urine.

Edema—Water retention in the body that often causes swelling of the hands and feet.

Cola nut *see* **Kola nut**

Colchicum

Definition

Colchicum is a genus of flowering plant consisting of about sixty species, perhaps the best known of which is *Colchicum autumnale*. *C. autumnale* is also known as "naked lady," "meadow saffron," or "autumn

Colchicum (Colchicum autumnale). *(Nature's Images / Photo Researchers, Inc.)*

crocus." The first of these names derives from the fact that the plant develops beautiful pink, purple, or white flowers before leaves appear. The plant is "naked," therefore, in regard to its lack of leaves although flowers have already appeared. In 2008, Botanic Gardens Conservation International, a program dedicated to the conservation of threatened and endangered plant species, declared that the best known form of colchicum, *C. autumnale*, was at risk of extinction. The primary reason for this situation, as with other plants of medicinal value, was overharvesting by commercial operators.

Description

Colchicum is usually an annual (less commonly, perennial) plant that grows best in rich soils. It is found in western Asia, along the Mediterranean coast, in England, and throughout many parts of Europe and the United States. The plant's name derives from the region of Colchis, near present-day Georgia and Turkey. In addition to its colorful flower, the plant has somewhat broad (about an inch), longish (about a foot) dark green leaves.

The leaves, seeds, and corms of the plant contain the alkaloid colchicine, which is very toxic. It is the colchicine, taken in moderate doses, that provides the plant's medicinal value. Herbalists use the corm as the primary source of colchicine for their medical preparations.

The first mention of the use of colchicum for medical purposes appears to be a treatise by the Greek physician Pedanius Dioscorides (c. 40 A.D - c. 90 A.D) in his work *De Materia Medica*. Colchicine was first isolated from the colchicum plant by French chemists P. S. Pelletier and J. Caventon in 1820.

Medical Use

Historically, the primary use for colchicum has been in the treatment of **gout**, first mentioned by Dioscorides in the first century A.D. That application continues to be the most popular today. In addition, colchicum has been recommended for use with rheumatism, **gonorrhea**, **neuralgia**, enlarged prostate, pericarditis, dropsy (**edema**), **hepatitis**, **cirrhosis**, and inflammatory conditions. Research is currently being conducted on its possible use as an anti-cancer agent. In the United States, colchicine has been approved by the Food and Drug Administration (FDA) for use in the treatment of gout, familial Mediterranean **fever**, secondary amyloidosis, scleroderma, and Behçet's disease. Researchers have found that the basis of colchicine's action is its tendency to bind to tubulin, a chemical compound found in microtubules, basic components of cell structure. The presence of colchicine interferes with the process of mitosis (cell division), slowing down or interrupting the continued growth of cells. It is this property that makes colchicine a candidate as an anti–cancer agent since an essential characteristic of **cancer** cells is the rapid rate at which they reproduce.

Preparation

Medicinal extracts of colchicum are prepared from the plant's seeds or corm. If the later, the corm is harvested during and just following the plant's flowering. The bulb is dried whole or after first having been cut into thin slices. The dried product is then used to make an extract, tincture, or wine for medical use.

Side Effects

Colchicum has a relatively low therapeutic index. Therapeutic index is the ratio of a drug's potential benefits to its risks. Drugs with low therapeutic index must be carefully monitored since even a modest increase in the amount of drug ingested can cause serious side effects. Among the less serious side effects of colchicum are the following:

- nausea
- loss of appetite
- diarrhea
- hair loss

A number of more serious side effects may occur, requiring medical attention. These effects include:

- skin rash and/or itching
- stomach pain
- blood in the urine

KEY TERMS

Alkaloid—A nitrogen containing compound found in plants.

Corm—A small, underground bulb or stem that holds food for the development of a young plants.

Extract—A concentrated solution of a liquid made by removing water from the original solution.

Therapeutic index—The ratio of the benefits to be obtained from a drug compared to the risks of using that drug.

Tincture—An alcoholic solution of a substance, usually a naturally occurring plant material.

- muscle weakness
- numbness or tingling in the hands or feet
- fever or chills
- swelling of the mouth or face
- pain or difficulty in urinating

Interactions

As of 2008, the International Programme on Chemical Safety has reported no interactions of colchicum with other herbal medications or drugs.

Cold, common *see* **Common cold**

Cold sore

Definition

A cold sore is a fluid-filled blister that usually appears at the edge of the lips. Cold sores are caused by a herpes simplex virus infection.

Description

A cold sore is a fluid-filled, painful blister that is usually on or around the lips. Other names for cold sores are **feverblisters**, oral herpes, labial herpes, herpes labialis, and herpes febrilis. Cold sores most often occur on the lips, distinguishing them from the common canker sore that is usually located inside the mouth. Cold sores do not usually occur inside the mouth except during the initial episode. **Canker sores** usually form either on the tongue or inside the cheeks.

Cold sores are caused by a herpes virus. There are eight different kinds of human herpes viruses. Only two of these, herpes simplex, types 1 and 2, can cause cold sores. It is commonly believed that herpes simplex virus type 1 infects above the waist and herpes simplex virus type 2 infects below the waist. This is not completely true. Both herpes virus type 1 and type 2 can cause herpes lesions on the lips or genitals but recurrent cold sores are almost always type 1.

Oral herpes is very common. More than 60% of Americans have had a cold sore and almost 25% of those infected experience recurrent outbreaks. Most of these persons became infected before age 10. Anyone can become infected by herpes virus and once infected, the virus remains latent for life. Herpes viruses are spread from person to person by direct skin-to-skin contact. The highest risk for spreading the virus is the time period beginning with the appearance of blisters and ending with scab formation. However, infected persons need not have visible blisters to spread the infection to others since the virus may be present in the saliva without obvious oral lesions.

Viruses are different from bacteria. While bacteria are independent and can reproduce on their own, viruses enter human cells and force them to make

KEY TERMS

Latent—A nonactive virus in a dormant state within a cell. Herpes virus is latent in the nervous system.

Prodrome—Symptoms that warn of the beginning of disease. The herpes prodrome consists of pain, burning, tingling, or itching at a site before blisters are visible.

Recurrence—The return of an active infection following a period of latency.

more virus. The infected human cell is usually killed and releases thousands of new viruses. The cell death and resulting tissue damage causes the actual cold sores. In addition, herpes virus can infect a cell and instead of making the cell produce new viruses, it hides inside the cell and waits. Herpes virus hides in the nervous system. This is called "latency." A latent virus can wait inside the nervous system for days, months, or even years. At some future time, the virus "awakens" and causes the cell to produce thousands of new viruses which causes an active infection.

This process of latency and active infection is best understood by considering the cold sore cycle. An active infection is obvious because cold sores are present. The first infection is called the "primary" infection. This active infection is then controlled by the body's immune system and the sores heal. In between active **infections** the virus is latent. At some point in the future, latent viruses become activated and once again cause sores. These are called "recurrent" infections. Although it is unknown what triggers a latent virus to activate, several conditions seem to bring on infections. These include **stress**, illness, **fatigue**, exposure to sunlight, **menstruation**, fever, and diet.

Causes and symptoms

While anyone can be infected by herpes virus, not everyone will show symptoms. The first symptoms of herpes occur within two to 20 days after contact with an infected person. Symptoms of the primary infection are usually more severe than those of recurrent infections. The primary infection can cause symptoms like other viral infections including fatigue, **headache**, fever, and swollen lymph nodes in the neck.

Typically, 50–80% of persons with oral herpes experience a prodrome (symptoms of oncoming disease) of **pain**, burning, **itching**, or tingling at the site where blisters will form. This prodrome stage may last anywhere from a few hours, to one or two days. The herpes infection prodrome occurs in both the primary infection and recurrent infections.

In 95% of patients with cold sores, the blisters occur at the outer edge of the lips which is called the "vermilion border." Less often, blisters form on the nose, chin, or cheek. Following the prodrome, the disease process is rapid. First, small red bumps appear, which quickly form fluid-filled blisters. The painful blisters may either burst and form a scab or dry up and form a scab. Within two days of the first red bumps, all the blisters have formed scabs. The skin heals completely and without scarring within six to 10 days.

Some children have a very serious primary (first episode) herpes infection called gingivostomatitis. This causes fever, swollen lymph glands, and numerous blisters inside the mouth and on the lips and tongue, which may form large, open sores. These painful sores may last up to three weeks and can make eating and drinking difficult. Because of this, young children with gingivostomatitis are at risk for dehydration (excessive loss of water from the body).

Most people experience fewer than two recurrent outbreaks of cold sores each year. Some people never experience outbreaks while others have more frequent occurrences. In most people, the blisters form in the same area each time and are triggered by the same factors (such as stress, sun exposure, etc.).

Diagnosis

Because oral herpes is so common, it is diagnosed primarily by symptoms. It can be diagnosed and treated by the family doctor, dermatologists (doctors who specialize in skin diseases) and infectious disease specialists. Laboratory tests may be performed to look for the virus. Because healing sores do not shed much virus, a sample from an open sore is taken for viral culture. A sterile cotton swab is wiped over open sores and the sample used to infect human cells in culture. Cells that are killed by herpes virus have a certain appearance under microscopic examination. The results of this test are available within two to 10 days.

Oral herpes may resemble a bacterial infection called **impetigo**. This skin infection is most commonly seen in children and causes herpes-like blisters around the mouth and nose. Also, because oral herpes can occur inside the mouth, the blisters could be mistaken for common canker sores. Therefore, doctors need to determine whether the blisters are oral herpes, canker sores, or impetigo. The diagnosis and treatment of herpes infections should be covered by most insurance providers.

Treatment

There is no cure for cold sores but many alternative treatments can reduce outbreaks and shorten healing time. During an outbreak of cold sores, salty foods, citrus foods (oranges etc.), and other foods that irritate the sores should be avoided. Wash the sores once or twice a day with a warm, saline solution and pat gently to dry. Application of ice or a cold wet teabag for 10 minutes four or five times a day can relieve the itching and burning.

Supplements

Vitamin and mineral supplements and diet may have an effect on the recurrence and duration of cold sores. In general, cold sore sufferers should eat a healthy diet of unprocessed foods such as vegetables, fruits, and whole grains. Alcohol, **caffeine**, chocolate, nuts, and sugar should be avoided.

An imbalance in the **amino acids lysine** and **arginine** is thought to be a contributing factor in herpes virus outbreaks. A diet that is rich in the amino acid lysine may help prevent recurrences of cold sores. Foods that contain high levels of lysine include most vegetables, legumes, fish, turkey, and chicken. In one study, patients taking lysine supplements had milder symptoms during an outbreak, a shorter healing time, and had fewer outbreaks than patients who did not take lysine. Patients should take 1,000 mg of lysine three times a day during a cold sore outbreak and 500 mg daily on an ongoing basis to prevent recurrences. The effectiveness of lysine supplementation in treating herpes infections is controversial. Intake of the amino acid arginine should be reduced. Foods rich in arginine that should be avoided are chocolate, peanuts, almonds, and other nuts and seeds.

Vitamin C and **bioflavonoids** (a substance in fruits that helps the body to absorb and use vitamin C) have been shown to reduce the duration of a cold sore outbreak and reduce the number of sores. The **vitamin B complex** includes important vitamins that support the nervous system where herpes viruses are dormant. B complex vitamins also can help manage stress, an important contributing factor to the outbreak of herpes viruses. Some studies have shown that correcting **iron**, folate, vitamin C, or **vitamin B_{12}** deficiencies improves cold sores. **Vitamin E** speeds healing and reduces pain. Squeeze the oil from a vitamin E capsule onto a cotton ball and apply to the sore for 30 minutes to one hour.

Herbals

Mints are effective antivirals. **Lemon balm** or Melissa (*Melissa officinalis*) is comparable to the antiviral acyclovir in the treatment of cold sores. Apply lemon balm cream to the sore several times a day. Alternatively, prepare lemon balm tea, drink the tea and apply the dregs to the sore for one or two hours. The patient may also drink several strong cups of teas prepared from **hyssop**, oregano, **rosemary**, **thyme**, and **sage**. **Licorice** may be added to the tea.

Licorice (*Glycyrrhiza glabra*) is an antiviral and immune system stimulant. Licorice is available as a capsule or an ointment. Gradually take up to 300 mg a day. Apply ointment that contains glycyrrhetinic or glycyrrhizic acid directly to the sore as necessary. Ingestion of licorice may cause loose stools and high blood pressure.

Chinese medicine

Treatment with Qing Dai San (Natural Indigo Powder) mixed with cold boiled water and applied to the sore is generally all that is needed. For recurrent cold sores, the following oral preparations can be taken:

- Yin Huang Kou Fu Yi (Honeysuckle and Scutellaria Fluid): one ampule three times daily
- Yin Qiao Jie Du Pian (Honeysuckle and Forsythia Tablet to Resolve Toxin): two to four tablets three times daily
- Huang Lian Shang Qing Wan (Coptis Pill to Clear Heat of Upper Jiao): 5 g, two to three times daily

Other treatments for cold sores include:

- Pepto-Bismol. Rub liquid into cold sore.
- Laser therapy. Ten daily treatments with low-intensity laser significantly lowered the incidence of oral herpes outbreaks as compared to placebo.
- Mild electric current. Preliminary studies of a small device that delivers a mild electric current to the cold sore site have shown shorter duration of pain and blisters.

Allopathic treatment

There is no cure for herpes virus infections. There are antiviral drugs available which have some effect in lessening the symptoms and decreasing the length of herpes outbreaks. There is evidence that some may also prevent future outbreaks. These antiviral drugs are most effective when taken as early in the infection process as possible. For the best results, drug treatment should begin during the prodrome stage before blisters are visible.

Acyclovir (Zovirax) has been the drug of choice for herpes infection and can be given intravenously or

taken by mouth. It can be applied directly to sores as an ointment but is not very useful in this form. A liquid form for children is also available. Acyclovir is effective in treating both the primary infection and recurrent outbreaks. When taken by mouth to prevent an outbreak, acyclovir reduces the frequency of herpes outbreaks. In 2001, a report showed that use of high-dose acyclovir during primary infection will reduce the extent of latent infection. The use of penciclovir (Denavir) cream as soon as the prodrome symptoms appear speeds healing.

Over-the-counter lip products which contain the chemical phenol (such as Blistex Medicated Lip Ointment) and numbing ointments (Anbesol) help to relieve cold sores. Pharmacists also recommend the over-the-counter medicine Abreva, the only cold sore medicine approved by the U.S. Food and Drug Administration (FDA) to shorten healing time. Acetaminophen (Tylenol) or ibuprofen (Motrin, Advil) may be taken if necessary to reduce pain and fever.

Expected results

Oral herpes can be painful and embarrassing but it is not a serious infection. There is no cure for oral herpes but outbreaks usually occur less frequently after age 35. Alternative medicines can reduce the pain, prevent outbreaks, and shorten the course of cold sores. The spread of herpes virus to the eyes is very serious. Herpes virus can infect the cells in the cornea and cause scarring that may impair vision.

Prevention

The only way to prevent oral herpes is to avoid contact with infected persons. This is not an easy solution because many people are not aware that they are infected and can easily infect others. As of 2008 there were no known herpes vaccines available, although vaccines are being tested.

Several practices can reduce the occurrence of cold sores and the spread of virus to other body locations or people. These practices are:

- Avoidance of sun exposure to the face. Before getting prolonged exposure to the sun, apply sunscreen to the face and especially to the lips. Wearing a hat with a large brim is also helpful.
- Avoid touching cold sores. Squeezing, picking, or pinching blisters can allow the virus to spread to other parts of the lips or face and infect those sites.
- Wash hands frequently. Persons with oral herpes should wash their hands carefully before touching others. An infected person can spread the virus to others even when he or she has no obvious blisters.
- Avoid contact with others during active infection. Infected persons should avoid kissing or sexual contact with others until after the cold sores have healed.
- Wear gloves when applying ointment to a child's sore.
- Be especially careful with infants. Never kiss the eyes or lips of a baby who is under six months old.
- Be watchful of infected children. Do not allow infected children to share toys that may be put into the mouth. Toys that have been mouthed should be disinfected before other children play with them.
- Maintain good general health. A healthy diet, plenty of sleep, and exercise help to minimize the chance of getting a cold or the flu, which are known to bring on cold sores. Also, good general health keeps the immune system strong which helps to keep the virus in check and prevent outbreaks.
- Participate in a stress reduction program. Yoga, massage, aromatherapy, meditation, hypnosis, or biofeedback can relieve stress which may reduce outbreaks.

Coleus

Description

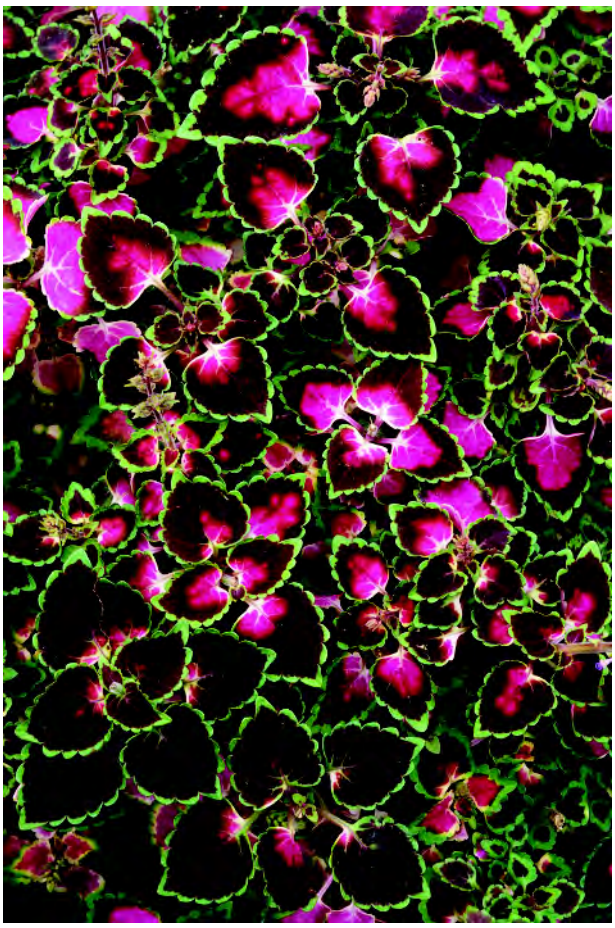
Coleus forskohlii is a perennial plant in the mint family with a strong, camphor-like odor. It is native to areas of India, Myanmar, Nepal, and Sri Lanka and grows well in warm temperate or subtropical areas. Coleus has long been used in traditional Indian (Ayurvedic) medicine, but it gained popularity when forskolin, a chemical extract of the root, demonstrated properties that make it a potential treatment for **asthma**, **bronchitis**, **glaucoma**, congestive heart failure, and other conditions. Forskolin was first identified by Western researchers in the 1970s, but as of 2008 the effects of the whole coleus plant and its extracts had not been as well studied.

Another species of coleus, *Coleus kilimandschari*, is found in parts of Africa and has been used in Rwandan folk medicine to treat **infections** and autoimmune diseases. Some studies of Rwandan coleus indicate that it is effective against a variety of disorders involving destruction of red blood cells. As of 2008, however, Rwandan coleus had not been studied as intensively as *Coleus forskohlii*, and its extracts awaited further analysis.

General use

Forskolin increases the levels of a cell-regulating compound called cyclic adenosine monophosphate (cAMP). This property allows it to stabilize mast cells that contain histamine and other inflammatory substances. Mast cells are one type of cell responsible for allergic response. Preventing the release of these compounds could make forskolin valuable in the treatment of diseases with an allergic component, such as asthma and **eczema**.

Another benefit of the increase of cAMP is forskolin's ability to relax smooth muscles. The bronchioles, uterus, arteries, gastrointestinal tract, and bladder all contain smooth muscle that is responsive to the antispasmodic effects of forskolin. As an antispasmodic, forskolin has potential, as yet unproven in humans, to treat conditions that involve cramping or smooth muscle contraction. These include asthma, painful menstrual periods, **angina**, **irritable bowel syndrome**, bladder infections, and high blood pressure.



Coleus. *(© John Glover / Alamy)*

People with asthma may benefit from the use of forskolin in its capacity as an antispasmodic. During an asthma attack, the smooth muscle within small passageways of the lungs (bronchioles) constricts and makes breathing difficult. The action of forskolin is similar to that of some standard inhalers containing such medications as albuterol, a beta agonist bronchodilator. Both substances relax the smooth muscle and improve the person's breathing ability. Studies of forskolin for the treatment of asthma have shown positive results in both oral and inhaled preparations. By 2008, several small studies had shown that coleus extract and forskolin effectively relax smooth muscle in human airways.

Other allergic conditions, including eczema, may also respond well to forskolin. Levels of cAMP are

reduced in the bronchioles and skin of people suffering from asthma and eczema. The lack of cAMP causes histamine release and subsequent allergic symptoms, including bronchoconstriction and local reaction. Forskolin may be able to prevent the onset of symptoms in susceptible people by increasing cAMP levels. It can theoretically be helpful for any condition that is caused, wholly or partially, by an allergic reaction. Professional help should be sought regarding the use forskolin for this indication, particularly because of potential interactions with other medications used for asthma.

Psoriasis can be treated by taking forskolin supplements. In this condition, skin cells multiply at a rate much greater than normal. Itchy, silvery patches are formed on the skin. This condition may be due to an imbalance of cell regulating chemicals, including cAMP, that can be normalized by forskolin.

Cardiovascular diseases, such as congestive heart failure, angina, and high blood pressure, have the potential to be treated by forskolin. As of 2008, several small studies suggest that the extract appears to relax the smooth muscles in the walls of the arteries. The **relaxation** of the arteries decreases blood pressure, **pain** due to angina, and strain on the heart. Maximum benefit may be achieved in conjunction with other botanicals or medications, such as dobutamine. Cardiovascular effects of forskolin are an active area of research.

Blood vessels in the brain are dilated by forskolin, which could have clinical applications for patients who are at risk of, or recovering from, **stroke**. Forskolin also decreases the risk of abnormal blood clotting. This is another desirable effect for stroke patients and those with other cardiovascular conditions that cause, or result from, increased susceptibility to **blood clots**. However, as of 2008, these effects had not been well studied in humans.

The high pressure inside the eye that occurs with glaucoma has been reduced with forskolin in some small studies in humans. No safety data are available about this use, nor has the effectiveness of forskolin been compared to other products that are available to reduce pressure within the eye.

A 2007 study at Duke University found that forskolin extract injected into mice was effective in treating bladder infections. As of 2008, no research had been done to determine if this benefit carries over to humans taking oral supplements of forskolin.

An infusion of the leaves of *Coleus forskohlii* has traditionally been used in Indian medicine for the treatment of **gas**, bloating, abdominal pain, and menstrual cramps. Other unproven uses include treatment on melanoma (an aggressive **skin cancer**), **AIDS**, **hypothyroidism**, **insomnia**, irritable bowel disease, **schizophrenia**, diabetes, erectile dysfunction, **depression**, **cancer** metastasis, immune dysfunction, and parasites. As of 2008, there was no accepted scientific evidence to indicate coleus/forskolin is effective in treating any of these diseases.

As of 2008, dietary supplements containing forskolin were heavily promoted as an aid to weight loss and building lean body mass. There was no scientific evidence in humans, however, that forskolin is effective in this capacity.

Preparations

Crude preparations of *Coleus forskohlii* may not contain enough forskolin to exert a clinical effect. Forskolin extracts are available. One recommended dose is 50 mg two or three times daily of a preparation containing 18% forskolin. A healthcare provider knowledgeable in the clinical use of botanicals should be consulted before undertaking treatment with this extract.

Precautions

Forskolin can be a powerful medication and has effects on many systems of the body. It has been described as a central nervous system depressant that can cause sedation. It should not be taken without a person being aware of potential effects on other parts of the body. For this reason, professional supervision is recommended.

People with low blood pressure or gastric ulcers may wish to avoid forskolin due to potential exacerbation of these conditions. Children and women who are pregnant or breastfeeding should also avoid this substance. There is some evidence that use of forskolin by pregnant women delays fetal development. Those individuals who have chronic liver or kidney disease should use great caution in taking this medication, particularly if other herbs or medications are being used due to the current lack of data about potential risks.

Side effects

Forskolin does not appear to be toxic based on studies done on animals; however, it has been reported by veterinarians to lower the blood pressure of cats and dogs. As of 2008, the most common side effect reported for coleus leaves is **contact dermatitis** (skin rash) in people who are allergic to the plant. The

KEY TERMS

Angina—Symptoms of pressure or burning in the chest that result from inadequate oxygen in the heart, generally due to coronary artery spasm or blockage.

Antispasmodic—Any substance that relieves or prevents muscle spasm, particularly in smooth muscle.

Ayurvedic medicine—A 5,000-year-old system of holistic medicine developed on the Indian subcontinent. Ayurvedic medicine is based on the idea that illness results from a personal imbalance or lack of physical, spiritual, social, or mental harmony.

Beta agonist—Class of substances that relieve bronchoconstriction, among other effects.

Bronchioles—Small tubes in the lungs leading to the alveoli, where gas exchange occurs.

Forskolin—Chemical compound extracted from coleus root that appears to be effective in treating asthma, eczema, colic, and other conditions.

Histamine—A substance released from cells that causes some of the symptoms of an allergic reaction.

overall safety and side effects of forskolin, however, had not yet received in-depth analysis as of 2008.

Interactions

Forskolin may intensify the effects of other medications taken concurrently. Caution should be used when taking any botanical or prescription medication. Forskolin should not be taken in conjunction with anti-asthmatic, anticoagulant, or antihypertensive medications without the supervision of a health care provider.

Colic

Definition

Colic is persistent, unexplained crying and discomfort in an otherwise healthy baby between the ages of two weeks and about five months.

Description

Colic affects 10-20% of all infants. It is more common in boys than in girls and most common in a family's first child. Symptoms of colic usually appear when a baby is 14-21 days old, reach a peak at the age of three months, and disappear within the next eight weeks.

Causes and symptoms

Some babies who have colic are simply fussy. Others cry so hard that their faces turn red, then pale. Episodes may occur frequently but intermittently, usually beginning with prolonged periods of crying in the late afternoon or evening. Crying may intensify, taper off, and then get even louder. It can last for just a few minutes or continue for several hours. During a colicky episode, babies' bellies often look swollen, feel hard, and make a rumbling sound. Many babies grow rigid, clench their fists, curl their toes, and draw their legs toward their body. A burp or a bowel movement can end an attack. Most babies who have colic do not seem to be in **pain** between attacks.

One cause of colic may be the swallowing of large amounts of air, especially during feeding time. Air may then become trapped in the digestive tract and cause discomfort. Other possible causes include:

- immaturity of the digestive system
- food intolerances

- too little or too much food
- lack of sleep
- loneliness
- overheated formula
- overstimulation resulting from too much noise, light, or activity
- stress and tension on the part of the mother and other caregivers
- foods the mother eats, if breast-feeding, which are allergens or irritants for the baby

Diagnosis

Colic is suspected in an infant who:

- has cried loudly for at least three hours a day at least three times a week for three weeks or longer
- is not hungry but cries for several hours between dinnertime and midnight
- demonstrates the clenched fists, rigidity, and other physical traits associated with colic

The baby's medical history and a parent's description of eating, sleeping, and crying patterns are used to confirm the diagnosis of colic. Physical examination and laboratory tests are used to rule out infection, intestinal blockage, and other conditions that can cause abdominal pain and other colic symptoms.

Treatment

Parents should consult their healthcare practitioner before giving any herbal or allopathic medications to very young children. Teas made with **chamomile** (*Matricaria recutita*), **lemon balm** (*Melissa officinalis*), **peppermint** (*Mentha piperita*), **catnip** (*Nepeta cataria*), or dill (*Anethum graveolens*) can lessen bowel inflammation and reduce **gas**. **Slippery elm** powder (*Ulmus fulva*) is soothing and healing for the digestive system. Homeopathic remedies that may be effective for colic include *Bryonia* 30c every five minutes as needed, and *Chamomilla* 6c every five minutes for up to an hour. A homeopath can be further consulted for remedies to help strengthen the child's entire constitution. In addition, it is helpful to give the Bach flower essence called **Rescue Remedy** to the infant and to the caregivers. This will help to calm both baby and caregivers.

Hands-on treatments are often helpful in treating colic. Squeezing the **acupressure** point at the webbing between the thumb and index finger of either hand can calm a crying child. Gently massaging the abdomen with a circular motion can also be soothing. Applying warm compresses over the child's abdomen can also relieve cramping.

Soothing movements may help to calm the baby. Colicky babies cry less when they are soothed by the motion of a swing, a car ride, or being carried in a parent's arms. Taking the infant for a walk may also be soothing and encourage sleep. Rocking the baby in a quiet, darkened room can reduce overstimulation as well.

Giving small, frequent feedings rather than a few large feedings will be easier on digestion for a bottle-fed baby. For those who breastfeed, food allergens can be transmitted through the milk of the mother. Therefore, foods that cause problems in the infant should be removed from the mother's diet. These are most often likely to be coffee, tea, chocolate, citrus fruit, peanuts, wheat, and vegetables belonging to the cabbage family, including broccoli.

Allopathic treatment

Medications do not cure colic. Doctors sometimes recommend simethicone (Mylicon drops) to relieve gas pain. Generally, parents are advised to take a practical approach, using home remedies. However, a doctor should be notified if a baby with colic:

- develops a rectal fever higher than 101°F (38.3°C)
- cries for more than four hours without relief
- vomits
- has diarrhea or stools that are black or bloody
- continually loses weight
- continually eats less than normal

Expected results

Colic is distressing, but it is not dangerous. Symptoms almost always disappear before a child is six months old.

Prevention

To help prevent air from being swallowed during feedings, the infant's back can be gently massaged to release trapped gas bubbles. Keeping the infant in a sitting position while feeding is also helpful. Bottle-fed babies can swallow air if the nipple holes in the bottle are either too large or too small. This can be checked by filling the bottle with formula, turning it upside down, and counting the number of drops released as the bottle is being shaken or squeezed. The hole should allow the release of formula at the rate of one drop per second. Alternatively, a different style of nipple may

improve nursing. A pharmacy should be consulted for additional guidance.

Cow's milk can often be disruptive to an infant's digestion. When cow's milk is the source of the symptoms, bottle-fed babies should be switched to a **soy protein** formula. (Regular soymilk should not be used, as it is not formulated for the nutritional needs of a nursing infant.) Goat's milk is easier to digest than cow's milk, and is also an acceptable substitute. Alternately, a tablespoon of **acidophilus** liquid or powder can be added to eight ounces of the infant's formula. A tablespoon of yogurt can also be used for this purpose. If an intolerance to cow's milk is suspected in a breastfed infant, the mother should eliminate dairy products from her diet, gradually reintroduce after seven days, and monitor the baby's symptoms. This should be done with any suspected allergen or irritating foods.

Patience Paradox

Colitis

Definition

Colitis, also called ulcerative colitis, is an **inflammatory bowel disease** closely related to Crohn's disease. In individuals with colitis, the lining of the colon (large intestine) becomes inflamed, cells lining the wall die, and ulcers form on the colon wall.

General Description

Colitis is an inflammatory bowel disease of uncertain origin. In this disease, the lining of the colon and rectum become inflamed and develop sores (ulcers) that produce pus and mucus. In mild cases, only the lining of the intestine is affected, but in severe cases, these ulcers may penetrate deeper layers of the colon or even perforate (break through) the colon wall. In ulcerative colitis, the inflamed area is continuous and develops only in the rectum and colon. This condition contrasts with Crohn's disease in which the inflamed area develops in patches and can occur in multiple places in the digestive system from the mouth to the rectum.

About 2 million Americans have ulcerative colitis, which is a lifelong disease. The disease develops most often before the individual reaches age 30, although it can develop as late as age 60. People of European ancestry and those of Jewish ethnicity are more likely to develop ulcerative colitis. There is no cure, although treatment can bring symptoms under control or cause them to go into remission (disappear) for long periods.

Causes and symptoms

The cause of colitis is unclear. As of 2008, scientists believed that persons who develop colitis carry an inherited susceptibility to developing the disease. Research has shown that people who have a parent or sibling with colitis are more likely to develop the disease, and identical twins are both highly likely to be affected. However, inheritance does not completely predict who will develop colitis. Researchers believe that when a person with an inherited susceptibility to the disease is exposed to an outside agent, an inappropriate autoimmune reaction is triggered. As a result, the immune system attacks the body's own cells lining the intestine. No single outside trigger agent has been isolated. Suspect agents are bacteria, viruses, and environmental toxins. In the past, it was thought that food **allergies** could trigger colitis. Practitioners of conventional medicine subsequently suspected that this was not the cause, although some alternative medical practitioners continued to accept the food allergy theory.

Symptoms associated with colitis include abdominal **pain** and cramps; frequent, urgent bowel movements; **diarrhea** and blood, pus, and mucus in the stool; and **fever**. Other signs of colitis occur because the disease interferes with the ability of the digestive system to absorb nutrients. These symptoms include **fatigue**, loss of appetite, weight loss, dehydration, and in severe cases, electrolyte imbalance. Because the immune system responds inappropriately, other parts of the body may be affected. The individual may develop joint pain, liver, kidney, and eye problems, and skin **rashes**. Although colitis is not caused by **stress** or food allergies, stress and certain foods tend to worsen symptoms.

Diagnosis

Symptoms of colitis mimic those of several other bowel diseases. Colitis is often diagnosed after extensive testing has ruled out other causes. After a health history and physical examination, the physician will order additional tests, including blood tests and a stool sample. The stool sample is examined for blood and parasites. Imaging tests include a barium enema and x rays of the intestine. By cleansing the intestine and filling it with barium, a white, chalky, non-toxic substance, abnormalities of the bowel are more easily seen on the x-ray film. Ultrasound and computed tomography, two non-invasive imaging techniques, may also be done. A definitive diagnosis is usually obtained by a colonoscopy, an invasive procedure that allows the physician to examine the colon lining for the entire length of the colon.

Treatment

The goal of colitis treatment is to control symptoms. As of 2008, there was no cure for the disease. Treatment is individualized and depends on the severity of the disease, but usually conventional pharmaceuticals are needed. Nevertheless, complementary treatments listed below often help relieve symptoms and improve quality of life when used with conventional treatment. Patients should discuss the use of complementary treatments with their physician before beginning any treatment.

Diet

Certain foods seem to worsen symptoms of colitis in many people. Individuals must determine their own problem foods and learn to avoid them. General suggestions for dietary changes that help many people include the following:

- Drink 8–10 glasses of water or clear fluids daily to prevent dehydration, which is especially important for people who have frequent watery bowel movements.
- Avoid high fiber foods. If symptoms are under control, some high-fiber foods may gradually be added back into the diet.
- Experiment with whether dairy products worsen symptoms; many people find that milk and cheese seem to exacerbate their symptoms.
- Avoid caffeine because it stimulates the digestive tract.
- Avoid drinking alcohol.
- Eat a low-fat diet.
- Eat smaller, more frequent meals.

Herbs

Certain herbal remedies have been shown to improve symptoms for some people. These include the following:

- Psyllium. Recommended by both alternative and conventional physicians, psyllium absorbs water and adds bulk to the stool.
- Boswellia resin (*Boswellia sacra*.) is thought to have anti-inflammatory properties. In a small study, when taken with sulfasalazine (a pharmaceutical drug), it increased the number of patients whose symptoms went into remission.
- Aloe (*Aloe vera*) juice or oral gel is thought to improve the chance of remission.
- Turmeric *Curcuma longa* is thought to have useful anti-inflammatory properties.

Supplements

Many people with moderate to severe symptoms develop vitamin and mineral deficiencies that need to be corrected with supplements and/or a multivitamin. Alternative practitioners also recommend a wide range of supplements that have shown mixed results in small trials. Some of these are:

- Probiotics. Probiotics are beneficial living organisms, usually bacteria that supplement the beneficial bacteria normally found in the intestines. Some studies have found that a non-disease producing strain of *Escherichia coli* helps some people with ulcerative colitis remain in remission. Probiotics and their effects on digestive diseases were active areas of research in 2008. Several Food and Drug Administration approved clinical trials of probiotics were being conducted in the United States for people with colitis. Information on trials enrolling participants is available at the Clinical Trials Web site (http://www.clinicaltrials.gov). There is no cost to the patients who participate.
- Fish oil. Some studies have found that fish oil supplements increased weight gain and decreased the need for anti-inflammatory drugs, while others found fish oil was ineffective in patients with ulcerative colitis.
- Folic acid (Vitamin B-9). Sulfasalazine inhibits the absorption of folic acid, so people taking this drug may need supplementation. However, taking folic acid supplements can mask a vitamin B-12 deficiency, so people taking folic acid may also need to take B-12.
- Dehydroepiandrosterone (DHEA). This natural steroid hormone is produced in small amounts by the body. Improvement was seen only with large

supplement doses with a high likelihood of undesirable side effects.

- Iron. People who have a lot of blood in their stool are at risk of becoming iron deficient.

Stress reduction

Although stress does not cause colitis, it often worsens symptoms, so stress reduction techniques should be incorporated into the daily routine.

- Exercise. Mild to moderate exercise can help stabilize bowel function and improve mood.
- Yoga helps to relax the body and relieve tension.
- Meditation calms the body and mind.
- Biofeedback training helps individuals have more control over their body and allows individuals to consciously enter a relaxed state.
- Support groups allow people to share tips and frustrations in an atmosphere of mutual understanding.

Allopathic treatment

Conventional medicine treats the symptoms of ulcerative colitis primarily with pharmaceutical drugs, although many conventional practitioners also recommend some of the complementary therapies suggested above.

Medications used to treat diarrhea symptoms include diphenoxylate (Lomotil, Lofene), and loperamide (Imodium, Kaopectate). Anticholinergic drugs, which block the communication between nerves and muscles and thus reduce contraction of the intestine, include Anaspaz, Cystospaz, and Bentyl.

Anti-inflammatory drugs are at the heart of conventional medical treatment for ulcerative colitis. Sulfasalazine is the most common anti-inflammatory drug used because patients can take it for long maintenance periods, and it can be given with other drugs. Other anti-inflammatories include Asacol and Pentasa. If these drugs do not provide adequate symptom relief, patients may be given corticosteroids such as prednisone. Corticosteroid drugs have substantial side effects and can be taken only for a short time during symptom flare-ups.

People with severe symptoms and complications beyond the digestive system may be hospitalized and given intravenous (IV) steroid drugs or drugs that suppress the immune system. Since colitis is suspected of being caused by an inappropriate immune system response, suppressing the activity of the immune system should reduce symptoms. Once a flare-up is controlled, the patient continues on a maintenance dose of some combination of diarrhea-control, anti-inflammatory, and immunosuppressant drugs.

KEY TERMS

Colonoscopy—A procedure in which the colon is cleansed and the a lighted fiber optic instrument is inserted through the anus to allow the physician to view the entire length of the colon and detect abnormalities in the colon lining, including polyps and ulcers.

Electrolyte—Ions in the body that participate in metabolic reactions. The major human electrolytes are sodium (Na+), potassium (K+), calcium (Ca 2+), magnesium (Mg2+), chloride (Cl-), phosphate (HPO4 2-), bicarbonate (HCO3-), and sulfate (SO4 2-).

Rectum—The last few inches of the large intestine that store waste until it is eliminated from the body through the anus.

Steroid—A family of compounds that share a similar chemical structure. This family includes estrogen and testosterone, vitamin D, cholesterol, and the drugs cortisone and prednisone.

Between 25% and 40% of people with ulcerative colitis develop symptoms so severe that they eventually need surgery to remove their colon. When the colon is removed, the final portion of the small intestine is connected to a hole (stoma) in the abdomen. The individual wears a bag outside the body to collect waste. The bag must be emptied at regular intervals. Alternately, if part of the rectum is left intact the small intestine may be connected directly to the rectum after the colon is removed. Waste leaves the body through the anus in the regular manner. Bowel movements are more frequent and watery, as fluid that would normally be absorbed in the colon now passes out of the body.

Expected results

Colitis cannot be cured. Most people go though periods of remission followed by periods of flare-ups when symptoms worsen. Remission can last from months to years depending on the individual.

Prevention

Ulcerative colitis cannot be prevented. About 5% of people who have ulcerative colitis later develop colon **cancer**. Regular yearly colonoscopies can detect colon cancer early when it can be easily treated.

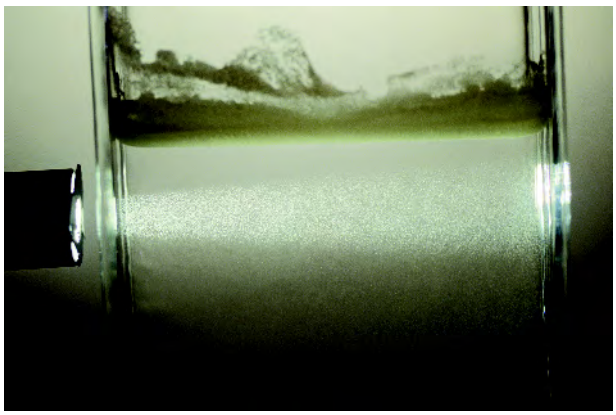
Colloidal silver

Description

A colloid is a suspension of submicroscopic particles in a medium of a different material. Colloidal silver is metallic silver suspended in water.

Some minerals are required in the diet for optimum health. These are known as essential minerals. Contrary to claims by some manufacturers of colloidal products, silver is not an essential mineral.

On the other hand, silver undoubtedly has antimicrobial properties, as do some other metals such as **copper**. Historically, coins or other items made of silver were used to help keep water from becoming contaminated and to keep milk fresh for longer periods when refrigeration was not available. This method may still be used today in some remote areas of the world. Silver is also impregnated into some water filtration systems used both for swimming pools and for drinking water.



Light shines through a colloidal solution. *(Charles D. Winters / Photo Researchers, Inc.)*

Despite the proven antibacterial, antiviral, and antifungal properties of silver in vitro, it is unclear whether it can exert the same effects when taken into the body. It is unclear what concentration of silver reaches the area where the infection is occurring before being bound, disseminated, or excreted. Another question is whether the ingested silver would have an adequate time of contact with the target organisms to produce the desired effect. Silver has a greater chance of benefiting a patient with local and topical **infections**.

Colloidal silver products are often touted as the answer to the problem of microbial resistance to antibiotics. While it is certainly true that antibiotics are overused, leading to antibiotic-resistant bacteria, substantive evidence that colloidal silver is a safe and effective replacement for antibiotics does not yet exist.

General use

Silver is already used in some compounds that are commonly used against infections. Silvadine is a frequently used agent to prevent infection in burn patients. Silver nitrate was used in the eyes of newborns for years to prevent blindness caused by contracting **gonorrhea**, a sexually transmitted disease (STD), during the passage through the birth canal. The medication was not, however, effective against **chlamydia**, another STD that causes neonatal **conjunctivitis**. Silver nitrate can also be very irritating to the tissues of the eye. Erythromycin and tetracycline are now more frequently used in the United States for neonatal prophylaxis.

The claims made for colloidal silver are innumerable. Silver has been said to be effective against hundreds of **strains** of bacteria, and to be supportive in the treatment of colds and flu, **hepatitis**, Epstein-Barr

KEY TERMS

Antimicrobial—A substance that destroys or inhibits the growth of disease-causing organisms.

Epstein-Barr—A virus in the herpes family that causes mononucleosis and other diseases.

In vitro—An artificial environment; not in a living organism.

virus, **pneumonia**, **bronchitis**, and yeast infections. It has also been recommended for topical use in the mouth, eyes, ears, nose, sinuses, and for a wide variety of skin conditions. It is difficult to determine which of the claims, if any of them, have merit because substantive research data are lacking. Most of the reported effects are based on in vitro or anecdotal evidence. Extrapolations from such testimonials would be challenging due to the variability in particle size, concentration, quality of the preparation, and total dose.

Preparations

Silver colloid is created by grinding, wave method (such as ultrasonic), liquid, chemical, or electrical modes of manufacture. Methods vary according to how large the particles of silver are that are produced, and whether they carry an electrical charge. Particles that are very small and charged repel each other enough that they tend to remain in a suspended state for a longer time rather than settling. Currently, the electrocolloidal process is the most used, and considered to be the best at creating very small, charged particles.

Colloidal silver may be purchased ready for use, but products have been found to be inconsistent in content, varying from 15–120% of the silver concentration they are labeled to contain. Commercially produced products vary greatly in particle size, potency, stability, and contents. Some contain stabilizers or trace elements in addition to silver, which are considered undesirable. Others have been found to have bacterial contaminants.

The Food and Drug Administration (FDA) at one time considered it a medication that was exempted from the standard regulations as a result of being used and marketed prior to 1938. Since that time, the exemption has been revoked. In the United States, silver is now considered a dietary supplement as opposed to an over-the-counter medication. As such, specific claims to benefit or treat medical conditions cannot be made.

As an alternative to manufactured colloidal silver products, assorted kits are available to make colloidal silver for personal use. These kits generally use an electrical current to disperse particulate silver into the carrier. Important factors for producing colloidal silver at home are the purity of the silver, the purity of the water, and proper timing to form the desired concentration. Stability of the colloid is variable, and the silver will tend to gradually settle as the charge on the particles dissipates.

Precautions

The deposition of silver under the skin can cause a condition called argyria. This condition is not common, but the skin of those who are affected is permanently stained a blue or gray color. The type of silver compound, length of treatment, concentration, and total dose required to cause argyria is a matter of some debate. There seems to be a great individual variation in susceptibility. Proponents claim that the true colloidal form of silver cannot cause the condition, but for safety purposes, all silver consumed should be considered a potential contributor to argyria. Some colloidal silver products include this warning on the label.

Extremely large doses of silver, much beyond what is recommended by proponents for therapeutic use, may cause neurologic signs or organ damage. Most of the studies of toxicity have been performed using salts of silver, such as silver nitrate, which have a higher silver concentration and greater toxicity than colloidal forms. The latter are generally in the range of 5–10 parts per million (PPM), which is equal to a 0.0005–0.001% solution.

Side effects

There are no reported side effects.

Interactions

Interaction of colloidal silver with foods, medications, or herbs are not documented.

Colonic irrigation

Definition

Colonic irrigation is also known as **hydrotherapy** of the colon, high colonic, entero-lavage, or simply colonic. It is the process of cleansing the colon by passing several gallons of water through it with the use of special equipment. It is similar to an enema but treats the whole colon, not just the lower bowel. This has the effect of flushing out impacted fecal matter, toxins, mucous, and even parasites, which often build up over the passage of time. It is a procedure that should only be undertaken by a qualified practitioner.

Practitioner massaging a patient's lower abdomen during colonic irrigation, a procedure in which the colon is flushed out with water or another liquid. *(Annabella Bluesky / Margie Finchell / Photo Researchers, Inc.)*

Origins

Cleansing the colon with the use of hydrotherapy is not a new concept. Forms of colonic irrigation have been used successfully for decades to relieve chronic toxicity and even acute cases of toxemia.

Benefits

Anyone suffering from **gas**, bloating, cramping pains, **acne** and other skin complaints, arthritis, and a list of bowel complaints such as **diverticulitis** and irritable bowel etc., may benefit from colonic irrigation. In particular, **cancer** patients are often advised to undertake a course of colonic irrigation sessions as an essential part of their treatment. When a biological cancer therapy begins to enable the body to breakdown a cancerous mass, it is essential that speedy and effective elimination of the resulting toxins is achieved.

Colon and bowel cancer remain among the leading causes of death in the United States, and alternative practitioners suggest that it can be prevented by efficient hygiene procedures. Providing that care is taken to replace the natural organisms that flourish in the bowel, many health benefits can be expected from colonic irrigation. In general, alternative practitioners maintain that an ill-functioning bowel is the source of all disease, and therefore keeping it clean will be an effective protection against disease.

Removing large amounts of toxic matter relieves the patient and can lead to the alleviation of symptoms such as arthritis, **chronic fatigue syndrome**, candidiasis, and a host of other illnesses. Properly executed, colonic irrigation can help restore normal peristaltic action to a sluggish bowel, thus reducing the need for more hydrotherapy treatments over time. In addition, removing the layer of fecal matter which coats the intestines in many individuals allows improved assimilation of the nutrients from foods and can alleviate symptoms of vitamin and other nutrient deficiencies. Many alternative health practitioners consider some form of hydrotherapy for the bowel to be essential in the treatment of degenerative diseases.

KEY TERMS

Dysbiosis—The condition that results when the natural flora of the gut are thrown out of balance, such as when antibiotics are taken.

Peristalsis—The natural wave-like action of a healthy bowel that transports matter from one end of the bowel to the other.

Probiotics—Supplements of beneficial microorganisms that normally colonize the gut.

Toxemia—Poisoning of the blood.

Description

Over time, many people develop a thick layer of fecal matter that coats their colon. It hardens and becomes impacted, reducing the efficiency of the bowel, and in some cases completely obstructs normal elimination of waste matter from the body. It is quite common for people to only have one bowel movement per day, some as few as one or two per week.

Alternative practitioners advise that we probably should have one bowel movement for every meal that we eat. If not, then we are not eliminating wastes completely, and if input exceeds output, then we will surely suffer the consequences at some point.

Incomplete elimination of body wastes may result in the following, depending on where the deposits end up:

- sluggish system
- joint pain and arthritis
- irritable bowel syndrome
- diverticulitis
- Crohn's disease
- leaky gut syndrome
- heart problem
- migraine
- allergies
- bad breath
- acne and other skin problems such as psoriasis
- asthma
- early senility and Alzheimer's disease
- chronic fatigue syndrome
- cancer, particularly of the bowel
- multiple sclerosis

During colonic irrigation, a small speculum is passed into the patient's bowel through the rectum. This is attached to a tube, which leads to a machine that pumps temperature-controlled water into the colon at a controlled rate (to be controlled by either the practitioner or the patient). The temperature of the water should ideally be kept as close to body temperature as possible.

The patient will temporarily be filled with water up to the level of the entire colon. Patients say they can feel the water up under their ribs but that the process, although sometimes uncomfortable, is not painful. The amount of water will vary but will generally be in the region of between two and six liters (or quarts) at any one time. This triggers peristaltic action and the patient will begin to expel the water along with fecal matter back through the tube and into the machine.

The fecal matter is flushed out through a viewing tube, so that what is eliminated may be monitored. Quite often, unsuspected parasites are expelled, along with very old fecal material, very dark in color, which may have been in the colon for years. Some therapists comment that it looks like **aging** rubber.

During the treatment, the therapist will gently massage the patient's abdomen to help dislodge impacted fecal matter. In addition to massage, sometimes **acupressure**, **reflexology**, or **lymphatic drainage** techniques may be used to loosen deposits and stimulate the bowel. It is important that the right amount of water is used, as too much will cause discomfort and too little will be ineffective. If correctly done, colonic irrigation is not painful at all and some patients claim to sleep through their treatment.

Sanitation is vital to this process. The tubes and speculums used are generally disposable, but other parts of the machine, such as the viewing tube, must be sterilized after each patient.

Normally, a series of treatments will be required to achieve desired results regarding the elimination of impacted, decaying matter, and restoration of bowel regularity. Initially only gas and recent fecal matter may be expelled. The residue attached to the colon wall is usually the result of years of neglect, and therapists say that one cannot expect complete relief in only one session.

Impacted fecal matter can cause an imbalance of the natural organisms that normally populate the bowel, causing what is known as dysbiosis. Under ideal conditions, the bowel is populated by a variety of naturally occurring organisms. It seems that the enzymes occurring in fresh fruit and vegetables encourage these beneficial organisms. One of the results of eating processed denatured foods is that this natural

balance is upset, and food may begin to rot in the bowel instead of being processed.

Decomposing matter can cause a toxic condition and may lead to many health problems, as **constipation** causes backed up pollution of the body cells. The process of repair and elimination of wastes enters a downward spiral which at best will cause **fatigue**, lack of energy and premature aging, and at worst can cause degenerative diseases, among them **allergies**, and even cancer and **Alzheimer's disease**.

The cost of colonic irrigation treatments varies, but is generally between $35-70 per session, which may last from 45 minutes to one hour. The cost of the machine itself ranges from $4,000-12,000, but again, it should be noted that only qualified therapists should conduct sessions.

Preparations

Most practitioners prefer that distilled or purified water is used for colonic irrigation, but others use sterilized tap water.

Precautions

It may be advisable to use a probiotic pessary after colonic irrigation, to ensure replacement of desirable natural flora. There are certain conditions that either partly or completely preclude the use of colonic irrigation, such as an active attack of **Crohn's disease**, bleeding ulcers, and hyperacidosis. If in doubt, a qualified practitioner should be consulted. Anyone suffering from these conditions should always notify the practitioner when receiving colonic irrigation treatments.

Side effects

Some allopathic practitioners claim that colonic irrigation flushes out essential electrolytes and friendly bacteria from the bowel and that it can be dangerous. Practitioners counter that this can easily be remedied with the use of **probiotics**, and that in any case, these possible disadvantages are easily offset by the benefits of having large amounts of putrefying matter, harmful organisms, and parasites removed from the system.

Research and general acceptance

Although many alternative health care practitioners swear by colonic irrigation, there is a large allopathic lobby that claims that there are no benefits to be had, and that there are dangers involved. However, there are many decades of records and research from the alternative health care community that indicate that this therapy may have a valuable place in the treatment of degenerative diseases and toxic conditions.

Training and certification

Trained technicians should conduct colonic irrigation sessions.

Color therapy

Definition

Color therapy, also known as chromatherapy, is based on the premise that certain colors are infused with healing energies. The therapy uses the seven colors of the rainbow to promote balance and healing in the mind and body.

Origins

Color therapy is rooted in Ayurveda, an ancient form of medicine practiced in India for thousands of years. Ayurveda is based on the idea that every individual contains the five basic elements of the universe: earth, water, air, fire, and ether (space). These elements are present in specific proportions unique to an individual's personality and constitution. When these elements are thrown out of balance through unhealthy living habits or outside forces, illness results. **Ayurvedic medicine** uses the energies inherent in the colors of the spectrum to restore this balance.

Color therapy was also used in ancient Egypt and China. In **traditional Chinese medicine** (TCM), each organ is associated with a color. In **qigong**, healing sounds are also associated with a color, which in turn corresponds to a specific organ and emotion.

KEY TERMS

Aromatherapy—The therapeutic use of plant-derived, aromatic essential oils to promote physical and psychological well-being.

Hydrotherapy—Water therapy; the use of water (hot, cold, steam, or ice) to relieve discomfort and promote physical well-being.

Yoga—An Indian philosophical and health movement that strives to achieve balance through relaxation, meditation, breathing exercises, and body movements.

Benefits

Each of the seven colors of the spectrum are associated with specific healing properties.

Violet

Violet promotes enlightenment, revelation, and spiritual awakening. Holistic healthcare providers use violet to soothe organs, relax muscles, and calm the nervous system.

Indigo

Indigo is also sedative and calming. It is said to promote intuition. Indigo may be useful in controlling bleeding and abscesses.

Blue

Blue promotes communication and knowledge. It eliminates toxins, and is used to treat liver disorders and **jaundice**.

Green

Because it is located in the middle of the color spectrum, green is associated with balance. Green is calming, and is used by Ayurvedic practitioners to promote healing of ulcers. It is said to have antiseptic, germicide, and antibacterial properties and is sometimes used by holistic color therapists to treat bacterial **infections**.

Yellow

Yellow is a sensory stimulant associated with wisdom and clarity. Yellow is thought to have decongestant and antibacterial properties, and is useful in stimulating both the digestive system and the lymphatic system.

Orange

Orange promotes pleasure, enthusiasm, and sexual stimulation. Ayurvedic practitioners believe it has antibacterial properties and may be useful in easing digestive system discomforts (e.g., flatulence, cramps).

Red

Red promotes energy, empowerment, and stimulation. Physically, it is thought to improve circulation and stimulate red blood cell production.

Description

The color spectrum is composed of different frequencies and wavelengths of light energy. Ayurvedic medicine uses the energy of colors to promote harmony and healing. The colors are said to be imbued with certain healing properties (i.e., red is energizing, blue is calming) and the vibrations generated by each color balance the individual.

Holistic healthcare providers who practice color therapy often relate the seven colors of the color spectrum to specific areas of the body known as the *chakras*. In **yoga**, the chakras are specific spiritual energy centers of the body. The therapeutic action of colors is related to the chakra they represent:

- first (root; or base of spine): red
- second (sacral; or pelvis/groin area): orange
- third (solar plexus) chakra: yellow
- fourth (heart) chakra: green
- fifth (throat) chakra: blue
- sixth (brow) chakra: indigo
- seventh (crown) chakra: violet

Therapeutic color can be administered in a number of ways. Practitioners of Ayurvedic medicine wrap their patients in colored cloth chosen for its therapeutic hue. Patients suffering from **depression** may be wrapped in reds and oranges chosen for their uplifting and energizing properties. Patients may also be bathed in light from a color-filtered light source to enhance the healing effects of the treatment.

Another method of color therapy treatment recommended in Ayurvedic medicine is to treat water with color and then drink the water for its purported healing properties. This is achieved by placing translucent colored paper or colored plastic wrap over and around a glass of water and placing the glass in direct sunlight so the water can soak up the healing properties and vibrations of the color.

Color may also be used environmentally to achieve certain calming or healing effects. Paint, wall

and window treatments, furniture, and decorative accessories may all be selected in specific color families. Clothing may be chosen in specific colors for its healing properties.

Color therapy can be used in conjunction with both **hydrotherapy** and **aromatherapy** to heighten the therapeutic effect. Spas and holistic healthcare providers may recommend color baths or soaks, which combine the benefits of a warm or hot water soak with healing **essential oils** and the bright hues used in color therapy.

Because color is composed of different light frequencies, certain types of music and **sound therapy** are sometimes used as a companion to the treatment by holistic healthcare providers. One such method, known as the 49th Vibrational Technique, uses a mathematical formula to translate the inaudible vibrations produced in the color spectrum to their audible counterparts. Red is associated with the musical note G, orange is A, yellow is A#, green is C, blue is D, indigo is D#, and violet is E. By combining both visual colors and their audible frequency counterparts, the therapeutic value of the color frequency is thought to be enhanced.

Preparations

Before administering any treatment, practitioners of Ayurvedic medicine will perform a thorough examination of and interview with the patient to determine his *prakriti*, or constitution. In Ayurveda, an individual's prakriti is determined at conception and remains unchanged during his or her lifetime. Treatment colors will be chosen based on the prakriti and the individual's specific imbalance of *doshas*, or energies. There are three doshas—vata, pitta, and kapha—that correspond to a person's temperament and body type. Most are a combination of the three (tridosha) with one predominating.

In some cases, holistic providers may take a photographic image of the patient's aura, or individual energy field, using a special camera that reads electrical impulses from the patient's hands. The camera produces an image of the patient with bands of color(s) around the body. The colors are then analyzed to determine the patient's unique aura energy pattern, and to decide what type of color therapy would be complementary to that aura.

Precautions

While color therapy may be an effective treatment for promoting **relaxation** and overall well-being, and as an adjunct, or complementary therapy in treating some disorders and illnesses, individuals with serious chronic or acute health problems should not rely solely on the therapy for treatment. Anyone with a chronic or acute health concern should seek the advice of a qualified medical practitioner.

Side effects

There are no known side effects to common practices of color therapy.

Research and general acceptance

Ayurvedic medicine has been a firmly entrenched practice of medicine in India for thousands of years. However, it is largely regarded as a complementary practice in the United States, although its popularity has grown in recent years as Ayurvedic spas and medical practices have grown in number. The benefits of color therapy have not been researched extensively and it is still considered a fringe therapy by the allopathic medical community.

Training and certification

Individuals practicing as color therapists and/or practitioners of Ayurvedic medicine do not require special certification or licensing.

Colorectal cancer

Definition

Colorectal **cancer** is a malignancy of the colon (bowel) and/or rectum. Excluding skin cancers, colorectal cancer is the third most common cancer diagnosed in men and in women in the United States. The American Cancer Society reported that about 112,000 new cases of colon cancer (55,000 men and 57,000 women) and 41,500 new cases of rectal cancer

(24,000 men and 17,500 women) were diagnosed in 2007. Colorectal cancer is the second leading cause of cancer-related deaths in the United States and is expected to have caused about 52,000 deaths (26,000 men and 26,000 women) in 2008.

Description

Colorectal cancer occurs in either the last 6 ft (1.8 m) of intestine, known as the large bowel or colon, and/or in the rectum, where the colon terminates and waste (feces) leaves the body. The majority of malignancies that occur in colorectal cancers are called *adenocarcinomas*. When an individual develops colorectal adenocarcinomas, malignant cancer cells grow inside the colon and/or the rectum. Large clusters of these cells form structures known as tumors.

Causes and symptoms

Causes and risk factors

The exact cause of colorectal cancer is unknown. However, there are a number of known risk factors that increase the odds for developing the disease. They include:

- Family history. Individuals who have one or more close relatives who were diagnosed with colorectal cancer may be at increased risk for the disease. In 2003, research showed that about 5% of colorectal cancer patients had inherited syndromes.
- History of bowel disease and/or colon polyps. Certain types of colon polyps, which are tumor-like, benign outgrowths of tissue within the colon, may act as an early warning sign of or a precursor to colorectal cancer. They may develop into malignancies later in life. Colon diseases that cause inflammation and irritation of the bowel, such as Crohn's disease and inflammatory bowel disease, also can increase an individual's risk of developing a colorectal malignancy.
- Obesity. Overweight individuals, especially those with an apple-shaped body type (where fat is concentrated around the waist) as opposed to a pear-shaped body (where fat is stored in the hips and thighs), are at an increased risk for colorectal cancer. A high fat diet also increases an individual's chance of developing colorectal cancer.
- Age. Individuals over age 50 are at an increased risk for colorectal cancer.
- Sedentary lifestyle. A moderate exercise program is thought to have a preventive effect against cancer.
- Night work. A 2003 study showed that working the night shift actually may increase risk of colorectal cancer in women. Exposure to light at night suppresses the body's natural production of melatonin, a hormone that helps keep certain intestinal cancers from proliferating.

Symptoms

Symptoms of colorectal cancer include:

- blood on the rectum or in the stool
- feelings of fecal urgency (feeling as if one has to have a bowel movement all the time)
- stomach and/or abdominal pain
- changes in bowel habits, including constipation, diarrhea, and/or pencil-thin stools
- extreme fatigue
- decreased appetite

Diagnosis

Early diagnosis is critical in successfully treating colorectal cancer. The simplest screening tests for colorectal cancer are a digital rectal exam and a fecal occult blood test (FOBT). In the digital rectal exam, a physician inserts a gloved finger into the rectum and feels for any irregularities. In the FOBT, stool samples are tested for traces of blood. The test can be done at home and sent to a lab for analysis. FOBT can reduce the death rate by about 33%. Unfortunately, in the United States, less than 35% of the population has received a FOBT.

A flexible sigmoidoscopy and/or a colonoscopy may be performed to view the interior of the colon. The former examines the rectum and lower colon for cancer, and the latter examines the full length of the colon. During these procedures, a doctor passes a flexible tube with a tiny, fiber-optic camera device (an endoscope) through the rectum and into the colon. The doctor can carefully examine the lining of the intestine for signs of cancer. Also, if a polyp is found during the examination, it is removed, usually by severing it with a sharp wire loop attached to the device. Since all polyps are removed, it prevents nonmalignant ones from developing into cancer. A tissue sample (a biopsy) of the colon is usually taken through the endoscope to examine under a microscope for evidence of malignancy. Both tests can cause discomfort and may be done under a local anesthetic if desired.

A lower GI (gastrointestinal) x-ray series can be helpful in determining how much of the intestine is involved in the disease. A chalky solution called barium, which acts as a contrast agent to illuminate the gastrointestinal tract on x-ray film, is administered

in enema form to the patient. In some cases, air also is pumped into the rectum to provide a clearer view of the large intestine. This is called a double-contrast barium enema. The pressure in the patient's abdomen from the air and barium contrast likely will cause some discomfort.

As of 2007, researchers were developing alternative screening methods that caused less or no discomfort compared to an endoscope. An x-ray technique using computed tomographic scanning (a CT scan) called virtual colonoscopy was in limited use as of 2007. Other methods being developed would use feces or blood samples to screen for cancer.

Several reasons are given for the low percentage of people over the age of 50 who get screened for colorectal cancer. One is that the procedure is uncomfortable and time-consuming. Another disincentive is the laxative preparation usually required prior to a colonoscopy. It is hoped that newer, less invasive detection techniques will increase the percentage of people who get tested.

For most people, a colonoscopy or sigmoidoscopy is recommended starting at age 50 and then repeated every 10 years for a colonoscopy and every five years for a sigmoidoscopy. Colonoscopies were first used in 1969.

After colorectal cancer is diagnosed, further testing is required to determine how far the cancer has spread. This procedure is known as staging. There are five different stages of colorectal cancer:

- Stage 0 (carcinoma in situ). The earliest stage of colorectal cancer indicates that cancerous cells have not spread beyond the colon lining.
- Stage I. The cancer has spread to the second and third layers of the inside wall of the colon but is still contained within the colon.
- Stage II. The cancer has spread beyond the colon but has not spread to the lymph nodes.
- Stage III. The cancer has spread to a nearby lymph node but has not spread throughout the body.
- Stage IV. The cancer has spread throughout the body.

There is a sixth subtype of cancer, called recurrent, which is used to classify colorectal cancer that was treated, seemed to resolve, and later recurs either in the colon or in another part of the body.

Treatment

The best chance for successful treatment is to detect colorectal cancer early. Colorectal cancer is a life-threatening disease, and a correct diagnosis and appropriate treatment with surgery, chemotherapy, and/or radiation is critical to controlling the illness.

Acupuncture and **guided imagery** may be useful tools in treating **pain** symptoms and improving immune function associated with colorectal cancer. Acupuncture involves the placement of a series of thin needles into the skin at targeted locations on the body, known as acupoints, in order to harmonize the energy flow within the human body.

Guided imagery involves creating a visual mental image of pain as a means of **relaxation**. Once the pain can be visualized, patients can adjust the image to make it more pleasing, and thus more manageable to them.

Movement therapies, such as **yoga**, t'ai chi, and **qigong** can aid recovering patients. These therapies may lessen pain symptoms and help individuals to relax and reduce **stress**.

A number of herbal remedies also are available to lessen pain symptoms and promote relaxation and healing. However, cancer patients should consult with their healthcare professional before taking them. Depending on the preparation and the type of herb, these remedies may interact with or enhance the effects of other prescribed medications. Herbs that promote healing of the digestive tract include **slippery elm** bark (*Ulmus rubra*), **marsh mallow** root (*Althaea officinalis*), and **goldenseal** (*Hydrastis canadensis*).

An analysis of five previous studies of nearly 1,500 participants reported that getting the recommended daily dosage of **vitamin D** can greatly reduce the risk of getting colorectal cancer. The study projected a two-thirds reduction in the risk of getting colorectal cancer for people who took 2,000 IU of vitamin D daily. As of 2007, the U.S. Food and Drug Administration (FDA) recommended that adults ages 50–70 should have a daily intake of 400 IU of vitamin D. The maximum safe daily intake set by the FDA of vitamin D is 2,000 IU.

Allopathic treatment

Treatment options include surgery, chemotherapy, and radiation. Colorectal cancer is treated in two ways, locally to eliminate tumor cells from the colon by surgery and radiation, and to systemically destroy cancer cells that have traveled to other parts of the body. Systemic therapy includes the use of chemotherapy drugs.

Surgery

The extent of surgery depends on the type of colorectal cancer, whether the disease has spread,

and the patient's age and health. A surgical procedure known as a bowel resection is performed for colon cancers, where the length of colon containing the cancerous cells is removed, along with nearby tissues and lymph nodes. The two ends of the remaining colon are then sewn back together.

For cancer affecting the rectum, several other surgical methods may be employed, including local excision of the cancer (where cancerous cells and nearby tissues are cut out of the rectum) and transanal resection, where invasive cancerous tissue is removed along with normal anal tissue.

Depending on the stage of the cancer and the degree of surgery required, some patients may need to have a colostomy. A colostomy involves surgically attaching the bowel to an opening in the abdominal wall where waste is eliminated into an attached bag.

The presence of cancer cells in the lymph nodes may require more extensive surgery. If the cancer has spread to the nodes, the patient will need either radiation, chemotherapy, hormone therapy, or a combination of all three after surgery. This is called "adjuvant therapy."

Radiation

Once the cancer has been removed, the doctor may recommend radiation treatment to destroy any remaining cancer cells. In cases where the cancer is located in hard to reach areas, radiation may be used to shrink the cancer growth or tumor. Radiation stops the cancer cells from dividing. It works especially well on fast-growing tumors. Unfortunately, it also stops some types of healthy cells from dividing. Healthy cells that divide quickly, like those of the skin and hair, are affected the most. For this reason, radiation can cause **fatigue**, skin problems, and **hair loss**.

Radiation therapy can be internal, where particles of radioactive materials are implanted into a tumor, or external, where energy rays (radiation) are directed at the cancer from outside the body. External radiation, the most common type of treatment for colorectal cancer, is usually administered five days a week for several weeks. Some studies indicate that radiation therapy decreases the likelihood of local recurrence of colorectal cancer by a significant margin. Some clinicians argue that the therapy is most effective when given before surgery rather than after. No definitive clinical trials proved the most effective timing as of late 2001.

Chemotherapy

Colorectal cancer surgery may be followed by chemotherapy in even the earliest stages. Chemotherapy is administered either orally or by injection into a blood vessel. It is usually given in cycles, followed by a period of time for recovery, followed by another course of drugs. Treatment time may range between four and nine months. In the fall of 2001, the Food and Drug Administration (FDA) approved trials for a new vaccine to help treat colorectal cancer. Investigators planned to give the vaccine in conjunction with chemotherapy to help prevent recurrence of the disease. In 2003, the FDA approved a new chemotherapy drug called Avastin to help fight metastatic spread of colorectal cancer.

Some types of chemotherapy produce significant side effects, including **nausea** and **vomiting**, temporary hair loss, mouth sores, skin **rashes**, fatigue, a weakened immune system, and **infertility**. However, most side effects are temporary and disappear once treatment has ended.

Expected results

The death rate for the disease has declined steadily over the last several decades of the 20th century, and since 1985, annual deaths due to colorectal cancer have declined at an average rate of 1.6% per year. Early detection is key to improved survival; patients with colorectal cancers detected early (at stage I) have a 96% survival rate. In comparison, patients who are diagnosed with stage IV colorectal cancer only have a 5% survival rate.

Prevention

Proper diet and **exercise** have been shown to help prevent many types of cancers, including colorectal cancer. Research published in 2003 confirmed the benefits of physical activity in reducing risk of colon and rectal cancers. A well-balanced diet consisting of a minimum of five servings of fruits and vegetables and six servings of food from other plant sources (i.e., cereals, grains, pastas) is recommended by the American Cancer Society. Additionally, patients may opt for a diet of whole foods. A number of fruits and vegetables have been shown to have antioxidant properties and may be useful in preventing cancer. These include **carotenoids**, which are found in fruit pigments; flavenoids found in vegetable pigments; and particularly **lycopene**, which is found in tomato juice.

Some clinical studies also have indicated that regular use of **green tea** (produced from the *Camellia sinensis* plant) may reduce the risk of certain types of cancer, including colorectal cancers. Green tea contains polyphenols, an antioxidant substance that also may inhibit the growth of existing cancer cells. In some

KEY TERMS

Adjuvant therapy—Treatment involving radiation, chemotherapy (drug treatment), hormone therapy, or a combination of all three.

Antioxidants—Enzymes that bind with free radicals to neutralize their harmful effects.

Free radicals—Reactive molecules created during cell metabolism that can cause tissue and cell damage like that which occurs in aging and with disease processes such as cancer.

Lymph nodes—Small, bean-shaped masses of tissue scattered along the lymphatic system that act as filters, removing fluids, bacteria, or cancer cells that travel through the lymph system. Cancer cells in the lymph nodes are a sign that the cancer has spread.

Malignant—Cancerous.

Polyp—A benign, tumor-like outgrowth.

animal studies, injections of tea extracts reduced the size of cancerous tumors. The antioxidant effects of green tea need to be studied further to more clearly define the role of the herb in cancer treatment and prevention.

Because early detection is so critical to recovery from colorectal cancer, patients considered at risk for the disease due to genetic, lifestyle, or environmental factors should undergo regular screening after age 50 (and possibly before, depending on the individual's personal and medical history). The American Cancer Society recommends the following screening tests:

- an annual FOBT plus a flexible sigmoidoscopy every five years; or
- a colonoscopy every 10 years; or
- a double contrast barium enema every five to 10 years.

A digital rectal exam also is recommended during each screening session.

Colostrum

Description

Colostrum is a thick yellow fluid, rich in protein, growth factors, and immune factors. It is secreted by the mammary glands of all female mammals during the first few days of lactation. It also contains essential nutrients and protease inhibitors that keep it from

being destroyed by the processes of digestion. Humans produce relatively small amounts of colostrum in the first two days after giving birth, but cows produce about 9 gallons (36 L) of colostrum. Bovine colostrum can be transferred to all other mammals, and is four times richer in immune factors than human colostrum.

Although colostrum has received widespread attention as a dietary supplement only since the late 1990s, it has a lengthy history of medicinal use. Ayurvedic physicians in India have used colostrum as a treatment for thousands of years. In the United States, mainstream medical practitioners recommended colostrum as a natural antibiotic before the discovery of penilcillin and sulfa drugs. In the 1950s, colostrum was used to treat **rheumatoid arthritis** (RA). Dr. Albert Sabin, the researcher who developed the first oral vaccine for poliomyelitis, found that colostrum contains antibodies against polio. He recommended colostrum as a dietary supplement for children who were vulnerable to polio.

The major components of colostrum include the following substances:

- Immunoglobulins. Immunoglobulins are globulin proteins that function as antibodies. They are the most plentiful immune factors found in colostrum. Immunoglobulin G (IgG) counteracts bacteria and toxins in the blood and lymphatic system; immunoglobulin M (IgM) seeks out and attaches itself to viruses in the circulatory system; immunoglobulins D and E (IgD and IdE) remove foreign substances from the bloodstream and activate allergic reactions. High-quality colostrum is certified to contain a minimum of 16% immunoglobulins.
- Lactoferrin. Lactoferrin is a protein that transports iron to red blood cells and helps to deprive viruses and harmful bacteria of iron.
- Proline-rich polypeptide (PRP). PRP is a hormone that regulates the thymus gland, helping to calm a hyperactive immune system or stimulate an underactive immune system.
- Growth factors. The growth factors in bovine colostrum include insulin-like growth factors (IgF-1 and IgF-2), an epithelial growth factor (EgF), transforming growth factors (TgF-A and TgF-B), and a platelet-derived growth factor (PDGF). Growth factors stimulate normal growth as well as the healing and repair of aged or injured skin, muscle, and other tissues. In addition, growth factors help the body to burn fat instead of muscle for fuel when a person is dieting or fasting.
- Growth hormone. Growth hormone slows some of the signs of aging.
- Leukocytes. Leukocytes are white cells that stimulate production of interferon, a protein that inhibits viruses from reproducing.
- Enzymes. Colostrum contains three enzymes that oxidize bacteria.
- Cytokines and lymphokines. These are substances that regulate the body's immune response, stimulate the production of immunoglobulins, and affect cell growth and repair.
- Vitamins. Colostrum contains small amounts of vitamins A, B_{12}, and E.
- Glycoproteins. Glycoproteins, or protease inhibitors, are complex proteins that protect immune factors and growth factors from being broken down by the acids in the digestive tract.
- Sulfur. Sulfur is a mineral that is an important building block of proteins.

General use

Colostrum is presently used to treat a variety of diseases and disorders. Applications that have been investigated in clinical trials include the following:

Bacterial and viral infections

A number of recent clinical studies have shown that colostrum is effective in reversing the inflammation of the digestive tract in HIV/AIDS patients caused by opportunistic **infections**. The antiviral, antifungal, and antibacterial properties of colostrum enable it to kill such pathogens as *E. coli*, *Candida albicans*, rotaviruses, and *Cryptosporidium*.

In 1980, a British researcher showed that a large proportion of the antibodies and immunoglobulins in colostrum are not absorbed by the body but remain in the digestive tract. There they attack food- and water-borne organisms that cause disease. More recent clinical studies have demonstrated that colostrum is effective in preventing intestinal infections by first keeping the bacteria from attaching themselves to the intestinal wall, and second by killing the bacteria themselves. Colostrum has proved to be capable of killing *Campylobacter*, *Helicobacter pylori*, *Listeria*, *Salmonella*, *Shigellosis*, and five types of streptococci.

Allergies and autoimmune diseases

The PRP in colostrum has been demonstrated to reduce or eliminate the **pain**, swelling, and inflammation associated with **allergies** and autoimmune diseases (**multiple sclerosis**, rheumatoid arthritis, lupus, myasthenia gravis). These effects are related to PRP's

KEY TERMS

Cytokines—Substances of low molecular weight that affect cell growth and repair, tissue inflammation, and immunity to diseases.

Glycoproteins—Complex proteins that protect immune factors and growth factors from being broken down by stomach acids. Glycoproteins are also called protease inhibitors.

Immunoglobulins—A group of globulin proteins that function as antibodies.

Lactoferrin—A protein found in colostrum that carries iron to red blood cells and appears to have anti-cancer activity.

Lymphocyte—A type of white blood cell that is important in the production of antibodies.

Opportunistic infection—A type of infection caused only under certain circumstances, as when a person's immune system is impaired.

Proline-rich polypeptide (PRP)—A hormone found in colostrum that regulates the thymus gland and the immune system. It helps to make colostrum an effective treatment for autoimmune disorders and possibly heart disease. Proline is an amino acid.

T cell—A type of lymphocyte that develops in the thymus gland, circulates in the blood and lymph, and regulates the body's immune response to infected or malignant cells.

ability to inhibit the overproduction of lymphocytes (white blood cells) and T-cells.

Heart disease

Recent research suggests that cardiovascular disease may be caused in part by alterations in the patient's immune system. One study indicated that 79% of patients with heart diseases had a certain type of *Chlamydia* (an intracellular parasite closely related to certain bacteria) associated with the formation of plaque in their arteries. The PRP in colostrum may be able to reverse **heart disease** in the same way it counteracts allergies and autoimmune diseases. In addition, the growth factors and growth hormone in colostrum appear to lower the blood levels of "bad" **cholesterol** while raising the blood levels of "good" cholesterol. These growth factors also repair damage to heart muscle and support the growth of new blood vessels in the part of the circulatory system that surrounds the heart.

Cancer

Since 1985, the cytokines contained in colostrum have been a major area of research in seeking a cure for **cancer**. Researchers have found that the lactoferrin in colostrum has some anti-cancer activity. In addition, the combination of immune factors and growth factors in colostrum appears to inhibit the growth of cancers.

Weight loss

The growth factor called IgF-1 that is contained in colostrum is needed by the body in order to metabolize fat. As humans grow older, their bodies produce less IgF-1. These lower levels of growth factor are associated with a higher rate of type 2 diabetes in older adults and with increased difficulty losing weight in spite of **exercise** and careful attention to diet. While colostrum by itself will not cause weight loss, it appears to be a useful part of a weight reduction program because of its IgF-1 content.

Sports medicine

The immune factors in colostrum appear to be helpful in protecting athletes from infections caused by the physical and emotional **stress** of competition. Using colostrum as a dietary supplement also increases the efficiency of the digestive tract for athletes in training. The intestines are able to make more nutrients available to the muscle cells and the body's vital organs. A 2002 report stated that cyclists taking 20 to 60 grams of bovine colostrums supplements per day showed significant performance improvements following a two-hour ride.

Open wounds

The growth factors in colostrum have been found to stimulate the growth of new skin and to repair tissues damaged by ulcers, injuries, **burns**, surgery, or inflammation. They are able to do this through their direct action on the cells' DNA and RNA. Powdered colostrum has been used in topical preparations for **gum disease**, sensitive teeth, mouth ulcers, **cuts**, and burns.

Other

Colostrum has been used outside clinical research to treat a variety of other conditions. Satisfied individuals have reported that colostrum has successfully treated skin disorders, **emphysema**, baldness in males, anger outbursts, **feverblisters**, **shingles**, **tendinitis**, thyroid disorders, **gout**, insect **bites**, vaginal yeast infections, and **anemia**.

Preparations

Colostrum is presently available in a variety of forms, including tablets, liquids, powders, and encapsulated powders. In general, the powdered forms are recommended as preferable to liquids or tablets, on the grounds that liquid colostrum has a short shelf life and the processing necessary to produce tablets destroys much of colostrum's biological activity. The recommended dose for adults with disease symptoms is 1,000–2,000 mg of powdered colostrum in capsules, taken twice daily with 8–12 oz of water. Preventive doses are left to the patient's choice. Children can be given colostrum but require less than adults.

In the United States, colostrum is taken from dairy cows within 24 hours after the birth of a calf. Only dairy cows that meet USDA health standards and have been raised on a feed supplemented with nutrients are used to supply colostrum. The calf needs four gallons of the nine that the cow produces. The remaining five gallons are collected by a USDA-certified dairy. The colostrum is frozen and kept at a temperature of 17°F (-8.3°C). After the frozen colostrum is taken to a processing plant, it is carefully thawed and evaluated for quality and immunoglobulin content. About 30% is rejected at this stage. The fat is then removed from the remaining colostrum, after which the colostrum is spray-dried at low heat. The colostrum is repeatedly tested during processing for freedom from bacterial contamination.

Precautions

Persons who are using colostrum as a dietary supplement in the United States should obtain it from a source licensed by the USDA.

Side effects

With the exception of allergic reactions in persons who are known to be allergic to cow's milk, colostrum does not produce any major side effects at any level of consumption. Mild flu-like symptoms that disappear with continued use of colostrum have been reported in children.

Interactions

No significant drug interactions between colostrum and standard pharmaceuticals have been reported.

Coltsfoot

Description

Coltsfoot is the plant *Tussilago farfara*, a member of the daisy family (Asteraceae). Coltsfoot is a perennial herb that grows to a height of 4-10 inches (10-25 cm). The stem is covered with white, downy fibers. Its leaves are hoof-shaped, and the flowers are yellow. The leaves, flowers, and occasionally the root are used medicinally.

Coltsfoot is a tough, invasive plant that lives in marginal soil, wasteland, roadsides, and sand dunes. In some areas coltsfoot is considered an undesirable weed. Although native to Europe, coltsfoot grows wild in North America and the temperate parts of China. Other names for coltsfoot are **cough** wort, horsefoot, horsehoof, bull's foot, ass's foot, foal's foot, British tobacco, butterbur, field hove, and flower velure. In Chinese it is called *kuan dong hua*.

General use

Coltsfoot has been used as a cough remedy in both **Western herbalism** and **traditional Chinese medicine** for at least 2,500 years. Coltsfoot was such a well-known and well-respected herb in eighteenth century France that apothecary shops advertised their presence by painting a picture of the herb on their signs. Chinese herbalists prefer to use the flower and flower buds, while Western herbalists most often choose to use the leaves.

Coltsfoot is recommended to treat:

- asthma
- bronchitis
- dry, hacking cough
- laryngitis and hoarseness

Coltsfoot has been used as a cough remedy in both Western herbalism and traditional Chinese medicine for at least 2,500 years. *(© Arco Images / Alamy)*

- lung cancer symptoms
- mouth and throat irritations
- sore throat
- wheezing

A decoction (boiling the herb down to a concentrated broth or tea to be taken internally) of coltsfoot root is sometimes used to induce sweating. Externally, a poultice of flowers is sometimes applied to the skin to treat **eczema**, **stings**, **bites**, and skin inflammations. Sometimes coltsfoot leaves are smoked to relieve cough.

Modern scientific investigation shows that coltsfoot contains a substance called mucilage (about 8%) that coats and soothes the throat. It is the presence of this substance that appears to make coltsfoot so effective in treating coughs and respiratory problems. Coltsfoot tea also appears to help clear the airways of mucus in some animal studies. **Smoking** coltsfoot will probably do more to irritate the throat than to soothe it.

Inhaling steam from a pot of boiling coltsfoot leaves is likely to produce little effect because so little of the medicinal material will reach the throat. The German Federal Health Agency's Commission E, established in 1978 to independently review and evaluate scientific literature and case studies pertaining to herb and plant medications, has approved the use of fresh or dried coltsfoot leaf in products to treat dry cough, hoarseness, and mild throat or mouth inflammations.

Despite evidence that coltsfoot does generally work, it is not without its problems. The leaves, and to a greater degree the buds and flowers, contain compounds called pyrrolizidine alkaloids. These compounds are known to damage the liver. They can cause liver **cancer** with extended exposure and may also cause the blood vessels of the liver to narrow dangerously. In one laboratory study, rats fed a diet of coltsfoot flower developed a high rate of cancerous liver tumors.

In the United States, the Food and Drug Administration (FDA) has labeled coltsfoot an herb of "undefined safety." Coltsfoot leaf also falls under some legal restrictions in Austria. German authorities, however, simply recommend that preparations containing coltsfoot leaf should not be taken for more than four to six weeks each year. There is, however, fairly unanimous agreement that the level of pyrrolizidine alkaloids in coltsfoot flowers is much higher than the level found in the leaves, and that medicinal preparations that use the flower or flower bud should be avoided. Some American herbalists are recommending that the internal use of coltsfoot be discontinued as a precaution until further research clarifies the risks involved.

Preparations

Coltsfoot leaves are harvested in early summer and can be used fresh or dried. In China, the flower heads are dug up in winter, before they emerge from the ground. When the root is used, it is harvested in the autumn.

Coltsfoot is most commonly prepared as a tea. It can also be made into a cough syrup when combined with **licorice**, **thyme**, or black cherry. Commercial preparations are also available.

Precautions

The safest course is to avoid the internal use of coltsfoot. Pregnant and nursing women and children

under the age of six should not be given coltsfoot. People who choose to use coltsfoot should avoid ingesting more than 1 gram of pyrrolizidine alkaloids daily. However, accurate measurement of pyrrolizidine alkaloids is difficult and this information is not easily available to many consumers.

Side effects

Coltsfoot is believed to increase the incidence of liver damage and cancerous liver tumors in both laboratory animals and humans.

Interactions

There are no studies of the interactions of coltsfoot with conventional pharmaceuticals or other herbal remedies.

Comfrey

Description

Comfrey (*Symphytum officinale*), or common comfrey, has been known by many names, including **boneset**, knitbone, bruisewort, black wort, salsify, ass ear, wall wort, slippery root, gum plant, healing herb, consound, or knit back. This distinctive herb, considered by the English herbalist Culpeper to be "under the dominion of the moon," is a member of the Boraginaceae family. The genus name *Symphytum* is from the Greek word *sympho* meaning to unite. The common name comfrey is from the Latin *confirmare* meaning to join together. The herb is named after its traditional folk use in compress and poultice preparations to speed the healing of **fractures**, broken bones, **bruises**, and **burns**. Comfrey is a perennial native of Europe and Asia and has been naturalized throughout North America. There are about 25 species of the herb, including prickly comfrey (*S. asperum*) and Russian comfrey (*S.* × *uplandicum*, known as okopnik). In Russian medicine, the herb is considered poisonous when used excessively.

Comfrey grows well in rich, moist, low meadows, or along ponds and river banks, where it may reach a height of 4 ft (1.2 m). Comfrey root is large, branching, and black on the outside with a creamy white interior containing a slimy mucilage. Hollow, erect stems, also containing mucilage, are covered with bristly hairs that cause **itching** when in contact with the skin. The thick, somewhat succulent, veined leaves are covered with rough hairs. They are alternate and lance shaped, with lower leaves as large as 10 in (25 cm) in length, and dark green on top and light green on the underside. Small, bell-shaped flowers grow from the axils of the smaller, upper leaves on red stalks. Flowers are mauve to violet and form in dense, hanging clusters, blooming in summer. The cup-like fruits each contain four small, black seeds.

General use

Comfrey root and other parts of the herb have been valued medicinally for more than 2,000 years. The specific name *officinale* designates its inclusion in early lists of official medicinal herbs. Comfrey has been prepared as a poultice or compress with healing properties for blunt injuries, fractures, swollen bruises, **boils**, carbuncles, varicose ulcers, and burns. The external application of comfrey preparations may minimize the formation of scar tissue. Poultices were also applied to ease breast **pain** in breast-feeding women. Comfrey, taken internally as a tea or expressed juice, has been used to soothe ulcers, hernias, **colitis**, and to stop internal bleeding. As a gargle it has been used to treat mouth sores and bleeding gums. The herbal tea has also been used to treat nasal congestion and inflammation, **diarrhea**, and to quiet coughing. The hot, pulped root, applied externally, was used to treat **bronchitis**, **pleurisy**, and to reduce pain and inflammation of **sprains**.

The herb is thought to loosen congestion, soothe irritated membranes and skin, reduce bleeding, tighten tissues, and heal **wounds**. The allantoin in comfrey, found most abundantly in the flowering tops, has been identified as the source of much of the herb's healing actions. Comfrey, applied externally to superficial wounds, promotes the healing of connective tissue, bones, and cartilage. Other constituents found in comfrey include tannins, resin, essential oil, gum, carotene, rosmarinic acid, **choline**, glycosides, sugars, beteasitosterol, and steroidal saponins.

KEY TERMS

Carbuncle—A skin infection creating deep, pus-filled boils.

Pleurisy—Inflammation of the pleura, the membranes enclosing the lungs and lining the chest cavity.

Comfrey contains vitamins A and B_{12}, and is high in **calcium**, **potassium**, and **phosphorus**. The herb has long been used as a cooked green vegetable in early spring, and the fresh, young leaves have been added to salads. The widespread suffering caused by the Irish potato famine of the 1840s motivated Henry Doubleday, an Englishman, to fund research into comfrey's potential as a nutritional food crop. Farmers have valued comfrey as a nutritious fodder for cattle. When the leaves are soaked in rainwater for a few weeks, they will produce a valuable fertilizer for the garden, especially beneficial to tomatoes and potatoes.

Modern herbalists, however, disagree strongly about comfrey's safety, particularly when herbal preparations are taken internally. A Japanese study in 1968 implicated comfrey constituents (known as pyrrolizidine alkaloids) as being toxic to the liver even when taken in small amounts. The study involved large amounts of comfrey extract rather than the whole herb. The most toxic of these pyrrolizidine alkaloids, according to Varro Tyler of the Purdue University School of Pharmacy, is echimidine. This alkaloid is found primarily in Russian comfrey and prickly comfrey rather than the common comfrey. However, Tyler cautions that other alkaloids toxic to the liver are present in common comfrey, and commercial preparations may not distinguish between the types of comfrey contained in the products offered for sale. Herbal products containing echimidine are prohibited for sale in Canada as medicines. In fact, all comfrey products made from the root, which contains a higher concentration of pyrrolizidine alkaloids, are restricted in Canada.

A 1978 Australian study reported that rats fed a large diet of comfrey leaf developed liver **cancer**. The research literature has reported some cases of liver toxicity attributed to long-term, internal use of comfrey. However, some Japanese doctors still continue to recommend a vinegar extract of comfrey to treat cases of **cirrhosis** of the liver, despite these previous research findings of the hazards associated with internal use. The research on the safety and effectiveness of comfrey as a medicine continues with some conflicting research results. In Germany, where standardized comfrey remedies are commercially available, the allowed dosage and duration of treatment is regulated. In the United States, however, commercial preparations may not be standardized to meet these dosage restrictions.

Preparations

Ointments, salves, and oil extracts of comfrey are available for external treatment. The crushed or powdered root and extracted juice of the herb are used to make poultices for external applications. Comfrey extract is an ingredient in commercially prepared medicines for chest congestion, coughs, and pain relief.

Precautions

Comfrey should not be used, either externally or internally, by pregnant or breast-feeding women. Many herbalists caution against internal use of comfrey. This caution is due to the dangers of the pyrrolizidine alkaloids that are toxic to the liver and may have cancer-causing effects, even in small amounts. Consumers should avoid external use of comfrey on deep wounds because the herb may promote premature healing of surface tissue before the deeper damage has been healed. Wounds must be thoroughly cleaned before application of comfrey remedies to avoid tissue forming over dirt particles. Comfrey preparations should not be used for more than four weeks. Gathering comfrey in the wild may be dangerous for the novice herbalist because the early spring leaves somewhat resemble the deadly ones of nightshade and, in some reported cases, ingesting comfrey in preparations contaminated with deadly nightshade has led to poisoning.

Side effects

No side effects are known with proper preparation and administration of *Symphytum officinale* in external, therapeutic applications. Internal use of herbal preparations should be avoided pending further research.

Interactions

None reported.

Common cold

Definition

The common cold is a viral infection of the upper respiratory system, which includes the nose, throat, sinuses, eustachian tubes, trachea, larynx, and bronchial tubes. Although more than 200 different viruses can cause a cold, 30 to 50% are caused by a group known as rhinoviruses. Almost all colds clear up in less than two weeks without complications.

Description

Colds, sometimes called rhinovirus or coronavirus **infections**, are the most common illness to strike any part of the body. Repeated exposure to viruses causing colds creates partial immunity. Although most colds resolve on their own without complications, they are a leading cause of visits to the doctor and of time lost from work and school. Treating symptoms of the common cold has given rise to a multi-million dollar industry in over-the-counter medications, yet none of these medications is actually anti-viral to the rhinovirus.

Cold season in the United States begins in early autumn and extends through early spring. It is unclear why colds occur more frequently in winter. Although it is not true that getting wet or being in a draft causes a cold (a person has to come in contact with the virus to catch a cold), certain conditions may lead to increased susceptibility. These include:

- fatigue and overwork
- emotional stress
- poor nutrition
- smoking
- inadequate rest or sleep
- living or working in crowded conditions

Colds make the upper respiratory system less resistant to secondary bacterial infection. Secondary bacterial infection may lead to a number of other complications, including middle **ear infection**, **bronchitis**, **pneumonia**, **sinus infection**, or **strep throat**. People with chronic lung disease, **asthma**, diabetes, or a weakened immune system are more likely to develop these complications.

Demographics

It is estimated that the average person has more than 50 colds during a lifetime. Anyone can get a cold, although preschool and grade school children catch them more frequently than adolescents and adults (five to seven episodes per year in preschool children compared with two to three episodes per year in adulthood). Among employed adults, colds cause an estimated 40 percent of all time lost from jobs.

According to a telephone survey published in the *Archives of Internal Medicine* in 2003, about 500 million non-influenza viral respiratory infections occur annually, with direct costs of $17 billion and indirect costs of $22.5 billion.

Causes and symptoms

Colds are caused by more than 200 different viruses. The most common groups include rhinoviruses and coronaviruses. Different groups of viruses are more infectious at different seasons of the year, but knowing the exact virus causing the cold is not important in treatment.

People with colds are contagious during the first two to four days of the onset of symptoms. Colds pass from person to person in several ways. When an infected person coughs, sneezes, or speaks, tiny fluid droplets containing the virus are expelled. If these are breathed in by other people, the virus may establish itself in their noses and airways.

Colds may also be passed through direct contact. For example, if a person with a cold touches his runny nose or watery eyes, then shakes hands with another person, some of the virus is transferred to the uninfected person. If that person then touches his mouth, nose, or eyes, the virus is transferred to an environment where it can reproduce and cause a cold.

Finally, cold viruses can be spread through inanimate objects (door knobs, telephones, toys) that become contaminated with the virus, a common method of transmission in child care centers. Another vector of transmission is air travel, due to closed air circulation.

Once acquired, the cold virus attaches itself to the lining of the nasal passages and sinuses, which causes the infected cells to release a chemical called histamine. Histamine increases the blood flow to the infected cells, causing swelling, congestion, and increased mucus production. Within one to three days, the infected person begins to show cold symptoms.

The first cold symptoms are usually a tickle in the throat, runny nose, and **sneezing**. The initial discharge from the nose is clear and thin. Later, it may change to a thick yellow or greenish discharge. Most adults do not develop a **fever** when they catch a cold. Young children may develop a low fever of up to 102°F (38.9°C).

Other symptoms of a cold include coughing, sneezing, nasal congestion, **headache**, muscle ache, **chills**, **sore throat**, hoarseness, watery eyes, **fatigue**, dull hearing and blocked eustachian tube (a danger when flying), and lack of appetite. The **cough** that accompanies a cold is usually intermittent and dry.

Most people begin to feel better four to five days after their cold symptoms become noticeable. All symptoms are generally gone within 10 days, except for a dry cough that may linger for up to three weeks.

Colds make people more susceptible to secondary bacterial infections such as strep throat, middle ear infections, and sinus infections. A person should consult with a doctor if the cold does not begin to improve within a week. A doctor should also be consulted if the individual experiences chest **pain**, fever for more than a few days, difficulty breathing, bluish lips or fingernails, a cough that brings up greenish-yellow or grayish sputum, skin rash, swollen glands, or whitish spots on the tonsils or throat. These may be signs of a secondary bacterial infection that needs to be treated with an antibiotic.

People who have **emphysema**, chronic lung disease, diabetes, or a weakened immune system—either from diseases such as **AIDS** or **leukemia** or as the result of medications (corticosteroids, chemotherapy drugs)—should consult their doctor if they get a cold. People with these health problems are more likely to develop a secondary infection.

Diagnosis

Colds are diagnosed by observing a person's symptoms and symptom history. There are no laboratory tests as of 2008 for detecting the cold virus. However, a doctor may perform a throat or nasal culture or blood test to rule out a secondary infection.

Influenza is sometimes confused with a cold, but the flu causes much more severe symptoms and is generally accompanied by a fever. **Allergies** to molds or pollens also can cause a runny nose and eyes. Allergies are usually more persistent than the common cold. An allergist or a physician can perform tests to determine if the cold-like symptoms are being caused by an allergic reaction. Also, some people get a runny nose when they go outside in winter and breathe cold air. This type of runny nose, however, is not a symptom of a cold.

Treatment

Patients should drink plenty of fluids and eat nutritious foods. In fact, the old adage, "Feed a cold, starve a fever," was scientifically proven true in 2002. Dutch scientists found that cold-fighting immune responses rose after consuming a full meal, while **fasting** increased those that combat most fevers. Chicken soup with **ginger**, scallions, and rice noodles is nutritious and has properties that help people recover. Rest, to allow the body to fight infection, is very important. Gargling with salt water (half teaspoon salt in one cup of water) helps to soothe a sore throat. A vaporizer also will make sufferers feel more comfortable. Rubbing petroleum jelly or some other lubricant under the nose will prevent irritation from frequent nose blowing. For babies, nasal mucus should be suctioned gently with an infant nasal aspirator. It may be necessary to soften the mucus first with a few drops of salt water.

Herbals

Herbals can be taken to stimulate the immune system, for antiviral activity, and to relieve symptoms. The following herbs are used to treat colds:

- Ginger (*Zingiber officinale*) reduces fever and pain, has a sedative effect, settles the stomach, and suppresses cough.
- Forsythia (*Forsythia suspensa*) fruit can be taken as a tea for its anti-inflammatory, fever reducing, and antimicrobial properties.
- Honeysuckle (*Lonicera japonica*) flower can be taken as a tea for its anti-inflammatory, fever reducing, and antimicrobial properties.
- Aniseed (*Pimpinella anisum*) can be added to tea to expel phlegm, induce sweating, ease nausea, and ease stomach gas.
- Slippery elm powdered bark (*Ulmus fulva*) can be taken as a tea or slurry or capsules to soothe sore throat, to ease cough, and to thin mucous.

- Echinacea (*Echinacea purpurea*, *augustifolia*), or *pallida*) may relieve cold symptoms and reduce the severity of symptoms and duration of colds, but as of 2008 further clinical studies were needed to demonstrate its effects on the common cold. The usual dosage is 500 mg of crude powdered root or plant thrice on the first day, then 250 mg four times daily thereafter. Echinacea may also be taken as a tincture. (*Andrographis*, also known as Indian echinacea, is another form of echinacea that has been shown to reduce the symptoms of colds as well as increase resistance to colds. However, echinacea does not appear to be effective in children.)
- Garlic may reduce the severity of cold symptoms and the duration of colds. A 2007 study published in *Molecular Nutrition & Food Research* showed that participants who received garlic were almost two-thirds less likely to develop a cold than those receiving placebo, and those who did have a cold recovered about one day faster in the garlic group as compared to the placebo group.
- Goldenseal (*Hydrastis canadensis*) has fever reducing, antibacterial, anti-inflammatory, and antitussive properties. The usual dose is 125 mg three to four times daily. Goldenseal should not be taken for more than one week. Goldenseal may also be prepared as a tincture.
- Astragalus (*Astragalus membranaceus*) boosts the immune system and improves the body's response to stress. The common dose is 250 mg of extract four times daily.
- Cordyceps (*Cordyceps sinensis*) modulates and boosts the immune system and improves respiration. The usual dose is 500 mg two to three times daily.
- Elder (*Sambucus*) has antiviral activity, increases sweating, decreases inflammation, and decreases nasal discharge. The usual dose is 500 mg of extract thrice daily.
- American ginseng (*Panax quinquefolius*) can help prevent colds and reduce the severity and duration of cold symptoms. In seniors, American ginseng may help prevent flu-like illnesses. The usual dose is 400 mg once daily.
- Stinging nettle (*Urtica dioica*) has antihistamine and anti-inflammatory properties. The common dose is 300 mg four times daily.
- Schisandra (*Schisandra chinensis*) helps the body fight disease and increases endurance.
- Grape (*Vitis vinifera*) seed extract has antihistamine and anti-inflammatory properties. The usual dose is 50 mg three times daily.
- Eucalyptus (*Eucalyptus globulus*) or peppermint (*Mentha piperita*) essential oils added to a steam vaporizer may help clear chest and nasal congestion and disinfect room air.
- Boneset infusion (*Eupatroium perfoliatum*) relieves aches and fever.
- Yarrow (*Achillea millefolium*) is a diaphoretic.
- Supplemental larch from the inner bark of the western larch tree has been shown in some clinical trials to fight persistent colds and ear aches.

Chinese medicines

Chinese herbal treatments are based on the specific symptoms of colds and include a variety of *Radix*, *Rhizoma*, *Semen*, and *Herba* species. Chinese patent medicines for cold include:

- Wu Shi Cha (Noon tea): once or twice daily.
- Yin Qiao Jie Du Pian (Honeysuckle and Forsythia Tablet to Overcome Toxins): four to six, twice daily.
- Sang Ju Gan Mao (Mulberry Leaf and Chrysanthemum to Treat Common Cold): one packet of infusion or four to eight tablets, twice or thrice daily.
- Ling Yang Gan Mao Pian (Atelopis Tablet for Common Cold): four to six, twice daily.
- Ban Lan Gen Chong Ji (Isatidis Infusion): one packet twice or thrice daily.
- Huo Xiang Zheng Qi (Agastache to Rectify Qi): 6 g or four to six tablets.

Other remedies

Exercise of moderate intensity, over a period of one year, has been shown to decrease the incidence of self-reported colds. However, further research was needed as of 2008 to define the specific effects of exercise on the common cold.

Ayurvedic medicine practitioners recommend gargling with a mixture of water, salt, and **turmeric** powder or astringents such as alum, sumac, **sage**, and **bayberry** to ease a sore throat.

Homeopaths recommend microdoses of Viscue album, Natrum muriaticum, **Allium cepa**, or Nux vomica.

VITAMIN C. Vitamin C supplements, at a daily dose of 1,000 mg, can help to slightly reduce the symptoms and duration of colds when taken throughout the cold season. Vitamin C supplementation at the onset of cold symptoms is not effective in reducing the symptoms or duration of a cold, and it does not prevent colds.

VITAMIN E. **Vitamin E** supplements, at a daily dose of 200 IU, can help to slightly reduce the incidence of colds when taken throughout the cold season. Further studies were needed as of 2008 to evaluate the effects of vitamin E supplementation on the common cold.

ZINC. The effectiveness of **zinc** in nasal gels or throat lozenges for preventing or treating the common cold, as well as reducing the severity and duration of cold symptoms, continued to be investigated in the late 2000s. Numerous studies have generated inconsistent, although generally positive, results. For example, one study of over 100 employees of the Cleveland Clinic who used zinc lozenges immediately after the onset of cold symptoms showed the duration of colds decreased by one-half, although there were no differences in duration of fevers or level of muscle aches. It has been suggested that the effectiveness of the zinc lozenge is dependant on its formulation. For example, certain flavoring agents, including citric acid and tartaric acid, and the sweetener glycine in some lozenge formulations may bind zinc and reduce effectiveness. The recommended dosage is to suck on one lozenge every two hours while awake, beginning at the first cold symptoms. Side effects are bad taste, **nausea**, and **vomiting**. The results of studies using zinc nasal gel are more controversial because side effects such as nasal pain and loss of smell may override potential benefits. Further research was needed in the late 2000s to determine the effects of zinc compounds on the common cold.

Allopathic treatment

As of 2008, there were no known medicines proven to prevent or cure the common cold. Antibiotics are useless against a cold and can enhance bacterial resistance, if used carelessly. Nonprescription products to relieve cold symptoms include ipratropium bromide, cromolyn **sodium**, antihistamines, antitiussives (cough suppressants), expectorants, decongestants, and/or pain relievers, but none has been found to shorten the duration of a cold. Over-the-counter cold remedies should not be given to infants without consulting a doctor first. Care should be taken not to exceed the recommended dosages, especially when combination medications or nasal sprays are taken. Aspirin should not be given to children with a cold because of its association with a risk of Reye's syndrome, a serious disease.

Ipratropium bromide, delivered via nasal spray, has been shown to improve symptoms of runny nose and sneezing, although side effects of nasal dryness and blood-tinged mucus can occur. Cromolyn sodium is a type of asthma medication—delivered via nasal spray, powder-filled inhalation capsules, or an aerosol via a metered dose inhaler—that has been shown to reduce the duration of cold symptoms.

Antihistamines are taken to relieve the symptoms of sneezing, runny nose, itchy eyes, and congestion. Side effects include **dry mouth** and drowsiness, especially with the first few doses. Some people have allergic reactions to antihistamines. Common over-the-counter antihistamines include Chlor-Trimeton, Dimetapp, Tavist, and Actifed. The generic name for two common antihistamines are chlorpheniramine and diphenhydramine.

Antitussives (cough suppressants), such as dextromethorphan and benzonatate, block the cough reflex and can be used to relieve symptoms of a non-productive cough. However, these medications are not recommended by the American College of Chest Physicians for treatment of cough associated with upper respiratory infections. Common brand names of over-the-counter dextromethorphan antitussives include Benylin, Delsym, Drixoral, Pertussin, and Robitussin. Tessalon is a common brand of benzonatate antitussive.

Expectorants, such as guaifenesin, help thin mucus so that coughing can remove secretions from the airway. Over-the-counter expectorant brands include Guiatuss, Robitussin, and Tusibron.

Decongestants reduce congestion and open inflamed nasal passages, making breathing easier. Decongestants can make people feel jittery or keep them from sleeping. They should not be used by people with **heart disease**, high blood pressure, or **glaucoma**. Some common decongestants are Neo-Synepherine, Novafed, and Sudafed. The generic names of common decongestants include pseudoephedrine and phenylephrine and in nasal sprays naphazoline, oxymetazoline, and xylometazoline. Nasal sprays and nose drop decongestants can act more quickly and effectively than decongestants found in pills or liquids because they are applied directly in the nose. Congestion returns after a few hours. Persons can become dependent on nasal sprays and nose drops, so they should not be used for more than a few days.

Many over-the-counter medications are combinations of both antihistamines and decongestants; an ache and pain reliever, such as acetaminophen (Datril, Tylenol, Panadol) or ibuprofen (Advil, Nuprin, Motrin, Medipren); and a cough suppressant (dextromethorphan). Common combination medications include Tylenol Cold and Flu, Triaminic, Sudafed Plus, and Tavist D.

Expected results

Given time, the body will make antibodies to cure itself of a cold. Most colds last seven to 10 days. Most

KEY TERMS

Ayurvedic treatment—A holistic system of medicine from India that focuses on using physical, psychological, and spiritual therapies to achieve a mind-body balance and optimal health.

Bronchial tubes—The major airways from the back of the throat to the lungs and their main branches.

Coronavirus—A genus of viruses that causes respiratory disease and gastroenteritis.

Corticosteroids—A group of hormones produced naturally by the adrenal gland or manufactured synthetically. They are often used to treat inflammation. Examples include cortisone and prednisone.

Eustachian tube—A thin tube between the middle ear and the pharynx. Its purpose is to equalize pressure on either side of the ear drum.

Homepathy—The treatment of illness according to a theory that "like cures like" which stimulates the body to heal itself.

Rhinovirus—A virus that infects the upper respiratory system and causes the common cold.

people start feeling better within four or five days. Occasionally, a cold will lead to a secondary bacterial infection that causes strep throat, bronchitis, pneumonia, sinus infection, or a middle ear infection.

Prevention

Prevention focuses on strengthening the immune system by eating a healthy diet low in sugars and high in fresh fruits and vegetables, practicing **meditation** to reduce **stress**, getting adequate sleep, and getting regular moderate exercise. Some steps persons can take to prevent catching a cold and to reduce their spread include:

- washing hands well and frequently
- covering the mouth and nose when sneezing
- avoiding close contact with someone who has a cold during the first two to four days of their infection
- not sharing food, eating utensils, or cups
- avoiding crowded places where cold viruses can spread
- keeping hands away from the face
- avoiding cigarette smoke
- taking Echinacea; 250 mg up to four times daily for three weeks on, one week off
- taking astragalus; 250 mg to 500 mg daily
- taking a multivitamin with zinc
- taking vitamin C; 1,000 mg
- taking *Anas barbariae hepatis*; one dose weekly

Research has shown that transmission of the rhinovirus may be prevented through the use of antiseptic skin cleansers containing salicylic acid or pyroglutamic acid. The cleansers have properties that can kill the viruses and help prevent hand-to-hand transmission, but further research on their effectiveness remained to be done in the late 2000s.

Conjunctivitis

Definition

Conjunctivitis is an inflammation of the transparent membrane lining of the conjunctiva, which covers the white part of the eye and the underside of the eyelid. Conjunctivitis can be caused by viral or bacterial infection, allergic reaction, or less commonly by

physical agents such as chemicals splashed into the eye or exposure of the eye to infrared or ultraviolet light. Conjunctivitis is also known as pink eye.

Description

Conjunctivitis is a common eye problem because the conjunctivae are continually exposed to microorganisms and environmental agents that can cause **infections** or allergic reactions. Conjunctivitis can be acute (short term) or chronic (long term) depending upon how long the condition lasts, the severity of symptoms, and the type of organism or agent involved. It can affect one or both eyes. Viral and bacterial conjunctivitis is highly contagious; physical transfer can easily spread it to others. Bacterial conjunctivitis is particularly likely to spread among children in childcare centers or schools.

Causes and symptoms

Conjunctivitis may be caused by a viral infection, such as a cold, acute respiratory infection, **measles**, herpes simplex, or herpes zoster. Symptoms include mild to severe discomfort in one or both eyes, redness, swelling of the eyelids, and a watery, yellow, or greenish discharge. The symptoms may last several days to several weeks. Infection with an adenovirus may cause a significant amount of pus-like discharge and a scratchy sensation in the eye. These symptoms may be accompanied by swelling and tenderness of the lymph nodes near the ear.

Bacterial conjunctivitis occurs in adults or children but is more common in children. It is caused by such organisms as *Staphylococcus*, *Streptococcus pneumoniae*, and *Haemophilus influenzae*. Symptoms of bacterial conjunctivitis include a pus-like discharge and crusty eyelids upon awakening. Redness of the conjunctivae can be mild to severe and may be accompanied by swelling. In people who are sexually active, conjunctivitis may be caused by **chlamydia** or the bacteria that cause **gonorrhea**. In these cases, there may be large amounts of pus-like discharge. Other symptoms may include hypersensitivity to light (photophobia), a watery mucous discharge, and tenderness in the lymph nodes near the ear that may persist for up to three months.

Non-contagious conjunctivitis can be caused by such environmental hazards as wind, smoke, dust, and allergic reactions caused by pollen, dust, or grass. Symptoms range from **itching** and redness to a mucous discharge. Persons who wear contact lenses may develop allergic conjunctivitis caused by the various lens solutions and foreign proteins contained in them.

Other less common causes of conjunctivitis include looking at the sun, sun lamps, plant lamps, or the electrical arcs used during welding. Accidental chemical splashes in the eye can also cause non-contagious conjunctivitis, as can blocked tear ducts in newborns.

Diagnosis

Although inflammation of the eye is often obvious, accurate diagnosis of the cause of conjunctivitis requires taking the patient's history to learn when symptoms began, how long the condition has existed, and the specific symptoms experienced. Diagnostic tests may include an eye examination and culture of the eye discharge to determine the organism responsible for causing the condition. Obtaining samples for culturing is relatively painless.

Treatment

Conjunctivitis caused by bacteria and gonococcal or chlamydial infection usually requires prescription antibiotics. Immune system enhancement with dietary supplements can aid in the resolution of allergic and viral conjunctivitis. Removal of the allergic agent is an essential step in treating allergic conjunctivitis. If home care brings no improvement within 48 to 72 hours, a physician should be consulted.

Nutritional therapy

The following dietary changes may be helpful in managing conjunctivitis by supporting and strengthening the immune system:

- Taking 25,000 IU (international units) of beta-carotene twice daily for 7 days. However, taking megadoses of beta-carotene for an extended time has been shown to increase the risk of developing lung cancer in smokers but not in non-smokers.
- Taking 500–1000 mg of vitamin C three times daily for 7 days.
- Taking 25 mg of zinc with meals three times daily for 7 days.

Homeopathy

A number of homeopathic remedies are designed to treat acute conjunctivitis. These include *Argentum nitricum* (silver nitrate), **pulsatilla** (windflower), **belladonna**, *Arsenicum album* (arsenic trioxide), sulphur (elemental sulphur) and **eyebright** (*Euphrasia officinalis*). Eye drops prepared with homeopathic remedies may be a substitute for pharmaceutical eye drops.

Herbal therapy

Herbal eyewashes made with eyebright (1 tsp dried herb steeped in 1 cup of boiling water for 10

minutes, then strained and used at once) or **chamomile** (*Matricaria recutita*; 2–3 tsp in 1 pint of boiling water) may be helpful. Eyewashes should be strained and cooled before use. They should be discarded promptly after use, as old infusions may become contaminated (non-sterile).

Other home remedies may help relieve the discomfort associated with conjunctivitis. A boric acid eyewash (1 tsp boric acid in 1 cup of water) can be used to clean and soothe the eyes. A warm compress applied to the eyes for 5 to 10 minutes three times a day can help relieve the discomfort of bacterial and viral conjunctivitis and may help open a blocked tear duct. A clean washcloth soaked in warm water can be used as a warm compress. The patient should close both eyes and apply the compress to the affected eye. A cool compress or cool, damp tea bags placed on the eyes can ease the discomfort and itching of conjunctivitis.

Allopathic treatment

The treatment of conjunctivitis depends on what agent caused the condition. In all cases, warm compresses applied to the affected eye several times a day may help to reduce discomfort.

Conjunctivitis due to a viral infection is usually treated by applying warm compresses to the eye. Viral conjunctivitis is not treatable by antibiotic eye drops or ointment. Usually symptoms of viral conjunctivitis worsen for three to five days then begin to improve, and the disease clears on its own. If there is no improvement, a doctor should be consulted.

In cases of bacterial conjunctivitis, a physician usually prescribes an antibiotic eye ointment or eye drops containing **sodium** sulfacetamide (Sulamyd) to be applied daily for 7 to 14 days. As with all antibiotics, it is important to complete the entire course of treatment and not stop using the medicine simply because symptoms improve. Patients should contact their doctor if the eyes fail to improve after 72 hours.

Antibiotic eye drops are instilled (put in drop by drop) into the eye by having the patient tilt the head back and pulling down the lower eyelid. The patient is asked to look upward while the medication is instilled into the conjunctival sac. The dropper should not touch the skin to prevent discharge from the eye from contaminating the eye drop solution. After the drops have been instilled, the patient should gently close the eyes for one minute in order not to squeeze out any of the medication.

For cases of conjunctivitis caused by a gonococcus (the bacteria that causes gonorrhea), a physician may prescribe an injection of ceftriaxone (Rocephin) and a topical antibiotic ointment containing erythromycin or bactracin to be applied four times daily for two to three weeks. For chlamydial infections, a topical antibiotic ointment containing erythromycin (Ilotycin) may be prescribed to be applied one or two times daily.

To apply an antibiotic ointment, the eye should be gently wiped with a sterile cotton ball moistened with sterile water to remove any discharge. Then, the lower eyelid can be pulled down and a thin ribbon of ointment applied in the lower conjunctival sac. If possible, single-dose dispensers of ointment should be used as a protection against contamination of the medication. The eyelids can be closed and massaged gently to distribute the ointment. Patients may find that their vision is blurry for a few minutes after the ointment is applied, but this is a normal side effect. In addition to topical antibiotics, oral erythromycin or tetracycline therapy may be indicated for three to four weeks. Sexual partners should also be treated.

Allergic conjunctivitis is treated by removing the allergic substance from a person's environment, if possible, applying cool compresses to the eye, and by administering eye drops four to six times daily for four days. Also, the antihistamine diphenhydramine hydrochloride (Benadryl) may help to relieve itchy eyes. Some doctors may prescribe ophthalmic steroids, but they are often unnecessary and have the potential to cause complications in some patients.

Expected results

Conjunctivitis caused by an allergic reaction should clear up once the allergen is removed. Allergic conjunctivitis, however, is likely to recur if the individual again comes into contact with the particular allergen. Conjunctivitis caused by a bacterium or a virus, if treated properly, usually resolves in about ten days. If there is no relief of symptoms in 48 to 72 hours or if there is moderate to severe eye **pain** or changes in vision, a physician should be notified immediately. If untreated or treated inappropriately, conjunctivitis may cause vision impairment by spreading to other parts of the eye such as the cornea.

Prevention

Many states require that children with conjunctivitis remain at home until the eye redness is gone in order to prevent spreading this highly contagious disease. Conjunctivitis sometimes can be prevented or the course of the disease shortened by following some simple practices:

KEY TERMS

Adenovirus—A virus that affects the upper respiratory tract.

Chlamydia—A common sexually transmitted disease in the United States that often accompanies gonorrhea. It is caused by a rickettsia called *Chlamydia trachomatis*.

Gonococcus—The bacterium *Neisseria gonorrheae* , which causes gonorrhea, a sexually transmitted infection of the genitals and urinary tract that may occasionally affect the eye, causing blindness if not treated.

Herpes simplex virus—A virus that can cause fever and blistering on the skin, mucous membranes, or genitalia.

Herpes zoster virus—Acute inflammatory virus attacking the nerve cells on the root of each spinal nerve with skin eruptions along a sensory nerve ending.

Inflammation—The body's response to tissue damage, with symptoms of warmth, swelling, redness, and pain in the affected part.

Staphylococcus—A genus of bacteria, which resembles a cluster of grapes, that can infect various body systems.

- Washing hands frequently using antiseptic soap and using single-use towels during the disease to prevent spreading the infection
- Avoiding sharing towels and wash cloths
- Avoiding chemical irritants and known allergens
- In areas where welding occurs, using the proper protective eye wear and screens to prevent damaging the eyes
- Using a clean tissue to remove discharge from eyes and washing hands to prevent the spread of infection
- If medication is prescribed, finishing the course of antibiotics as directed to make sure that the infection is cleared up and does not recur
- Avoiding wearing eye makeup or contact lenses during the infection and do not share eye makeup with others

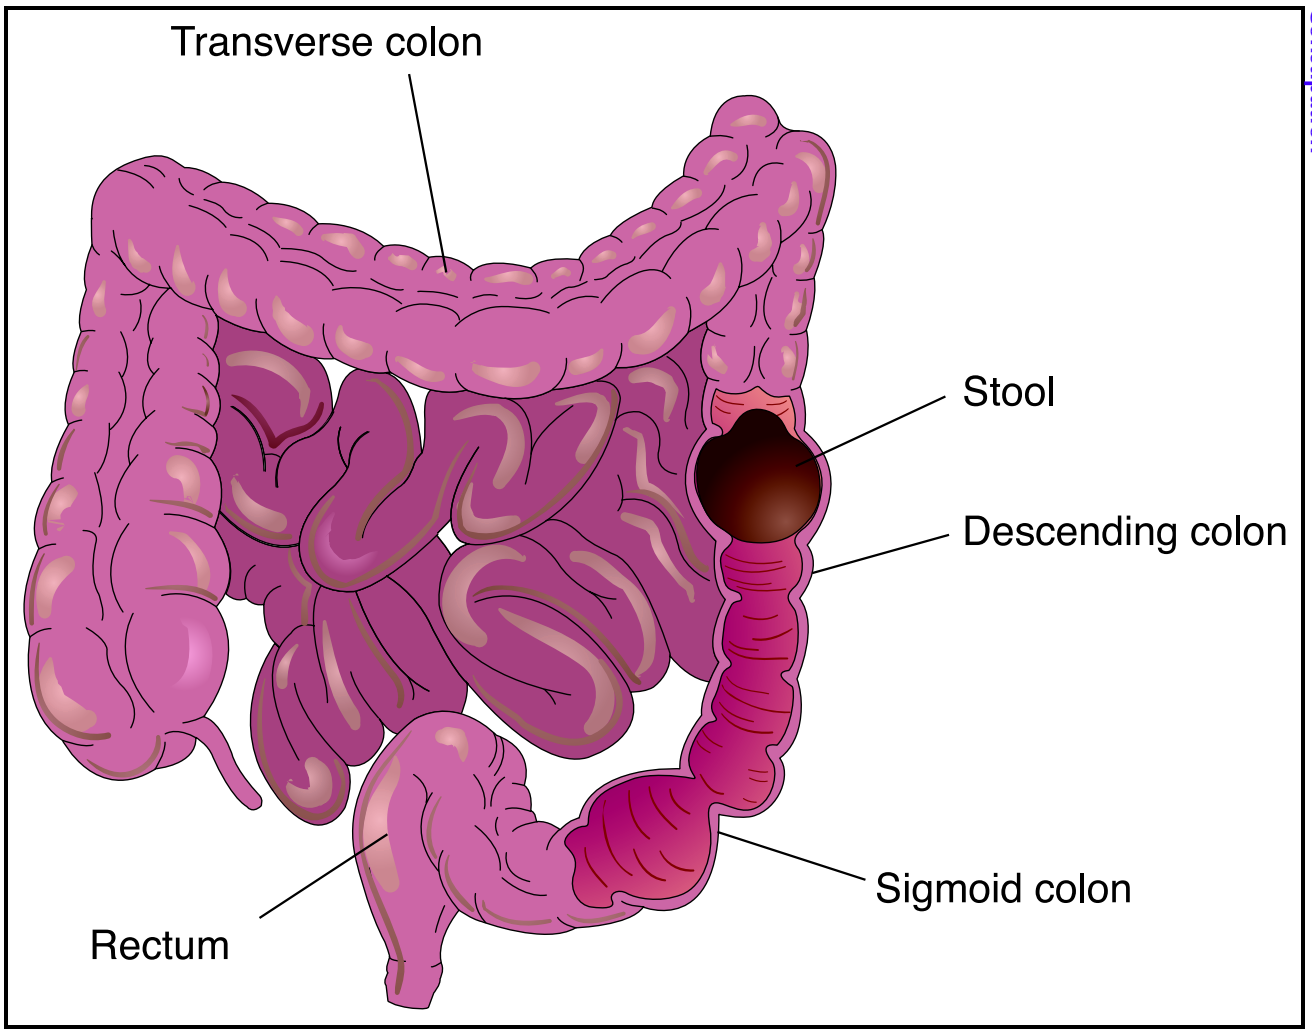
Constipation

Definition

Constipation is an acute or chronic condition in which bowel movements occur less often than usual or consist of hard, dry stools that are painful or difficult to pass. Bowel habits vary, but an adult who has not had a bowel movement in three days or a child who has not had a bowel movement in four days is considered constipated.



Constipation is an acute or chronic condition in which bowel movements occur less often than usual or consist of hard, dry stools that are painful or difficult to pass. *(Illustration by Electronic Illustrators Group. Cengage Learning, Gale)*

Description

Constipation is one of the most common medical complaints in the United States. Estimates show that chronic constipation affects between 2% and 28% of adults. In the United States, constipation results in more than 2.5 million visits to physicians and 92,000 hospitalizations each year, according to an article in the October 1, 2007 issue of *Family Practice News*. Studies have shown chronic constipation is two to three times more common in women than men. The highest rates per age group are in people aged 65 years or older. However, it can occur at any age and is more common among individuals who resist the urge to move their bowels at the body's signal. This often happens when children start school or enter daycare and feel shy about asking permission to use the bathroom.

Although this condition is rarely serious, it can lead to the following:

- bowel obstruction
- chronic constipation
- hemorrhoids (a mass of dilated veins in swollen tissue around the anus)
- hernia (a protrusion of an organ through a tear in the muscle wall)
- spastic colitis (irritable bowel syndrome, a condition characterized by alternating periods of diarrhea and constipation)
- laxative dependency

Chronic constipation may be a symptom of **colorectal cancer**, **depression**, diabetes, diverticulosis (small pouches in the muscles of the large intestine), **lead**

poisoning, or **Parkinson's disease**. An opioid overdose (as in excessive codeine from **cough** suppressants or heroin addiction) also may result in constipation.

In someone who is elderly or disabled, constipation may be a symptom of bowel impaction, a more serious condition in which feces are trapped in the lower part of the large intestine. A doctor should be called if an elderly or disabled person is constipated for more than a week or if a child seems to be constipated.

A doctor should be notified whenever constipation occurs after starting a new prescription, vitamin, or mineral supplement or is accompanied by blood in the stools, changes in bowel patterns, **fever**, or abdominal **pain**.

Causes and symptoms

Constipation usually results from not getting enough **exercise**, not drinking enough water or clear fluids, or from a diet that does not include an adequate amount of fiber-rich foods such as beans, bran cereals, fruits, raw vegetables, rice, and whole-grain breads.

Other causes of constipation include anal fissure (a tear or crack in the lining of the anus), chronic kidney failure, colon or rectal **cancer**, depression, hypercalcemia (abnormally high levels of **calcium** in the blood), **hypothyroidism** (underactive thyroid gland), illness requiring complete bed rest, **irritable bowel syndrome**, imbalanced bowel from food and flora **allergies**, and **stress**.

Constipation can also be a side effect of the following:

- aluminum salts in antacids
- antihistamines
- antipsychotic drugs
- aspirin
- belladonna (*Atopa belladonna,* source of atropine, a medication used to relieve spasms and dilate the pupils of the eye)
- beta blockers (medications used to stabilize irregular heartbeat, lower high blood pressure, reduce chest pain)
- blood pressure medications
- calcium channel blockers (medication prescribed to treat high blood pressure, chest pain, some types of irregular heartbeat and stroke, some non-cardiac diseases)
- codeine or opioids
- diuretics (drugs that promote the formation and secretion of urine)
- iron or calcium supplements
- narcotics (potentially addictive drugs that relieve pain and cause mood changes)
- tricyclic antidepressants (medications prescribed to treat chronic pain, depression, headaches, and other illnesses)

An adult who is constipated may feel bloated, have a **headache**, swollen abdomen, pass rock-like feces, or strain, bleed, or feel pain during bowel movements. A constipated baby may strain, cry, draw the legs toward the abdomen, or arch the back when having a bowel movement.

Diagnosis

Everyone becomes constipated once in a while, but a doctor should be notified if significant changes in bowel patterns last for more than a week or if symptoms continue more than three weeks after increasing activity and fiber and fluid intake.

The patient's observations and medical history help a primary care physician diagnose constipation. The doctor uses his fingers to see if there is a hardened mass in the abdomen and may perform a rectal examination. Other diagnostic procedures include a barium enema, which may reveal a blockage inside the intestine; laboratory analysis of blood and stool samples for internal bleeding or other symptoms of systemic disease; and a sigmoidoscopy (examination of the sigmoid area of the colon with a flexible tube equipped with a magnifying lens).

Physical and psychological assessments and a detailed history of bowel habits are especially important when an elderly person complains of constipation.

Treatment

Initially, alternative practitioners suggest that the patient drink an adequate amount of water each day (six to eight glasses), exercise on a regular basis, and eat a diet high in soluble and insoluble fibers. Soluble fibers include pectin, flax, and gums. Insoluble fibers include **psyllium** and bran from grains such as wheat and oats. Fresh fruits and vegetables contain both soluble and insoluble fibers, and since constipation is aggravated by folate, calcium, and **magnesium** deficiencies, sources of these nutrients, such as asparagus, spinach, **parsley**, and other dark green leafy vegetables, should be part of the daily diet. Various fruit juices can also help maintain normal bowel function: Sorbitol, the natural sugar found in apple juice, has known laxative properties. **Castor oil**, applied topically to the abdomen and covered by a heat source (a heating pad or hot water bottle), can help relieve constipation when used nightly for 20–30 minutes. For

babies, about 1 tablespoon of corn syrup mixed with warm water might help relieve constipation.

Acupressure

This form of needleless **acupuncture** is said to relax the abdomen, ease discomfort, and stimulate regular bowel movements when diet and exercise fail to do so. After lying down, patients close their eyes and take deep breaths. For two minutes, the practitioner applies gentle fingertip pressure to a point about two inches below the navel. **Acupressure** can also be applied to the outer edges of one elbow crease and maintained for 30 seconds before pressing the crease of the other elbow. This should be done three times a day to relieve constipation.

Aromatherapy

Six drops of **rosemary** (*Rosmarinus officinalis*) and six drops of **thyme** (*Thymus spp.*) diluted by one ounce of almond oil, olive oil, or another carrier oil can relieve constipation when used to massage the abdomen. A circular motion for massage is recommended, beginning up the right side of the abdomen, coming across the top, and down the left side. Massaging the leg from knee to hip in the morning, at night, and before trying to move the bowels is said to relieve constipation.

Herbal therapy

A variety of herbal therapies can be useful in the treatment of constipation. Several herbs, including **chamomile** (*Matricaria recutita*), **dandelion** root (*Taraxacum officinale*), and burdock (*Arctium lappa*), act as **bitters** which stimulate the movement of the digestive and excretory systems. There are also laxative herbs that assist with bowel movement. Two of these are **senna** and **buckthorn**. These laxative herbs are stronger acting on elimination than bitters and can sometimes cause cramping (mixing them with a calming herb like **fennel** or caraway can help reduce cramping). Both senna and buckthorn are powerful herbs that are best used with direction from an experienced practitioner, since they can have adverse side effects and the patient may become dependent on them. In fact, practitioners caution that senna can cause severe cramping.

Yoga

The knee-chest position, said to relieve **gas** and stimulate abdominal organs, involves the following moves:

- standing straight with arms at the sides
- lifting the right knee toward the chest
- grasping the right ankle with the left hand
- pulling the leg as close to the chest as possible
- holding the position for about eight seconds
- repeating these steps with the left leg

The cobra position, which can be repeated as many as four times a day, involves the following moves:

- lying on the stomach with legs together
- placing the palms just below the shoulders, holding elbows close to the body
- inhaling, then lifting the head (face forward) and chest off the floor
- keeping the navel in contact with the floor
- looking as far upward as possible
- holding this position for three to six seconds
- exhaling and lowering the chest

The spinal twist is another pose that is recommended for daily use in relieving constipation. Practicing **relaxation** and **meditation** can also have a powerful effect on the digestive system. Slow, steady music can relieve tension that leads to constipation.

Allopathic treatment

If changes in diet and activity fail to relieve occasional constipation, an over-the-counter laxative may be used for a few days. Preparations that soften stools or add bulk (bran, psyllium, ducosate **sodium**) work more slowly but are safer than Epsom salts and other harsh laxatives or herbal laxatives containing senna (*Cassia senna*) or buckthorn (*Rhamnus purshianna*), which, if used long term, can harm the nerves and lining of the colon because they are stimulants that cause waves of involuntary muscle contractions in the intestines.

A woman who is pregnant should never use a laxative. She can use **flaxseed**, bran, ducosate sodium, prunes, or oatmeal. Anyone who is experiencing abdominal pain, **nausea**, or **vomiting** should also avoid laxatives. A warm-water or mineral oil enema can relieve constipation, and a non-digestible sugar (lactulose) or special electrolyte solution is recommended for adults and older children with stubborn symptoms. If a patient has an impacted bowel, the doctor may insert a gloved finger into the rectum and gently dislodge the hardened feces.

One study compared a non-toxic food ingredient called polyethylene glycol to lactulose for relieving constipation in children. It showed that it may work faster, prove easier to administer, and be just as safe and effective. However, more research was suggested

before recommending the substance over lactulose. A small-scale study of children with chronic constipation reported in 2006 that an intake for four weeks of a cocoa husk supplement produced beneficial results.

In 2007, the anti-constipation prescription drug tegaserod (Zelnorm) was removed from the market after an analysis of previous studies (meta-analysis) of more than 18,000 people showed it increased the risk of cardiovascular events, including **heart attack**, **stroke**, and unstable **angina**. The risk was small but considered significant. The drug was used to treat people with irritable bowel syndrome who had constipation or chronic constipation. There was no proof the drug itself caused the cardiovascular events since all 13 people in the studies who reported cardiovascular events had pre-existing heart problems or had risk factors for **heart disease**.

Expected results

Changes in diet and exercise usually eliminate the problem of constipation.

Prevention

Most Americans consume between 11–18 grams of fiber a day. Consumption of 30 grams of fiber and between 6–8 glasses of water each day can generally prevent constipation, and 35 grams of fiber a day (an amount equal to five servings of fruits and vegetables, and a large bowl of high-fiber cereal) can relieve constipation. Fiber supplements containing psyllium (*Plantago psyllium*) usually become effective within about two days and can be used every day without causing dependency. Powdered flaxseed (*Linium usitatissimum*) works the same way. Insoluble fiber, such as wheat or oat bran, is as effective as psyllium but may give the patient gas at first.

Daily use of 500 mg **vitamin C** and 400 mg magnesium can prevent constipation. If symptoms do occur, each dosage can be increased by 100 mg a day, up to a maximum of 5,000 mg vitamin C and 1,000 mg magnesium. Use of preventive doses should be resumed after relief occurs. If the patient develops **diarrhea**, the vitamin C should be decreased. Calcium is also important. Children over five can take up to 1,300 mg and adults ages 19–50 can take up to 2,000 mg.

Sitting on the toilet for 10 minutes at the same time every day, preferably after a meal, can induce regular bowel movements. This may not become effective for a few months, and it is important to defecate whenever necessary.

Contact dermatitis

Definition

Contact **dermatitis** is the name given to any skin inflammation that results from surface contact. There are two kinds of contact dermatitis, irritant and allergic.

Description

Thousands of natural and synthetic substances can cause contact dermatitis, which is the most common skin condition requiring medical attention, and the foremost source of work-related disease. Florists, domestic workers, hairdressers, food preparers, and employees in heavy industry, construction, carpentry, dry cleaning, farming, health care, and the military are the people most at risk of contracting work-related contact dermatitis. Americans spend roughly $300 million a year in their quest for relief from contact dermatitis, not counting the considerable sums devoted by governments and businesses to regulating and policing the use of skin-threatening chemicals in the workplace. But exactly how many people suffer from contact dermatitis remains unclear; a 1997 article in the *Journal of the American Medical Association* notes that figures ranging from 1–15% have been put forward for Western industrial nations.

Causes and symptoms

Irritant contact dermatitis (ICD) is the more commonly reported of the two types of contact dermatitis, accounting for about 80% of cases. It can be caused by soaps, detergents, solvents, adhesives, fiberglass, and other substances that are able to directly injure the skin. Most attacks are mild and confined to the hands and forearms, but can affect any part of the body that comes in contact with the irritating substance. The symptoms can take many forms: redness, **itching**, crusting, swelling, blistering, oozing, dryness, scaliness, thickening of the skin, and a feeling of warmth at the site of contact. In extreme cases severe blistering can occur and open sores can form. Occupations that require frequent skin exposure to water, such as hairdressing and food preparation, can make the skin more susceptible to ICD.

Allergic contact dermatitis (ACD) results when repeated exposure to an allergen (an allergy-causing substance) triggers an immune response that inflames the skin. Tens of thousands of drugs, pesticides, cosmetics, food additives, commercial chemicals, and other substances have been identified as potential allergens. Fewer than 30, however, are responsible the majority of ACD cases. Common culprits include poison ivy, poison **oak**, and poison sumac; fragrances and preservatives in cosmetics and personal care products; latex items, including gloves and condoms; and formaldehyde. Many people find that they are allergic to the nickel in inexpensive costume jewelry. ACD is usually confined to the area of skin that comes in contact with the allergen, typically the hands or face. Symptoms range from mild to severe and resemble those of ICD. A patch test may be needed to determine which kind of contact dermatitis a person is suffering from.

KEY TERMS

Antibiotics—Substances used against microorganisms that cause infection.

Corticosteroids—A group of anti-inflammatory substances often used to treat skin conditions.

Immune response—The protective reaction by the immune system against foreign antigens (substances that the body perceives as potentially dangerous). The immune system combats disease by neutralizing or destroying antigens.

Diagnosis

Diagnosis begins with a physical examination and asking the patient questions about his or her health and daily activities. When contact dermatitis is suspected, the doctor attempts to learn as much as possible about the patient's hobbies, workplace duties, use of medications and cosmetics, etc.—anything that might shed light on the source of the disease. In some cases an examination of the home or workplace is undertaken. If the dermatitis is mild, responds well to treatment, and does not recur, ordinarily the investigation is at an end. More difficult cases require patch testing to identify the specific allergen.

Two methods of patch testing are currently used. The most widely used method, the Finn chamber method, employs a multiwell aluminum patch. Each well is filled with a small amount of the allergen being tested and the patch is taped to normal skin on the patient's upper back. After 48 hours the patch is removed and an initial reading is taken. A second reading is made a few days later. The second method of patch testing involves applying a small amount of the test substance directly to normal skin and covering it with a dressing that keeps air out and keeps the test

substance in (occlusive dressing). After 48 hours the dressing is taken off to see if a reaction has occurred. Identifying the allergen may require repeated testing, can take weeks or months, and is not always successful. Moreover, patch testing works only with ACD, though it is considered an essential step in ruling out ICD.

Treatment

Herbal therapy

Herbal remedies have been used for centuries to treat skin disorders, including contact dermatitis. An experienced herbalist or naturopathic doctor can recommend the remedies that will be most effective for a person's condition. Among the herbs often recommended are:

- Burdock (*Arctium lappa*). Burdock is taken internally as a tea or tincture.
- Calendula (*Calendula officinalis*). Calendula is a natural antiseptic and anti-inflammatory agent. It is applied topically in a lotion, ointment, or oil to the affected area.
- Aloe (*Aloe barbadensis*). Aloes soothes skin irritations. Its gel is applied topically to the affected area.

Poison ivy, poison oak, and poison sumac are common culprits in cases of allergic contact dermatitis. Following exposure to these plants, the development of the characteristic rash may be prevented by washing the area with soap and water within 15 minutes of exposure. The leaves of jewelweed (*Impatiens* spp.), which often grows near poison ivy, may neutralize the poison ivy allergen if rubbed on the skin right after contact. Several topical herbal remedies may help relieve the itching associated with allergic contact dermatitis, including the juice of **plantain** leaves (*Plantago major*); a paste made of equal parts of green clay and **goldenseal** root (*Hydrastis canadensis*); a paste made of salt, water, clay, and **peppermint** (*Mentha piperita*) oil; and calamine lotion.

Homeopathy

A homeopath treating a patient with contact dermatitis will do a thorough investigation of the individual's history and exposures before prescribing a remedy. Common homeopathic remedies include:

- Rhus toxicodendron
- Croton tiglium
- ledum
- anacardium
- graphites
- sulfur

Allopathic treatment

The best treatment for contact dermatitis is to identify the allergen or irritating substance and avoid further contact with it. If the culprit is, for instance, a cosmetic, avoidance is a simple matter, but in some situations, such as an allergy to an essential workplace chemical for which no substitute can be found, avoidance may be impossible or force the sufferer to find new work or make other drastic changes in his or her life. Barrier creams and such protective clothing as gloves, masks, and long-sleeved shirts are ways of coping with contact dermatitis when avoidance is impossible, though they are not always effective.

For the symptoms themselves, treatments in mild cases include cool compresses and nonprescription lotions and ointments. When the symptoms are severe, corticosteroids applied to the skin or taken orally are used. Contact dermatitis that leads to a bacterial skin infection is treated with antibiotics.

Expected results

If the offending substance is promptly identified and avoided, the chances of a quick and complete recovery are excellent. Otherwise, symptom management—not cure—is the best that medical treatment can offer. For some people, contact dermatitis becomes a chronic and disabling condition that can have a profound effect on employability and quality of life.

Prevention

Avoidance of known or suspected allergens or irritating substances is the best prevention. If avoidance is difficult, barrier creams and protective clothing can be tried. Skin that comes in contact with an offending substance should be thoroughly washed, the sooner the better.

Copper

Description

Copper is an essential mineral that plays an important role in **iron** absorption and transport. It is considered a trace mineral because it is needed in very small amounts. Only 70 to 80 mg of copper are found in the body of a normal healthy person. Even though the body needs very little copper, it is an important nutrient that has many vital physiological functions.

Copper is essential for normal development of the body because it functions in the following ways:

- Participates in a wide variety of important enzymatic reactions in the body.
- Is a component of or a cofactor for approximately 50 different enzymes. These enzymes need copper to function properly.
- Is essential for iron absorption and transport. Iron is needed to make hemoglobin, a main component of red blood cells. Therefore, copper deficiency is often linked to iron-deficiency anemia.
- Is required to build elastin and collagen, which are important components of bones and connective tissues. Therefore, copper is believed to protect the bones and joints against degeneration and osteoporosis.
- Is required for melanin production. People with copper deficiency may have pale skin and hair.
- Is a key mineral for the immune system. Copper promotes wound healing. Studies show that premature infants or children with genetic copper defects are at high risk of getting infections and significantly improve with copper supplementation.
- Attacks free radicals. A strong antioxidant, copper works by attaching itself to the enzyme superoxide dismutase (SOD). Copper also binds to a protein to form ceruloplasmin, which is an antioxidant.
- Helps the body produce energy. Copper participates in many oxidative reactions that break down fats in fat tissue to produce much needed energy. Copper deficiency has been associated with high cholesterol levels.
- Is necessary for normal functioning of insulin. Copper deficiency is also associated with poor blood glucose control.
- Is needed for normal functioning of the cardiovascular system.
- Protects the structure and function of the nervous system, including the brain. Copper protects nerve fiber by maintaining myelin, the insulating sheath that surrounds nerve cells. It also aids the transmission of nerve signals in the brains.

Adequate intake of copper

Age	mcg/day
Children 0-6 mos.	200 (AI)
Children 7-12 mos.	220
Children 1-3 yrs.	340
Children 4-8 yrs.	440
Children 9-13 yrs.	700
Children 14-18 yrs.	890
Adults ≥ 19 yrs.	900
Pregnant women	1,000
Breastfeeding women	1,300

Foods that contain copper	mcg
Beef, liver, 3 oz.	1,240
Oysters, cooked, 6 med.	374
Chocolate, semisweet, 1 cup	176
Mushrooms, shiitake, cooked, 1 cup	130
Cashews, dry roasted, 1 oz.	70
Peas, black-eyed, cooked, 1/2 cup	70
Soybeans, boiled, 1 cup	70
Beans, white, canned, 1 cup	60
Sunflower seeds, 1/4 cup	59
Chickpeas, cooked, 1 cup	57
Baked beans, with pork, 1 cup	54
Lentils, cooked, 1 cup	50
V-8 juice, canned, 1 cup	48
Potato skin, baked, 1	47
Raisins, seedless, 1 cup	46
Salmon, baked, 3 oz.	30

AI = Adequate Intake
mcg = microgram

(Illustration by GGS Information Services. Cengage Learning, Gale)

General use

Copper supplements may be beneficial in treating or preventing copper deficiency. Copper deficiency

used to be relatively rare because the body requires so little of it, only about 2 mg per day. In addition, it is available naturally in a variety of foods such as whole grains, shellfish, nuts, beans, and leafy vegetables. Additional sources of copper are the copper water pipes that run through homes or the copper cookware in the kitchen. These sources leach copper into the water we drink and the food we eat. The level of copper in drinking water is sometimes so high that it becomes a public concern. However, scientists now realize that copper deficiency, especially borderline cases, is more common than once thought. Copper deficiency is currently on the rise due to a decrease of whole foods in the diet and high consumption of fatty and processed foods.

Studies have showed that vegetarian **diets** generally contain more copper than diets of omnivores but that the absorption efficiency is lower for lacto-ovo vegetarians than for nonvegetarians. Since vegetarians ingest more copper, however, the lower efficiency is not a problem in the diet of vegetarians.

Besides dietary causes, certain diseases or conditions may reduce copper absorption, transport, or increase its requirements, resulting in abnormally low copper blood levels. Increased copper intake through diet or supplementation may be necessary in the following conditions:

- premature infants fed only cow's milk
- pregnant women
- malnutrition
- celiac disease, sprue, cystic fibrosis, or short-bowel syndrome (these diseases cause poor absorption of dietary copper)
- kidney disease
- high consumption of zinc or iron (these minerals interfere with copper absorption)
- highly processed foods (copper is stripped away during food processing)
- Menkes syndrome (copper deficiency caused by genetic defects of copper transport). Menkes syndrome patients cannot efficiently use copper supplied by the diet.

Symptoms of copper deficiency include:

- anemia
- malnourished infants
- prominently dilated veins
- pale hair or skin
- poorly formed bones
- nervous system disorders
- high cholesterol levels
- heart disease
- loss of taste
- increased susceptibility to infections
- infertility
- birth defects

Exceeding the daily requirement of copper is dangerous, however, because copper toxicity tends to occur. Copper toxicity is a very serious medical problem. Acute toxicity due to ingestion of too much supplement, for example, may cause **nausea**, **vomiting**, abdominal **pain**, **diarrhea**, **dizziness**, **headache**, and a metallic taste in the mouth. Chronic toxicity is often caused by genetic defects of copper metabolism, such as Wilson's disease. In this disease, copper is not eliminated properly and accumulates to toxic levels. Copper is, therefore, present at high concentration where it should not be, such as in the liver, the lens of the eye, kidneys, and brain.

Disease prevention

Copper is a good antioxidant. It works together with an antioxidant enzyme, superoxide dismutase (SOD), to protect cell membranes from being destroyed by free radicals. Free radicals are any molecules that are missing one electron. Because this is an unbalanced and unstable state, a radical acts in such a way as to complete its electron pair. Therefore, it reacts with any nearby molecules to either steal an electron or give away the unpaired electron. In the process, free radicals initiate chain reactions that destroy cell structures. Like other **antioxidants**, copper scavenges or reacts with these highly reactive radicals and changes them into inactive, less harmful forms. Therefore, it can help prevent **cancer**. In 2001, a study reported that concentrations of copper sulfate and ascorbate may inhibit **breast cancer** growth. With further study, the combination may even prove useful as a chemotherapy agent for certain breast cancer patients.

Copper may also help prevent degenerative diseases or conditions such as premature **aging**, **heart disease**, autoimmune diseases, arthritis, **cataracts**, **Alzheimer's disease**, or diabetes.

Osteoporosis

Copper may play a role in preventing **osteoporosis**. **Calcium** and **vitamin D** have long been considered the mainstay of osteoporosis treatment and prevention. However, one study has shown that they can be even more effective in increasing bone density and preventing osteoporosis if they are used in

combination with copper and two other trace minerals, **zinc** and **manganese**.

Rheumatoid arthritis

Copper has been a folklore remedy for **rheumatoid arthritis** since 1500 B.C. in ancient Egypt. Some people believe that wearing jewelry made of copper may relieve arthritic symptoms. Some researchers have attempted to verify the use of copper bracelets as a treatment for rheumatoid arthritis, but without success. Most studies show no effect at all, and the few that do were so poorly designed as to be of little use.

Preparations

Copper is contained in many multivitamin/mineral preparations. It is also available as a single ingredient in the form of tablets. These tablets should be swallowed whole with a cup of water, preferably with meals, to avoid stomach upset. A person may choose any of the following preparations: copper gluconate, copper sulfate, or copper citrate. However, copper gluconate may be the least irritating to the stomach.

Zinc and copper compete with each other for absorption in the gastrointestinal tract. As a result, excessive copper intake may cause zinc deficiency and vice versa. Therefore, a person should take zinc and copper supplements together in ratios of 10:1 or 15:1.

Precautions

Individuals who add copper supplements to their diets should consider the following precautions:

- Informing their doctors in order to gain proper instruction and monitoring of side effects. Copper toxicity due to excessive doses of copper supplements has been reported.
- Considering that recommended daily allowance (RDA) for copper varies with age and sex. It ranges from about 200 mcg/day for infants under the age of one year to 900 mcg/day for adult males and females. The RDA for pregnant and lactating women is 1,000 mcg/day and 1,300 mcg/day, respectively. Nausea and vomiting may occur in persons taking more than 20 mg of copper daily.
- It is not known if copper supplementation may harm a fetus. However, as with any drugs, pregnant or nursing women should not take copper or any other supplements or drugs without first consulting their doctors.
- In certain areas, drinking water may contain high levels of copper. Periodic checks of copper levels in drinking water may be necessary.

KEY TERMS

Antioxidants—Nutrients that deactivate reactive molecules (free radicals) and prevent harmful chain reactions.

Lacto-ovo vegetarian—People who do not eat meat, but do consume dairy products and eggs.

Minerals—Chemical elements that are found in plants and animals and are essential for life. There are two types of minerals: major minerals, which the body requires in large amounts, and trace elements, which the body needs only in minute amounts.

- Because individual antioxidants often work together to defend the body against free radicals, the balance among copper, zinc, and iron must be maintained. Excessive intake of one nutrient might result in a deficiency of other minerals and decreased resistance to infections and increased risk of heart disease, diabetes, arthritis, and other diseases.

Side effects

A person should stop taking copper supplements and seek medical help immediately if any of the following signs or symptoms occurs:

- anemia
- nausea
- vomiting
- abdominal pain

Interactions

Factors that increase copper concentrations

Certain disorders have been known to increase copper levels. Persons with these conditions should not take copper supplements as they may cause copper toxicity.

- recent heart attacks
- lupus erythematosus
- cirrhosis of the liver
- schizophrenia
- leukemia and some other forms of cancer
- viral infections
- ulcerative colitis (This inflammatory bowel disease may cause accumulation of copper in the body. Excessive amount of copper may worsen many

symptoms of this disease by increasing susceptibility to infections and inhibiting wound healing.)

- Wilson's disease (This disease causes accumulation of copper in the tissues. As a result, patients have liver disease, mental retardation, tremor, and poor muscle coordination. They also have copper deposits in the cornea of the eye. To manage this disease, patients are put on a low-copper diet and given penicillamine, a drug that attaches itself to copper and increases its excretion.)

Coptis

Description

Coptis is the underground stem (rhizome) or root of the plant *Coptis chinensis*. It is used in **traditional Chinese medicine** as a stomachic (a medication to improve digestive functions) and an antiseptic. Other related species are also called coptis and used in similar ways in other parts of the world. *Coptis anemonaefolia* is used in Japan. *Coptis trifolia* is used in North America, and *Coptis teeta* grows in India and is used in **Ayurvedic medicine**.

Coptis is used in traditional Chinese medicine as a stomachic (a medication to improve digestive functions) and an antiseptic. *(© Ross Frid / Alamy)*

Coptis is a low, creeping perennial evergreen that grows in damp boggy spots in woods. The plant produces a mass of thread-like golden rhizomes that are used in healing. *C. chinensis* is native to the cooler parts of Asia and is extensively cultivated in Szechwan province in China. *C. trifolia* is native to eastern North America as far south as the mountains of Tennessee. Other names for the various species of coptis used in healing include goldthread, Chinese goldthread mouth root, cankerroot, yellowroot, coptidis, mishmi bitter, and chonlin. The Chinese name for *C. chinensis* is *huang lian*.

General use

Coptis, or *huang lian*, has a long history of use in China. In traditional Chinese medicine (TCM), coptis is used to treat conditions associated with excess dampness and excess heat, such as **insomnia** and irritability. Heat in TCM means excessive activity, not high temperature, although the diseased part of the body could be red or inflamed. Coptis is said to have a cold nature and a bitter taste. In TCM, coptis is considered one of the 50 fundamental herbs. It is associated with the heart, liver, stomach, and large intestine.

More specifically, coptis is used to treat such gastrointestinal problems as **diarrhea**, **vomiting**, and bacterial dysentery. It is also used to treat chronic gall bladder inflammations. Other gastrointestinal

KEY TERMS

Berberine—A white or yellow water-soluble alkaloid with antibacterial properties. Coptis, goldenseal, and barberry are all plants that contain berberine.

Hemostatic—A type of medication that is given to stop bleeding.

Rhizome—A rootlike underground plant stem that typically produces new shoots from its upper surface and new roots from the lower one. Coptis rhizomes are the parts of the plant most commonly used for medicinal purposes.

Stomachic—A type of medication that is given to tonify the stomach or improve digestive functions.

Tincture—An alcohol-based extract prepared by soaking plant parts.

conditions treated with coptis include abdominal cramps, acid reflux (**heartburn**), ineffective or painful bowel movements, and bloody stools. Coptis is effective as a hemostatic, which means that it can be used to stop bleeding.

Chinese herbalists also use preparations made from coptis to relieve high **fever** and delirium. These preparations can be used as a gargle to relieve sore throats. Externally coptis can be used as a mouthwash to treat all kinds of mouth sores, including **canker sores**, tongue ulcers, and swollen gums. As an eyewash it is used for **conjunctivitis** (pink eye). On the skin it is used topically to treat **acne**, **boils**, carbuncles, **burns**, and infected **cuts**.

C. triflora is used in North America in some similar ways. In an interesting parallel, some Native American tribes used their native species of coptis as a wash for eye and mouth problems in much the same way as the Chinese. It was also used as a gargle for sore throats. Although it is not as popular in North America as in China, modern North American herbalists use coptis to treat **indigestion**. It is also used externally as a douche to treat vaginal **infections**. The herb is used in similar ways in India.

Modern scientific research supports many of the traditional uses of coptis. All species of this herb contain the compound berberine, which is a white or yellow water-soluble alkaloid. Berberine is known to have strong antibiotic effects. In test tube studies, berberine was shown to inhibit the growth of streptococcal bacteria responsible for some forms of **pneumonia**. This antibacterial activity supports the use of coptis to treat skin, mouth, eye, and vaginal infections.

Berberine also is known to stimulate the production of saliva, gastric juice, pancreatic juice, and bile, suggesting that there is a chemical basis for the traditional use of coptis in treating gastrointestinal disorders. Berberine is also found in such other healing plants as **goldenseal**, **barberry**, and Oregon grape. Preliminary test tube studies of berberine suggest that it may also be effective against **fungal infections**, some viruses, and certain intestinal parasites. The high level of interest in berberine in the research community means that more studies of coptis may soon be available.

Preparations

The rhizomes and roots of coptis are harvested in the autumn and are used either dried or fresh. The herb is available powdered or as a tincture. The dosage varies according to the condition being treated. The actions of coptis are similar to the actions of goldenseal (*Hydrastis canadensis*), and it is sometimes substituted for goldenseal in herbal remedies.

In Chinese herbalism, coptis is rarely used alone, but can be found as an ingredient in many formulas. These include hoelen and polyphorus, leonoris and achyranthes, tang gui and **gardenia**, and at least half a dozen other formulas.

Precautions

Berberine is known to cause contractions of the uterus in laboratory animals. For this reason, it is recommended that pregnant women not take coptis or any other herb containing berberine.

Side effects

No unwanted side effects have been reported when coptis is used in the amounts recommended by herbalists.

Interactions

Coptis is has been used for thousands of years in China in conjunction with other herbs with no reported interactions. Since coptis is used most extensively in Asian medicine, there are no studies of its interactions with Western pharmaceuticals.

Cordyceps

Description

Cordyceps sinensis, also called Chinese caterpillar fungus, Cs-4, *Dong Chong Xia Caoor*, or *semitake*, is a fungus native to the Tibetan plateau in China. The fungus is parasitic and grows in the moth caterpillar. Spores enter the host, germinate, and ultimately kill the larva. Although species of cordyceps are seen in Europe and the Americas, only the Chinese form has been used medically.

KEY TERMS

Fungus—A plant that lacks both leaves and flowers, and lives on decaying matter. The fungi may be single-celled or grow quite large. The group of fungi includes molds, yeasts, smuts, and mushrooms.

Lupus nephritis—Kidney damage associated with Systemic lupus erythematosis, an autoimmune disease. The kidney damage is gradual, but leads to complete kidney failure.

Parasitic—Behaving like a parasite; an organism that lives on, with, or in another organism. It draws its energy from the host, without providing any benefit to the host.

Standardized—To cause to conform to a standard. In medicine and pharmacy, this means that a given weight of an herb will contain a standardized percentage or weight of the active principle.

General use

Cordyceps has a long history of use in Chinese medicine. Its traditional roles have been restorative; improving the quality of life, and increasing energy and longevity.

Traditional uses of the thousand year "rejuvenation" herb include the following:

- impotence treatment
- increase fertility
- stimulate immune system
- improve resistance to bacteria
- increase resistance to viruses
- relieve fatigue
- vitality tonic for mind and body, especially in aging men

While most of the cordyceps research has been conducted in China, published studies in Europe and elsewhere indicate that the fungus may have many potentially useful properties. A Korean study of a related species of cordyceps indicates that it has components that may inhibit coagulation, making it potentially beneficial in **stroke** and **heart attack** prevention. A hot water extract of the fungus appeared to stimulate the immune system. This immune modulation effect is seen in other studies, which have reported that cordyceps may be useful in treating **Hepatitis** B. A study from Thailand reported that *Cordyceps nipponica* may have value in the treatment of **malaria**. Additional studies have indicated its possible benefit in preventing a recurrence of Lupus nephritis. However, another study that looked at herbs used as performance enhancers (to improve **exercise** and athletic performance), was unable to validate cordyceps' value for this purpose.

Another review concluded that cordyceps may be promising as a possible aid for **fatigue**, **stress**, heart health, lung function, and toxin exposure.

Cordyceps has physiological properties and benefits if used over time as a tonic, but taking it for a specific disease or problem remains an area needing further human studies and research. The traditional use of cordyceps was as an ongoing daily tonic, beginning in mid-life.

Preparations

Cordyceps capsules are available in varying strengths (400 mg, 450 mg, 615 mg, and 800 mg). The liquid preparation is sold in 1 gram per 1.5 ml strength.

Precautions

Cordyceps appears to be an exceptionally safe product with no established toxic dose. In 1996, there

were two reports of cordyceps products contaminated with lead, but this does not appear to be an ongoing problem.

There is a risk of allergic reaction to either the fungus or other ingredients in the formulation.

Formulations of cordyceps are not standardized. Products are labeled in terms of the quantity of dried fungus contained, but there is no way to determine the amount of active components in any product. Because of this, activity may vary between brands and between individual samples from the same company.

Side effects

Side effects appear to be mild. Patients have reported stomach upset, **dry mouth**, and **nausea**.

Interactions

At this time, the only established interaction is due to the anticoagulant effects of the fungus, which may increase the risk of bleeding in patients taking warfarin (commonly known by the brand name Coumadin) or other anticoagulant drugs.

Because of the many different activities that have been attributed to cordyceps, it seems likely that other drug interactions will be reported in the future.

Corns and calluses

Definition

A corn is an overgrowth of skin on a bony prominence, usually occurring on the feet and toes. It manifests as a rough and painful bump. A callus is a rough, thickened lump of dead skin that is usually painless. It may be found on the feet, the hands, or anywhere else there is repeated friction and pressure.

Description

Corns and calluses affect about 5% of the population of the United States. Women have corns more often than men, probably due to wearing ill-fitted shoes more often. Although calluses may form anywhere on the body, they are generally found on the heels and balls of the feet, the knees, and the palms of the hands. Calluses are usually larger than corns—they may measure more than an inch (2.5 cm) wide. Calluses usually only hurt if pressure is applied to them.

Causes and symptoms

Corns and calluses form to prevent injury to skin that is repeatedly pinched, rubbed, or irritated. Hereditary calluses may develop where there is no apparent friction. This condition runs in families and occurs most often in children.

The most common causes of the formation of corns and calluses are:

- shoes that have very high heels and shoes that do not fit properly
- tight socks or stockings
- deformities of the toes
- walking or standing on a hard surface for an extended time
- jobs or hobbies that cause steady or recurring pressure on the same spot

Corns may be extremely sore and surrounded by inflamed, swollen skin. A sharp **pain** will probably occur whenever downward pressure is applied, and a dull ache may be felt at other times.

KEY TERMS

Bursitis—An inflammation of the tissue sac, called a bursa, which surrounds and helps lubricate the joints.

Orthopedist—A specialist who is concerned with the bones, muscles, and joints and their points of interaction.

Pumice stone—A volcanic rock that can be used to remove overgrowths and smooth the skin.

Wart—A small, fleshy skin growth caused by a virus.

Diagnosis

Corns can be recognized on sight. They are sometimes mistaken for **warts**. However, if the lesion is a wart, it will bleed when scraped with a sharp implement. A callus will not bleed, but will shed a layer of dead skin. This can provide the basis of a general diagnosis.

Treatment

Standing and walking correctly can sometimes eliminate excess foot pressure and minimize the development and recurrence of corns and calluses. Bodywork systems such as **Aston-Patterning**, the **Feldenkrais** method, and **rolfing**, may help to correct body imbalances that lead to corns and calluses.

Two or three daily applications of **calendula** (*Calendula officinalis*) salve can soften skin and prevent inflammation. A mixture of one teaspoon of lemon juice, one teaspoon of dried **chamomile** (*Martricaria recutita*), and one crushed **garlic** clove (*Allium sativa*) can be applied directly to dissolve thickened skin.

A recommended Ayurvedic remedy is the nightly application of a paste made by combining one teaspoon of **aloe** vera gel with one half teaspoon of **turmeric** (*Curcuma longa*). The corn or callus should be covered with the paste and bandaged overnight. It should be soaked in warm water for 10 minutes every morning, and given a daily massage with mustard oil (*Brassica cruciferae*).

Allopathic treatment

The attention of a physician may be required if there is numbness, reduced feeling, or severe pain. Occasionally, an orthopedist may have to perform surgery to correct toe deformities or remove bits of bone that may be causing corns or calluses to develop. Medical attention is not usually required unless **diabetes mellitus**, poor circulation, or other problems make self-care difficult. The first step in home care of corns and calluses is to identify and eliminate sources of pressure and friction. Doughnut-shaped pads, wads of cotton, lamb's wool, or other kinds of inserts can be used to cushion affected areas. Soaking the feet in a solution of Epsom salts, or using hydrocortisone creams, petroleum jelly, or lanolin lotions can soften calluses. After which, they can be reduced or removed by rubbing the area with a pumice stone. This is not recommended for corns, however, as rubbing just makes them more painful.

It is important to consult with a healthcare provider if there is broken skin because it may become infected. In the case of an infection, affected layers of skin need to be removed, and pus may need to be drained. Oral antibiotics may be given to eliminate the infection. Cortisone may be injected into the affected area to decrease pain or inflammation.

Expected results

Most corns and calluses disappear within three weeks after the pressure that caused them is eliminated. However, if the causes of the condition are not remedied completely, or are allowed to recur, the corns and calluses may return. If there is continual pain associated with corns, it can change the way a person stands or walks. Such changes may eventually cause pain and dysfunction in the ankles, back, hips, or knees.

If a corn develops near a toe joint, **bursitis** may result, causing severe pain and inflammation. If cracks or other breaks in the skin develop, a staph infection may result. This is especially serious for people who have diabetes or poor circulation, as **gangrene** may develop from a resistant infection.

Prevention

Corns and calluses can usually be prevented by wearing shoes that fit properly. Feet should be measured, while standing, whenever buying new shoes. It is best to shop for shoes late in the day, when feet are likely to be swollen. It is also important to buy shoes with toe-wiggling room and to try new shoes on both feet. Pointy-toed shoes and high heels should be avoided. Worn down or uneven shoe soles and heels should be replaced or repaired. Corrective footwear or special insoles may be necessary. Socks and stockings should also be fitted appropriately at the feet. Gloves, kneepads, and other protective gear should be worn as needed to prevent rubbing and friction, especially

when engaging in heavy work or sports activities. Cutting or paring dead skin should be avoided, as it may lead to further injury or infection.

Patience Paradox

Cornsilk

Description

Cornsilk (*Zea mays*) is an herbal remedy made from stigmas, the yellowish thread-like strands found inside the husks of corn. The stigmas are found on the female flower of corn, a grain that is also known as maize and is a member of the grass family (Gramineae or Poaceae). The stigmas measure 4–8 in (10–20 cm) long and are collected for medicinal use before the plant is pollinated. Cornsilk can also be removed from corn cobs for use as a remedy.

If fertilized, the stigmas dry and become brown. Then yellow corn kernels develop. Corn is native to North America and now grows around the world in warm climates.

Cornsilk is also known as mother's hair, Indian corn, maize jagnog, Turkish corn, yu mi xu, and stigmata maydis.

General use

Some historians believe that corn has grown for more than 7,000 years in North America. About the time that Christopher Columbus brought the first corn to Europe, the grain grew throughout North and South America. The venerable plant's stigmas have long been used in folk medicine to treat urinary conditions including inflammation of the bladder and painful urination.

Cornsilk also served as a remedy for heart trouble, **jaundice**, **malaria**, and **obesity**. Cornsilk is rich in **vitamin K**, making it useful in controlling bleeding during **childbirth**. It has also been used to treat **gonorrhea**.

Cornsilk. *(Emilio Ereza / Alamy)*

For more than a century, cornsilk has been a remedy for urinary conditions such as acute and inflamed bladders and painful urination. It was also used to treat the prostate. Some of those uses have continued into modern times; cornsilk is a contemporary remedy for all conditions of the urinary passage.

Drinking cornsilk tea is a remedy to help children stop wetting their beds, a condition known as enuresis. It is also a remedy for urinary conditions experienced by the elderly.

Cornsilk is used to treat urinary tract **infections** and **kidney stones** in adults. Cornsilk is regarded as a soothing diuretic and useful for irritation in the urinary system. This gives it added importance, since today, physicians are more concerned about the increased use of antibiotics to treat infections, especially in children. Eventually, overuse can lead to drug-resistant bacteria. Also, these drugs can cause complications in children.

Furthermore, cornsilk is used in combination with other herbs to treat conditions such as cystitis (inflammation of the urinary bladder), urethritis (inflammation of the urethra), and parostitis (**mumps**).

Cornsilk is said to prevent and remedy infections of the bladder and kidney. The tea is also believed to diminish prostate inflammation and the accompanying **pain** when urinating.

Since cornsilk is used as a kidney remedy and in the regulation of fluids, the herb is believed to be helpful in treating high blood pressure and water retention. Cornsilk is also used as a remedy for **edema** (the abnormal accumulation of fluids).

Cornsilk is used to treat urinary conditions in countries including the United Sates, China, Haiti, Turkey, and Trinidad. Furthermore, in China, cornsilk as a component in an herbal formula is used to treat diabetes.

In addition, cornsilk has some nonmedical uses. Cornsilk is an ingredient in cosmetic face powder. The herb used for centuries to treat urinary conditions acquired another modern-day use. Cornsilk is among the ingredients in a product advertised to help people pass their drug tests.

Preparations

Some herbalists say that cornsilk is best used when fresh, but it is also available in dried form. Cornsilk can be collected from the female flower or from corn cobs. In addition, cornsilk is available commercially in powdered and capsule form and as an extract. Cornsilk is usually brewed as a tea, a beverage that is said to be soothing.

Cornsilk tea or infusion can be made by pouring 1 cup (240 ml) of boiling water over 2 tsp (2.5 g) of dried cornsilk. The mixture is covered and steeped for 10–15 minutes. The tea should be consumed three times daily.

In addition, a tincture of 1 tsp (3-6 ml) of cornsilk can be taken three times daily. Tincture can be purchased over the counter, or made at home by mixing the herb with water or alcohol at a ratio of 1:5 or 1:10.

Cornsilk is also available in capsule form. The usual dosage for 400-mg capsules is two capsules. These are taken with meals three times daily.

A remedy for bedwetting

Herbal remedies can be part of the treatment when children wet their beds. Methods of stopping this behavior include having the child **exercise** during the day, drink fewer beverages in the evening, and drink a cup of cornsilk tea one hour before bedtime. Cornsilk could be the only ingredient in the tea. However, cornsilk can be part of an herbal combination if **bedwetting** is caused by lack of nervous control of the bladder.

Cornsilk combinations

Cornsilk combines well with other herbs to remedy a range of urinary conditions. One remedy for a bed-wetting tea is to combine one part of cornsilk, **St. John's wort**, **horsetail**, **wild oat**, and **lemon balm**.

An herbal practitioner can recommend other combination remedies to treat more complicated conditions. For example, when a person has cystitis, cornsilk can be combined with **yarrow**, **buchu**, couchgrass, or bearberry.

Furthermore, cornsilk may be an ingredient in a commercial remedy taken to maintain the urinary tract system. Other ingredients could include yarrow and **marsh mallow**.

Precautions

Cornsilk is safe when taken in proper dosages, according to sources including *PDR (Physician's Desk Reference) for Herbal Medicines*, the 1998 book based on the findings of Germany's Commission E. The commission published its findings about herbal remedies in a 1997 monograph.

Before beginning herbal treatment, people should consult a physician, practitioner, or herbalist. Herbs like cornsilk are not regulated by the U.S. Food and Drug Administration (FDA), a process that involves research and testing.

If a person decides to collect fresh cornsilk, attention should be paid to whether the plants were sprayed with pesticides.

Side effects

There are no known side effects when cornsilk is taken in designated therapeutic dosages.

Interactions

Information is not available about whether there is an interaction when cornsilk is taken with medication. People taking medications should first check with their doctor or health practitioner before using cornsilk.

Cornus

Description

Cornus (*Cornus officinalis*) is a tree of the dogwood family used in Chinese medicine. Its Chinese name is *shan zhu yu*. Cornus grows to a height of 30 ft (10 m) in the woodland regions of East Asia from China to Korea. The fruit is used in healing. It is harvested when ripe, then dried for future use. The small fruits can also be eaten as food, either raw or cooked. They contain about 8.6% sugar and have a slightly astringent taste. The bark from the stem is also used as an anti-malarial tonic.

Chinese cornus should not be confused with the North American tree *Cornus florida*, better known as dogwood or American boxwood. Dogwood and Chinese cornus are in the same plant family but have somewhat different healing properties. The bark of *Cornus florida* is used in Western herbal healing.

General use

Cornus has been used in China for more than 2,000 years. In the Chinese system of health, yin aspects must be kept in balance with yang aspects. Ill health occurs when the energies and elements of the body are out of balance or in disharmony. Health is restored by taking herbs and treatments that restore this balance.

Cornus is strongly associated with the kidneys, the reproductive system, and, to a lesser extent, the liver. It is made into a slightly warm yin tonic and classified as having a sour taste. In Chinese medicine sour herbs are believed to help control body fluids and conditions such as bed-wetting, excessive sweating, heavy or prolonged **menstruation**, and premature ejaculation.

Cornus is rarely used alone. It is an ingredient in many herbal formulas where it is used to stabilize and bind. It has astringent properties that are thought to boost the power of other herbs. Cornus can be combined with both yin and yang herbs to remedy deficiencies in either area because it conserves *jing*, the essence of life. In Chinese medicine jing, when referring to a man, means sperm. The ability to conserve jing is a result of the stabilizing and binding properties and the ability to control body fluids.

Although the results are not completely clear, some studies have shown that the fruit of cornus has antibacterial and antifungal properties. In some studies extracts of the fruit inhibited the growth of some **strains** of *Staphylococcus* bacteria. It may also be effective against *Salmonella* and *Shigella*, both bacteria that cause gastrointestinal disturbances. Chinese researchers also claim that cornus reduces the blood sugar level in animals, enhances immune system response, and increases sperm motility. Few scientific studies have been done on this herb outside of China.

Cornus fruit is also used in formulas that strengthen the back and knees, both areas associated with kidney jing. It is also used in formulas that control body fluids and treat excessive sweating, urine leakage, sperm leakage (spermatorrhea), and heavy, prolonged menstruation. Cornus is also an ingredient in formulas that treat ringing of the ears (**tinnitus**), poor hearing, **dizziness**, extreme shock, and a wide range of other conditions. The bark is boiled, and the resulting astringent decoction is used in formulas that treat fevers and as an anti-malarial. Interestingly, in **Western herbalism** the bark of dogwood, cornus's cousin, is also used against **malaria**. Cornus is also used to treat diabetes, arthritis, and **impotence**.

Preparations

Both cornus fruit and bark usually are prepared as a decoction that can be added to other tonics and healing formulas. They can also be prepared as a tincture. The dosage varies depending on the formula.

Some formulas that contain cornus include:

- eight immortal long life pill
- phellodendron
- supreme creation
- Buddha's yang
- dragon jing
- endocrine health
- essence restorative

KEY TERMS

Decoction—Decoctions are made by boiling an herb, then straining the solid material out. The resulting liquid is the decoction.

Tincture—An alcohol-based extract prepared by soaking plant parts.

Yang—Yang aspects are qualities such as warmth, activity, light, and activity.

Yin—Yin aspects are the opposite of yang aspects and are represented by qualities such as cold, stillness, darkness, and passiveness.

Precautions

People experiencing painful or difficult urination should not use cornus.

Side effects

Since cornus is rarely used alone, it is difficult to separate any side effects it may cause from those caused by other herbs in the formula. No side effects specifically attributable to cornus have been reported.

Interactions

Cornus is has been used for thousands of years in conjunction with other herbs with no reported interactions. Since cornus is used almost exclusively in Chinese medicine, there are no studies of its interactions with Western pharmaceuticals, although it should not be used while taking a diuretic since cornus is an antidiuretic.

Coronary thrombosis *see* **Heart attack**

Corydalis

Description

Corydalis is the name of a group of herbs used in different parts of the world to relieve **pain**. *Corydalis yanhusuo* is a species used primarily in Chinese herbal medicine. *C. gariana*, native to the Himalayas, is used medicinally in India. A related species, *Corydalis cava*, is used in European herbalism. Another closely related species, is *Corydalis canadensis* (also called *Dicentra canadensis*) and known by the common name corydalis or turkey corn, is found in North America. There are other species of *Corydalis* found throughout the world. Although the names are somewhat confusing, many are used by herbal therapists in similar ways and are included under the umbrella label corydalis.

C. yanhusuo is a small herb that grows in mixed sun and shade at the edge of woodlands. It is native to Siberia, northern China, and Japan, but is cultivated in other cool parts of China. *C. yanhusuo* grows to about 8 in (20 cm) in height and has narrow leaves and pink flowers. The rhizome (underground stem) is used in healing. *C. yanhusuo* is called *yan hu suo* in Chinese. Some sources suggest that *C. yanhusuo* is used interchangeably with the related species *C. solida*, which is called by the same Chinese name.

C. cava is a perennial that grows in shady forests. It is native to southern Europe and has spread throughout the continent. *C. cava* grows to a height of about 11 in (30 cm). Its flowers range in color from red to yellowish to white, with occasional lilac, brownish-red, or dark blue flowers. The tubers (knobby, fleshy underground stems) are used medicinally. Alternative names for the North American species of corydalis include turkey corn, squirrel corn, and early fumitory.

KEY TERMS

Corydaline—An alkaloid derived from corydalis that has some effectiveness as a pain reliever.

Decoction—A liquid made by simmering an herb in water and then straining it.

Diuretic—A substance or medication that increases the production of urine.

Qi—In traditional Chinese medicine, the vital life force or energy that permeates the body.

Tincture—An alcohol-based extract prepared by soaking plant parts.

General use

In **traditional Chinese medicine** (TCM), *C. yanhusuo* is said to have a warm nature and a pungent, bitter taste. It is associated with the heart, liver, and spleen. *C. yanhusuo* is used to relieve pain resulting from almost any cause. It is especially used to treat menstrual cramps, chest pains, and abdominal pain. Corydalis is also the preferred herb in treating pain from traumatic injuries. Some herbalists report that frying corydalis in vinegar enhances its ability to ease pain.

Along with its ability to relieve pain, *C. yanhusuo* is used as a general aid to blood circulation and to promote the circulation of *qi*, or vital energy. Some Chinese herbalists also report using corydalis as a sedative and to lower blood pressure. The herb is frequently found in combination with other plants in Chinese formulas that treat stabbing pain sensations, painful periods, and the like.

In Western medicine, the various corydalis species are used to treat shaking and involuntary tremors. They can be used to treat people with **Parkinson's disease**. Corydalis is also used as a painkiller; a diuretic; a sedative that slows the pulse and depresses the central nervous system; and a tonic that invigorates the circulation. Occasionally it is used to treat mild forms of **depression**. In fact, the uses of the various corydalis species are surprisingly similar around the world.

Research scientists have isolated several potent alkaloid compounds from corydalis. The strongest of these is corydaline. It has the ability to block certain receptors in the brain associated with the sensation of pain. There is good evidence from Chinese studies that corydalis is effective in relieving pain and menstrual cramps. Evidence for the other uses of corydalis is limited to test tube and animal studies. One 1999 study at the University of Maryland Dental School found that an extract of *C. yanhusuo* was successful in reducing artificially induced inflammation in the paws of rats, although it was less successful than some other TCM herbs that were tested.

Preparations

Corydalis tubers and rhizomes are dug either in the spring or fall, before or after the leaves are actively growing. They are dried and kept in a cool place before use. Corydalis can be made into a tea, a tincture, or a decoction. Commercial extracts are also available.

Corydalis is usually combined with other herbs. One popular treatment for menstrual pain is a decoction of corydalis and cinnamon. In traditional Chinese medicine, corydalis is found in almost all formulas to treat menstrual pain, other pain formulas, and formulas to improve the circulation.

Precautions

Chinese herbalists report that pregnant women should not take corydalis. Since corydalis contains a compound that depresses the central nervous system, it should be used cautiously when using other central nervous system depressant drugs or alcohol. This herb should be taken under the supervision of a trained herbalist.

Side effects

Although no poisonings from corydalis have been reported, overdose is likely to produce shaking and tremors.

Interactions

Some Western herbalists report that corydalis is incompatible with tannic acid and vegetable astringents. Corydalis has been used in many Asian formulas without any reported interactions. Few, if any, scientific studies have been done on its interactions with Western pharmaceuticals.

Cotton root bark

Description

Cotton root and the cotton plant are known as *Gossypium herbaceum*. Cotton is a member of the mallow or Malvaceae family. The cotton plant is an evergreen shrub that is native to Asia and Africa. It is also grown in the southern United States, Egypt, and countries along the Mediterranean Sea. The plant was cultivated to produce cotton fiber for clothing. Cotton root bark, the inner bark, and cotton seeds are all used as herbal remedies. While the seeds also served as a food, cotton root bark has been known for centuries as a "female medicine."

The herbal remedy is known as cotton root bark, *Gossypium herbaceum*, and cotton.

General use

Gossypium is the Latin word for cotton-producing plant, and this evergreen shrub has been cultivated for thousands of years in India. That form of cultivation was brought to China and Egypt in approximately 500 B.C. Europeans brought cotton cultivation to the New World in 1774.

Traditional uses

While *Gossypium herbaceum* was grown to produce cotton fiber, other parts of the plant served as medical remedies and food products. Cotton root bark was used as a folk remedy for numerous female conditions ranging from nonmenstrual bleeding from the uterus to inducing labor contractions. While it was used to make **childbirth** easier, cotton root bark was also taken as an abortifacient (to induce miscarriages).

Cotton root bark was not just a woman's remedy. Chewing on the roots was said to stimulate the sexual organs, giving cotton root the reputation of being an aphrodisiac. The root also had uses not related to reproduction. Cotton was also a remedy for conditions including snake bite, dysentery, and **fever**. Furthermore, cotton seed was once a food product and a remedy. A seed oil emulsion was given as an intravenous treatment for people with nutritional deficiencies.

Some of cotton root bark's remedial uses came to North America with the Africans enslaved by Europeans. Women used cotton bark root to stimulate menstrual flow and for help with difficulties during childbirth. Cotton had a different use when slave owners raped women; they drank cotton root tea to induce abortions.

KEY TERMS

Abortifacient—A drug or substance that induces an abortion.

Aphrodisiac—A drug or other agent that is reputed to arouse sexual desire.

Gossypol—A chemical found in cotton seed oil that is thought to immobilize sperm.

Contemporary uses

Contemporary uses of cotton root bark cover nearly every aspect of the female reproductive system. Generally, a tea made from this herb is consumed to produce a normal menstrual cycle. Numerous other uses are listed in such sources as the *PDR (Physician's Desk Reference) for Herbal Medicines*, the 1998 book based on the findings of Germany's Commission E. The European group's findings about herbal remedies were published in a 1997 monograph.

Cotton root bark is used as an aid during childbirth and as a remedy for the absence of **menstruation**, irregular menstruation, and painful menstruation. Pregnant women take cotton root bark to increase uterine contractions, to expel the afterbirth, and to help with the secretion of milk. Cotton root bark is also taken for difficulties experienced during **menopause**.

Furthermore, cotton root bark is currently used as a male contraceptive in China because it is said to immobilize the sperm. Cotton root bark supposedly blocks production of sperm without affecting a man's potency. In June 2000, clinical trials were underway regarding this use of cotton root bark.

In addition, cotton root bark still has a reputation as an aphrodisiac. Evidence of this property of the herb, however, is anecdotal. No clinical research or studies have proven that cotton root bark stimulates or increases sexual desire.

In addition to the medicinal uses of cotton root, oil from cotton seed is currently used in soap and in the production of margarine, shortening, cooking oil, and salad oil.

Preparations

While cotton root bark was taken as a tea in folk medicine, other forms of the herb are used in contemporary alternative medicine. Cotton root bark is currently used as a liquid extract or a tincture. The dosage

for both the tincture and liquid extract is 0.5–1 tsp (2–4 ml) of either solution. This amount can be divided into two daily doses; a single dose consists of 20–40 drops (0.25–0.5 tsp). The extract or tincture can be added to a small amount of water.

Cotton root bark can be combined with **goldenseal** (*Hydrastis canadensis*) in herbal preparations.

Precautions

Cotton root bark has varied uses, and opinions are varied about whether this remedy is safe to use. According to the *PDR for Herbal Medicines*, cotton root bark is safe when taken in therapeutic doses. Other herbalists state that no part of *Gossypium herbaceum* should be taken internally without first consulting with a doctor or health practitioner. This precaution is particularly important for pregnant women. Although cotton root bark is a remedy for conditions related to childbirth, manufacturers of herbal products advise women to seek medical advice before using it.

Although health risks have not been reported, poisonings have occurred when animals ate cottonseed cakes over a long period of time. Some of those cases were fatal.

In addition, gossypol is a chemical found in cottonseed oil that is believed to immobilize sperm. Men who cook with this oil may find themselves temporarily infertile.

Side effects

Cotton root bark has not been identified as producing side effects.

Interactions

There are no identified interactions associated with taking cotton root bark.

Cough

Definition

A cough is a forceful release of air from the lungs that can be heard. Coughing protects the respiratory system by clearing it of irritants and secretions.

Description

While people can generally cough at will, a cough is usually a reflex triggered when an irritant stimulates one or more of the cough receptors found at different points in the respiratory system. These receptors then send a message to the cough center in the brain, which in turn tells the body to cough. A cough begins with a deep breath in, at which point the opening between the vocal cords at the upper part of the larynx (glottis) shuts, trapping the air in the lungs. As the diaphragm and other muscles involved in breathing press against the lungs, the glottis suddenly opens, producing an explosive outflow of air at speeds greater than 100 mi (160 km) per hour.

In normal situations, most people cough once or twice an hour during the day to clear the airway of irritants. However, when the level of irritants in the air is high or when the respiratory system becomes infected, coughing may become frequent and prolonged. It may interfere with **exercise** or sleep, and it may also cause distress if accompanied by **dizziness**, chest **pain**, or breathlessness. In the majority of cases, frequent coughing lasts one to two weeks and tapers off as the irritant or infection subsides. If a cough lasts more than three weeks, it is considered a chronic cough, and physicians will try to determine a cause beyond an acute infection or irritant.

Coughs are generally described as either dry or productive. A dry cough does not bring up a mixture of mucus, irritants, and other substances from the lungs (sputum), while a productive cough does. In the case of a bacterial infection, the sputum brought up in a productive cough may be greenish, gray, or brown. In the case of an allergy or viral infection it

KEY TERMS

Antitussives—Drugs used to suppress coughing.

Expectorant—Drug used to thin mucus.

Gastroesophageal reflux—Condition in which stomach acid backs up into the esophagus.

Glottis—The opening between the vocal cords at the upper part of the larynx.

Larynx—A part of the respiratory tract between the pharynx and the trachea, having walls of cartilage and muscle, and containing the vocal cords.

Sputum—The mixture of mucus, irritants, and other substances expelled from the lungs by coughing.

may be clear or white. In the most serious conditions, the sputum may contain blood.

Causes and symptoms

In the majority of cases, coughs are caused by respiratory **infections**, including:

- colds or influenza, the most common causes of coughs
- bronchitis, an inflammation of the mucous membranes of the bronchial tubes
- croup, a viral inflammation of the larynx, windpipe, and bronchial passages that produces a bark-like cough in children
- whooping cough, a bacterial infection accompanied by the high-pitched cough for which it is named
- pneumonia, a potentially serious bacterial infection that produces discolored or bloody mucus
- tuberculosis, another serious bacterial infection that produces bloody sputum
- fungal infections, such as aspergillosis, histoplasmosis, and cryptococcoses

Environmental pollutants, such as cigarette smoke, dust, or smog, can also cause a cough. In the case of cigarette smokers, the nicotine present in the smoke paralyzes the hairs (cilia) that regularly flush mucus from the respiratory system. The mucus then builds up, forcing the body to removed it by coughing. Post-nasal drip, the irritating trickle of mucus from the nasal passages into the throat caused by **allergies** or sinusitis, can also result in a cough. Some chronic conditions, such as **asthma**, chronic **bronchitis**, **emphysema**, and cystic fibrosis, are characterized in part by a cough. A condition in which stomach acid backs up into the esophagus (gastroesophageal reflux) can cause coughing, especially when a person is lying down. A cough can also be a side effect of medications that are administered via an inhaler. It can also be a side effect of beta-blockers and ACE inhibitors, which are drugs used for treating high blood pressure.

Diagnosis

To determine the cause of a cough, a physician should take an exact medical history and perform an exam. Information regarding the duration of the cough, what other symptoms may accompany it, and what environmental factors may influence it aid the doctor in his or her diagnosis. The appearance of the sputum will also help determine what type of infection, if any, may be involved. The doctor may even observe the sputum microscopically for the presence of bacteria and white blood cells. Chest x rays may help indicate the presence and extent of such infections as **pneumonia** or **tuberculosis**. If these actions are not enough to determine the cause of the cough, a bronchoscopy or laryngoscopy may be ordered. These tests use slender tubular instruments to inspect the interior of the bronchi and larynx.

Treatment

Coughs due to bacterial or viral upper respiratory infections may be effectively treated with complementary therapies. The choice of remedy will vary and be specific to the type of cough the patient has. Lingering coughs or coughing up blood should be treated by a trained practitioner.

Nutrition & diet

Many health practitioners advise increasing fluid intake and breathing in warm, humidified air as ways of loosening chest congestion. Avoiding mucous-producing foods can be effective in healing a cough condition. These mucous-producing foods can vary, based on individual intolerance, but dairy products are a major mucous-producing food for most people. Other foods to avoid are sugar and foods high in **sodium**. Others recommend hot tea flavored with honey as a temporary home remedy for coughs caused by colds or flu.

Various vitamins may be helpful in preventing or treating conditions (including colds and flu) that lead to coughs. They include **vitamin C**, **vitamin E**, **zinc**, **vitamin A**, and **folic acid**.

Herbal medicine

There are many Western herbs, as well as herbs used in **traditional Chinese medicine** (TCM), that

soothe the throat, quiet coughs, and act as expectorants. Some include:

- marsh mallow
- licorice
- aniseed
- fritillaria
- loquat

Homeopathic remedies

Depending on the type of cough and its duration, several homeopathic remedies include:

- Aconite for dry coughs with fever
- Antimonium tartaricum for productive coughs
- Bryonia for intense, dry coughs accompanied by thirst
- Drosera for violent coughing
- Rumex crispus for tickling coughs

Allopathic treatment

Treatment of a cough generally involves addressing the condition causing it. An acute infection such as pneumonia may require antibiotics, an asthma-induced cough may be treated with the use of bronchodialators, or an antihistamine may be administered in the case of an allergy. Cough medicines may be given if the patient cannot rest because of the cough or if the cough is not productive, as is the case with most coughs associated with colds or flu. The two types of drugs used to treat coughs are antitussives and expectorants.

Expected results

Because the majority of coughs are related to the **common cold** or **influenza**, most will end in 7-21 days. The outcome of coughs due to a more serious underlying disease depends on the pathology of that disease.

Prevention

It is important to identify and treat the underlying disease and origin of the cough. Avoid **smoking** and coming in direct contact with people experiencing cold or flu symptoms. Wash hands frequently during episodes of upper-respiratory illnesses.

Cradle cap

Definition

Cradle cap is a form of seborrheic **dermatitis**, a minor inflammatory disease of the scalp, face, and occasionally other areas of the body. It is a common scalp problem in infants and younger children.

Description

Cradle cap appears as thick, oily yellowish or brownish patches on the skin, particularly the scalp. It is also often found around the eyebrows, around the nose, behind the ears, and in the genital area. The skin itself often appears to be red, flaky, and irritated underneath the oily patches. It most often affects children who are between two weeks and two years old. Although cradle cap may be unsightly, it is usually not harmful to the child.

Causes and symptoms

During infancy and early childhood, the glands that produce sweat and oil are in a highly reactive state. Cradle cap is most likely due to a buildup of sweat and oil produced by these overactive glands. This buildup may also cause an irritation of the skin. Sometimes an overgrowth of the yeast called *Pityrosporum ovale* may also contribute to the condition. Occasionally, cradle cap is a symptom of more serious problems.

Newborn infant suffering from cradle cap, a form of seborrheic dermatitis, an itchy, flaky rash. *(Ian Boddy / Photo Researchers, Inc.)*

Diagnosis

Cradle cap is easily recognizable, and usually it requires no further diagnosis. However, if the rash seems to be very itchy or irritating, it may be necessary to rule out **eczema**. If there are additional symptoms, a healthcare provider should be consulted for a physical exam and possible testing.

Treatment

Most remedies for cradle cap can be applied directly to the oily patches on the skin. Tannins, for example, can help to slow down oil production, as well as clear away the cradle cap. Warm caffeinated tea, German **chamomile** tea (*Matricaria recutita*), burdock tea (*Arctium lappa*), or diluted **witch hazel** extract (*Hamamelis virginiana,*) can be rubbed into the skin with a cloth several times per day.

A **comfrey** rinse can also be used. It should be rubbed onto the affected area with a washcloth. The rinse can be used after shampooing or bathing, or it can be applied to dry skin. This treatment can be given nightly for up to ten days until the symptoms are gone. The comfrey rinse can be made by boiling two ounces (about 57 grams) of comfrey root, *Symphytum officinale,* in one quart (or one liter) of water. The tea should be simmered for 20 minutes and then allowed to cool. A batch of the comfrey rinse can be used and stored in the refrigerator for up to four days.

A rule of thumb in science is that like dissolves like; therefore, any type of food grade oil can be used to dissolve the oily buildup found in cradle cap. Olive oil, **wheat germ** oil, and **sesame oil** are particularly favored. **Aromatherapy** may be used by adding in 1-2 drops of the essential oil of **lavender**, *Lavandula angustifolia*. The oil should be applied to the skin and left overnight. It can then be removed gently and slowly with a baby brush or a fine-tooth comb. The area should be washed or shampooed afterwards with a very mild soap.

Slippery elm (*Ulmus fulva*) is useful in soothing a variety of skin problems, and can be applied to affected areas several times per day. The herb can also be misted liberally with water or used as a tea. Ointments containing *Calendula officinalis* or **plantain** (*Plantago major*) are also appropriate to use on areas of cradle cap. These herbs can often clear up an outbreak in as little as four days.

Internal remedies for cradle cap can be quite effective. These include tincture of **burdock root**, which can help to balance oil and sweat production. Burdock is also a good general tonic to take to keep the skin healthy. Burdock should be given for at least three weeks for full effect. A tincture of the wild pansy flower, *Viola tricolor,* can also be given. **Biotin**, a B vitamin, works well for cradle cap and can be given at dosages of 10 micrograms (mcg) for age 0-6 months; 15 mcg for age 6-12 months, and 20 mcg for age one to three years.

Allopathic treatment

Generally, cradle cap does not need to be treated medically. If the condition is resistant to treatment or it starts spreading, however, an over-the-counter **dandruff** shampoo may be used once per day until the cradle cap has improved. Shampoos containing coal tar derivatives may be highly irritating and are not recommended for use on children under two.

A 0.5% or 1% hydrocortisone cream is available over-the-counter and can be applied two or three times per day to stubborn cases of cradle cap. If a *Pityrosporum ovale* infection is suspected, a dermatologist may prescribe ketoconazole (Nizoral) cream or shampoo.

These medications are strong and should be used for as short a time as possible.

If crusting, pus, redness, or **pain** are present, a physician should be consulted. There may be an underlying infection caused by the infant's scratching, which can introduce bacteria into the skin. Antibiotics may have to be prescribed. Other symptoms, such as poor growth or **diarrhea** may point to immune system problems requiring medical assessment and treatment.

Expected results

Usually cradle cap will eventually resolve with no aftereffects, even without treatment. However, it can take quite some time to clear. Most home remedies should clear up cradle cap in a few weeks or months.

Prevention

Washing the hair more often than two or three times per week may dry the skin out, making it more vulnerable to cradle cap, so limited hair washing is recommended.

Patience Paradox

Cramp bark

Description

Cramp bark (*Viburnum opulus*) is a deciduous tree or shrub that is native to Europe and the eastern United States. It is a member of the Caprifoliaceae family. It is also cultivated for use as an ornamental tree or shrub. Other names for cramp bark include guelder rose, snowball tree, king's crown, high **cranberry**, rose **elder**, water elder, Whitsun rose, May rose, dog rowan tree, Whitsun bosses, silver bells, and gaiter berries.

Dried cramp bark of the Viburnum opulus plant can be used to relieve menstrual, muscle and stomach cramps. *(Geoff Kidd / Photo Researchers, Inc.)*

Cramp bark grows in low grounds, woodlands, thickets, and hedges. This large shrub grows 5-10 ft (1.5-3 m) tall. The flowers, which appear in spring and summer, are large (3-5 in [8-13 cm] across), flat-topped clusters of snow-white florets. The inner florets are very small, complete flowers while the florets along the outer edge of the cluster are large and showy but cannot produce fruit. The fruits, which appear in August, are drooping clusters of bright red oval shiny, translucent berries. Cramp bark berries are edible, but have a very bitter taste. The leaves of cramp bark are lobed and turn a rich purple color in the fall. The bark is grayish-brown, faintly cracked lengthwise, and has scattered brown-colored **warts**. The bark has a strong odor and a bitter, astringent taste.

Constituents and bioactivities

Cramp bark contains a wide variety of biologically active compounds. The constituents of cramp

bark are very similar to those of a close relative called **black haw** (*Viburnum prunifolium*). Cramp bark and black haw may be used interchangeably under certain conditions but should not be considered interchangeable in the strict sense. The constituents of cramp bark include:

- acid compounds (acetic, baldrianic, capric, chlorogenic, cinnamic, citric, malic, ursolic, and valerianic)
- amyrins (alpha-amyrin and beta-amyrin)
- astragalin
- beta-sitosterol
- coumarins (scopoletin and scopoline)
- elements (aluminum, calcium, chromium, cobalt, iron, magnesium, manganese, phosphorus, potassium, selenium, silicon, sodium, tin, and zinc)
- esculetin
- glucosides (viburnine)
- glycosides (quercetin)
- hydroquinones (arbutin, methylarbutin, and free hydroquinone)
- myricyl alcohol
- paeoniside
- pectin
- protein
- resin
- tannins (catechin and epicatechin)
- viopudial

Cramp bark has antispasmodic (relieves **muscle spasms**), anti-inflammatory (relieves inflammation), nervine (calms and soothes the nerves), hypotensive (lowers blood pressure), astringent (causes local contraction), emmenagogic (induces **menstruation**), and sedative (reduces activity and excitement) properties. The berries of cramp bark have antiscorbutic (effective against scurvy) properties due to their **vitamin C** content.

General use

Historically, the Native American Meskwaki people used cramp bark to treat cramps and pains located anywhere in the body, whereas the Penobscot people used cramp bark to treat **mumps** and swollen glands. Cramp bark was named for its primary medicinal use—to relieve **muscle cramps** and other conditions caused by muscle overcontraction.

Cramp bark is presently used to relieve any overly tense muscle or muscle spasm of the body. This includes the muscles of the uterus, air passages, intestines, arms, legs, and back. In addition, it can be used to prevent muscle tension and **pain**. Cramp bark is also used to treat symptoms that are associated with excess muscle tension, including menstrual pain (**dysmenorrhea**) caused by uterine muscle contractions, and breathing difficulties associated with **asthma**. **Colic**, spastic **constipation**, **irritable bowel syndrome**, and the physical indications of nervous tension are also treated with cramp bark.

Cramp bark has also been used to treat hysteria, nervous complaints, debility, convulsions, fits, lockjaw, heart palpitation, tension headaches, spasmodic stricture (narrowing of a passage), bladder muscle spasms, high blood pressure, rheumatism, circulatory problems, and **heart disease**. It is effective in treating cases of arthritis in which joint pain and weakness have led to severe muscle contractions. Cramp bark relaxes the muscles, allowing improvement in blood circulation that can return normal function to the arthritic joints.

Cramp bark is used to treat excessive blood loss during menstruation and **menopause**, and to induce menstruation in women with light or delayed periods. A woman may treat dysmenorrhea prophylactically (before symptoms appear) by taking cramp bark the day before painful menstruation is expected. Cramp bark is also used to treat **endometriosis** and threatened miscarriage.

In addition to its medicinal uses, cramp bark has a few culinary applications. Cramp bark berries have been used to make jelly and alcoholic beverages, and they are used in certain food dishes.

KEY TERMS

Antiscorbutic—An agent that is effective against scurvy, like the vitamin C found in cramp bark.

Astringent—A substance that constricts or binds skin cells.

Emmenagogue—A substance or medication given to bring on a woman's menstrual period.

Prophylactic—Use of a treatment to prevent a disease or condition before symptoms appear.

Sedative—A substance or medication used to soothe or reduce nervous irritation or overstimulation.

Tincture—An alcoholic solution prepared from herbal medicinal agents.

Preparations

The bark of cramp bark is peeled off the tree during the spring and summer months. The bark

should be peeled off in strips carefully in order not to kill the tree. The bark is chopped up and dried. Cramp bark can be made into a decoction (a water extract), a tincture (an alcoholic extract), or a lotion. Liquid preparations of cramp bark have a reddish-brown color, a slight odor, and an astringent taste.

The decoction is prepared by adding 2 tsp of the dried bark to 1 cup water. The mixture is brought to a boil, the heat is reduced, and the decoction is simmered gently for 10–15 minutes.

Although the recommended doses of the decoction are variable, it is safe to drink up to three cups daily. The dose of decoction for menstrual pain is 0.5 cup every three hours.

Tinctures are more concentrated and act faster (within 30 minutes) than teas or decoctions. The tincture may be taken for long-term conditions caused by muscular tension such as irritable bowel syndrome. Again, the recommended doses vary somewhat, but up to 8 ml may be taken three times a day. The suggested dose of tincture for irritable bowel syndrome is 0.5 tsp in hot water twice a day. The suggested dose of tincture for menstrual cramps is 1 tsp in water three times a day.

A lotion prepared from cramp bark may be rubbed into the skin to relieve painful muscles.

To relieve cramping and back pain at night, cramp bark may be mixed with **lobelia** (*Lobelia inflata*). Cramp bark may also be used with **Mexican yam** (*Dioscorea villosa*) for ailments of the gastrointestinal and genitourinary systems.

Precautions

Some sources state that the berries of cramp bark are toxic and should not be eaten.

Side effects

Cramp bark is safe for both short- and long-term use. In 2008, there were no indications that cramp bark causes any side effects. Pregnant women and women who are lactating (breast-feeding), however, should not use any herbal medicines without first consulting a physician.

Interactions

As of 2008, there were no indications of any interactions between cramp bark and any other drug or herbal medicine.

Cranberry

Description

The cranberry plant, a familiar source of berries used in juices and relishes in the United States, has been in existence since the Iron Age. The Romans were the first to recognize its medicinal uses by the local inhabitants of what is now England. Herbalist Henry Lyte documented its healing effects in 1578. Since then, the cranberry plant has been a popular folk remedy for a variety of illnesses, including **gout**, rheumatism, **diarrhea**, **constipation**, scurvy, fevers, skin **infections** and other skin problems such as **eczema**. Cranberries are well known as a treatment for such women's health problems as cystitis, and urinary and genital infections.

Currently, there are approximately 150 species of cranberry. The best known and most popular is the American cranberry (*Vaccinium macrocarpon*), because of the size and juiciness of its fruit. It is a member of the Heath (*Ericaceae*) family. *Vaccinium macrocarpon* is a low-lying fruit plant grown commercially in North America. The shrub bears beautiful pink flowers that grow into rounded reddish-black berries. The berries are harvested early in the fall, and made into juices, jellies, or relishes. Juice made from cranberries is a popular, tart fruit drink. The United States presently produces about 98% of the world's cranberries.

Scientists have learned that the chemical composition of cranberries includes many substances that promote healing, such as:

- Proanthocyanidins and anthocyanins. These bioflavenoids make up the pigment of the leaves, and produce the color of the berries. More importantly, proanthocyanidins are responsible for cranberry's best-known medicinal effect, preventing bladder and urinary tract infections by inhibiting bacterial colonization. They may also help relieve diarrheal symptoms.
- Organic acids, including quinic, malic, and citric acids. Quinic acid is considered the most important among these organic acids. These compounds, which are responsible for the sour taste of cranberries, acidify the urine and prevent kidney stones.
- Vitamins and minerals. Cranberries are rich sources of vitamins including vitamin A, carotene, thiamine, riboflavin, niacin, and vitamin C. They also contain many essential minerals such as sodium, potassium, calcium, magnesium, phosphorus, copper, sulfur, iron, and iodide. These vitamins and minerals are strong antioxidants that enable cranberries to help protect the body against such infections as colds or influenza. Because of their high vitamin C content, cranberries were used in the past to prevent a vitamin C deficiency known as scurvy.
- Fiber. Like many other fruits, cranberries are a good source of fiber.

General use

Prevention and treatment of urinary tract infections

Urinary tract infections (UTIs) are extremely common in women, affecting one of every two females during their lifetime. Men have urinary infections as well, but less frequently than women. A woman contracts a urinary tract infection when bacteria gets into the relatively short female urethra and moves up to the bladder. Once in the bladder, the bacteria grow and spread to other parts of the urinary tract. If left untreated, UTIs can cause serious **kidney infections** that may require hospitalization. The disease is relatively easy to treat, but tends to recur.

In the United States, urinary tract infections result in more than five million medical treatment visits each year. The most frequently prescribed treatment for urinary tract infections is antibiotics. There are also simple self-protective measures that women can take against UTIs. These include:

- Drinking a lot of fluid, which increases the amount of urine produced and helps to flush out infectious microorganisms.

KEY TERMS

Antioxidants—A substance that is capable of countering the damaging effects of oxidation in the body's tissues. Ingredients in the cranberry perform antioxidant functions in the body.

Astringent—Any acidic substance that draws together and constricts tissue.

Bioflavenoids—Plant substances that have a wide range of properties, including anti-inflammatory, anti-carcinogenic, and antioxidant.

Proanthocyanidins—Bioflavenoids found in cranberries, responsible for the fruit's effectiveness in preventing urinary tract infections.

Vulvovaginal candidiasis—A yeast-like fungal infection of the vulva and vagina, which can be related to regular consumption of cranberry.

- Emptying the bladder immediately after having intercourse.
- Using oral contraceptives rather than a diaphragm, which tends to put pressure on or irritate the urethra.
- Drinking cranberry juice as a preventive measure for women. As early as the 1840s, German physicians observed that cranberry juice prevented urinary tract infections. This effect was attributed to the cranberry's high acidity.

Recent research has confirmed the effectiveness of cranberries in preventing UTIs. Two studies in the mid-1990s, one involving women 65 years or older and the other with younger women between the ages of 18 and 45, showed that cranberries are effective in preventing bladder infections. Regardless of age, women can significantly reduce their risk of urinary tract infections by consuming 10 ounces of cranberry juice daily. Scientists, however, have learned that the effectiveness of cranberry juice is not related to its acidity, as was previously believed. Researchers found that the cranberry's antibacterial properties come from its proanthocyanidins (or condensed tannins). Proanthocyanidins inhibit *chia coli* bacteria from attaching to the inside walls of the bladder, allowing them to be easily flushed out with urine before they multiply and cause infections.

A careful review of all studies involving the cranberry's role in preventing UTIs concluded that cranberry juice or concentrate is beneficial in preventing infections in women, but its benefits have not been proven in children or males. The reviewers also noted

that many women did not complete the full one-year study period.

Prevention of kidney stones

Kidney stones are most often caused by high levels of ionized **calcium** (as in calcium salts) in the urine. Cranberries can help prevent this condition because they are rich in quinic acid, which increases the acidity of the urine. As a result, the levels of ionized calcium in the urine are lowered.

A person needs to drink 16 ounces of unsweetened cranberry juice (two glasses) daily to effectively prevent kidney stones. Cranberry capsules or powdered concentrates are also available. It is important not to consume too much cranberry, because very high acidity in the urine actually increases the risk of kidney stones. A person would need to drink at least one liter of cranberry juice per day for a prolonged period of time for this to occur.

Prevention of colds and influenza

A daily glass of cranberry juice is a good source of **vitamin C** and **antioxidants**. These nutrients help support the body's immune function and prevent **cancer** as well as such common infections as colds or **influenza**.

Other uses

Cranberries may serve as a digestive aid. Because of their high acidity, they help to digest fatty foods and to increase the appetite.

Some early laboratory studies suggest that cranberries may help to prevent gingivitis (**gum disease**) and coronary (heart) disease. These studies have not yet been confirmed by clinical research in humans.

Cranberry has been a folk remedy for diarrhea. Proponents of this use suggest that the proanthocyanidins in cranberries, in addition to having antibacterial activity, also act as astringents. They cause proteins to clump together to form rigid cakes that prevent bacteria from using the proteins for food. However, the effectiveness of cranberries in the treatment of diarrhea remains unproven.

Various cranberry preparations have also been used to treat skin disorders such as **acne**, **dermatitis**, and **psoriasis**; bed-wetting; **burns** and **wounds**; and **stress** and **depression**. There is currently insufficient scientific evidence to support these uses.

A recent study suggests that cranberry juice may inhibit the formation of dental plaque by preventing bacteria from collecting (coaggregating) on the tooth film formed by proteins in the saliva. These preliminary findings await further testing.

Preparations

There are many types of cranberry preparations available, partly because cranberry products are among the top 10 best sellers in the health food market. They include:

- Cranberry juice. For prevention of urinary tract infections and kidney stones, recommended products include those containing pure cranberry juice rather than mixtures that are only 25–27% cranberry juice. Four to six ounces of unadulterated cranberry juice daily is recommended for the prevention of UTIs. Some herbalists advocate the use of cranberry for treatment of mild urinary tract infections; dosages of 10–32 oz (0.3–1 kg) daily have been used. Cranberry juice may not be effective, however, for established infections. It should be taken only as a complementary measure rather than as an alternative to antibiotics in the treatment of active UTIs. If a woman experiences such symptoms of cystitis as chills, fever, fatigue, and burning pain during urination, she should contact her doctor immediately for antibiotic treatment.
- Dried cranberry powder capsules (475–500 mg). Because most commercial cranberry juice contains high levels of sugar, these capsules may be a better alternative for diabetic patients or dieters. Each capsule equals 0.5 ounces of cranberry juice. Nine to 15 capsules daily is the recommended dosage for the prevention of urinary tract infections.
- Powdered concentrates. These forms of cranberry are available in different strengths. Women should follow the dosages recommended by manufacturers.
- Fresh or dried cranberries. Dried untreated cranberries can be found in health food stores. They can be stored up to a year. Cranberries are also available fresh or frozen in most grocery stores or supermarkets. Because of their tartness, most people may find it difficult to consume them in sufficient quantity to obtain their therapeutic benefits.
- Cranberry herbal teas. These products can be obtained from health food stores or via the Internet.

Precautions

Cranberries should be used with care or modification in patients with certain diseases, including:

- Active urinary tract infections. Cranberries should not be substituted for antibiotic treatment, but used only as a supplementary therapy.

- Irritable bowel syndrome (IBS). Large quantities of cranberry juice or capsules may cause diarrhea in IBS patients.
- Diabetes. Patients with diabetes should use sugar-free cranberry juice, or take capsules or powdered concentrates.

Side effects

The most common side effects associated with excessive cranberry consumption are diarrhea and an increased risk of developing kidney stones.

Regular cranberry consumption by women trying to prevent UTIs may result in *vulvovaginal candidiasis*. Alterations in the normal vaginal bacteria may lead to increased fungal growth.

Interactions

There are no identified drug interactions associated with cranberry consumption.

Cranial manipulation *see* **Craniosacral therapy**

Craniosacral therapy

Definition

Craniosacral therapy is a holistic healing practice that uses very light touching to balance the craniosacral system in the body, which includes the bones, nerves, fluids, and connective tissues of the cranium and spinal area.

Origins

The first written reference to the movement of the spinal nerves and its importance in life, clarity, and "bringing quiet to the heart" is found in a 4,000-year-old text from China. Craniosacral work was referred to as "the art of listening." Bone setters in the Middle Ages also sensed the subtle movements of the body. They used these movements to help reset **fractures** and dislocations and to treat headaches.

In the early 1900s, the research of Dr. William Sutherland, an American osteopathic physician, detailed the movement of the cranium and pelvis. Before his research it was believed that the cranium was a solid immovable mass. Sutherland reported that the skull is actually made up of 22 separate and movable bones that are connected by layers of tissue. He called his work cranial **osteopathy**. Nephi Cotton, an American chiropractor and contemporary of Sutherland, called this approach craniology. The graduates of these two disciplines have refined and enhanced these original approaches and renamed their work as sacro-occipital technique, cranial **movement therapy**, or craniosacral therapy.

Dr. John Upledger, an osteopathic physician, and others at the Department of Biomechanics at Michigan State University, College of Osteopathic Medicine learned of Sutherland's research and developed it further. He researched the clinical observations of various osteopathic physicians. This research provided the basis for Upledger's work which he named craniosacral therapy.

Benefits

According to Upledger, craniosacral therapy is ideally suited for **attention-deficit hyperactivity disorder**, headaches, chronic middle **ear infection**, **pain**, and general health maintenance. It is recommended for **autism**, **fibromyalgia**, **heart disease**, **osteoarthritis**, **pneumonia**, **rheumatoid arthritis**, chronic sinus **infections**, and **gastroenteritis** (inflammation of the lining of the stomach or small intestine). It is also used with other therapies to treat **chronic fatigue syndrome**, back pain, and menstrual irregularity. In addition, other craniosacral practitioners have reported benefits for eye dysfunction, **dyslexia**, **depression**, motor coordination difficulties, temporomandibular joint dysfunction (TMD), hyperactivity, **colic**, **asthma** in babies, floppy baby syndrome, whiplash, **cerebral palsy**, certain birth defects, and other central nervous system disorders.

Description

Craniosacral therapy addresses the craniosacral system. This system includes the cranium, spine, and sacrum which are connected by a continuous membrane of connective tissue deep inside the body, called the dura mater. The dura mater also encloses the brain and the central nervous system. Sutherland noticed that cerebral spinal fluid rises and falls within the compartment of the dura mata. He called this movement the primary respiratory impulse; today it is known as the craniosacral rhythm (CSR) or the cranial wave.

Craniosacral therapists can most easily feel the CSR in the body by lightly touching the base of the skull or the sacrum. During a session they feel for disturbances in the rate, amplitude, symmetry, and quality of flow of the CSR. A therapist uses very gentle touch to balance the flow of the CSR. Once the cerebrospinal fluid moves freely, the body's natural healing responses can function.

A craniosacral session generally lasts 30–90 minutes. The client remains fully clothed and lays down on a massage table while the therapist gently assesses the flow of the CSR. Upledger describes several techniques which may be used in a craniosacral therapy session. The first is energy cyst release. "This technique is a hands-on method of releasing foreign or disruptive energies from the patient's body. Energy cysts may cause the disruption of the tissues and organs were they are located." The therapist feels these cysts in the client's body and gently releases the blockage of energy.

Sutherland first wrote about a second practice called direction of energy. In this technique the therapist intends energy to pass from one of his hands, through the patient, into the other hand.

The third technique is called myofascial release. This is a manipulative form of bodywork that releases tension in the fascia or connective tissue of the body. This form of bodywork uses stronger touch.

Upledger's fourth technique is position of release. This involves following the client's body into the positions in which an injury occurred and holding it there. When the rhythm of the CSR suddenly stops the therapist knows that the trauma has been released.

The last technique is somatoemotional release. This technique was developed by Upledger and is an offshoot of craniosacral therapy. It is used to release the mind and body of the residual effects of trauma and injury that are "locked in the tissues."

The cost of a session varies due to the length of time needed and the qualifications of the therapist. The cost may be covered by insurance when the therapy is performed or prescribed by a licensed health care provider.

Precautions

This gentle approach is extremely safe in most cases. However, craniosacral therapy is not recommended in cases of acute systemic infections, recent skull fracture, intracranial hemorrhage or aneurysm, or herniation of the medulla oblongata (brain stem). Craniosacral therapy does not preclude the use of other medical approaches.

Side effects

Some people may experience mild discomfort after a treatment. This may be due to re-experiencing a trauma or injury or a previously numb area may come back to life and be more sensitive. These side effects are temporary.

Research and general acceptance

More than 40 scientific papers have been published that document the various effects of craniosacral

WILLIAM SUTHERLAND (1873–1954)

William Garner Sutherland studied osteopathy under its founder, Andrew Taylor Still. Dr. Sutherland made his own important discovery while examining the sutures of cranial bones the skull bones that protect the brain. What he noticed is that the sutures were designed for motion. Sutherland termed this motion the *Breath of Life.* Through his experi ments and research he determined that primary respiration was essential to all other physiological functions.

When Sutherland developed his techniques for cra niosacral therapy, he wanted it to serve as a vehicle for listening to the body's rhythmic motions, and treat the patterns of inertia, when those motions become congested. He believed that the stresses any physical or emotional trauma created an imbalance in the body that needed correction to restore it to full health. The therapy is a hands on method so that the therapist can feel the subtle ties of the patterns of movement and inertia. Sutherland felt that this was the way to encourage self healing and resto ration of the body's own mechanisms, taking a holistic approach to creating optimal health.

The Craniosacral Therapy Educational Trust, based on Sutherland's pioneering work is located at 10 Normington Close, Leigham Court Road, London SW16 2QS, United Kingdom. The phone number is 07000 785778.

therapy. There are also 10 authoritative textbooks on this therapy. The most notable scientific papers include Viola M. Fryman's work documenting the successful treatment of 1,250 newborn children with birth defects. Edna Lay and Stephen Blood showed the effects on TMD, and John Wood documented results with psychiatric disorders. The American Dental Association has found craniosacral therapy to be an effective adjunct to orthodontic work. However, the conventional medical community has not endorsed these techniques.

Training and certification

Craniosacral therapy is offered as part of the standard training in osteopathy, **chiropractic**, and **rolfing**. Massage therapists, nurses, dentists, physical therapists, and other health care practitioners can receive training through a series of workshops and seminars. The Upledger Institute offers two levels of national certification, involving a rigorous three part exam process of written, oral, and hands-on testing. The Milne Institute certifies practitioners through a two year training program that covers anatomy, physiology, symptomatology, psychology, **meditation** practice, and training in sensitivity, perception and intuition. Today there are around 40,000 practitioners certified to practice crainiosacral therapy.

Creatine

Definition

Creatine is a nitrogenous organic acid that occurs in vertebrates. Its molecular formula is $C_4H_9N_3O_2$.

Description

With its promises of bigger muscles and improved athletic performance, creatine has generated more interest and controversy than almost any other dietary supplement in the 2000s. It is widely used by body builders and athletes at all levels, from famous baseball sluggers to high school jocks. Even without taking supplements, all people have a small amount of this compound in their bodies. Some of it comes from

food, especially meat and fish, while the rest is made by the body from **amino acids**. No one disputes the fact that creatine plays an important role in converting food into energy. The real question is whether taking extra amounts of creatine can make muscles bigger, boost athletic performance, or improve the health of people with muscle or nerve disease.

Creatine is considered important because it can increase the amount of energy available to working muscles. The compound is used by the body to make a chemical compound called adenosine triphosphate (ATP), the immediate fuel source used by muscles during short but intense bursts of activity. Through its conversion into phosphocreatine, a related substance, creatine appears to delay muscle **fatigue** by re-supplying muscles with ATP. Because creatine can be stored for later use by cells, consuming extra amounts of the substance may create a deeper energy reserve for muscles and other tissues. Excess creatine is eliminated by the kidneys, which means that creatine supplements may be of little value to people who have sufficient levels of the compound, since the kidneys automatically remove extra amounts.

A significant amount of research was required as of 2008 to determine the long-term effects of taking creatine, proper dosage, and whether age, gender, or the presence of existing diseases can affect use of the supplements. As of 2008, a review of research on 12 proposed uses of the drug reported by the National Institutes of Health found, in all cases, inconclusive scientific evidence for the suggested application. The 12 uses were as follows:

- Congestive heart failure
- Enhanced athletic performance and endurance
- Enhanced muscle mass/strength
- GAMT (guanidinoacetate methyltransferase) deficiency
- Heart muscle protection during heart surgery
- High cholesterol
- Huntington's disease
- Hyperornithinemia
- McArdle's disease
- Muscular dystrophy
- Myocardial infarction
- Neuromuscular disorders

General use

Creatine supplements are generally used by weight lifters and athletes who wish to optimize their workouts or enhance athletic performance. It is important to distinguish fact from myth regarding the possible benefits of creatine. The scientific evidence suggests that creatine may not have much usefulness as a muscle-enhancing agent, although it does appear to moderately improve performance in exercises or sports that require short, repeated bursts of high-energy activity. For example, creatine may provide a slight energy boost to the muscles of a weight lifter during extended repetitions or a basketball player who makes yet another drive to the hoop. However, creatine does not appear to increase aerobic capacity or improve performance in endurance-type activities such as marathon running. Apart from its uses in body building and athletics, creatine may prove beneficial in the treatment of certain diseases involving the muscles or nerves.

As of 2008, more than 3,200 research studies on creatine had been conducted in the preceding three decades. Many of those studies investigated the effects of creatine on athletic performance in a wide variety of sports, including short- and long-distance running, rugby, weight-lifting, swimming, hockey, and tennis. In September 2007, the National Library for Health (NLH) conducted a study of research on the use of creatine for enhancing athletic performance. It focused first on two research reviews carried out in 2005. One study of all the research conducted since 1999 found activities involving jumping, sprinting, or cycling generally benefited from the ingestion of creatine. For other types of athletic activity, the results were contradictory. The second report covered more than 500 studies on the use of creatine for the enhancement of athletic performance. The report found that 70% of the studies reviewed reported statistically significant improvement in at least some types of athletic performance.

The NLH also reviewed four studies that had been completed in the two preceding years. It found that three of the four placebo-controlled studies found no relationship between the use of creatine supplements and improved athletic performance among ice hockey players, tennis players, sprinters, and other types of runners.

In addition to its possible use in sports, creatine has been recommended for the treatment of a number of other diseases affecting the muscles or nerves, including Huntington's disease, **Lou Gehrig's disease** (ALS, amyotrophic lateral sclerosis), and congestive heart failure. Creatine is not considered a cure for these diseases but may help to alleviate symptoms (such as muscle weakness and fatigue) or possibly extend survival. Most research reported as of 2008 suggested that patients with neuromuscular disorders tolerate creatine therapy satisfactorily, but they do not appear to benefit significantly from the therapy.

Preparations

Dosage of creatine usually consists of a loading dose of 10 to 30 g a day (divided into several doses) for four to six days, followed by a maintenance dose of 2 to 5 g a day. It is not clear if the high loading dosage is actually necessary. Smaller dosages (3 g a day) may achieve the same effects if taken for several weeks.

Even without taking supplements, most people get about 1 g of creatine from food. Some authorities believe it is safer for people to avoid creatine supplements altogether in favor of eating foods that contain creatine. The best sources of creatine are meat, poultry, and fish. Getting too much dietary creatine is not considered a significant risk because only small amounts of the substance are present in food.

Precautions

Creatine supplements are not known to be harmful when taken in recommended dosages, although some precautions should be observed. People with kidney disease should not use creatine without medical supervision. Due to lack of sufficient medical study, creatine should be used with caution in children under age 16, women who are pregnant or breast-feeding, and people with liver disease.

The long-term health risks associated with taking creatine were unknown as of 2008. Surprisingly, though, use of the supplement was increasing in the late 2000s, even among children and adolescents. Some adults have used the drug on a long-term basis without knowing the effects of long-term use.

Side effects

A slight weight gain due to water retention is probably the most common side effect. **Nausea**, cramping, dehydration, **diarrhea**, and increased blood pressure have also been reported.

To avoid possible side effects, individuals ought not to take creatine immediately before or during **exercise**.

Individuals ought to drink plenty of fluids (six to eight glasses a day) while using creatine in order to prevent dehydration.

Interactions

Taking creatine with large amounts of carbohydrates may increase its effectiveness. **Caffeine** may decrease the effects of the supplement.

The international review group Natural Standard suggests that interactions are possible between creatine and a number of drugs and herbs, including diuretics such as hydrochlorothiazide and furosemide; drugs that may damage the kidneys, such as trimethoprim and cimetidine; anti-inflammatory drugs, such as ibuprofen, cyclosporine, amikacin, gentamicin, and tobramycin; cholesterol-lowering medications, such as lovastatin; and two herbal preparations, **bitter melon** *(Momordica charantia)* and red yeast *(Monascus purpureus)*.

KEY TERMS

Amino acids—The building blocks of protein.

Meta-analysis—An analysis of previous medical studies.

Crohn's disease

Definition

Crohn's disease is a type of **inflammatory bowel disease** (IBD), resulting in swelling and dysfunction of the intestinal tract.

Description

Crohn's disease involves swelling, redness, and loss of function of the intestine, especially the small intestine. Research suggests that this inflammation is caused by an error in the immune system, which attacks the body itself instead of attacking foreign invaders, such as viruses or bacteria. The inflammation of Crohn's disease most commonly occurs in the last part of the ileum (a section of the small intestine), and often includes the large intestine (the colon). However, inflammation may also occur in other areas of the gastrointestinal tract, including the mouth, esophagus, or stomach. Crohn's disease differs from ulcerative **colitis**, the other major type of IBD, in two important ways:

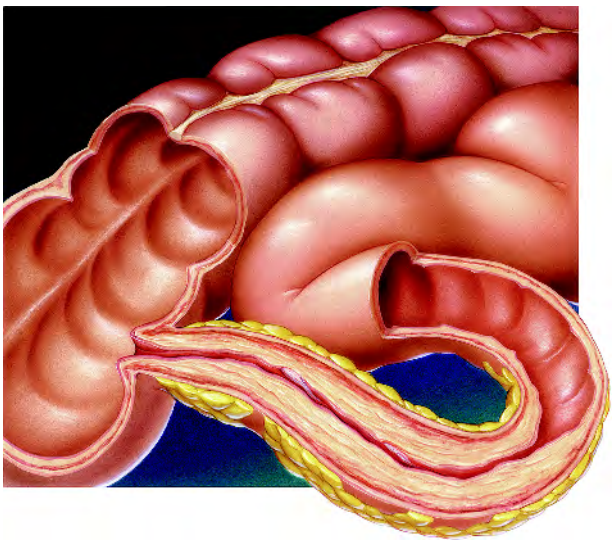
- The inflammation of Crohn's disease may be discontinuous, meaning that areas of involvement in the intestine may be separated by normal, unaffected segments of intestine. The affected areas are called regional enteritis, whereas the normal areas are called skip areas.
- The inflammation of Crohn's disease affects all the layers of the intestinal wall, while ulcerative colitis affects only the lining of the intestine.

Also, ulcerative colitis does not usually involve the small intestine; in rare cases it involves the terminal ileum (so-called backwash ileitis).

In addition to inflammation, Crohn's disease causes ulcerations, or irritated pits, in the intestinal wall. These pits occur because the inflammation has made areas of tissue shed away.

While Crohn's disease and ulcerative colitis are similar, they are also very different. Although it can be difficult to determine whether a patient has Crohn's disease or ulcerative colitis, it is important to make every effort to distinguish between these two diseases. Because the long-term complications of the diseases are different, treatment depends on careful diagnosis of the specific IBD present.

Crohn's disease may be diagnosed at any age, although most diagnoses are made between the ages of 15 to 35. About 20 to 40 people out of 10,000 suffer from this disorder, with men and women having an equal chance of being stricken. Caucasians are more frequently affected than other racial groups, and people of Jewish origin appear three to six times as likely to suffer from IBD. IBD runs in families; an IBD patient has a 20% chance of having relatives who are fellow sufferers.



Crohn's disease, inflammation of the ileum, the terminal portion of the small intestine, and characterized by abdominal pain and deep ulceration. *(Brian Evans / Photo Researchers, Inc.)*

Crohn's disease is a chronic disorder. While the symptoms can be improved, there is no known cure for the underlying disease as of the late 2000s.

Causes and symptoms

The cause of Crohn's disease is unknown. No infectious agent (virus, bacteria, or fungi) has been identified as the etiologic agent. Still, some researchers have theorized that some type of infection may have originally been responsible for triggering the immune system, resulting in the continuing and out-of-control cycle of inflammation that occurs in Crohn's disease. Other evidence for a disorder of the immune system includes the high incidence of other immune disorders that may occur along with Crohn's disease.

The first symptoms of Crohn's disease may include **diarrhea**, **fever**, abdominal **pain**, inability to eat, weight loss, and **fatigue**. Some patients experience severe pain that mimics appendicitis. It is rare, however, for patients to notice blood in their bowel movements. Because Crohn's disease severely limits the ability of the affected intestine to absorb the nutrients from food, a patient with Crohn's disease can have

signs of malnutrition, depending on the amount of intestine affected and the duration of the disease.

The combination of severe inflammation, ulceration, and scarring that occurs in Crohn's disease can result in serious complications, including obstruction, **abscess** formation, and fistula formation.

An obstruction is a blockage in the intestine. This obstruction prevents the intestinal contents from passing beyond the point of the blockage. The intestinal contents back up, resulting in **constipation**, **vomiting**, and intense pain. Although rare in Crohn's disease (because of the increased thickness of the intestinal wall due to swelling and scarring), a severe bowel obstruction can result in an intestinal wall perforation (a hole in the intestine). Such a hole in the intestinal wall allows the intestinal contents, usually containing bacteria, to enter the abdomen. This complication can result in a severe, life-threatening infection.

Abscess formation is the development of a walled-off pocket of infection. A patient with an abscess has bouts of fever, increased abdominal pain, and, in some cases, a lump or mass that can be felt through the wall of the abdomen.

Fistula formation is the formation of abnormal channels between tissues. These channels may connect one area of the intestine to another neighboring section of intestine. Fistulas may join an area of the intestine to the vagina or bladder, or they may drain an area of the intestine through the skin. Abscesses and fistulas commonly affect the area around the anus and rectum (the very last portions of the colon where waste leaves the body). These abnormal connections allow bacteria that normally live in the intestine to enter other areas of the body, causing potentially serious **infections**.

Patients suffering from Crohn's disease also have a significant chance of experiencing other disorders. Some of these may relate specifically to the intestinal disease, and others appear to have some relationship to the imbalanced immune system. The faulty absorption state of the bowel can result in **gallstones** and **kidney stones**. Inflamed areas in the abdomen may press on the tube that drains urine from the kidney to the bladder (the urethra). Urethra compression can cause urine to back up into the kidney, enlarge the urethra and kidney, and can potentially lead to kidney damage. Patients with Crohn's disease also frequently suffer from the following:

- arthritis (inflammation of the joints)
- spondylitis (inflammation of the vertebrae, the bones of the spine)
- ulcers of the mouth and skin
- painful, red bumps on the skin
- inflammation of several eye areas
- inflammation of the liver, gallbladder, and/or the channels (ducts) that carry bile between and within the liver, gallbladder, and intestine

The chance of developing **cancer** of the intestine is greater than normal among patients with Crohn's disease, although this chance is not as high as among those patients with ulcerative colitis.

Diagnosis

Diagnosis is first based upon a patient's symptoms. Blood tests may reveal an increase in certain types of white blood cells, an indication that some type of inflammation or infection is occurring in the body. Blood tests may also reveal **anemia** and other signs of malnutrition due to malabsorption (low blood protein; variations in the amount of **calcium**, **potassium**, and **magnesium** present in the blood; and changes in certain markers of liver function). Stool samples may be examined to make sure that no infectious agent is causing the diarrhea, and to see if the waste contains blood.

A colonoscopy may be performed to view the interior of the colon. During colonoscopy, a doctor passes a flexible tube with a tiny, fiber-optic camera device (an endoscope) through the rectum and into the colon. The doctor can then carefully examine the lining of the intestine for signs of inflammation and ulceration that might suggest Crohn's disease. A tissue sample (biopsy) of the intestine can also be taken through the endoscope to examine under a microscope for evidence of Crohn's disease.

Both an upper and lower GI (gastrointestinal) x-ray series can be helpful in determining how much of the intestine is involved in the disease. In the upper GI (also called a small bowel series), the patient drinks a chalky solution consisting of a salt of barium, which acts as a contrast agent to illuminate the gastrointestinal tract on x-ray film. After the barium is ingested, x rays are taken at specific time intervals as the barium passes through the stomach and into and through the small intestine. The lower GI series provides an x-ray study of the large intestine. The patient is given an enema containing a barium salt, and in some cases, air is also pumped into the rectum to provide a clearer view of the large intestine. This procedure is called a double-contrast barium enema.

Treatment

Crohn's disease is a chronic, often progressive, illness. A correct diagnosis and appropriate treatment with anti-inflammatory medications is critical to controlling the disease.

Some Crohn's patients find that certain foods are hard to digest, including milk, large quantities of fiber, and spicy foods. Dietary adjustments are usually necessary to minimize pain, diarrhea, and other symptoms.

Acupuncture and **guided imagery** may be useful tools in treating pain associated with Crohn's disease. Acupuncture involves the placement of thin needles into the skin at targeted locations on the body known as acupoints in order to harmonize the energy flow within the human body. To treat chronic pain, such as that involved with Crohn's disease, an acupuncturist frequently places the acupuncture needles along what is known as the large intestine meridian.

Guided imagery involves creating a visual mental image of one's pain in one's mind. Once the pain can be visualized, the patient can adjust the image to make it more pleasing and, thus, more manageable.

Several herbal remedies are also available to lessen pain symptoms and promote **relaxation** and healing. These include **peppermint** oil, **slippery elm** (*Ulmus rubra*), **marsh mallow** (*Althaea officinalis*), and Chinese herbs. However, Crohn's patients should consult with their healthcare professional before taking them. Depending on the preparation and the type of herb, these remedies may aggravate the digestive tract or interact with prescription drugs that are being taken to control the inflammation of Crohn's disease.

Allopathic treatment

Allopathic treatments for Crohn's disease try to reduce the underlying inflammation, the resulting malabsorption/malnutrition, the uncomfortable symptoms of cramping abdominal pain and diarrhea, and any possible complications (obstruction, abscesses, and fistulas).

Inflammation can be treated with a drug called sulfasalazine. Sulfasalazine is made up of two parts. One part is related to the sulfa antibiotics; the other part is a form of the anti-inflammatory chemical, salicylic acid. Sulfasalazine is not well-absorbed from the intestine, so it stays mostly within the intestine, where it is broken down into its components. It is believed that the salicylic acid component actively treats Crohn's disease by reducing inflammation. Some patients do not respond to sulfasalazine, particularly those with more severe disease. These patients require steroid medications (such as prednisone). Steroids, however, must be used carefully to avoid the complications of these drugs, including increased risk of infection and weakening of bones (**osteoporosis**).

In 2001, the Food and Drug Administration (FDA) approved use of budesonide capsules for mild and moderate cases of Crohn's disease involving the small and large intestines. Although a steroid, budesonide allows the drug to release into the intestines, where it can be mostly metabolized. As a result, less of the drug enters the patient's system, meaning fewer undesirable side effects may occur. Some potent immunosuppressive drugs that interfere with the products of the immune system and hopefully decrease inflammation may be used for those patients who do not improve on steroids. One addition to the various drugs used to treat Crohn's disease is natalizumab (Tysabri), originally developed and approved for the treatment of **multiple sclerosis**. The U.S. Food and Drug Administration (FDA) approved natalizumab in January 2008 for use with moderate to severe cases of Crohn's disease.

Serious cases of malabsorption/malnutrition may need to be treated by providing nutritional supplements. These supplements must be in a form that can be absorbed from the damaged, inflamed intestine. When patients are suffering from an obstruction, or during periods of time when symptoms of the disease are most acute, they may need to drink specially formulated, high-calorie liquid supplements. Those patients who are severely ill may need to receive their **nutrition** through a needle inserted intravenously.

A number of medications are available to help decrease the cramping and pain associated with Crohn's disease: loperamide, tincture of opium, and codeine. Some fiber preparations (methylcellulose or **psyllium**) may be helpful, although some patients do not tolerate them well.

The first step in treating an obstruction involves general attempts to decrease inflammation with sulfasalazine, steroids, or immunosuppressive drugs. A patient with a severe obstruction must stop taking all food and drink by mouth, allowing the bowel to rest. Abscesses and other infections require antibiotics. Surgery may be required to repair an obstruction that does not resolve on its own, to remove an abscess, or to repair a fistula. Such surgery may involve the removal of a section of the small intestine. In extremely severe cases of Crohn's disease of the colon that do not respond to treatment, a patient may need to have the entire large intestine removed (an operation called a

KEY TERMS

Abscess—A walled-off pocket of pus caused by infection.

Endoscope—A medical instrument that can be passed into an area of the body (e.g., the bladder or intestine) to allow examination of that area. The endoscope usually has a fiber-optic camera, which allows a greatly magnified image to be shown on a television screen viewed by the operator. Many endoscopes also allow the operator to retrieve a small sample (biopsy) of the area being examined.

Fistula—An abnormal channel that creates an open passageway between two structures that do not normally connect.

Gastrointestinal tract—The entire length of the digestive system, including the mouth, pharynx, esophagus, stomach, small intestine, large intestine, rectum, and anus.

Immune system—The body system responsible for producing various cells and chemicals that fight infection by viruses, bacteria, fungi, and other foreign invaders. In autoimmune disease, these cells and chemicals turn against the body itself.

Inflammation—The result of the body's attempts to fight off and wall off an area that is infected. Inflammation results in the classic signs of redness, heat, swelling, and loss of function.

Obstruction—A blockage.

Ulceration—A pitted area or break in the continuity of a surface, such as the skin or mucous membrane.

colectomy). In this case, a piece of the remaining small intestine is pulled through an opening in the abdomen. This bit of intestine is fashioned surgically to allow a special bag to be placed over it. This bag catches the body's waste, which no longer can be passed through the large intestine and out through the anus. This opening, which remains in place for life, is called an ileostomy. However, as an alternative to ileostomy, small intestines are often shaped into substitute rectal pouches, and the patient may not always need the ileostomy.

Expected results

Crohn's disease is a lifelong illness. The severity of the disease can vary, and patients can experience periods when the disease is not active and they are symptom free. However, the complications and risks of Crohn's disease tend to increase over time. Well over 60% of all patients with Crohn's disease require surgery, and about half of these patients require more than one operation over time. About 5 to 10% of all Crohn's patients die of their disease, primarily due to massive infection.

Prevention

Crohn's disease is a chronic, lifelong disorder for which there is no prevention as of 2008. Some drugs, including azathioprine (Imuran, Azasan), 6-mercaptopurine (Purinethol), and methotrexate may help keep the disease in remission, although each drug has some potentially serious side effects also.

Croup

Definition

Croup is a common ailment of early childhood involving inflammation of the larynx, trachea, bronchial tubes, and lungs. The condition is characterized by a harsh, barking **cough**, **wheezing**, and difficulty in breathing.

Description

Croup is most likely to be found in children between the ages of three months to six years. Most incidences occur during the cold weather seasons.

Spasmodic croup is usually mild and may be due to bacterial infection or **allergies**. For the most part, the child will not have a **fever**. Viral croup, also called laryngotracheobronchitis, is more severe and is often accompanied by fever. Both types follow a very similar course, which depends on the severity of the illness.

In many instances, a child may have had a cold or the flu just before the onset of croup symptoms. These symptoms tend to come on very suddenly. It is not uncommon for a child with croup to waken in the middle of the night coughing violently and gasping for breath. In fact, the croup symptoms will usually be worse at night and get better during the day.

Causes and symptoms

During the immune system response to an infection or an allergic reaction, the respiratory passages become swollen, and they are congested with mucus and fluid. They also become more and more irritated. There is a great deal of coughing, and the child may become hoarse. The airways are narrowed, and the breathing is difficult and noisy. This leads to the characteristic symptom of stridor, or noisy aspiration, as the child attempts to draw in air through narrowed passages. The constriction of these airways is usually accompanied by a high-pitched cough, often described as sounding like the bark of a seal.

Diagnosis

Diagnosis of croup is primarily based on a good history taken by the health care provider, including the physical symptoms of the illness, the presentation of the illness, and its progression. If a physical exam is performed, it will probably include listening with a stethoscope for the breathing sounds which are characteristic of croup. When the symptoms appear to be severe, or the history suggests it, x rays may be taken to rule out epiglottitis (infection of the epiglottis) or aspiration of a foreign body, which are emergency situations.

KEY TERMS

Aspiration—Accidental inhaling of an object such as food into the airway passages. This is dangerous, in that it may cause obstruction and difficulty breathing.

Corticosteroid—A hormonal drug that acts on the immune system to control inflammation and swelling.

Epiglottitis—A serious bacterial infection that can develop rapidly and lead to airway obstruction.

Epinephrine—A hormonal drug used chiefly to stimulate to the heart

Inflammation—Reaction by body tissues to infection or injury. Usually the area will be hot, red, painful, and swollen due to the immune response.

Intravenous fluids—In cases of immediate need for hydration, nourishment, or medicine, a needle with tubing is inserted directly into the vein.

Intubation—A procedure in which a flexible tube is carefully passed down the throat to keep the breathing passage open.

Stridor—A noisy wheezing sound during breathing that may indicate an airway obstruction.

Treatment

Supportive measures

Most treatment can be done at home, using relaxing and supportive measures to relieve symptoms. Steam inhalation is quite helpful in this respect. A cool-mist humidifier is recommended, as a hot vaporizer is often hazardous, especially around young children.

One of the best ways to produce a lot of moist air in a short time is to make use of the bathroom shower. The procedure is to close the bathroom door and turn on the cool water shower faucet full blast. Then the child can be a held while seated on a chair or the closed commode, breathing in steam as it fills the room. This can be done for up to 15 minutes, and often brings instant relief from congestion.

Cool air seems to relax and soothe the respiratory system. Therefore, taking a car ride with the window down will sometimes effect good results in reducing the coughing associated with croup.

There is a strong possibility of dehydration due to the illness. Increasing fluid intake as much as possible and insuring plenty of rest will enhance immune functioning, helping the body to help itself. In addition, **smoking** should be prohibited within the house.

Herbs

Respiratory herbs can be used to soothe swollen and irritated tissues, reduce inflammation, and gently loosen and expel mucus. The following herbs should be given three times per day diluted in water or other liquids until symptoms are gone:

- *Grindelia* spp., gum weed, 1-2 ml
- *Sambucus nigra,* elder flowers, 2-4 ml
- *Glycyrrhiza glabra,* licorice root, 1-3 ml
- *Verbascum thapsus,* mullein, 2-4ml
- *Astragalus senticocosus,* 2-4 ml (This herb is an immune system stimulant and should be given as a preventative for those who have chronic bouts of croup.)

Slippery elm bark can also be taken, as it is soothing to the throat.

Homeopathy

Aconite is the most favored remedy to use for croup. If it does not work, Spongia can be tried, especially if the breathing sounds as if wood were being sawed. Alternately, try Hepar sulphuris, indicated by a mucus-filled cough. Give a dosage of 12X or 30C every 30 minutes until the child is able to fall asleep.

Allopathic treatment

In most cases, croup can be easily and successfully treated at home. However, if the symptoms become severe, the child will need to be seen by a physician. Prompt medical attention is needed if:

- The child's fever goes up to 104°F (39.9°C).
- The child seems pale or bluish around the mouth or fingernails.
- The child refuses all liquids or can't swallow.
- The child is drooling a great deal.
- The child's breathing becomes increasingly rapid or difficult.

Severe cases may warrant the use of inhalants, such as epinephrine, to reduce swelling and ease the child's breathing. Inhalants have limited effectiveness over time, and care must be taken to avoid undesirable side effects. Oxygen may also be administered in more severe cases. Corticosteroids are given to decrease **pain** and swelling.

If a child is hospitalized for further observation or treatment, intravenous (IV) fluids may be given to reduce dehydration. In a few very severe cases, a tube has to be inserted through the nose or mouth (intubation) to keep the airway passage open for breathing. There is a slight risk of injury to the respiratory system during the introduction and the removal of the tube.

Expected results

Croup ordinarily lasts three to seven days. Most cases are mild and gradually improve with care. Some children have recurring bouts with croup, but they usually outgrow this by seven years of age.

It is important to monitor a child with croup throughout the night. An adult should probably consider sleeping or resting nearby. If the child is having a serious struggle with breathing, emergency services should be contacted immediately. This means either calling 911 or making a trip to the nearest emergency room. Hospital visits are necessary in about one to 15% of the reported cases of croup.

Prevention

Croup is generally the result of an infectious disease. Avoiding exposure to others with respiratory **infections** is the best way to avoid getting croup. Children should be taught to maintain good hygiene practices such as not eating food from the silverware or dishes of others and washing their hands. Care should be taken with colds and the flu so that there is no progression to symptoms of croup.

In general, an adequate intake of vitamins A and C, **bioflavonoids**, and **zinc** can help to prevent the respiratory infections and allergic reactions that lead to croup.

Patience Paradox

Crystal healing

Definition

A crystal is a mineral that is nearly transparent and colorless or has a slight color. Practitioners of crystal healing believe that crystals, particularly quartz crystals such as amethyst or clear quartz, contain energy that enhances healing of both body and mind. They believe that crystals can be "charged" with this healing energy, in a manner similar to the charging of a flashlight battery. The charged crystal can then be used to alter the energy patterns in the person receiving treatment. Some crystal healers also say that arrowheads and other stones can be used to diagnose illness.

Origins

Aboriginal, shamanistic cultures throughout the world, including Native Americans and the Inuit of northern Canada, have long believed in the healing properties of semiprecious and precious stones. These views were further developed and widely popularized during the late twentieth century by New Age healers.

Benefits

Crystal healing is used to enhance healing of a wide range of physical and mental ailments. For example, amethyst is said to be useful against **acne**, atacamite against venereal diseases, agate against ulcers, and lapis lazuli against **stroke** symptoms. Crystals may also be used to counter environmental hazards such as electromagnetic radiation, food additives, and polluted air and water. They are thought by some to minimize the detrimental effects of **caffeine**, tobacco, and alcohol. In addition, some practitioners use crystals before and after surgery to minimize trauma.

Description

Although its effectiveness is disputed, crystal healing is generally safe and inexpensive. Crystals are used in a wide variety of ways. The best results are said to occur when both the patient and the healer are holding crystals. The healer may hold a stone in one hand while using the other to touch the body part in need of healing. Crystals may also be worn as pendants (this is said to be particularly effective in treating thymus gland problems). Appropriate stones can be selected, healers say, by simply picking up various crystals and determining which ones seem to harmonize with the frequencies of the patient's body. This may be indicated by a feeling of warmth or tingling. Some healers work solely with crystals while others combine them with aura or chakra work.

KEY TERMS

Aura—A person's vital energy field; the energies are said to be seen as colors and represent states of being. Halos have been considered a type of aura.

Chakra—A theoretical rotating wheel of energy within the body, believed to cause illness when out of alignment.

Placebo effect—The tendency of an ineffective therapy to benefit a patient who believes in the healing ability of the therapy.

Preparations

Numerous techniques are used to prepare crystals before therapeutic use. One such technique is clearing, which involves using an invocation to remove negative emotional energy from the stone. Another method is cleansing, which is said to maintain the crystal's existing energy level but converts negative energy to positive. This may be accomplished by immersing the stone for a minimum of 24 hours in dry salt or saline solution. Crystals can also be charged, like a battery, by exposing them to running water, magnets, sunlight, moonlight, pyramids, fire, laser light, or living animals, birds, fish, or plants.

Some practitioners attempt to charge stones by putting them near a mother who is giving birth, or someone who is dying. Crystals have been wrapped in a newborn's placenta, then given to the child seven years later. Gem stones that have been near meteorite fragments, earthquakes, volcanoes, or trees struck by lightening are also highly valued for healing properties.

Some healers believe that healing crystals can be programmed with human thoughts. This may be done by placing a crystal against the forehead, then visualizing a desired outcome.

Precautions

Crystal healing is largely viewed as an enhancement to other therapies. It should not be used exclusively in cases of serious illness.

Side effects

There are few, if any, proven side effects to crystal healing.

Research and general acceptance

Medical professionals place little credence in crystal therapy, attributing any observed benefits to **placebo effect**. Their skepticism stems from a lack of

scientific evidence for the healing effects of crystals, and from differences of opinion among practitioners about how the therapy actually works.

Training and certification

Practitioners of crystal healing tend to be New Age spiritual healers. A number of schools in Europe and North America offer courses in crystal therapy, but the field is largely unregulated. Many individuals use crystals for self-healing.

Cupping

Definition

Cupping is a technique used in **traditional Chinese medicine** (TCM) for certain health conditions. Glass or bamboo cups are placed on the skin with suction, which is believed to influence the flow of energy and blood in the body. Cupping should not be confused with the percussive technique in **Swedish massage** called "cupping" or "clapping."

Origins

Cupping was originally called "horn therapy" in ancient China, but variations of it have been used in Turkey, Greece, France, Italy, and Eastern Europe. Cupping has a long history of use in **acupuncture** practice and has been combined with bloodletting, but it is a therapy in its own right. There are specialist cupping practitioners in Japan.

Cupping therapy on woman's back. *(© Photo Researchers, Inc. Reproduced by permission.)*

KEY TERMS

Meridian—Subtle channel in the body where qi flows.

Qi—Universal life energy present in air, food, water, sunlight, and the body.

Traditional Chinese medicine—System of healing originating in ancient China using acupuncture, herbal remedies, and other methods.

Benefits

Cupping is a safe, non-invasive, and inexpensive technique. It is used by practitioners of Chinese medicine to treat colds, lung **infections**, and problems in the internal organs. It is also used to treat muscle and joint **pain** and spasms, particularly in the back. Cupping can be used on people for whom the injection of acupuncture needles poses a problem or risk. Cupping therapy is thought to stimulate blood circulation.

Description

Practitioners of traditional Chinese medicine begin treatment by diagnosing a patient through interviews, close examinations of the pulse, tongue and other parts of the body, and other methods. TCM strives to balance and improve the flow of *qi*, or life energy, which travels throughout the body in channels called meridians. According to traditional Chinese medicine, illness is caused when qi does not move properly in the body. Acupuncturists are trained to determine where qi is stagnated, weak, or out of balance.

Acupuncturists use cupping for specific problems in the flow of qi. Cupping disperses and moves qi by exerting suction and pressure. Cupping is used when the qi is blocked at certain points, or when qi needs to be drawn to the surface of the body from deep within. For instance, cupping is used to treat lung infections and colds, because it is believed that the suction disperses and energizes the qi that has become blocked and stagnated in the lungs. Cups can also pull out "wind-cold" that in Chinese medicine is believed to cause lung infections.

Patients usually lie down for a cupping treatment. Cups are made of bamboo or strong glass. To create a vacuum, a flame from a lighter or a burning cotton ball is placed in an upside-down cup. When the oxygen in the cup is burned off, the cup is placed directly on the skin, where it is held in place by a surprisingly strong suction. Often, the skin inside the cup visibly rises. There are also cups available that use pumps instead of burning to create the proper suction. Cupping is generally a painless procedure.

Multiple cups may be used at a time to cover an area thoroughly. Cups may be left in the same place for several minutes, or removed quickly and placed elsewhere. Cups are sometimes placed over acupuncture needles that have been inserted. Moving cupping may also be performed, by first rubbing the skin with a small amount of oil to allow the cups to slide around. After cupping, patients may remain lying down for several minutes. When cups are used to treat colds and lung infections, patients are advised to wrap up in blankets to stay warm after treatment. Acupuncturists may also prescribe herbal remedies, dietary changes, and other health recommendations.

Precautions

Cupping should be performed by experienced professionals. Although it is a simple treatment, people should not attempt it on themselves. Improper glass vessels can shatter and cause injury, and cupping may cause bruising.

Side effects

Cupping causes blood to be drawn to the surface of the skin, which can cause red marks, swelling, and bruising.

Curanderismo

Definition

Curanderismo is a holistic system of Latin American folk medicine. This type of folk medicine has characteristics specific to the area where it is practiced (Guatemala, Nicaragua, Honduras, Argentina, Mexico, the southwestern region of the United States, etc.).

Curanderismo blends religious beliefs, faith, and **prayer** with the use of herbs, massage, and other traditional methods of healing. Curanderismo can be defined as a set of traditional beliefs, rituals, and practices that address the physical, spiritual, psychological, and social needs of the people who use it.

The Spanish verb *curar* means to heal. Therefore, curanderismo is translated as a system of healing. The goal of curanderismo is to create a balance between the patient and his or her environment, thereby sustaining health.

The healer who practices curanderismo is referred to as a *curandero* (male healer) or *curandera* (female healer). Healing terms vary with the language and culture of the area in which the system is practiced. For example, a female healer in Argentina is called a *remedieras*.

Origins

Curanderismo in Mexico is based on Aztec, Mayan, and Spanish influences. The ancient native cultures believed that a delicate balance existed between health, nature, and religion. Illness occurred when one of these areas was out of balance.

The use of nature's resources was very important to the native cultures. In the fifteenth century, the Huaxtepec garden was developed by the Aztec leader Montezuma I. This garden was a collection of several thousand medicinal plants. The Aztec priests used this garden to perform research on the medicinal properties of the plants.

When the Spanish conquistadors came to Mexico in the sixteenth century, they destroyed the garden and all of the priests' research because the Catholic Church considered these "sciences" to be blasphemous. Although the written knowledge was destroyed, the plant wisdom was remembered, passed down by the native peoples, and became an integral part of curanderismo.

The Spanish missionaries who were sent to the New World introduced the native peoples to the Catholic religion and European healing philosophies. Prayers to Catholic saints were soon integrated into healing rituals. Another doctrine that was passed on to the native peoples by the Europeans was their belief in witchcraft, sorcery, and other superstitions, and the philosophy that illness is often caused by supernatural forces.

As the native and Spanish cultures intermingled over the centuries, a new culture was formed, as was the folk medicine of curanderismo.

KEY TERMS

Anthropology—The study of the origin and physical, social, and cultural development and behavior of groups of people.

Benefits

Curanderismo is used to treat ailments arising from physical, psychological, spiritual, or social conditions. Illness is said to be caused by either natural or supernatural forces.

Naturally caused illness is treated with herbal medicine, massage, and prayer. Much of this illness is thought to be brought about by intense emotions caused by trauma or a specific event. Susto, for example, is an illness that is caused by fright. A startling event such as a fire, earthquake, dog attack, car accident, or death may cause the patient to become ill. Symptoms of susto are **insomnia**, **diarrhea**, extreme nervousness, sadness, **depression**, loss of appetite, loss of brilliance in the eyes, and lack of dreams. The events are thought to dislodge a person's spirit from the body.

Bilis is an ailment that is the result of excessive emotional **stress**. Bilis is caused by prolonged anger and fear. The ailment is thought to occur when excessive bile is trapped in the system and causes tension, irritability, and loss of appetite.

Empacho and **colic** are ailments treated by massage and herbs. Empacho is a blocked intestine disease where the intestines are plugged by something indigestible such as chewing gum or unbaked dough. To treat this condition, the curandera performs a massage in which she pulls on the skin of the back just above the coccyx (tailbone). When the skin makes a snapping noise the food has been loosened. Herbal tea is also given to complement the massage.

Colic is caused by excessive coldness of the stomach, and mint is used for such digestive problems.

Supernaturally caused illnesses or conditions are initiated by witchcraft, sorcery, or hexes. Physical symptoms might manifest as nervous breakdowns, paranoia, **schizophrenia**, depression, or excessive worrying. Supernatural forces can also create social problems. A person who has a streak of continued bad luck, or who suffers from marital problems, the loss of a job, or car troubles will deem the problem to be caused by a supernatural force. To heal these ailments

and remove the hex or problem, the curandera uses rituals, spiritual cleansings, herbs, and prayer.

Description

Prayer is the foundation of curanderismo. Curanderas have strong religious faith and believe that they were given the ability to heal as a gift from God. Curanderas pray to spirits and/or Catholic saints for help in healing their patients, often praying to specific saints for particular conditions.

A traditional healing session may include one or more of the following: spiritual cleansing (*limpia*), ritual, massage, and/or herbal therapy. Curanderas use a variety of objects in their healing sessions, including herbs and spices, eggs, lemons, flowers, fruits, holy water, pictures of saints, crucifixes, candles, incense, and oils. Each object has a specific purpose.

Holy water is used for protection from negativity or evil spirits. Eggs and lemons are patted on the patient's body to absorb negative energies. **Rosemary**, basil, and rue branches are brushed on the body to remove negativity.

Candles are burned to absorb negative energy and create a healing environment. Different colored candles are burned for different reasons: red for strength, blue for harmony, pink for good will. Incense is used to purify the room, while **garlic** and oils are used as protection from negativity and bad spirits.

Research and general acceptance

Although much of the Hispanic community is currently devoted to the practice of curanderismo, many people fear that it will be lost from lack of interest on the part of the younger generation or reliance on mainstream medical procedures. There is a great deal of research on curanderismo in the field of anthropology.

Training and certification

Curanderas are generally trained informally. The information is passed from generation to generation (i.e., mother to daughter). Often the curandera starts out as an apprentice to a more experienced curandera.

Curcumin

Definition

Curcumin is a biologically active phytochemical compound found in the root and rhizome of **turmeric** (*Curcuma longa L.*). Turmeric is native to India and cultivated throughout China, Southeast Asia, and in other tropical climates. It is a perennial species in the **ginger** (Zingaberaceae) family of flowering plants. Curcumin (diferuloyl methane), Demethoxycurcumin and Bisdemethoxycurcumin, collectively called curcuminoids, are polyphenolic pigments extracted from the orange-gold colored root of turmeric. Curcumin is the most abundant curcuminoid found in the turmeric root, providing about 75 percent of the total curcuminoids, which together comprise less than 10 percent of turmeric.

General use

The aromatic, pungent, and spicy-flavored turmeric root is one of the key ingredients in many Indian curries, imparting its distinctive color. This tropical herb is a staple dietary spice throughout Asia and India. It has been used for centuries as a food preservative, fabric dye, cosmetic, and ritual herb. More recently turmeric was used as a non-toxic food coloring agent in mustards and other foods. In scientific laboratories, turmeric paper, made by soaking paper in a tincture of turmeric, is used to detect alkaloids and boric acid.

Chinese and Ayurveda medicine

The wide range of therapeutic benefits of curcumin-rich turmeric root have long been recognized in Chinese herbal medicine, where the herb is known as *jianghuang*. In Ayurveda, India's ancient system of medicine, turmeric is called *haldi* and is valued as the internal healer. Turmeric has proven effective in the extensive clinical practice of eastern medicine for treatment of inflammation, **pain**, gastrointestinal, pulmonary and liver disorders, and numerous other conditions.

Curcumin acts to promote digestion, stimulate the gall bladder and the flow of bile, aid in nutrient absorption, check **diarrhea**, prevent **blood clots**,

lower **cholesterol**, regulate menses, and treat **premenstrual syndrome** (PMS). Curcumin's pain relieving qualities are helpful with arthritis, **toothache**, **colic** and chest and abdominal pain, among other traditional uses.

For external treatments, the antibiotic, astringent, and antiseptic turmeric root is prepared as an ointment or poultice to treat **bruises**, **cuts** and abrasions, **scabies** (combined with **neem** *(Azadirachta indical)*, **boils** and other infected areas of the skin, and as a remedy for ailments of the eyes, including **conjunctivitis**. The volatile oils of turmeric root also act as a mosquito repellant and prevent bacterial infection in **wounds**. In India a common folk tonic for new mothers is a beverage made of turmeric and ginger root powder added to warm milk and honey. A paste of turmeric is sometimes applied to the skin to protect against sun damage.

Western medicine

Extensive scientific research was underway in the late 2000s to validate in western terms the traditional uses in Eastern medicine for the remarkably diverse turmeric root and its constituent curcumin. Many studies of curcumin have been in laboratory or animal research. Animal studies, however, do not always prove as successful in human clinical trials. Curcumin extract has been investigated with both *in vivo* and *in vitro* research. Numerous studies have demonstrated curcumin to be an effective treatment for a wide range of medical conditions, including the following:

- Alzheimer's disease
- Cardiovascular risks
- Crohn's disease
- Digestive disorders
- Herpes simplex
- Melanoma and other cancers
- Rheumatoid arthritis
- Gallbladder disease
- Type II diabetes

Research

Laboratory and animal research has demonstrated the anti-inflammatory, antioxidant, and anticancer properties of turmeric and its constituent curcumin. Scientists have demonstrated curcumin's action to induce apoptosis, a naturally occurring form of cell death that eliminates damaged or diseased cells in cases of lymphoma and melanoma. Additional research is needed with humans to further verify the health benefits of a turmeric-rich diet and dietary supplements of curcumin extract.

In laboratory tests in the 1990s, researchers at Harvard Medical School and elsewhere reported curcumin as active against both acutely and chronically infected HIV cells. However, later clinical trials called into question the efficacy of curcumin extract in treatment of HIV.

A study published in 2006 in the *Journal of Alzheimer's Disease* reported that curcumin extract may protect against progression of Alzheimer's because of its action to inhibit the build-up of amyloid plaques in the brain. Curcumin can cross the blood-brain barrier and bind to the amyloid plaques that cause Alzheimer's, aiding in their removal from the system. In a 2006 study of non-demented elderly Asians who consumed a regular diet of turmeric-rich curry, cognitive function was found to be higher than in individuals who did not consume dietary turmeric.

Toronto scientists, reporting in the *Journal of Clinical Investigation* in 2008, found that curcumin could prevent and reverse hypertrophy, restore heart function, and reduce scar formation in mice with enlarged hearts. Additional studies have demonstrated the heart-healthy action of curcumin and its ability to protect against **heart disease** by lowering high blood cholesterol levels and preventing blood clotting.

One clinical trial in patients with **rheumatoid arthritis** compared curcumin to phenylbutazone, a nonsteroidal anti-inflammatory drug (NSAID) prescribed to alleviate arthritic pain. Patients receiving the curcumin extract showed significant improvement with therapeutic effects comparable to those obtained with phenylbutazone, though without the risk of possible serious side effects of the prescription drug.

A 2008 study at Michigan State University demonstrated that curcumin in low concentrations acted to interfere with replication of *Herpes simplex* virus. Scientists began testing curcumin as a possible treatment for skin, breast, and colon **cancer**.

Curcumin extract helps to stimulate the production of bile and break down fats and has been shown in animals to reduce secretion of stomach acid. Curcumin, taken orally, has been shown to have activity against Crohn's disease. Curcumin's use as a digestive aid has been approved by the German Commission E, formed by the German government to evaluate the safety and efficacy of herbs and herb combinations. The official monographs of the Commission, available through the American Botanical Council, provide "approved uses, contraindications, side effects, dosage, drug interactions and other therapeutic information

essential for the responsible use of herbs and phytomedicines," according to the council.

Preparations

Turmeric root

Turmeric root is traditionally collected in winter when the aerial part is dying off. The root is washed, boiled or steamed thoroughly, dried and then ground into a powder just prior to use.

Curcumin extract

Curcumin is commercially available as a fluid extract, capsule, or tincture. For maximum effectiveness, curcumin must be taken with a meal. Researchers have discovered that curcumin undergoes a chemical transformation during absorption from the intestine. Although the phytochemical is almost totally insoluble in water, it is completely soluble in fat. In India, raw turmeric juice is mixed with warm milk and taken as a morning drink to purify blood, relieve bronchial **asthma**, or as a general tonic. The digestive enzyme **bromelain**, extracted from the stem and the fruit of the pineapple plant *(Ananas comosus)*, is sometimes taken in combination with curcumin. The medical benefit depends upon the chemical content and biological activity of the curcumin supplements.

Recommended doses for adults range from 250 to 500 mg of turmeric extract capsules standardized at 90 to 95%; curcumin, three times daily, with a meal. The root, sliced or ground, can be taken in amounts up to 3,000 mg per day. The tincture can be taken in dosages up to 30 drops, four times daily. If taken on an empty stomach, curcumin may cause gastric irritation and ulceration.

KEY TERMS

Amyloid plaques—Protein fragments produced normally in the body that accumulate and form hard, insoluble plaques between the nerve cells in the brain and interfere with neural activity.

Apoptosis—Structural changes within cells of a multi-cell organism leading to controlled and regulated cell death, also called programmed cell death (PCD); a natural means to eliminate unnecessary and unhealthy cells.

Crohn's disease—A chronic, recurrent inflammation of the intestine and digestive tract; an inflammatory bowel disease (IBD) that most commonly affects the small intestine.

in vivo—A Latin term meaning living. In science, the term denotes those experiments conducted on or within living organisms.

in vitro—A Latin term meaning glass. In science the term denotes those experiments conducted in a laboratory, but not with living organisms.

Phytochemicals—Beneficial chemical substances found in plants and fruits and thought to work synergistically in whole foods to provide disease protection and promote health.

Polyphenols—A group of phytonutrient compounds present in various foods, including onions, apples, grapes, berries, certain nuts, green tea and red wine. Polyphenolic compounds include tannins, lignins, and flavonoids and are an abundant source of dietary antioxidants.

Precautions

Turmeric root has been demonstrated in numerous human trials to be safe in amounts up to 2,500 mg per day. It is traditionally used freely as a food spice with no significant adverse effects. Curcumin has been shown to stimulate the production of bile and to facilitate the emptying of the gallbladder, so persons with gastrointestinal disorders, ulcer, **gallstones**, or bile duct obstructions should not take curcumin. The safety of curcumin extract for use by very young children or pregnant or nursing women has not been established.

Drug interactions

People should not take curcumin while taking certain blood thinning medicines. **Breast cancer** patients undergoing chemotherapy are advised to limit intake of dietary turmeric and avoid use of the curcumin extract as it may inhibit the anti-tumor action of cyclophosphamide, a chemical used in treating breast cancer.

Side effects

No side effects have been reported other than risk of stomach upset in very high dosages and if taken on an empty stomach.

Cuscuta

Description

Cuscuta is the name of a group of plants in the morning glory family, of which the species *Cuscuta epithymum* is most commonly used in healing. A member of the Cuscutaceae family, species of cuscuta are found almost everywhere in the world, although cuscuta is more often called Chinese dodder in English-speaking countries. Other names are hellweed, devil's gut, beggarweed, strangle tare, scaldweed, dodder of **thyme**, greater dodder, and lesser dodder. In Chinese, cuscuta seeds are called *tu si zi*.

Cuscuta is a parasitic plant. It has no chlorophyll and cannot make its own food by photosynthesis. Instead, it grows on other plants, using their nutrients for its growth and weakening the host plant. Agriculturalists consider cuscuta a destructive weed and attempt to eradicate it. It parasitizes wild and cultivated plants and is especially destructive to such commercially valuable

Cuscuta. *(© Frank Blackburn / Alamy)*

crops as flax, **alfalfa**, beans, and potatoes. It also grows on such common ornamentals as English ivy, petunias, dahlias, and chrysanthemums. For medicinal purposes, herbalists prefer *C. epithymum* that grows on thyme.

Cuscuta is a leafless plant with branching stems ranging in thickness from thread-like filaments to heavy cords. The seeds germinate like other seeds. The stems begin to grow and attach themselves to nearby host plants. Once they are firmly attached to a host, the cuscuta root withers away. The mature plant lives its entire life without attachment to the ground. The stems of cuscuta are used in **Western herbalism**, and the seeds are used in **traditional Chinese medicine** (TCM). Cuscuta is used as an individual remedy and in combination with other herbs.

General use

Despite the fact that cuscuta is unpopular with farmers, it has a long history of folk use. In Western herbalism, cuscuta was traditionally used to treat liver, spleen, and gallbladder disorders such as **jaundice**. It was also used to support liver function. It is still used, although rarely, in that way by modern herbalists. It is also a mild laxative. Other traditional Western claims for cuscuta are that it is a mild diuretic and that it can be used to treat **sciatica** and scurvy. Externally, it can be gathered fresh and applied to the skin to treat scrofuladerma. Extracts of the herb have a very bitter taste.

In traditional Chinese medicine, the seeds of cuscuta, called *tu si zi*, have been used for thousands of years. In the Chinese understanding of health, *yin* aspects inside the person and outside in the environment must be kept in balance with *yang* aspects. Ill health occurs when the energies and elements of the body are out of balance or in disharmony with nature. Health is restored by taking herbs and treatments that restore internal and external balance.

According to traditional Chinese healers, cuscuta seeds have a neutral nature and a pungent, sweet taste. They are associated with the liver and kidneys and are used in formulas that help both yin and yang deficiencies, depending on the patient's condition and the other herbs in the formula. Cuscuta was considered both an aphrodisiac and a longevity herb because it slowed down the loss of fluids from the body.

Contemporary Chinese herbalists use cuscuta in formulas to treat a range of conditions, including the following:

- impotence
- premature ejaculation
- sperm leakage
- frequent urination
- ringing in the ears
- lower back pain
- sore knees
- white discharge from the vagina (leucorrhea)
- dry eyes
- blurred vision
- tired eyes

Cuscuta is also used in the Indian system of Ayurvedic healing to treat jaundice, muscle **pain**, coughs, and problems with urination.

Cuscuta in combinations

Cuscuta is one of nine herbs included in the manufacture of two Chinese herbal remedies, Astra Essence and Equiguard. Each contains eight other similar ingredients according to package ingredients listed in 2008.

Astra Essence, a product of Health Concerns, contains the following herbs:

- Herba Epimedii (stem and leaves)
- Fructus Rosae Laevigatae (fruit)
- Fructus Rubi (fruit)
- Fructus Psoraleae (fruit)
- Radix Morindae Officinalis (root)
- Fructus Schisandrae (fruit)
- Fructus Ligustri Lucidi (fruit)
- Semen Cuscutae (seed)
- Radix Astragali (root)

The uses of Astra Essence include a tonic for **infertility**, **impotence**, balanced kidney tonfication, and to reduce the frequency of urination. Other uses are a preventative for **hair loss** and to balance blood glucose in diabetes. The formula is said to help slow **aging** and prevent adverse effects caused by premature aging and the kidney deficiency caused by a fast-paced lifestyle. These include the loss of memory and hearing. Furthermore, Astra Essence is said to help with the side effects of chemotherapy and radiation.

Equiguard, a product of Integrated Chinese Herbal Nutraceuticals, contains the following herbs:

- Herba Epimedii, Fructus
- Rosae Laevigatae
- Fructus Rubi, Fructus
- Psoraleae, Radix
- Morindae Officinalis
- Fructus Schisandrae

- Fructus Schisandrae
- Fructus Ligustri Lucidi
- Semen Cuscutae, Radix
- Astragali, Hydroxypropyl Methylcellulose

Equiguard is marketed as a natural blend of Chinese herbs that helps kidney and prostate disorders. Men age 50 and older may experience prostrate-related difficulties such as difficulty urinating, frequent urination, and discomfort when urinating. Equiguard is said to promote healthy kidney function, support prostate health, and normalize urination, according to the Web site maintained by Equiguard.

Cuscuta research

As of 2008, little scientific research had been performed in the West on cuscuta. A purgative compound had been isolated from the herb, however, that supports its traditional use as a liver and gallbladder tonic. Other research done at Asian universities indicated that cuscuta seeds contain a complex carbohydrate that stimulates the immune system and that it has some antioxidant properties as well. Research into the antioxidant properties of cuscuta included a study described in the April 2007 issue of the *Journal of Ethnopharmacology*. Researchers at Kaohsiung University in Taiwan studied the effect of cuscuta on rats and concluded that data suggested that cuscuta could prevent hepatic (affecting the liver) injuries and that this was probably done through cuscuta's **antioxidant** activities.

Equiguard research

Research performed at New York Medical College indicates that the combination of ingredients in Equiguard may be effective in the treatment of **prostate cancer**. The preparation inhibited the growth of **cancer** cells, increased the rate of self-destruction (apoptosis) of cancer cells, and prevented the surviving cells from forming colonies.

Preparations

In Western herbalism, the entire thread-like stems of cuscuta are used. They are boiled in water along with such herbs as **ginger** and allspice to make a decoction. In Chinese herbalism, only the seeds are used. They are almost always used in combination with other herbs, as in concha marguerita and ligastrum formulas.

Cuscuta is available in capsule and tablet form. Herbal combinations containing cuscuta are also available in tablet and capsule forms. The dosage depends on the strength of the remedy and the condition being treated.

KEY TERMS

Antioxidant—An enzyme or other organic substance that is able to counteract the damaging effects of oxidation in living tissue.

Diuretic—Any substance that increases the production of urine.

Sciatica—Pain in the lower back, buttocks, hips, and thigh caused pressure on the sciatic nerve.

Scrofuloderma—Abscesses on the skin associated with tuberculosis and caused by mycobacteria.

Scurvy—A disease caused by the absence of vitamin C in the diet.

Yang aspects—Yang aspects, in nature and in the human body, include such qualities as warmth, activity, light, and forcefulness.

Yin aspects—Yin aspects are the opposite of yang aspects and are represented by such qualities as cold, stillness, darkness, and passivity.

Precautions

The United States Food and Drug Administration does not regulate herbal remedies such as cuscuta, which means that the remedies have not proven to be safe or effective. In addition, ingredients are not standardized to comply with federal regulations.

Women who are pregnant, nursing mothers, and children should not take cuscuta as a single herb or in combination products. No special precautions are necessary when cuscuta is used in the doses normally prescribed by herbalists.

Side effects

As of 2008, no side effects had been reported when cuscuta is used in doses prescribed by herbalists.

Interactions

Cuscuta has been used for centuries with other Chinese herbs without any reported interactions. There were no known interactions between cuscuta and Western pharmaceuticals, as of 2008.

Cuts and scratches

Definition

Cuts are **wounds** that break through the skin and sometimes reach the underlying tissue. Scratches are usually superficial wounds where the skin is scraped by a sharp object.

Description

The skin is a barrier between the environment and the rest of the body. Usually it offers protection from the invasion of infective organisms. If the skin is broken by cutting or scratching, there is an increased possibility of infection, along with **pain** and blood loss. Most cuts and scratches are relatively minor and respond well to home remedies. Deep cuts may require medical help and repairing the skin with stitches to heal properly.

KEY TERMS

Ghee—Butter heated to remove the fat, used in Ayurvedic foods and remedies.

Keloids—An excessive overgrowth of collagen scar tissue, often found in young women and African Americans.

Lymph nodes—Structures that form white blood cells and help fight infection in the body.

Poultice—Fresh chopped herbs applied to an injured part of the body, and often covered with a cloth, for healing pains, diseases, and infections.

Causes and symptoms

A cut or scratch is often due to an accidental injury or intentional violence. Age-related changes may be a contributing factor, because the skin becomes more thin and fragile with age, and thus, more susceptible to cuts and scratches. Infection is a primary concern in dealing with cuts and scratches. Signs of infection include redness, pain or tenderness, local swelling, warmth, a discharge from the wound site, **fever**, swollen lymph nodes, and red streaks spreading out from the wound site.

Diagnosis

Minor cuts and scratches do not usually require diagnosis. However, if an infection sets in, the wound may need to be assessed by a healthcare provider taking a history of the injury and performing a physical exam.

Treatment

Homeopathic topical preparations can be useful in treating cuts and scratches. Calendula and *Hypericum perforatum* are herbs that can be applied topically as a cream, gel, or ointment. Hypericum 30c can be taken internally, as well. It is particularly indicated if the cut is very painful. Staphysagria 30c is indicated for deep cuts and stab wounds. **Aconite** 30c may be given every 30 minutes for up to three to five doses if a person is very anxious as well as injured.

Ayurvedic medicine recommends several simple applications for minor cuts and scratches. These

include fresh **aloe** vera gel, plain ghee, and coconut oil. **Licorice** (*Glycirrhiza glabra*) and **turmeric** (*Curcuma longa*) can be added to any of these to make a paste that will help the skin heal.

Western herbal remedies that promote the healing of cuts and scratches include a strong tea made from *Calendula officinale* flowers, which can be used as a soak or a wash for wounds; distilled **witch hazel** (*Hamamelis virginiana*) which may also stop bleeding; **goldenseal** (*Hydrastis canadesis*) powder or salve, a specific for skin healing; a poultice of crushed **plantain** leaves (*Plantago* spp.); and **comfrey** root salve (*Symphytum officinale*). Raw honey can also be directly applied to help disinfect superficial wounds and to promote healing. *Echinacea* spp. tincture can also be used as a disinfectant or antimicrobial to the affected site. The alcohol in the tincture may cause the wound to sting. Topical applications should not be used on a deep wound until some initial healing has occurred.

According to **aromatherapy**, a spray of diluted **essential oils** can be used as an antiseptic. They may also repair skin damage and encourage new cell growth. Tea tree, **lavender**, **myrrh**, benzoin, bergamot, **chamomile**, tea tree, **eucalyptus**, **juniper**, **rosemary**, helichrysum, eucalyptus, rose geranium, and sandalwood are all appropriate to use on cuts and scratches. About 10 drops of the full-strength oil should be added, singularly or blended, to two ounces of distilled water and one half ounce of goldenseal tincture or alcohol. The essential oil mixture should be shaken well before each use, and it can then be sprayed on two or three times per day.

Vitamins E and A are necessary for the skin to heal well and quickly. These vitamin oils can be squeezed directly from their capsules onto the affected areas several times per day. They can be taken orally, as well, along with a multivitamin containing vitamins A, C, E, and B complex. Healing following an injury is also speeded up by supplementation with the **amino acidsarginine** and glycine. **Bromelain**, the digestive enzyme from pineapple, can be taken between meals as needed to reduce inflammation.

Allopathic treatment

Most cuts and scratches are minor and can be handled at home. A physician should be consulted if:

- The cut is very large or deep.
- There is uncontrolled bleeding.
- There is damage to muscles, nerves, or other deep tissues.
- The wound edges are very jagged or do not seem to join together for healing.
- The wound site is very dirty or contains difficult-to-remove foreign material, such as gravel.
- There is weakness or numbness below the injury.
- The cut is on the face, chest, fingers, genitals, back, stomach, palm of the hand, or over a joint.
- There are signs of infection.
- The lymph nodes become swollen.
- The injured person has a history of diabetes, poor circulation, mitral valve prolapse, an artificial heart valve, or an artificial hip.

A cut or scratch should be washed with a mild soap and water. Tweezers that have been disinfected by washing in hot, soapy water and soaking in rubbing alcohol can be used to remove any dirt, glass, or gravel remaining in the wound. Pressure can be applied directly to wound with clean gauze pad until bleeding has stopped. The wound can be protected while it heals by covering it with an adhesive bandage. The use of an antibiotic or antiseptic ointment is optional. The use of rubbing alcohol and hydrogen peroxide are not recommended for minor cuts and scratches, as they can cause irritation of the wound.

Aspirin, acetaminophen, or nonsteroidal anti-inflammatory drugs (NSAIDs), such as ibuprofen, naproxen, or ketoprofen can be taken to reduce pain. If there is a lot of bleeding, however, aspirin and NSAIDs should be avoided because they may interfere with blood clotting. Keeping the edges of the wound together can help keep dirt out, speeds healing, and decreases scarring. Stitches are helpful in this regard, but they, too, can cause scarring. Butterfly bandages or steri-strips may also be used to keep the wound closed. If a cut is more than 0.5 in (1.25 cm) deep, stitches will usually be needed.

Expected results

Most cuts and scratches are superficial, and heal within a few days. Sometimes keloids form, and these painless scars become gradually less prominent and visible over a period of months to years. Deep cuts may result in permanent decrease in function. Serious damage may also result if an infected wound is left untreated.

Prevention

It is especially easy to get cuts and scratches while working outdoors. Protective clothing and gloves are therefore recommended for any kind of manual labor outside the house. Using a moisturizer on the skin

ensures that it will not become dried out. Dry skin is much more susceptible to cuts, scratches, and cracking than moist skin. Care should be taken to avoid accidents in the home. The safety of problem areas should be addressed. For example, hardwood floors and stairs are often slippery, as are loose rugs and broken steps or floorboards. Also, the shower can be a major site of home injuries. Furniture may have to be moved if there are repeated accidents. Overexposure to the sun's rays should be avoided, as it is a major cause of fragile skin leading to injury. In addition, a **tetanus** booster shot is recommended every 10 years.

Cymatic therapy

Definition

Cymatic therapy is a form of **sound therapy** that is not applied through hearing, but by instruments that send audible sound waves directly into the body through the skin. This process is said to promote a healing environment in the body. The process may be known as Cymatherapy, which is a trademarked name for an organization that sells instruments and provides cymatic training.

Origins

Sound, particularly in the form of music, drumbeats, or chanting, was used for healing purposes in numerous ancient traditions. The physiological effects of different types of music on blood pressure and other bodily indicators were first noticed during the late 1800s. Eighteenth-century German scientist Ernst Chladni demonstrated the relationship between sound and matter. Chladni, who came to be known as the "Father of Accoustics," discovered that when he moved a violin bow around a plate containing sand that the action caused the grains of sand to form geometric patterns. During the twentieth century, Hans Jenny, a Swiss scientist elaborated on that research.

Jenny studied the effect of sound on metal plates containing material such as sand, liquid, and powder. He discovered that the sound caused the formation of elaborate patterns in the materials. He coined the word "cymatics," deriving it from the Greek word *kyma* (a great wave). Jenny published his findings in a 1967 book titled *Cymatics: A Study of Wave Phenomena & Vibration,* which discussed the structure, dynamics, and effects of sound vibrations and featured photographs of his research on sound patterns. Jenny's book was republished in 2001.

Cymatic therapy was largely developed during the 1960s by Sir Peter Guy Manners, an English medical doctor and osteopath. He believed that everything vibrated to its own frequency and that when a frequency changed, so did its form. Manners maintained that conditions such as illness represented an imbalance in the sound or harmonic frequency of cells. If **cancer** waves affected a kidney, the person could be treated by exposure to the frequency of a healthy kidney. The application of the healthy frequency to the skin over time would restore a healthy balance to the kidney, according to Manners. He created a therapeutic cymatic instrument that was said to emit more than 800 controlled audible frequencies.

Benefits

Practitioners of cymatic therapy believe that sound is capable of rearranging the structure of molecules and, therefore, has unlimited potential as a tool for healing. They claim to have successfully treated otherwise incurable and terminal diseases. At the same time, they acknowledge that some patients seem to be unaffected by sound therapy. The treatment has been used on patients with tumors, internal **bruises**, calcified joints, bacterial or viral **infections**, blood diseases, and other problems.

Description

Sound consists of mechanical vibrations that travel through a medium such as air, water, or in the case of cymatic therapy, the body. Sound healers believe that all parts of the body vibrate and thus produce sound, either at a healthy, harmonious frequency, or at an inharmonious, unhealthy frequency. Using a computerized instrument, cymatic therapists direct healing

frequencies into the body to restore resonance and harmony. The healing frequencies are related to those emitted by a healthy organ or body part. In this way, cymatic healers say, the immune system and other natural regulatory functions are stimulated. Frequencies may be applied directly or transmitted along **acupuncture** meridians.

Cymatic therapy does not directly heal, practitioners say. Rather, it creates a near-optimal environment for organs or cells. In such an environment, they say, the body can heal itself without drugs or surgical intervention. The therapy may also be delivered without such equipment, with the use of instruments such as tuning forks.

Products marketed by Cymatherapy in February 2008 included the Cyma 1000, an instrument registered with the United States Food and Drug Administration (FDA) as a therapeutic massager. The instrument was described as "an electrically powered device intended for medical purposes, such as to relieve minor muscle aches and pains," according to the registration that was revised on April 1, 2006. The registration as a Class 1 Device did not mean that the product was approved by the FDA, only that the registration was filed with the federal agency.

The Cyma 1000 is marketed on the Cymatherapy Web site as "simply an acoustic massager that emits relaxing tones" and not a product "intended to diagnose, treat, cure, or prevent any disease." The machine provided more than 500 "commuations (harmonious combinations of five frequencies)." It sold for $9,950 in 2008.

Precautions

Patients with cardiac pacemakers are advised to avoid this therapy. Because of the controversial nature of cymatic treatment, people with pre-existing medical conditions should consult a physician before beginning cymatic therapy treatment.

The FDA does not approve Class 1 devices such as cymatic therapy instruments, which means the instruments have not been rigorously tested for safety and effectiveness. In addition, the American Cancer Society cautioned that claims that sound waves could promote a healing environment were not scientifically proven. The society warned people not to rely solely on cymatic therapy or delay seeking conventional treatment for cancer.

Side effects

Cymatic therapy was thought to be generally free of adverse side effects, as of February 2008.

Research and general acceptance

The variability with which different body tissues absorb and reflect sound is universally acknowledged. It is this variability that makes ultrasound scanning a useful form of medical imaging. However, few physicians are convinced that healing can be facilitated by tuning a sound device to a patient's cellular vibrations. Hence, medical doctors tend to be highly skeptical about cymatic therapy. There were no large studies of the effectiveness of cymatic therapy as of February 2008.

Training and certification

Cymatic devices are used by a variety of alternative practitioners, including osteopaths, acupuncturists, and chiropractors. Specific training is needed to operate the machines. This can be obtained through books, tapes, seminars, and correspondence courses. In most jurisdictions, the field is unregulated and patients must, therefore, take care to ensure the competence of their healer.

Cymatherapy offered a certification course that consisted of 200 credit hours and cost $2,000 in February 2008, according to the Web site. Training as a certified cymatherapist included 182 hours of course credit and a three-day workshop. The topics studied included anatomy, psychology, and technology of sound (cymatics).

Cyperus

Description

Cyperus refers to a family of marsh-dwelling grass-like plants known as sedges. Perhaps the best-known member of this family is the reed, which ancient Egyptians used to make papyrus. However, many other members of this family have proven useful as food and medicine. *Cyperus articulatus* and *Cyperus rotundus* are the two species most often associated with healing.

C. articulatus, also called adrue or Guinea rush, is a tall sedge that mainly grows in Jamaica, Turkey, and along the Nile River in Egypt. The medicinal part of the plant is its root or tuber. This part is blackish in color and shaped like a top. Tubers are usually about 0.7–1 in (1.1–2.5 cm) long and about 0.5–0.7 in (1.3–1.7 cm) in diameter. The tubers may be connected in groups of two or three by underground stems. They are harvested and dried for healing. The herb is bitter in taste and aromatic, similar to **lavender**.

C. rotundus is used primarily in Asia and Africa, but it also grows in Australia, Europe, and North America. It is an invasive plant that grows in low, damp places near water. Like *C. articulatus*, the tuber is the part of the plant used in healing. Its Chinese name is *xiang fu*, and it has been used in **traditional Chinese medicine** for thousands of years. *C. rotundus* is also called tiririca, nutsedge, nutgrass, musta, mutha, and a host of other local names.

General use

C. articulatus is used mainly for digestive disorders. It is an antiemetic, meaning that it suppresses **vomiting**. This is useful in reducing the symptoms of **morning sickness** during **pregnancy**. Because it gives the body a general feeling of warmth, *C. articulatus* is sometimes used as a sedative, generally in connection with suppressing **nausea**. Cyperus is also used to relieve **gas** in the stomach and intestines. In the Peruvian Amazon, native people use the herb to treat infection, and in Africa it is used to treat **epilepsy**.

There are few scientific studies of *C. articulatus*. An Argentinean study conducted in 1995 looked at the bacteria-killing properties of the herb. It concluded that decoctions of *C. articulatus* completely inhibited the growth of one species of *Staphylococcus* bacteria and partially inhibited the growth in one species of *Pseudominas* bacteria. Both of these bacteria **strains** are capable of causing severe, and sometimes fatal, **infections**. It was ineffective in tests against five other infection-causing organisms.

Cyperus rotundis flower spike. *(Nigel Cattlin / Photo Researchers, Inc.)*

Another study published in the *Journal of Ethnopharmacology* in 1996 by Swiss investigators found that extracts of *C. articulatus* reduced certain types of spontaneous neuron firings in the brains of rats. These scientists suggested that this suppression might be the basis for the effectiveness of *C. articulatus* in treating **headache** and epilepsy. In the early 2000s, no studies on *C. articulatus* were published in scholarly, peer-reviewed journals.

C. rotundus is used in Chinese medicine and Japanese Kampo formulations. It is rarely used alone and can be found in formulas that relieve **pain**, especially pain associated with **menstruation**. It is also used in formulas for stomachache and **diarrhea**, to improve menstrual function, to treat **impotence** or heighten sexual potency, to treat bacterial infections, dry or tired eyes, and in tonics for general wellness. In other Asian and African countries, *C. rotundus* is also used as a diuretic and to treat high blood pressure. It is also spread on the skin as a bactericide and a fungicide to prevent infection of **wounds**. A study published in 2007 supported the idea that *C. rotundus* has antibacterial properties. Researchers found that an extract of *C. rotundus* substantially reduced the growth of *Streptococcus mutans*, a bacteria responsible for the formation of dental plaque and tooth decay (dental caries).

Preparations

C. articulatus is usually prepared as a decoction or liquid extract to be taken internally. *C. rotundus* may

Cyperus. *(© blickwinkel / Alamy)*

be prepared two different ways. It can be boiled to make a liquid to be mixed with other herbs. The tubers can also be ground into a paste with or without other herbs. The paste can either be formed into pills to be taken internally or applied externally to wounds or skin **rashes**. This paste is also sometimes applied directly to the temples to treat headaches.

Precautions

As of early 2008, no particular precautions had been reported as being necessary in using cyperus.

Side effects

As of the early 2000s, no side effects had been reported in using cyperus. This herb has a long tradition of folk use, but its effects on humans had not been studied in any structured way.

Interactions

Cyperus is often used in conjunction with other herbs in Chinese formulations with no reported interactions. Cyperus is, however, reported to be mixed with hallucinogenic plants by certain tribes living in the Brazilian rain forest, in order to prolong the action of the hallucinogens. As of 2008, there were no studies of interactions between cyperus and standard Western pharmaceuticals. One Korean report on several compounds isolated from cyperus, however, indicated that it inhibits the action of benzodiazepine tranquilizers and modifies the effectiveness of several neurotransmitters in the central nervous system.

KEY TERMS

Antiemetic—A preparation or medication given to stop vomiting.

Antimalarial—Any substance that reduces the effects of the tropical disease malaria.

Bactericide—A substance that kills bacteria.

Decoction—A preparation made by boiling an herb, then straining the liquid to remove solid material. The liquid is then taken internally as a drink.

Diuretic—Any substance that increases the production of urine.

Fungicide—A substance that kills fungi.

Kampo—Traditional Japanese system of herbal medicine.

Neuron—A nerve cell that transmits electrical impulses.

Cystitis *see* **Bladder infection**

Cysts, ovarian *see* **Ovarian cysts**

D

Damiana

Description

Damiana, a member of the Turneraceae family, is an aromatic shrub with small yellow flowers that grows on dry, sunny, rocky hillsides in south Texas, Southern California, Mexico, and Central America. The two species used in herbal healing, both of which are referred to as damiana, are *Turnera aphrodisiaca* and *Turnera diffusa*. Damiana usually grows to a height of about 24 in (60 cm). Its pale green leaves, which turn yellow-brown when dried, are 0.5–1 in (15–25 mm) long and quite narrow. They have serrated (jagged) edges. The leaves and sometimes the stems of the plant have medicinal uses. Other names for damiana include old woman's broom, Mexican damiana, pastorata, hierba del venado, oreganello, and the bourrique.

General use

Damiana affects primarily the urinary and reproductive systems. It has been used as an aphrodisiac and to boost sexual potency in men by the native peoples of Mexico, including the Mayan Indians, for thousands of years. It is said to act as a sexual stimulant and produce a feeling of general well being. Damiana is sometimes used in men to treat spermatorrhea, premature ejaculation, sexual sluggishness, and prostate complaints. It is often used in combination with other herbs to treat **impotence**.

During the twentieth century, damiana shifted from being primarily a male sexual remedy to also being prescribed for women. In women it is used to treat painful **menstruation**, **menopause** disorders, and headaches caused by menstruation.

Both men and women use damiana to relieve **anxiety**, nervousness, and mild **depression**, especially if these symptoms have a sexual component. The herb is also used as a general tonic to improve wellness. As a general tonic it is said to act as a stimulant, improve circulation, and regulate hormonal activity. Some herbal practitioners use it as a diuretic. Damiana tonic should be used moderately and not be taken on a long-term basis.

Damiana has been used traditionally to improve digestion and to treat **constipation**, as in large doses it has a mild laxative effect. Other uses include treatment of **asthma**, **cough** and flu, and nephritis. During the 1960s, damiana was touted as a recreational drug. Some users claimed that damiana produced a mild "high" or hallucinogenic effect similar to **marijuana** that lasts an hour to an hour and a half.

In addition to its medicinal uses, damiana is used in Mexico to flavor liqueurs, tea, and other beverages and foods. It tastes slightly bitter, and the leaves have a strong resinous aroma when crushed.

Despite its long history and frequent use in many different cultures, scientists as of 2008 were unable to isolate any active ingredients that would account for damiana's aphrodisiac, stimulant, or hallucinogenic properties. The herb contains a volatile oil that may mildly irritate the genitourinary system. This volatile oil may be at the root of damiana's reputation as an aphrodisiac.

The German Federal Health Agency's Commission E, which was established in 1978 to independently review and evaluate scientific literature and case studies pertaining to herb and plant medications, found no proof that damiana acts either as a sexual stimulant or as a hallucinogen. That said, they found no proof that damiana is likely to cause harm. A 1999 study on rats conducted in Italy found that extracts of *Turnera diffusa* had no effect on sexually potent rats, but it did increase the performance of sexually sluggish or impotent rats. There have been no clinical trials involving humans. As of 2008, the safety and efficacy of this herb had not been evaluated by the United States Food and Drug Administration (FDA).

Damiana has been used as an aphrodisiac and to boost sexual potency in men by the native peoples of Mexico, including the Mayan Indians, for thousands of years. *(© Geoffrey Kidd / Alamy)*

KEY TERMS

Aphrodisiac—Anything that arouses or increases sexual desire.

Diuretic—Any substance that increases the production of urine.

Hallucinogen—A substance that causes the perception of a stimulus or object when it is not really present.

Nephritis—An inflammation or irritation of the kidney.

Spermatorrhea—Involuntary discharge of semen without an orgasm occurring; sperm leakage.

Tincture—An alcohol-based extract prepared by soaking plant parts.

Preparations

The leaves and occasionally the stems of damiana are used medicinally. They are normally harvested while the plant is in flower and then are dried. Dried leaves turn a yellow-brown color and may be powdered, used in capsules, or steeped in water or alcohol. Damiana is always used internally, never topically.

Traditionally, damiana has been prepared as a tea or infusion. Although folk recipes vary, generally about 1 cup (250 ml) of boiling water is added to 1/2 cup (1 g) of dried leaves, and allowed to steep about 15 minutes. One cup of this infusion is drunk two to three times daily. This infusion is slightly bitter and has an astringent quality.

Damiana is also available as a tincture of which 1–3 ml is taken two or three times a day. If taken in capsule or tablet form, 3–8 g twice a day may be taken. Damiana is also available in concentrated drops. Damiana is often used in conjunction with other herbs having similar properties, and it is often found as an ingredient in herbal mixtures or formulas. Their manufacture and purity is not regulated by the FDA.

Precautions

Scientific evidence indicates that damiana is one of the safest substances commonly taken for sexual enhancement. It has a long history of traditional medicinal and food use with no harmful consequences reported. It is believed to be unlikely to cause harm or have negative side effects when taken in the designated doses. However, individuals who have diabetes, a history of **breast cancer**, **bipolar disorder**, **schizophrenia**, Alzheimer's disease, or Parkinson's disease should consult a physician before taking this herb. No rigorous scientific studies as of 2008 have examined the effects of long-term use of damiana.

Side effects

Large doses of damiana may cause loose stools because of the herb's laxative properties. Occasional allergic reactions have been reported, but otherwise, no unwanted side effects have been documented.

Interactions

People who are taking pharmaceutical drugs to control blood sugar levels should consult their healthcare provider before starting damiana, since the herb may interact with these drugs. Damiana is often used in combination with other herbs without any negative effects.

Dance therapy

Definition

Dance therapy is a type of **psychotherapy** that uses movement to further the social, cognitive, emotional, and physical development of the individual. Dance therapists work with people who have many kinds of emotional problems, intellectual deficits, and life-threatening illnesses. They are employed in psychiatric hospitals, day care centers, mental health centers, prisons, special schools, and private practice. They work with people of all ages in both group and individual therapy. Some also engage in research.

Dance therapists try to help people develop communication skills, a positive self-image, and emotional stability.

Origins

Dance therapy began as a profession in the 1940s with the work of Marian Chace. A modern dancer, she began teaching dance after ending her career with the Denishawn Dance Company in 1930. In her classes, she noticed that some of her students were more interested in the emotions they expressed while dancing (loneliness, shyness, fear, etc.) than the mechanics of the moves. She began encouraging them by emphasizing more freedom of movement rather than technique.

In time, doctors in the community started sending her patients. They included antisocial children, people with movement problems, and those with psychiatric illnesses. Eventually, Chace became part of the staff of the Red Cross at St. Elizabeth's Hospital. She was the first dance therapist employed in a formal position by the federal government. Chace worked with the emotionally troubled patients at St. Elizabeth's and tried to get them to reach out to others through dance. Some of them were schizophrenics and others were former servicemen suffering from **post-traumatic stress disorder**. Success for these patients meant being able to participate with their class in moving to rhythmic music. "This rhythmic action in unison with others results in a feeling of well-being, **relaxation**, and good fellowship," Chace said.

Dance therapy in a mental health unit. *(© Photo Researchers, Inc. Reproduced by permission.)*

KEY TERMS

Authentic movement—A type of movement that is influenced heavily by Jungian analysis, and works by analyzing the internal images of the patient. Patients are also urged to dance only when they feel the "impulse" to move.

Freudian analysis—A type of psychological treatment where the therapist seeks to help the patient resolve conflicts and traumas buried in the subconscious.

Jungian analysis—A method of psychological treatment where the patient strives to understand the internal, often mythic images in his or her thoughts and dreams.

Psychotherapy—A medical treatment that seeks to resolve psychological traumas and conflicts, often by discussing them and emotionally reliving difficult events in the past.

Test anxiety—A name for the stress and anxiousness that commonly occur in students before they take exams.

Chace eventually studied at the Washington School of Psychiatry and began making treatment decisions about her patients along with other members of the St. Elizabeth's medical team. Her work attracted many followers and the first dance therapy interns began learning and teaching dance therapy at St. Elizabeth's in the 1950s.

Other dancers also began using dance therapy in the 1940s to help people feel more comfortable with themselves and their bodies. These dancers included Trudi Schoop and Mary Whitehouse. Whitehouse later became a Jungian analyst and an influential member of the dance therapy community. She developed a process called "movement in-depth," an extension of her understanding of dance, movement, and depth psychology. She helped found the contemporary movement practice called "authentic movement." In this type of movement, founded on the principles of Jungian analysis, patients dance out their feelings about an internal image, often one that can help them understand their past or their current life struggles. One of Whitehead's students, Janet Alder furthered Whitehead's work in authentic movement by establishing the Mary Starks Whitehouse Institute in 1981.

In 1966, dance therapy became formally organized and recognized when the American Dance Therapy Association (ADTA) was formed.

Benefits

Dance therapy can be helpful to a wide range of patients—from psychiatric patients to those with **cancer** to lonely elderly people. Dance therapy is often an easy way for a person to express emotions, even when his or her experience is so traumatic he or she can not talk about it. It is frequently used with rape victims and survivors of sexual abuse and incest. It can also help people with physical deficits improve their self-esteem and learn balance and coordination.

Dance therapists also work with people who have chronic illnesses and life-threatening diseases to help them deal with **pain**, fear of death, and changes in their body image. Many people with such illnesses find dance therapy classes to be a way to relax, get away from their pain and emotional difficulties for a while, and express feelings about taboo subjects (such as impending death).

Dance therapy is suitable even for people who are not accomplished dancers, and may even be good for those who are clumsy on the dance floor. The emphasis in dance therapy is on free movement, not restrictive steps, and expressing one's true emotions. Children who cannot master difficult dances or can not sit still for traditional psychotherapy often benefit from free-flowing dance therapy. Even older people who cannot move well or are confined to wheelchairs can participate in dance therapy. All they need to do is move in some way to the rhythm of the music.

Dance therapy can be useful in a one-on-one situation, where the therapist works with only one patient to provide a safe place to express emotions. Group classes can help provide emotional support, enhanced communication skills, and appropriate physical boundaries (a skill that is vital for sexual abuse victims).

Description

There are currently more than 1,200 dance therapists in 46 states in the United Sates and in 29 foreign countries. Like other mental health professionals, they use a wide range of techniques to help their patients. Some of the major "schools of thought" in dance therapy include the Freudian approach, Jungian technique, and object relations orientation. Many therapists, however, do not ascribe to just one school, but use techniques from various types of dance therapy.

The authentic movement technique is derived from the Jungian method of analysis in which people work with recurring images in their thoughts or dreams to derive meaning in their life. Instead of asking the patient to dance out certain emotions, the therapist

instructs the patient to move when he or she feels "the inner impulse." The moves are directed by the patient and the therapist is a noncritical witness to the movement. The moves are supposed to emerge from a deep level within the patient.

In Freudian technique, dance therapists work with patients to uncover feelings hidden deep in the subconscious by expressing those feelings through dance.

In object relations technique, the therapist often helps the patient examine problems in his or her life by considering the primary initial relationship with the parents. Emotions are expressed in a concrete, physical way. For instance, a patient would work out his fears of abandonment by repeatedly coming close to and dancing at a distance from the therapist.

Dance therapists sometimes use other types of therapy along with dance, such as art or drama. Therapists also discuss what happens during a dancing session by spending time in "talk therapy." Dance therapists use visualizations during sessions, too. For example, the therapist might instruct patients to imagine they are on a beautiful, peaceful beach as they dance.

In one frequently used technique, the therapist mirrors the movements of the patient as he or she expresses important emotions. This is especially powerful in private one-on-one therapy. It is thought that this device provides a sense of safety and validates the patient's emotions.

The underlying premise of dance therapy is that when people dance, they are expressing highly significant emotions. A fist thrust out in anger into the air or a head bent in shame has deep significance to a dance therapist. Through dance therapy, the theory goes, patients are able to more easily express painful, frightening emotions, and can progress from there. After experiencing dance therapy, they can talk about their feelings more freely and tear down the barriers they have erected between themselves and other people. The hope is that eventually they can go on to live more psychologically healthy lives.

Preparations

People who want to use dance therapy should find a qualified therapist. The ADTA provides lists of qualified therapists. The person should begin dance therapy with an open mind and a willingness to participate so he or she can get the most benefit.

Precautions

A qualified dance therapist should have completed a graduate program in dance therapy approved by the ADTA and should be registered with the ADTA. He or she should not just be a dancer, but should also have extensive training in psychology.

Side effects

No known side effects.

Research and general acceptance

Dance therapy was once dismissed as simply an ineffective, "feel good" treatment, but it is now more respected. Many research studies have proven that dance therapy can be an effective tool to help people overcome psychological problems.

In a 1993 study, older people with cognitive deficits showed that dance therapy could significantly increase their functional abilities. Patients improved their balance, rhythmic discrimination, mood, and social interaction.

In 1999, a pilot study of 21 university students showed that those who took a series of four to five group dance therapy sessions in a period of two weeks significantly reduced their test **anxiety** as measured by a well-known exam called the Test Anxiety Inventory. Afterwards, the subjects reported that their dance movement experience was positive and provided them with psychological insight. The researchers concluded that dance therapy could be a viable method of treatment for students who have overwhelming test anxiety, and should be researched further.

In another 1999 study presented at the ADTA national conference in November 1999, dance therapist Donna Newman-Bluestein reported success in using techniques of dance therapy with cardiac patients. In a **stress** reduction class, health professionals used dance therapy methods to teach body awareness, relaxation, self-expression, creativity, and empathy. According to Newman-Bluestein, the dance therapy techniques helped the patients deal with such stressful emotions as anger, increased their self-awareness, made them more relaxed, and helped them adjust emotionally to having **heart disease**.

Training and certification

Dance therapists should have dance experience and a liberal arts background with coursework in psychology for their undergraduate degree. Professional dance therapy training takes place on the graduate level. A qualified dance therapist has received a graduate degree from a school approved by the ADTA, or has a master's degree in dance or psychology and has taken additional dance therapy credits.

After graduation, dance therapists can become registered with the ADTA, meaning that they are qualified to practice. After two years they may receive an additional recognition when they become an Academy of Dance Therapist Registered. They can then teach dance therapy and supervise interns.

Dance therapists can also obtain psychological credentials by taking a test and becoming registered by the National Board for Certified Counselors, Inc.

Dandelion

Description

Dandelion (*Taraxacum officinale*) is a common meadow herb of the Asteraceae or sunflower family. There are about 100 species of dandelion, and all are beneficial. This sun-loving beauty is a native of Greece, naturalized in temperate regions throughout the world, and familiar to nearly everyone. The perennial dandelion grows freely wherever it can find a bit of earth and a place in the sun. Dandelion's nutritive and medicinal qualities have been known for centuries.

Dandelion's common name is derived from the French *dent de lion*, a reference to the irregular and jagged margins of the lance-shaped leaves. There are numerous folk names for this widely-used herb. They include pissabed, Irish daisy, blow ball, lion's tooth, bitterwort, wild endive, priest's crown, doonhead-clock, yellow gowan, puffball, clock flower, swine snort, fortune-teller, and cankerwort. The generic name is thought to be derived from the Greek words *taraxos*, meaning disorder, and *akos*, meaning remedy. Another possible derivation is from the Persian *tark hashgun*, meaning wild endive, one of dandelion's common names. The specific designation *officinale* indicates that this herb was officially listed as a medicinal. Dandelion held a place in the United States *National Formulary* from 1888 until 1965, and the dried root of dandelion is listed in the *United States Pharmacopoeia* (USP).

Dandelion may be distinguished from other similar-looking herbs by the hollow, leafless flower stems that contain a bitter milky-white liquid also found in the root and leaves. The dark green dandelion leaves, with their irregular, deeply jagged margins, have a distinctive hairless mid-rib. The leaves are arranged in a rosette pattern, and may grow to 1.5 ft (45.7 cm) in length. They have a lovely magenta tint that extends up along the inner rib of the stalkless leaf. When the plant is used as a dye, it yields this purple hue. Dandelion blossoms are singular and round, with compact golden-yellow petals. They bloom from early spring until well into autumn atop hollow stalks that may reach from 4–8 in (10.2–20.3 cm) tall. The golden blossoms yield a pale yellow dye for wool. After flowering, dandelion develops a round cluster of achenes, or seed cases. As many as 200 of these narrow seed cases, each with a single seed, form the characteristic puffball. Each achene is topped with a white, feathery tuft to carry it on the breeze. Dandelion's tap root may grow fat, and reach as deep as 1.5 ft (45.7 cm) in loose soil. The root has numerous hairy rootlets. Dandelion is a hardy herb and will regrow from root parts left in the ground during harvest.

General use

Dandelion has a long history of folk use. Early colonists brought the herb to North America. The native people soon recognized the value of the herb and sought it out for its medical and nutritious benefits. The entire plant is important as a general tonic, particularly as a liver tonic. It may be taken as an infusion of the leaf, a juice extraction, a root decoction, or a tincture. Fresh

KEY TERMS

Achene—Any small, dry, hard seed case or fruit that does not split open at maturity to discharge the seed. Dandelion seeds are held inside achenes.

Cholagogue—A substance that stimulates the flow of bile.

Infusion—The most potent form of extraction of an herb into water. Infusions are steeped for a longer period of time than teas.

Tincture—The extraction of a herb into an alcohol solution for either internal or external use.

leaves may be added to salads or cooked as a potherb. The juice extracted from the stem and leaf is the most potent part of the plant for medicinal purposes. It has been used to eradicate **warts** and soothe **calluses**, bee **stings**, or sores. Infusions of dandelion blossoms have been used as a beautifying facial, refreshing the skin.

Dandelion is a nutritive herb rich in **potassium**, calicum, and **lecithin**, with **iron**, **magnesium**, **niacin**, **phosphorus**, proteins, silicon, **boron**, and **zinc**. Dandelion provides several B vitamins along with vitamins C and E as well as vitamin P. Chemical constituents in the leaf include bitter glycosides, **carotenoids**, terpenoids, **choline**, potassium salts, iron, and other minerals. The root also has bitter glycosides, tannins, triterpenes, sterols, volatile oil, choline, asparagin, and inulin.

Many herbalists regard the dandelion as an effective treatment for liver disease, useful even in such extreme cases as **cirrhosis**. It cleanses the bloodstream and increases bile production, and is a good remedy for gall bladder problems as well. The herb is also a boon to such other internal organs as the pancreas, kidneys, stomach, and spleen. The dried leaf, taken as a tea, is used as a mild laxative to relieve **constipation**. Dandelion leaf is also a good natural source of potassium, and will replenish any potassium that may be lost due to the herb's diuretic action on the kidneys. This characteristic makes dandelion a safe diuretic in cases of water retention due to heart problems.The herb is useful in cases of **anemia** and **hepatitis**, and may lower elevated blood pressure. Dandelion may also provide relief for rheumatism and arthritis. Dandelion therapy, consisting of therapeutic doses of dandelion preparations taken over time, may help reduce stiffness and increase mobility in situations of chronic degenerative joint disease. The root, dried and minced, can be used as a coffee substitute, sometimes combined with roasted acorns and rye.

Preparations

All parts of the dandelion have culinary and medicinal value. It is best to harvest fresh young dandelion leaves in the spring. The small, young leaves are less bitter, and may be eaten uncooked in salads. Larger leaves can be lightly steamed to reduce bitterness. Leaves gathered in the fall are naturally less bitter. Dandelion blossoms, traditionally used in wine making, may be gathered throughout the flowering season. The deep, fleshy taproot should be gathered in the fall. It takes careful digging and loosening to extract the root intact, although any root parts left in the soil will eventually produce another plant. The root should be washed. Thicker roots should be sliced down their length to facilitate drying. The pieces should be spread out on a paper-lined tray in a light, airy room out of direct sunlight and stored in tightly sealed dark glass containers. Dried dandelion root may be somewhat less potent than the fresh root.

Leaf infusion: Place 2 oz of fresh dandelion leaf, less if dried, in a warmed glass container. Bring 2.5 cups of fresh nonchlorinated water to the boiling point and add it to the herbs. Cover the mixture and steep for 15–20 minutes, then strain. Drink the infusion warm or cold throughout the day, up to three cups per day. The prepared tea can be kept for about two days in the refrigerator.

Tincture: Combine 4 oz of finely-cut fresh dandelion root and leaf (or 2 oz of dry powdered herb) with 1 pt of brandy, gin, or vodka in a glass container. The alcohol should be enough to cover the plant parts and have a 50/50 ratio of alcohol to water. Cover and store the mixture away from light for about two weeks, shaking several times each day. Strain and store in a tightly capped dark glass bottle. A standard dose is 10–15 drops of the tincture in water, up to three times a day.

Precautions

Dandelion acts as a cholagogue, which means that it increases the flow of bile. It should not be used by persons with closure of the biliary ducts and other biliary ailments.

Side effects

Dandelion is a safe and nutritious herb widely used throughout the world. No health hazards have been reported when dandelion is used in designated therapeutic doses. According to the *PDR For Herbal Medicine*, however, some "superacid gastric complaints"

could be triggered by using the herb. Dandelion stems contain a liquid latex substance that may be irritating to the skin of senstitive persons.

Interactions

No interactions have been reported between dandelion and standard medications.

Dandruff

Definition

Dandruff is the common name for a mild form of seborrheic **dermatitis** of unknown cause. It is a natural and harmless scalp condition in which the shedding of dead skin cells occurs at an unusually fast rate. Because of the oily skin often associated with this condition, these cells clump together and flake off as dandruff.

Description

Dandruff is very common. Up to one-third of the U.S. population is affected by this condition. While it is not considered a disease, dandruff is a cosmetic concern for many people.

The following problems tend to exacerbate dandruff:

- cold weather
- dry indoor heating

Close-up view of the scalp of a 50 year old man with severe dandruff. *(Dr. P. Marazzi / Photo Researchers, Inc.)*

- stress (physical or emotional)
- food allergies
- nutritional deficiencies (B-complex vitamins or omega-3 fatty acids)
- use of hair spray and gels
- use of hair-coloring chemicals
- use of electric hair curlers or blow dryers

Causes and symptoms

Dandruff is caused by an overgrowth of skin cells that make up the scalp. It is not known what accelerates this cell growth. Scientists have suggested that dandruff may be a hypersensitive reaction to the proliferation of *Pityrosporum ovale*, a yeast that occurs naturally on the scalp. Another theory that held for some time linked dandruff to a fungus. A 2002 report said that scientists had identified new fungi of the Malassezia that seem to exist in overabundance on the scalps of those affected with the disease.

Diagnosis

Dandruff is easy to diagnose. The condition is characterized by the appearance of white flakes on the hair or on the shoulders and collar. People with oily hair tend to have dandruff more often. Dandruff usually does not require medical treatment. However, if, in addition to dandruff, a person also has greasy scaling on the face, eyebrows and eyelashes and thick, red patches on the body, he or she may have the more severe form of seborrheic dermatitis. This condition may require medical advice and treatment.

KEY TERMS

Cytostatic—Suppressing the growth and multiplication of cells.

Flake—A small, thin skin mass.

Scale—Any thin, flaky, plate-like piece of dry skin.

Seborrheic dermatitis—An inflammatory condition of the skin of the scalp, with yellowish greasy scaling of the skin and itching. Other areas of the body may also be affected. Mild seborrheic condition is called dandruff.

Treatment

Alternative treatments for dandruff include nutritional therapy, herbal therapy and **relaxation** therapy.

Nutritional therapy

The following nutritional changes may be helpful:

- Identification and avoidance of potential allergenic foods.
- Limited intake of milk and other dairy products, seafoods and fatty treats. These foods tend to exacerbate dandruff.
- Reduction or elimination of animal proteins and eating mostly whole grains, fresh vegetables, beans and fruit.
- Avoiding citrus until dandruff clears.
- Diet supplemented with B-complex vitamins which may alleviate dandruff condition.
- Avoiding excess salt, sugar, and alcohol.
- Taking 1 tablespoon of flaxseed oil per day. Flaxseed oil is rich in omega-3 fatty acids, which may be effective in treating a variety of skin conditions including dandruff.

From a traditional medical approach, dandruff may be the body's way of eliminating excess protein accumulated but not assimilated in the system. It may also be a symptom of liver and kidney imbalances. A more stabilizing diet is needed, reducing highly acidic foods such as tomatoes and certain spices.

Herbal therapy

Massaging **tea tree oil** (*Melaleuca alternifolia*) into the scalp may help prevent or relieve dandruff. This oil can relieve scaling and **itching**. Ayurvedic treatment also includes various oil therapies, called *suehana* for the head. Increased **exercise** can increase circulation and help eliminate fats and oils.

Relaxation therapies

Relaxation techniques such as **meditation** or **yoga** may help relieve **stress**, which exacerbates dandruff.

Allopathic treatment

There is no cure for this natural harmless skin condition. Because a greasy scalp is associated with dandruff condition, more frequent hair washing using regular shampoo is usually all that is needed. In more severe cases, medicated shampoo may be necessary.

The two most commonly used anti-dandruff shampoos are **selenium** sulfide and **zinc** pyrithione. Both of these are cytostatic agents. Cytostatic drugs slow down the growth and formation of top skin layer on the scalp. To get the best result, one should leave the shampoo on for as long as possible. It is recommended that a person lather the anti-dandruff shampoo at the beginning of the shower, leave it on until the end of the shower, then rinse, lather, and rinse again. As a result of treatment with any of these drugs, dandruff will become less noticeable. Because it can be irritating, shampoo containing selenium sulfide should not be used if the skin is cut or abraded.

Products containing salicylic acid and **sulfur** are reserved for more severe cases. Salicylic acid loosens the dead skin cells so that they can be sloughed off more easily. Sometimes, antibacterial shampoos are used to reduce bacteria on the scalp.

Recently, antifungal products, such as ketoconazole (Nizoral) shampoos, are available over-the-counter (1% preparation) and by prescription (2% preparation). These shampoos are often prescribed by dermatologists to reduce the growth of *P. ovale*. These preparations may be helpful if dandruff is not relieved by other shampoo treatments.

The most severe and recalcitrant dandruff conditions may require tar shampoos. These shampoos reduce the growth of top skin cells on the scalp. It is recommended that the shampoo be left on the hair for at least 10 minutes for best results. Coal tar shampoos can be messy and can stain blond or white hair. Coal tar also can be carcinogenic (causing **cancer**). The FDA approves this product because when used as shampoo, because it contacts the scalp for only a short period of time. Still, it is a good idea to use alternative treatments for this relatively harmless condition.

Because anti-dandruff shampoos may lose effectiveness after a while, it may be helpful to rotate

between a medicated shampoo and a regular shampoo or try a different type of anti-dandruff shampoo.

Expected results

While one can not cure dandruff, it can be easily managed. A mild dandruff condition often responds to more frequent hair washes with regular shampoo. More severe conditions may require anti-dandruff preparations.

Prevention

Preventive measures include regular hair washing, reducing stress, eating healthy foods and increasing humidity inside the house. In addition, excessive use of hair curlers, hair sprays and gels, and frequent hair coloring should be avoided. These tend to irritate the scalp and may worsen dandruff.

Deglycyrrhizinated licorice

Description

Deglycyrrhizinated **licorice**, or DGL, is a specific type of preparation derived from the licorice root. It is used differently than herbal licorice because it is much higher in agents that soothe or heal mucous membranes, and lower in other constituents found in licorice root and full extracts of licorice root. DGL may also be spelled, deglycyrrhizinated liquorice. The herb, licorice, from which DGL is derived, is known by the names *Glycyrrhiza*, sweet root, and *Yasti-madhu* with the glycyrrhizin removed.

Licorice is a perennial herb, which is native to the Middle East, and widely cultivated in Europe, the Middle East, and Asia. The root has a long history of use as a medicament and flavoring agent. Its name, *Glycyrrhiza* (sweet root) has been attributed to the first century Greek physician, Dioscorides.

Glycyrrhizin is the cause of pseudoaldosteronism, a condition mimicking the effects of excessive levels of the adrenal hormone aldosterone. The deglycyrrhizinated product was developed to concentrate the demulcent and healing aspects of licorice, while avoiding excess exposure to glycerrhizin and its adverse effects when taken in high doses.

General use

Deglycyrrhizinated licorice is used to soothe and protect the lining of the stomach and duodenum (upper small intestine)—the common sites of gastric ulcers. Ulcers in the stomach are known as peptic ulcers, while those in the small intestine are duodenal ulcers. DGL has been studied for the treatment of peptic and duodenal ulcers, and appears to be both safe and effective for long-term maintenance therapy for certain patients who have these ulcers. Some marketers claim that DGL has anti-inflammatory, antimicrobial, and antioxidant activities. However, these claims are unsubstantiated.

One study, using a mouthwash containing deglycyrrhizinated licorice, showed dramatic improvement in the healing and **pain** of mouth ulcers.

Preparations

DGL is available as:

- capsules, 250 milligrams (mg)
- chewable tablets (with or without sugar), 140 and 380 mg

KEY TERMS

Aldosterone—A hormone produced by the adrenal gland, instrumental in the regulation of sodium and potassium resorption by the kidney.

Demulcent—An oily or sticky substance used to soothe irritation in mucous membranes.

Expectorant—A medication that promotes the secretion or expulsion of phlegm, mucus, or other matter from the respiratory tract.

Gastritis—Inflammation of the stomach, particularly of its mucous membrane.

Lozenge—A medicated candy intended to be dissolved slowly in the mouth to soothe irritated tissues of the throat.

Milk alkali syndrome—A disorder of the kidneys caused by long-term treatment of ulcers with antacids, particularly alkaline compounds such as sodium bicarbonate, and large amounts of calcium.

- lozenges, 400 mg
- wafers, 380 mg
- liquid, various concentrations

Precautions

Deglycyrrhizinated licorice appears to be very safe. However, severe allergic reactions are possible. There has been one report of a case of milk alkali syndrome in a patient who was drinking unusually large amounts of milk. This has led to a caution against taking **calcium** supplements and deglycyrrhizinated licorice at the same time. It is usually safe at normal dose levels.

Although there have been few studies conducted to determine whether interactions between deglycyrrhizinated licorice and conventional drugs exist, research has failed to identify problems.

Side effects

Gastritis, **nausea**, and **diarrhea** are reported side effects.

Interactions

All clinically significant adverse interactions with licorice have been due to the effects of the glycyrrizic acid. They would not be anticipated with this component removed. DGL reportedly reduces the gastric ulceration caused by aspirin and other non-steroidal anti-inflammatory drugs.

Dementia

Definition

Dementia is a loss of mental ability severe enough to interfere with normal activities of daily living, lasting more than six months, not present since birth, and not associated with a loss or alteration of consciousness.

Description

Dementia is a group of symptoms caused by gradual death of brain cells. The loss of cognitive abilities that occurs with dementia leads to impairments in memory, reasoning, planning, and personality. While the overwhelming majority of people with dementia are elderly, the condition is not an inevitable part of **aging**. Instead, dementia is caused by specific brain diseases. **Alzheimer's disease** is the most common cause, followed by vascular or multi-infarct dementia.

The prevalence of dementia has been difficult to determine, partly because of differences in definition among different studies, and partly because there is some normal decline in functional ability with age. Dementia affects 5–8% of all people between ages 65

and 74, and up to 20% of those between 75 and 84. Estimates for dementia in those 85 and over range from 30–47%. Between two and four million Americans have Alzheimer's disease; that number is expected to grow to as many as 14 million by the middle of the twenty-first century as the population as a whole ages.

The cost of dementia can be considerable. While most people with dementia are retired and do not suffer income losses from their disease, the cost of care is often enormous. Financial burdens include lost wages for family caregivers, medical supplies and drugs, and home modifications to ensure safety. Nursing home care may cost several thousand dollars a month or more. The psychological cost is not as easily quantifiable but can be even more profound. Individuals with dementia lose control of many of the essential features of their life and personality, and loved ones lose a family member even as they continue to cope with the burdens of increasing dependence and unpredictability.

Causes and symptoms

Causes

Dementia is usually caused by degeneration of brain cells in the cerebral cortex, the part of the brain responsible for thoughts, memories, actions, and personality. Death of brain cells in this region leads to the cognitive impairment that characterizes dementia.

The most common cause of dementia is Alzheimer's disease (AD), accounting for half to three-fourths of all cases. The brain of a person with AD becomes clogged with two abnormal structures, called neurofibrillary tangles and senile plaques. Neurofibrillary tangles are twisted masses of protein fibers inside nerve cells, or neurons. Senile plaques are composed of parts of neurons surrounding a group of proteins called beta-amyloid deposits. Why these structures develop is unknown. As of 2008, research indicated possible roles for inflammation, blood flow restriction, and accumulation of aluminum in the brain and toxic molecular fragments known as free radicals or oxidants.

Several genes have been associated with higher incidences of AD, although the exact role of these genes is still unknown. In 2001, investigators discovered a rare mutation in the amyloid precursor protein (APP) that is linked to early-onset Alzheimer's. The discovery pointed scientists toward new ideas for targeting and treating the disease.

Vascular dementia is estimated to cause from 5–30% of all dementias. It occurs from a decrease in blood flow to the brain, most commonly due to a series of small strokes (multi-infarct dementia). Other cerebrovascular causes include: vasculitis from **syphilis**, **Lyme disease**, or **systemic lupus erythematosus**; subdural hematoma; and subarachnoid hemorrhage. Because of the usually sudden nature of its cause, the symptoms of vascular dementia tend to begin more abruptly than those of Alzheimer's dementia. Symptoms may progress stepwise with the occurrence of new strokes. Unlike AD, the incidence of vascular dementia is lower after age 75.

Other conditions that may cause dementia include:

- AIDS
- Parkinson's disease
- Lewy body disease
- Pick's disease
- Huntington's disease
- Creutzfeldt-Jakob disease
- brain tumor
- hydrocephalus
- head trauma
- multiple sclerosis
- prolonged abuse of alcohol or other drugs
- vitamin deficiency: thiamin, niacin, or B_{12}
- hypothyroidism
- hypercalcemia

Symptoms

Dementia is marked by a gradual impoverishment of thought and other mental activities. Losses eventually affect virtually every aspect of mental functioning. The slow progression of dementia is in contrast with delirium, which involves some of the same symptoms, but has a very rapid onset and fluctuating course with alteration in the level of consciousness. However, delirium may occur with dementia, especially since the person with dementia is more susceptible to the delirium-inducing effects of many types of drugs.

Symptoms include:

- Memory losses. Short-term memory loss is usually the first symptom noticed. It may begin with misplacing valuables such as a wallet or car keys, then progress to forgetting appointments, where the car was left, and the route home, for instance. More profound losses may eventually follow, such as forgetting the names and faces of family members.
- Impaired abstraction and planning. The person with dementia may lose the ability to perform familiar tasks, to plan activities, and to draw simple conclusions from facts.

- Language and comprehension disturbances. Individuals may be unable to understand instructions or follow the logic of moderately complex sentences. Later, they may not understand their own sentences, and they may have difficulty forming thoughts into words.
- Poor judgment. Individuals may not recognize the consequences of their actions or be able to evaluate the appropriateness of behavior. Behavior may become crude or offensive, overly-friendly, or aggressive. Personal hygiene may be ignored.
- Impaired orientation ability. Individuals may not be able to identify the time of day, even from obvious visual clues or may not recognize their location, even if familiar. This disability may stem partly from losses of memory and partly from impaired abstraction.
- Decreased attention and increased restlessness. Individuals may begin an activity and quickly lose interest and wander away frequently. Wandering may cause significant safety problems when combined with disorientation and memory losses. Individuals may begin to cook something on the stove then become distracted and wander away while it is cooking.
- Personality changes and psychosis. Individuals may lose interest in once-pleasurable activities and become more passive, depressed, or anxious. Delusions, suspicion, paranoia, and hallucinations may occur later in the disease. Sleep disturbances may occur, including insomnia and sleep interruptions.
- Apathy. A four-year study by researchers at the University of Nebraska Medical Center reported in 2007 that apathy may be a behavioral marker for dementia. Apathy—a loss of motivation—is identified by symptoms such as diminished initiation, poor persistence, lack of interest, indifference, low social interactions, muted emotional responses, and a lack of insight, according to study researchers. The incidence of apathy may be as high as 80% in people with primary dementia, and the rate increases as the severity of dementia increases, the study reported.

Diagnosis

Since dementia usually progresses slowly, diagnosing it in its early stages can be difficult. Several office visits over several months or more may be needed. Diagnosis begins with a thorough physical exam and complete medical history, usually including comments from family members or caregivers. A family history of either Alzheimer's disease or cerebrovascular disease may provide clues to the cause of symptoms. Simple tests of mental function, including word recall, object naming, and number-symbol matching, are used to track changes in the person's cognitive ability. Some studies suggest that positron emissions tomography (PET) scans of the brain might be able to identify those at risk for Alzheimer's. As these tests become more widely available, they may offer hope for earlier detection of dementia.

Depression is common in the elderly and can be mistaken for dementia; therefore, ruling out depression is an important part of the diagnosis. Distinguishing dementia from the mild normal cognitive decline of advanced age is also critical. The medical history includes a complete listing of drugs being taken, since a number of drugs can cause dementia-like symptoms.

Determining the cause of dementia may require a variety of medical tests, chosen to match the most likely etiology. Cerebrovascular disease, hydrocephalus, and tumors may be diagnosed with x rays, CT or MRI scans, and vascular imaging studies. Blood tests may reveal nutritional or metabolic deficiencies or hormone imbalances.

Treatment

Nutritional supplements

Some nutritional supplements may be helpful, especially if dementia is caused by deficiency of these essential nutrients:

- Acetyl-L-carnitine: improves brain function and increases attention span, enhances ability to concentrate and increases energy in patients with Alzheimer's disease.
- Antioxidants (vitamin E, vitamin C, beta-carotene, or selenium): may slow disease progression by preventing the damaging effects of free radicals. An 18-year long study of more than 4,000 persons reported in 2007 that people who take 50 mg a day of beta-carotene for at least 15 years are less likely to develop dementia than those who do not take the dietary supplement.
- B-complex vitamins and vitamin B_{12}: may significantly improve mental function in patients who have low levels of these essential nutrients.
- Coenzyme Q10: helps deliver more oxygen to the brain.
- DHEA: may increase brain function in old people.
- Magnesium: may be helpful if the dementia is caused by magnesium deficiency and/or accumulation of aluminum in the brain.
- Phosphotidylserine: deficiency of this nutrient may decrease mental function and cause depression.
- Zinc: may boost short-term memory and increase attention span.

Herbal treatment

Herbal remedies that may be helpful in treating dementia include Chinese or **Korean ginseng**, **Siberian ginseng**, **gotu kola**, and *Ginkgo biloba*. Of these, **ginkgo biloba** is the most well-known and widely accepted by

Western medicine. Ginkgo extract, derived from the leaves of the *Ginkgo biloba* tree, interferes with a circulatory protein called platelet-activating factor. It also increases circulation and oxygenation to the brain. Ginkgo extract has been used for many years in China and is widely prescribed in Europe for treatment of circulatory problems. A 1997 study of patients with dementia appeared to show that gingko extract could reduce their symptoms. Some scientists believe that, taken early enough in the process, *Ginkgo biloba* can delay the onset of Alzheimer's, but this claim has not yet been sufficiently backed by supportive studies. A traditional Chinese herb, *ba wei di huang wan,* is useful in helping slow cognitive and physical decline in people with dementia, according to the American Geriatrics Society.

Homeopathy

A homeopathic physician may prescribe patient-specific homeopathic remedies to alleviate symptoms of dementia.

Acupressure

This form of therapy uses hands to apply pressure on specific **acupressure** points to improve blood circulation and calm the nervous system.

Aromatherapy

Aromatherapists use **essential oils** as inhalants or in baths to improve mental performances and to calm the nerves.

Chelation therapy

This controversial treatment may provide symptomatic improvement in some patients. However, its effectiveness has not been supported by clinical studies. In addition, this form of therapy may cause kidney damage. Therefore, it should only be given under the watchful eyes of a qualified physician.

Other therapy

A Canadian study reported in 2008 that **relaxation** techniques, such as music and **massage therapy**, can decrease agitation and improve the quality of life in persons with dementia. The study showed that playing favorite music to patients and giving them a massage by hand, used individually or together, significantly reduced agitation in people with mild to moderate dementia in a nursing home setting.

Allopathic treatment

As of 2008, there were no therapies that can reverse the progression of Alzheimer's disease. Therefore, treatment of dementia begins with treatment of the underlying disease when possible. Aspirin, estrogen, **vitamin E**, selegiline, propentofylline, and milameline were being evaluated for their ability to slow the rate of progression.

Care for individuals with dementia can be difficult and complex. Patients cope with functional and cognitive limitations, while family members or other caregivers assume increasing responsibility for the person's physical needs.

Symptoms of dementia may be treated with a combination of **psychotherapy**, environmental modifications, and medication. Behavioral approaches may be used to reduce the frequency or severity of problem behaviors, such as aggression or socially inappropriate conduct.

Modifying the environment can increase safety and comfort while decreasing agitation. Home modifications for safety include removal or lock-up of hazards such as sharp knives, dangerous chemicals, and tools. Child-proof latches or Dutch doors may be used to limit access as well. Lowering the hot water temperature to 120°F (48.9°C) or less reduces the risk of scalding. Bed rails and bathroom safety rails can be important safety devices, as well. Confusion may be reduced with simpler decorative schemes and presence of familiar objects. Covering or disguising doors (with a mural, for example) may reduce the tendency to wander. Positioning the bed in view of the bathroom can decrease incontinence.

Two drugs, tacrine (Cognex) and donepezil (Aricept), are commonly prescribed for Alzheimer's disease. These drugs inhibit the breakdown of acetylcholine in the brain, prolonging its ability to conduct chemical messages between brain cells. They provide temporary improvement in cognitive functions for about 40% of patients with mild-to-moderate AD. Hydergine is sometimes prescribed as well, though it is of questionable benefit for most patients. Drugs that are frequently used in dementia patients include antianxiety (for agitation and **anxiety**), antipsychotics (for paranoia, delusions or hallucinations), and antidepressants (for depressive symptoms). Evaluation of any medical side effects from the medications should be ongoing.

Long-term institutional care may be needed for individuals with dementia, as profound cognitive losses often precede death by a number of years. Early planning for the financial costs of nursing home care is critical. Useful information about financial planning for long-term care is available through the Alzheimer's Association.

Expected results

The prognosis for dementia depends on the underlying disease. On average, people with Alzheimer's

KEY TERMS

Donepezil—A drug commonly prescribed for Alzheimer's disease that provides temporary improvement in cognitive functions for some patients with mild-to-moderate forms of the disease.

Ginkgo extract—Made from the leaves of the *Ginkgo biloba* tree, this extract, used in other countries to treat circulatory problems, may reduce the symptoms of patients with dementia.

Neurofibrillary tangles—Abnormal structures, composed of twisted masses of protein fibers within nerve cells, found in the brains of persons with Alzheimer's disease.

Senile plaques—Abnormal structures, composed of parts of nerve cells surrounding protein deposits, found in the brains of persons with Alzheimer's disease.

Tacrine—A drug commonly prescribed for Alzheimer's disease that provides temporary improvement in cognitive functions for some patients with mild-to-moderate forms of the disease.

disease live eight years past their diagnosis, with a range from one to twenty years. Vascular dementia is usually progressive, with death from **stroke**, infection, or **heart disease**.

Prevention

There is no known way to prevent Alzheimer's disease, although several drugs are under investigation and may reduce its risk or slow its progression. Nutritional supplements, including **antioxidants**, may also help protect against Alzheimer's disease. Some studies also show that use of nonsteroidal anti-inflammatory agents (over-the-counter **pain** relievers such as ibuprofen and naproxen) may lower risk of Alzheimer's. The risk of developing multi-infarct dementia may be reduced by reducing the risk of stroke. Sources of aluminum, which can be found in aluminum cookware, canned sodas, and certain antacids and deodorants, should be avoided.

Depression

Definition

Depression, also known as depressive disorders or unipolar depression, is a mental illness characterized by a profound and persistent feeling of sadness or despair and/or a loss of interest in things that once were pleasurable. Disturbance in sleep, appetite, and mental processes are a common accompaniment.

Symptoms of childhood/adolescent depression

- Drop in school performance
- Appetite changes (usually loss, but sometimes can be an increase)
- Weight loss or gain
- Stomachaches
- Insomnia
- Excessive daytime sleepiness
- Social withdrawal
- Drug or alcohol abuse
- Isolation
- Apathy
- Fatigue
- Lack of concentration

(Illustration by Corey Light. Cengage Learning, Gale)

Symptoms of adult depression

- Long-term sadness
- Feelings of worthlessness or guilt
- Lack of interest in sex
- Loss of concentration, memory, and ability to make decisions
- Loss of interest in activities
- Fatigue
- Weight loss or gain
- Insomnia or oversleeping
- Increased use of alcohol or drug use
- Anxiety
- Suicidal thoughts
- Slowed speech and physical movement

(Illustration by Corey Light. Cengage Learning, Gale)

Description

Everyone experiences feelings of unhappiness and sadness occasionally. However, when these depressed feelings start to dominate everyday life without a recent loss or trauma and cause physical and mental deterioration, they become what is known as depression. Each year in the United States, depression affects an estimated 17 million people at an approximate annual direct and indirect cost of $53 billion. One in four women is likely to experience an episode of severe depression in her lifetime, with a 10–20% lifetime prevalence, compared to 5–10% for men. The average age a first depressive episode occurs is in the mid-20s, although the disorder strikes all age groups indiscriminately, from children to the elderly.

There are two main categories of depression: major depressive disorder and dysthymic disorder. Major depressive disorder is a moderate to severe episode of depression lasting two or more weeks. Individuals experiencing this major depressive episode may have trouble sleeping, lose interest in activities in which they once took pleasure, experience a change in weight, have difficulty concentrating, feel worthless and hopeless, or have a preoccupation with death or suicide. In children, major depression may appear as irritability.

While major depressive episodes may be acute (intense but short-lived), dysthymic disorder is an ongoing, chronic depression that lasts two or more years (one or more years in children) and has an average duration of 16 years. The mild to moderate depression of dysthymic disorder may rise and fall in intensity, and those afflicted with the disorder may experience some periods of normal, nondepressed mood of up to two months in length. Its onset is gradual, and dysthymic patients may not be able to pinpoint exactly when they started feeling depressed. Individuals with dysthymic disorder may experience a change in sleeping and eating patterns, low self-esteem, **fatigue**, trouble concentrating, and feelings of hopelessness.

Depression also can occur in **bipolar disorder**, an affective mental illness that causes radical emotional changes and mood swings, from manic highs to depressive lows. The majority of bipolar individuals experience alternating episodes of mania and depression.

Causes and symptoms

The causes behind depression are complex and not yet fully understood. While an imbalance of certain neurotransmitters, the chemicals in the brain that transmit messages between nerve cells, is believed to be key to depression, external factors such as upbringing (more so in dysthymia than major depression) may be as important. For example, it is speculated that, if an individual is abused and neglected throughout childhood and adolescence, a pattern of low self-esteem and negative thinking may emerge, and from that, a lifelong pattern of depression may follow. A 2003 study reported that two-thirds of patients with major depression stated they also suffered from chronic **pain**. It is not clear what the relationship is, because while pain inducing conditions are a common cause of depression, one of the first symptoms of depression may be pain.

Heredity seems to play a role in those who develop depression. Individuals with major depression in their immediate family are up to three times more likely to have the disorder themselves. It would seem that biological and genetic factors may make certain individuals predisposed or prone to depressive disorders, but environmental circumstances may often trigger the disorder.

External stressors and significant life changes, such as chronic medical problems, death of a loved one, divorce or estrangement, miscarriage or neonatal death, or loss of a job also can result in a form of depression known as adjustment disorder. Although periods of adjustment disorder usually resolve themselves, occasionally they may evolve into a major depressive disorder.

Major depressive episode

Individuals experiencing a major depressive episode have a depressed mood and/or a diminished interest or pleasure in activities. Children experiencing a major depressive episode may appear or feel irritable, rather than depressed. In addition, five or more of the following symptoms occur on an almost daily basis for a period of at least two weeks:

- significant change in weight
- insomnia or hypersomnia (excessive sleep)
- psychomotor agitation or retardation
- fatigue or loss of energy
- feelings of worthlessness or inappropriate guilt
- diminished ability to think or to concentrate or indecisiveness
- recurrent thoughts of death or suicidal and/or suicide attempts

Dysthymic disorder

Dysthymia commonly occurs in tandem with other psychiatric and physical conditions. Up to 70% of dysthymic patients have both dysthymic disorder and major depressive disorder, known as double depression. **Substance abuse**, panic disorders, personality disorders, social **phobias**, and other psychiatric conditions also are found in many dysthymic patients. Dysthymia is prevalent in patients with certain medical conditions, including **multiple sclerosis**, **AIDS**, **hypothyroidism**, **chronic fatigue syndrome**, **Parkinson's disease**, diabetes, and postcardiac transplantation. The connection between dysthymic disorder and these medical conditions is unclear, but it may be related to the way the medical condition and/or its pharmacological treatment affects neurotransmitters. Dysthymic disorder can lengthen or complicate the recovery of patients who also have medical conditions.

Along with an underlying feeling of depression, people with dysthymic disorder experience two or more of the following symptoms on an almost daily basis for a period of two or more years (most suffer for five years), or one year or more for children:

- under or overeating
- insomnia or hypersomnia
- low energy or fatigue
- low self-esteem
- poor concentration or trouble making decisions
- altered libido
- altered appetite
- altered motivation
- feelings of hopelessness

Diagnosis

The guidelines for diagnosis of major depressive disorder and dysthymic disorder are found in the *Diagnostic and Statistical Manual of Mental Disorders* (4th ed.) (*DSM IV*). In addition to an interview, several clinical inventories or scales may be used to assess a patient's mental status and determine the presence of depressive symptoms. Among these tests are: the Hamilton Depression Scale (HAM-D), Child Depression Inventory (CDI), Geriatric Depression Scale (GDS), Beck Depression Inventory (BDI), and the Zung Self-Rating Scale for Depression. These tests may be administered in an outpatient or hospital setting by a general practitioner, social worker, psychiatrist, or psychologist.

Treatment

A variety of alternative medicines have proven to be helpful in treating depression. A recent report from Great Britain emphasized that more physicians should encourage alternative treatments such as behavioral and self-help programs, supervised **exercise** programs, and watchful waiting before subscribing antidepressant medications for mild depression. Chocolate, coffee, sugar, and alcohol can negatively affect mood; however, this connection may be due to emotional associations of these foods rather than pharmacologic effects. In a 2007 study, researchers found that when women following a weight loss program thought about chocolate, without eating it, they experienced feelings of guilt, which could be tied to minor depression. Similar responses might be associated with other forbidden substances. **Essential fatty acids** may reduce depression and boost mood. Expressing thoughts and feelings in a journal is therapeutic. **Aromatherapy**, particularly citrus fragrance, has had a positive effect on depression. **Psychotherapy** or counseling is an integral component of treatment because it can find and treat the cause of the depression.

Psychosocial therapy

Psychotherapy explores a person's life to bring forth possible contributing causes of depression. During treatment, therapists help individual patients to become aware of their thinking patterns and how these originated. There are several different subtypes of psychotherapy, but all have the common goal of helping patients develop healthy problem solving and coping skills.

Cognitive-behavioral therapy assumes that the patient's faulty thinking causes the current depression and focuses on changing thought patterns and perceptions. Therapists help their patients identify negative or distorted thought patterns and the emotions and behavior that accompany them and then retrain the patients to recognize the thinking and react differently to it.

Chinese medicine and herbals

The principle of treatment of depression involves regulating qi, reducing phlegm, calming the mind, and promoting mental resuscitation. The Chinese medicine *Bai Jin Wan* (White Metal Pill) is used to treat depression (5 g twice daily). A practitioner may prescribe a variety of treatments—including lifestyle changes—depending on the type and severity of the depression.

There is some evidence that **acupuncture** is a helpful treatment for depression. One double-blind study found that patients who received acupuncture specific for depression were significantly less depressed than control patients who had either nonspecific acupuncture or no treatment.

St. John's wort (*Hypericum perforatum*) is the most widely used antidepressant in Germany. Many studies on the effectiveness of St. John's wort have been performed. One review of the studies determined that St. John's wort is superior to placebo and comparable to conventional antidepressants. In early 2000, well designed studies comparing the effectiveness of St. John's wort versus conventional antidepressants in treating depression were conducted in the United States. Despite uncertainty concerning its effectiveness, a 2003 report said acceptance of the treatment continued to increase. A 2006 study compared hypericum with placebo in patients with either minor depression or dysthymia. The treatment showed significant advantages in the non-dysthymia patients only. A poll showed that about 41% of 15,000 science professionals in 62 countries said they would use St. John's wort for mild to moderate depression. Although St. John's wort appears to be a safe alternative to conventional antidepressants, care should be taken, as the herb can interfere with the actions of some pharmaceuticals. The usual dose is 300 mg three times daily.

Orthomolecular therapy

Orthomolecular therapy refers to therapy that strives to achieve the optimal chemical environment for the brain. The theory behind this approach is that mental disease is caused by low concentrations of specific chemicals. Linus Pauling believed that mental disease was caused by low concentrations of the B vitamins, **biotin**, **vitamin C**, or **folic acid**. Supplementation with vitamins B_1, B_2, and B_6 improved the symptoms of depression in geriatric patients taking tricyclic antidepressants. The **amino acids** tryptophan, tyrosine, and phenylalanine have been shown to have positive effects on depression, although large, controlled studies need to be carried out to confirm these findings.

S-ADENOSYL-METHIONINE. In several small studies, S-adenosyl-methionine (SAM, SAMe) was shown to be more effective than placebo and equally effective as tricyclic antidepressants in treating depression. The usual dosage is 200 mg to 400 mg twice daily. In 2003, a U.S. Department of Health and Human Services team reviewed 100 clinical trials on SAMe and concluded that it worked as well as many prescription medications without the side effects of stomach upset and decreased sexual desire.

5-HYDROXYTRYPTOPHAN. 5-hydroxytryptophan (5-HT, **5-HTP**) is a precursor to serotonin. Most of the commercially available 5-HT is extracted from the plant *Griffonia simplicifolia*. In several small studies, treatment with 5-HT significantly improved depression in more than half of the patients. One review of these studies suggests that 5-HT has antidepressant properties; however, large studies must be performed to confirm this finding. The usual dose is 50 mg three times daily. Side effects include **nausea** and gastrointestinal disturbances.

Homeopathic remedies

Homeopathic remedies can be helpful treatments for depression. A British study claims that more than 75% of treated patients show a favorable response to homeopathic therapy after the second visit. A homeopathic practitioner should be consulted for dosages, but common remedies are:

- *Arum metallicum* for severe depression
- Ignatia for adjustment disorder
- Natrum muriaticum for depression of long duration

Light therapy

Light therapy is helpful in controlling the depression of **seasonal affective disorder** (SAD). Treatment consists of exposure to light of a high intensity and/or specific spectra for an hour per day from a light box placed on the floor or on a table. The light intensity is usually 10,000 lux, which is similar to the light of a sunny day. The opposite may be used as well, which is the use of a dawn simulator for those patients who have an overdose of light exposure and require more sleep with less light. Most persons will see an effect within three to four weeks. Side effects include headaches, eyestrain, irritability, and **insomnia**. A week or more in a sunny climate may improve SAD.

Allopathic treatment

Depression usually is treated with antidepressants and/or psychosocial therapy. When used together correctly, therapy and antidepressants constitute a powerful treatment plan for depressed individuals.

Drugs

Selective serotonin reuptake inhibitors (SSRIs), such as fluoxetine (Prozac) and sertraline (Zoloft), reduce depression by increasing levels of serotonin, a neurotransmitter. Some clinicians prefer SSRIs for treatment of dysthymic disorder. **Anxiety**, **diarrhea**, drowsiness, **headache**, sweating, nausea, poor sexual functioning, and insomnia are all possible side effects of SSRIs. A recent study shows this generation of drugs increases patients' risk of gastrointestinal bleeding.

Tricyclic antidepressants (TCAs) are less expensive than SSRIs but have more severe side effects, including persistent **dry mouth**, sedation, **dizziness**, and cardiac arrhythmias. Because of these side effects, caution is taken when prescribing TCAs to elderly patients. TCAs include amitriptyline (Elavil), imipramine (Tofranil), and nortriptyline (Aventyl, Pamelor). A 10-day supply of TCAs can be lethal if ingested all at once, so these drugs may not be a preferred treatment option for patients at risk for suicide.

Monoamine oxidase inhibitors (MAOIs), such as tranylcypromine (Parnate) and phenelzine (Nardil), block the action of monoamine oxidase (MAO), an enzyme in the central nervous system. Patients taking MAOIs must avoid foods high in tyramine (found in aged cheeses and meats) to avoid potentially serious hypertensive side effects.

Heterocyclics include bupropion (Wellbutrin) and trazodone (Desyrel). Bupropion is prescribed to patients with a seizure disorder. Side effects include agitation, anxiety, confusion, **tremor**, dry mouth, fast or irregular heartbeat, headache, low blood pressure, and insomnia. Because trazodone has a sedative effect, it is useful in treating depressed patients with insomnia. Other possible side effects of trazodone include dry mouth, gastrointestinal distress, dizziness, and headache. In 2003, Wellbutrin's manufacturer released a once-daily version of the drug that offered low risk of sexual side effects or weight gain.

Electroconvulsive therapy

Electroconvulsive therapy (ECT) usually is employed after all therapy and pharmaceutical treatment options have been explored and exhausted. However, it is sometimes used early in treatment when severe depression is present and the patient refuses oral medication or when the patient is becoming dehydrated, extremely suicidal, or psychotic.

The treatment consists of a series of electrical pulses that move into the brain through electrodes on the patient's head. ECT is given under general anesthesia, and patients are administered a muscle relaxant to prevent convulsions. Although the exact mechanisms behind the success of ECT therapy are not known, it is believed that the electrical current modifies the electrochemical processes of the brain, consequently relieving depression. Headaches, muscle soreness, nausea, and confusion are possible side effects immediately following an ECT procedure. **Memory loss**, typically transient, has also been reported in ECT patients. ECT

KEY TERMS

Dysthemia—A state of chronic, mild depression.

Hypersomnia— Excessive sleeping (can be from 9 20 hours, or more); a symptom of dysthymic and major depressive disorder.

Neurotransmitter—A chemical in the brain that transmits messages between neurons, or nerve cells. Changes in the levels of certain neurotransmitters, such as serotonin, norepinephrine, and dopamine, are thought to be related to depressive disorders.

Psychomotor agitation—Disturbed physical and mental processes (e.g., fidgeting, wringing of hands, racing thoughts); a symptom of major depressive disorder.

Psychomotor retardation—Slowed physical and mental processes (e.g., slowed thinking, movement, and talking); a symptom of major depressive disorder.

Seasonal affective disorder (SAD)—Depression caused by decreased daylight during the winter months.

causes severe memory problems for months or years in one out of every 200 patients treated.

Late in 2001, a study reported on a pacemaker-like device used to treat **epilepsy** adapted for patients with depression. An implanted electronic device sends intermittent signals to the vagus nerve, which in turn carries the signals to the brain, connecting in areas known to regulate mood. Although still experimental at that time, early results in treating depression were encouraging.

Expected results

Untreated or improperly treated depression is the number one cause of suicide in the United States. Proper treatment relieves symptoms in 80–90% of depressed patients. After each major depressive episode, the risk of recurrence climbs significantly—50% after one episode, 70% after two episodes, and 90% after three episodes. For this reason, patients need to be aware of the symptoms of recurring depression and may require long-term maintenance treatment.

Overall, recommendations in the early 2000s from mental health clinicians suggested that the recovery process for patients with depression works best when mental health professionals focus on the whole person behind the disorder. In addition to prescribing medications, they also should address patients' self-esteem, feeling of control, and determination. They emphasize that patients with depression need a sense of optimism and should be encouraged to seek the support of family members and friends.

Prevention

Patient education in the form of therapy or self-help groups is crucial for training patients with depressive disorders to recognize early symptoms of depression and to take an active part in their treatment program. Extended maintenance treatment with antidepressants may be required in some patients to prevent relapse. Early intervention with children with depression is effective in halting development of more severe problems.

Dermatitis

Definition

Dermatitis is a general term used to describe inflammation of the skin.

Description

Most types of dermatitis are characterized by a pink or red rash that itches.

Contact dermatitis is an allergic reaction to something that irritates the skin and is manifested by one or more lines of red, swollen, blistered skin that may itch or weep. It usually appears within 48 hours after coming into contact with a substance to which the skin is

sensitive. The condition is more common in adults than in children. The rash most people develop when exposed to poison ivy is an example of contact dermatitis.

Contact dermatitis can occur on any part of the body, but it usually affects the hands, feet, and groin. Contact dermatitis usually does not spread from one person to another, nor does it spread beyond the area exposed to the irritant unless affected skin comes into contact with another part of the body. In the case of some irritants, such as poison ivy, contact dermatitis can be passed to another person or to another part of the body by direct contact. Contact dermatitis can develop when the first contact occurs or after years of use or exposure.

Stasis dermatitis is characterized by scaly, greasy-looking skin on the lower legs and around the ankles. Stasis dermatitis is most apt to affect the inner side of the calf.

Nummular dermatitis, which is also called nummular eczematous dermatitis or nummular **eczema**, generally affects the hands, arms, legs, and buttocks of men and women older than 55 years of age. This stubborn, inflamed rash forms circular, sometimes itchy, patches and is characterized by flares and periods of inactivity.

Itching, scaling, swelling, and sometimes blistering characterize atopic dermatitis. In early childhood it is called infantile eczema and is characterized by redness, oozing, and crusting. It is usually found on the face, inside the elbows, and behind the knees.

Seborrheic dermatitis may be dry or moist. It is characterized by greasy scales and yellowish crusts on the scalp, eyelids, face, external surfaces of the ears, underarms, breasts, and groin. In infants it is called **cradle cap**.

Causes and symptoms

Allergic reactions are genetically determined, and different substances cause contact dermatitis to develop in different people. A reaction to resin produced by poison ivy, poison **oak**, or poison sumac is the most common source of symptoms. It is, in fact, the most common allergy in the United States, affecting one of every two people.

Flowers, herbs, and vegetables (e.g., fresh okra, jalapeno peppers) can affect the skin of some people. **Burns** and **sunburn** increase the risk of dermatitis developing, and chemical irritants that can cause the condition include the following:

- chlorine
- cleansers
- detergents and soaps
- fabric softeners
- glues used on artificial nails
- perfumes
- topical medications

Stasis dermatitis, a consequence of poor circulation, occurs when leg veins can no longer return blood to the heart as efficiently as they once did. When that happens, fluid collects in the lower legs and causes them to swell (**edema**). Stasis dermatitis can also result in a rash that can develop into sores known as stasis ulcers.

The cause of nummular dermatitis is not known, but it usually occurs in cold weather and is most common in people who have dry skin. Hot weather and **stress** can aggravate this condition, as can the following:

- allergies
- fabric softeners
- soaps and detergents
- wool clothing
- bathing more than once a day

Atopic dermatitis can be caused by **allergies**, **asthma**, or stress. There appears to be a genetic predisposition for atopic conditions. It is sometimes caused by an allergy to nickel in jewelry.

Seborrheic dermatitis, for which there may also be a genetic predisposition, is usually caused by overproduction of the oil glands. In adults it can be associated with **diabetes mellitus** or gold allergy. In infants and adults it may be caused by a **biotin** or vitamin B deficiency.

Diagnosis

The diagnosis of dermatitis is made on the basis of how the rash looks and its location. The doctor may scrape off a small piece of affected skin for microscopic examination. The patient may be directed to discontinue use of any potential irritant that has recently come into contact with the affected area to see if the rash disappears. Two weeks after the rash disappears, the patient may resume use of the suspect substances, one at a time, until the condition recurs. Eliminating the substance most recently added should eliminate the irritation.

If the origin of the irritation has still not been identified, a dermatologist may perform one or more patch tests, which involves dabbing a small amount of a suspected irritant onto skin on the patient's back. If no irritation develops within a few days, another patch

test is performed. The process continues until the patient experiences an allergic reaction at the spot where the irritant was applied.

Treatment

General herbal therapies for dermatitis can be useful for some conditions. Among the herbs most often recommended are:

- burdock root (*Arctium lappa*)
- calendula (*Calendula officinalis*) ointment
- chamomile (*Matricaria recutita*) ointment
- cleavers (*Galium* ssp.)
- evening primrose oil (*Oenothera biennis*)
- nettles (*Urtica dioica*)

Patients who have a history of dermatitis should remove their rings before washing their hands. They should use bath oils or glycerin-based soaps and bathe in lukewarm saltwater.

Treatments for contact dermatitis

Contact dermatitis can be treated botanically and homeopathically. Specific homeopathic remedies are designed for individuals. Grindelia (*Grindelia* spp.) and **sassafras** (*Sassafras albidum*) can help when applied topically. Oatmeal baths are helpful in relieving the itch. Bentonite clay packs or any mud-pack draws the fluid and helps dry up the lesions. Practitioners of natural medicine do not recommend cortisone creams as they suppress the reaction rather than clear it.

Treatments for atopic dermatitis

NUTRITIONAL THERAPY. Because most cases of atopic dermatitis are caused by food allergy, the following dietary changes are often recommended:

- Identification and avoidance of allergenic foods. Foods that often cause allergy in infants include milk, eggs, peanuts, tomatoes, seafood, wheat, and soybean.
- Supplementing daily diet with vitamin A (5,000 U), vitamin E (400 IU), and zinc (45–60 mg) or alternatively, taking multivitamin-and-mineral supplement one tablet once daily.
- Taking fish oils supplements. Adults should take 540 mg of EPA and 360 mg of docosahexaenoic acid (DHA) per day.

Additionally, flavonoids such as **quercetin**, **grape seed extract**, **green tea** extract, and **ginkgo biloba** may be helpful for some people.

HERBAL THERAPY. The following herbal preparations may be helpful in treating atopic dermatitis:

- *Glycyrrhiza glabra* (licorice)
- *Arctium lappa* (burdock, gobo)
- *Taraxacum officinale* (dandelion)

Treatments for seborrheic dermatitis

Treatments for this common skin disorder include nutritional therapy and topical applications.

NUTRITIONAL THERAPY. Diet is one of the major causes of seborrheic dermatitis especially in infants. Therefore, the following dietary changes and nutritional supplements are often necessary:

- Identification and avoidance of foods that may cause allergies. Common allergenic foods in infants are wheat, corn, citrus, peanuts, eggs, and seafood.
- Eating biotin-rich foods (soy foods, sesame, barley) or taking biotin supplements. Seborrheic dermatitis may be caused by biotin deficiency. Infants often respond well to biotin treatment alone (without vitamin B-complex supplementation).
- Taking daily multivitamin and mineral supplement that provides high amounts of vitamin B-complex, especially vitamin B_6 and zinc. Seborrheic adults often require both vitamin B-complex and biotin supplements.
- Flaxseed oil in the amount of one tablespoon per day for adults. Flaxseed oil is a good source of omega-3 fatty acids that help moisturize the skin and decrease inflammation.

TOPICAL TREATMENT. Selenium-based shampoos are often used to treat greasy scales and crusts on the scalp. Some adults with seborrheic scales on the scalp, nose, brow, and around the mouth respond well to topical treatment with **pyridoxine** (50 mg/g) ointment.

Stasis dermatitis

Stasis dermatitis should be treated by a trained practitioner. This condition responds well to topical herbal therapies; however, the underlying cause of poor circulation must also be addressed.

Allopathic treatment

Treating contact dermatitis begins with eliminating or avoiding the source of irritation. Prescription or over-the-counter corticosteroid creams can lessen inflammation and relieve irritation. Creams, lotions, or ointments not specifically formulated for dermatitis can intensify the irritation. Oral antihistamines are sometimes recommended to alleviate itching, and

antibiotics are prescribed if the rash becomes infected. Medications taken by mouth to relieve symptoms of dermatitis can make skin red and scaly and cause **hair loss**.

Patting rather than rubbing the skin after bathing and thoroughly massaging lubricating lotion or nonprescription cortisone creams into still-damp skin can soothe red, weepy nummular dermatitis. Highly concentrated cortisone preparations should not be applied to the face, armpits, groin, or rectal area.

Coal-tar salves can help relieve symptoms of nummular dermatitis that have not responded to other treatments, but these ointments have an unpleasant odor and stain clothing.

Patients who have stasis dermatitis should elevate their legs as often as possible and sleep with a pillow between the lower legs. It is important that these patients receive treatment that addresses the cause of their poor circulation.

Tar or **zinc** paste may also be used to treat stasis dermatitis. Because these compounds must remain in contact with the rash for as long as two weeks, the paste and bandages must be applied by a nurse or a doctor.

Coal-tar shampoos may be used for seborrheic dermatitis that occurs on the scalp. Sun exposure after the use of these shampoos should be avoided because the risk of sunburn of the scalp is increased.

Expected results

Dermatitis is often chronic, but symptoms can generally be controlled. Contact dermatitis can be eliminated by avoiding the substance that causes the skin reaction.

Prevention

Contact dermatitis can be prevented by avoiding the source of irritation. If the irritant cannot be avoided completely, the patient should wear gloves and other protective clothing whenever exposure is likely to occur.

Immediately washing the exposed area with soap and water may stem allergic reactions to poison ivy, poison oak, or poison sumac.

Clothing should be loose fitting and 100% cotton. New clothing should be washed in dye-free, unscented detergent before being worn.

Injury to the lower leg can cause stasis dermatitis to ulcerate (form open sores). If stasis ulcers develop, a doctor should be notified immediately.

KEY TERMS

Allergic reaction—An inappropriate or exaggerated genetically determined reaction to a chemical that occurs only on the second or subsequent exposures to the offending agent, after the first contact has sensitized the body.

Corticosteroid—A group of synthetic hormones that are used to prevent or reduce inflammation. Toxic effects may result from rapid withdrawal after prolonged use or from continued use of large doses.

Patch test—A skin test that is done to identify allergens. A suspected substance is applied to the skin. After 24 to 48 hours, if the area is red and swollen, the test is positive for that substance.

Rash—A spotted, pink or red skin eruption that may be accompanied by itching and is caused by disease, contact with an allergen, food ingestion, or drug reaction.

Ulcer—An open sore on the skin, resulting from tissue destruction, that is usually accompanied by redness, pain, or infection.

Yoga and other **relaxation** techniques may help prevent atopic dermatitis caused by stress.

Avoidance of sweating may aid in preventing seborrheic dermatitis.

A patient who has dermatitis should notify a doctor if any of the following occurs:

- fever develops
- skin oozes or other signs of infection appear
- symptoms do not begin to subside after seven days' treatment
- contact with someone who has a wart, cold sore, or other viral skin infection

Detoxification

Definition

Detoxification is one of the more widely used treatments and concepts in alternative medicine. It is based on the principle that illnesses can be caused by the accumulation of toxic substances (toxins) in the body. Eliminating existing toxins and avoiding new toxins are essential parts of the healing process. Detoxification utilizes a variety of tests and techniques.

Origins

Detoxification methods of healing have been used for thousands of years. **Fasting**, a method used often in detoxification treatments, is one of the oldest therapeutic practices in medicine. Hippocrates, the ancient Greek known as the father of Western medicine, recommended fasting as a means for improving health. **Ayurvedic medicine**, a traditional healing system that has developed over thousands of years, uses

Common herbs used for detoxification

Antibiotics	Anticatarrhals (help eliminate mucus)	Blood Cleansers
Clove	Boneset	Burdock root
Echinacea	Echinacea	Dandelion root
Eucalyptus	Garlic	Echinacea
Garlic	Goldenseal root	Oregon grape root
Myrrh	Hyssop	Red clover blossoms
Prickly ash bark	Sage	Yellow dock root
Propolis	Yarrow	
Wormwood		

Diaphoretics/Skin Cleaners	Diuretics	Laxatives
Boneset	Cleavers	Buckthorn
Burdock root	Corn silk	Cascara sagrada
Cayenne pepper	Horsetail	Dandelion root
Elder flowers	Juniper berries	Licorice root
Ginger root	Parsley leaf	Rhubarb root
Goldenseal root	Uva ursi	Senna leaf
Peppermint	Yarrow dock	Yellow dock
Oregon grape root		
Yellow dock

detoxification methods to treat many chronic conditions and to prevent illness.

Detoxification treatment has become a cornerstone of alternative medicine. Conventional Western medicine accepts that environmental factors can play a significant role in many illnesses. Environmental medicine is a field that studies exactly how those environmental factors influence disease. Diseases such as **asthma**, **cancer**, **chronic fatigue syndrome** and conditions such as **multiple chemical sensitivity** are strongly influenced by exposure to toxic or allergenic substances in the environment. The United States Centers for Disease Control estimate that over 80% of all illnesses have environmental and/or lifestyle causes.

Detoxification has become a more common treatment as people have been made more aware of environmental pollution. Heavy metals such as lead, mercury, cadmium, and arsenic are by-products of industry. Agriculture chemicals, many of which are known to cause health problems, are also found in food, air, and water. American agriculture uses nearly 10 pounds of pesticides per person on the food supply each year. These toxins have become almost unavoidable. Pesticides that are used only on crops in the southern United States have been found in the tissue of animals in the far north of Canada. DDT, a cancer-causing insecticide that has been banned for decades, is still found in the fatty tissue of animals, birds, and fish, even in extremely remote regions such as the North Pole.

The problem of toxins in the environment is compounded because humans are at the top of the food chain and are more likely to be exposed to an accumulation of toxic substances in the food supply. For instance, pesticides and herbicides are sprayed on grains that are then fed to farm animals. Toxic substances are stored in the fatty tissue of those animals. In addition, those animals are often injected with synthetic hormones, antibiotics, and other chemicals. When people eat meat products, they are exposed to the full range of chemicals and additives used along the entire agricultural chain. Detoxification specialists call this build up of toxins bioaccumulation. They assert that the bioaccumulation of toxic substances over time is responsible for many physical and mental disorders, especially ones that are increasing rapidly such as asthma, cancer, and mental illness. Although there is no scientific proof for many of their assertions, detoxification therapies have increased in popularity.

Benefits

Alternative medical practitioners claim that detoxification is helpful for those individuals suffering from many chronic diseases and conditions, including **allergies**, **anxiety**, arthritis, asthma, chronic **infections**, **depression**, diabetes, headaches, **heart disease**, high **cholesterol**, low blood sugar levels, digestive disorders, mental illness, and **obesity**. It is helpful for people with diseases, such as cancer that are influenced by environmental factors and for those who have been exposed to high levels of toxic materials as a result of accident or occupation. People who have allergies or immune system problems that conventional medicine is unable to diagnose or treat, including chronic **fatigue** syndrome, environmental illness/multiple chemical sensitivity, and **fibromyalgia**, often turn to detoxification therapy for relief. Symptoms for those suffering these conditions may include unexplained fatigue, increased allergies, hypersensitivity to common materials, food intolerances, chronic **indigestion**, aches and pains, low grade **fever**, headaches, **insomnia**, depression, sore throats, sudden weight loss or gain, lowered resistance to infection, general malaise, and disability. Detoxification also can be used as a beneficial preventative measure and as a tool to increase overall health, vitality, and resistance to disease.

Description

Toxins in the body include heavy metals and various chemicals such as pesticides, industrial pollutants, and food additives. Drugs and alcohol also have toxic effects in the body. Toxic wastes are produced as a normal by-product of cellular metabolism and by the bacteria that live in the intestine.

The body has natural methods of detoxification. The liver is the principle organ of detoxification, assisted by the kidneys and intestines. Toxins can be excreted from the body by the kidneys, bowels, skin, and lungs. Detoxification treatments become necessary when the body's natural detoxification systems become overwhelmed. Long-term effects of improper diet, **stress**, overeating, sedentary lifestyles, illness, and poor health habits can cause this in general. When a build up of toxic substances in the body creates illness, it is called toxemia. Some people's digestive tracts become unable to digest food properly, due to years of overeating and **diets** that are high in fat and processed foods and low in fiber (the average American diet). Obstruction of food passing through the large intestine can lead to the growth of harmful microbes.

This state is known as toxic colon syndrome or intestinal toxemia.

Detoxification therapies try to activate and assist the body's own detoxification processes. They also try to eliminate additional exposure to toxins and strengthen the body and immune system so that toxic imbalances will not occur in the future.

Testing for toxic substances

Detoxification specialists use a variety of tests to determine the causes contributing to toxic conditions. These causes include infections, allergies, addictions, toxic chemicals, and digestive and organ dysfunction. The results of blood, urine, stool, and hair analyses, as well as allergy tests, can indicate problems that may be resolved with detoxification therapy. Detoxification therapists usually have access to laboratories that specialize in sophisticated diagnostic tests for toxic conditions.

People who have toxemia are often susceptible to infection because their immune systems are weakened. Parasites, bacteria, viruses, and fungi can cause infections. Detoxification therapists will screen patients for underlying infections that may be contributing to illness.

Liver function is studied closely using blood and urine tests because the liver is the principle organ in the body responsible for removing toxic compounds. Results of the tests may identify where problems are occurring and may point to specific types of toxins. Blood and urine tests can also screen for toxic chemicals such as PCBs (environmental poisons), formaldehyde (a common preservative), pesticides, and heavy metals. Another useful blood test is a test for **zinc** deficiency, which may indicate **heavy metal poisoning**. Hair analysis is used to test for heavy metal levels in the body. Blood and urine tests that check immune system activity, and hormone levels can also indicate specific toxic compounds. A 24-hour urine analysis, where samples are taken around the clock, allows therapists to determine the efficiency of the digestive tract and kidneys. Together with stool analysis, these tests may indicate toxic digestive system disorders. Certain blood and urine tests may point to nutritional deficiencies so that proper recovery diets can be designed for patients as well.

Detoxification therapists may also perform extensive allergy and hypersensitivity tests. Intradermal (between layers of the skin) and sublingual (under the tongue) allergy tests are used to determine a patient's sensitivity to a variety of common substances, including formaldehyde, auto exhaust, perfume, tobacco, chlorine, jet fuel, and other chemicals.

Food allergies require additional tests because these allergies often cause reactions that are delayed for several days after the food is eaten. The radioallergosorbent test (RAST) is a blood test that determines the level of antibodies (immunoglobulins) in the blood after specific foods are eaten. The cytotoxic test is a blood test that determines if certain substances affect blood cells, including foods and chemicals. The enzyme-linked immunoserological assay activated cell test (ELISA-ACT) is considered one of the most accurate tests for allergies and hypersensitivity to foods, chemicals, and other agents. Other tests for food allergies are the elimination and rotation diets, in which foods are systematically evaluated to determine the ones that are causing problems.

Detoxification therapists usually interview and counsel patients closely to determine and correct lifestyle, occupational, psychological, and emotional factors that may be contributing to illness.

Detoxification therapies

Detoxification therapists use a variety of healing techniques after a diagnosis is made. The first step is to eliminate a patient's exposure to all toxic or allergenic substances. These include heavy metals, chemicals, radiation (from x rays, power lines, cell phones, computer screens, and microwaves), smog, polluted water, foods, drugs, **caffeine**, alcohol, perfume, excess noise, and stress. If **mercury poisoning** has been determined, the patient will be advised to have mercury fillings from the teeth removed, preferably by a holistic dentist.

Specific treatments are used to stimulate and assist the body's detoxification process. Dietary change is immediately enacted, eliminating allergic and unhealthy foods, and emphasizing foods that assist detoxification and support healing. Detoxification diets are generally vegetarian diets low in fat, high in fiber, with a raw food emphasis. Processed foods, alcohol, and caffeine are avoided. Nutritional supplements such as vitamins, minerals, **antioxidants**, **amino acids**, and **essential fatty acids** are often prescribed. **Spirulina** is a sea alga that is frequently given to assist in eliminating heavy metals. Lipotropic agents are certain vitamins and nutrients that promote the flow of bile and fat from the liver.

Many herbal supplements are used in detoxification therapies as well. **Milk thistle** extract, called silymarin, is one of the more potent herbs for detoxifying the liver. Naturopathy, Ayurvedic medicine, and **traditional Chinese medicine** (TCM) recommend numerous herbal formulas for detoxification and

immune strengthening. If infections or parasites have been found, these are treated with herbal formulas and antibiotics in difficult cases.

For digestive tract disorders, herbal laxatives and high fiber foods such as **psyllium** seeds may be given to cleanse the digestive tract and promote elimination. Colonics are used to cleanse the lower intestines. **Digestive enzymes** are prescribed to improve digestion, and **acidophilus** and other friendly bacteria are reintroduced into the system with nutritional supplements.

Fasting is another major therapy in detoxification. Fasting is one of oldest and quickest ways to promote the elimination of stored toxins in the body and to prompt the healing process. People with severe toxic conditions are supervised closely during fasting because the number of toxins in the body temporarily increases as they are being released.

Chelation therapy is used by detoxification specialists to rid the body of heavy metals. Chelates are particular substances that bind to heavy metals and speed their elimination. Homeopathic medicine also offers remedies for removing heavy metals.

Sweating therapies can detoxify the body because the skin is a major organ of elimination. Sweating helps release those toxins that are stored in the subcutaneous (under the skin) fat cells. Saunas, therapeutic baths, and **exercise** are some of these treatments. Body therapies may also be prescribed, including **massage therapy**, **acupressure**, **shiatsu**, manual lymph drainage, and **polarity therapy**. These body therapies seek to improve circulatory and structural problems, reduce stress, and promote healing responses in the body. Mind/body therapies such as **psychotherapy**, counseling, and stress management techniques may be used to heal the psychological components of illness and to help patients overcome their negative patterns contributing to illness.

Practitioners and treatment costs

The costs of detoxification therapies can vary widely, but can be quite expensive depending on the number of tests and treatments required. Some of these tests may not be covered by medical insurance. Detoxification treatments can be lengthy and involved since illnesses associated with toxic conditions usually develop over many years and may not resolve quickly. Detoxification treatments may be lengthy because they often strive for the holistic healing of the body, mind, and emotions.

Practitioners may be conventionally trained medical doctors with specialties in environmental medicine or interests in alternative treatment. The majority of detoxification therapists are alternative practitioners, such as naturopaths, homeopaths, Ayurvedic doctors, or traditional Chinese doctors. Insurance coverage varies, depending on the practitioner and the treatment involved. Consumers should review their individual insurance policies regarding treatment coverage.

KEY TERMS

Allergen—A foreign substance, such as mites in house dust or animal dander that, when inhaled, causes the airways to narrow and produces symptoms of asthma.

Antibody—A protein, also called immunoglobulin, produced by immune system cells to remove antigens (the foreign substances that trigger the immune response).

Ayurvedic medicine—A 5,000 year old system of holistic medicine developed on the Indian subcontinent. Ayurvedic medicine is based on the idea that illness results from a personal imbalance or lack of physical, spiritual, social, or mental harmony.

Fibromyalgia—A condition of debilitating pain, among other symptoms, in the muscles and the myofascia (the thin connective tissue that surrounds muscles, bones, and organs).

Hypersensitivity—The state where even a tiny amount of allergen can cause severe allergic reactions.

Multiple chemical sensitivity—A condition characterized by severe and crippling allergic reactions to commonly used substances, particularly chemicals. Also called environmental illness.

Toxemia—The presence of toxic substances in the bloodstream.

Preparations

Patients can assist diagnosis and treatment by keeping detailed diaries of their activities, symptoms, and contact with environmental factors that may be affecting their health. Reducing exposure to environmental toxins and making immediate dietary and lifestyle changes may speed the detoxification process.

Side effects

During the detoxification process, patients may experience side effects of fatigue, malaise, aches and pains, emotional duress, **acne**, headaches, allergies, and symptoms of colds and **influenza**. Detoxification specialists claim that these negative side effects are

part of the healing process. These reactions are sometimes called "healing crises". They are caused by temporarily increased levels of toxins in the body due to elimination and cleansing.

Research and general acceptance

Although environmental medicine is gaining more respect within conventional medicine, detoxification treatment is scarcely mentioned by the medical establishment. The research that exists on detoxification is largely testimonial, consisting of individual personal accounts of healing without statistics or controlled scientific experiments. In the alternative medical community, detoxification is an essential and widely accepted treatment for many illnesses and chronic conditions.

Devil's claw

Description

Devil's claw (*Harpagophytum procumbens*) is an African plant whose fruit looks like a giant claw. The plant grows in an arid climate and is found in Namibia, Madagascar, the Kalahari Desert, and other areas on the African continent. The tuberous roots are used in traditional medicine. The root is collected when the rainy season ends. The root is chopped and dried in the sun for three days. Devil's claw is also known as grapple plant and wood spider.

General use

Devil's claw has been used for numerous conditions in several areas of the world. In South Africa, the root and tuber have been used for centuries as an all-purpose folk remedy. Devil's claw has been used to reduce **fever** and **pain**, to treat **allergies** and **headache**, and to stimulate digestion. Traditional healers also used devil's claw to treat inflammatory conditions such as arthritis, rheumatism, and lower back pain. Devil's claw has also been used as a remedy for liver and kidney disorders.

Devil's claw root was also used in folk medicine as a pain reliever and for complications with pregnancies. In addition, an ointment made from devil's claw was used for skin injuries and disorders.

European colonists brought the African plant back to their continent where it was used to treat arthritis. In the United States, use of devil's claw dates back to the time of slavery. The slaves brought herbs and herbal knowledge with them to the new continent.

Devil's claw has been used as an herbal remedy in Europe for a long time. Current uses for devil's claw are much the same as they were centuries ago. In Europe, the herb is still a remedy for arthritis and other types of joint pain, such as **rheumatoid arthritis**, **osteoarthritis**, and **gout** (a painful joint inflammation disease).

Devil's claw (*Harpagophytum procumbens*). *(PHOTOTAKE Inc. / Alamy)*

Devil's claw is also used for soft tissue conditions with inflammation, like **tendinitis** and **bursitis**. The bitter herb is also used as a remedy for loss of appetite and mildly upset stomach.

The herb is currently used for other conditions such as problems with **pregnancy**, **menstruation**, and **menopause**. Devil's claw is also regarded as a remedy for headaches, **heartburn**, liver and gallbladder problems, allergies, skin disorders, and nicotine poisoning.

European research during the late 1990s indicated that devil's claw relieved arthritis and joint pain conditions. The herb also helped with soft muscle pain such as tendinitis. However, there is no evidence that proves devil's claw is an effective remedy for other conditions such as difficulties during pregnancy and skin disorders.

Preparations

Several forms of devil's claw are used. In Europe, doctors treat some conditions like arthritis with an injection of devil's claw extract. The herb is taken internally as a tea or in capsule form. When taken for pain relief, devil's claw must be taken regularly for up to one month before results are seen. An ointment form of devil's claw can be applied to the skin to treat **wounds** or scars.

Herbal tea and tincture

Devil's claw tea is prepared by pouring 1.25 cups (300 ml) boiling water over 1 tsp (4.5 g) of the herb. The mixture, which is also called an infusion, is steeped for eight hours and then strained. The daily dosage is 3 cups of warm tea.

For most conditions, the average daily dosage is 1 tsp (4.5 g) of devil's claw herb. However, the amount is reduced to 1/3 tsp (1.5 g) when devil's claw is taken for appetite loss.

In a tincture, the herb is preserved with alcohol. The tincture steeps for two weeks and is shaken daily. It is then strained and bottled. When devil's claw tincture is used as a remedy, the dosage is 1 tsp (4.5 g) taken three times per day for a specified period.

Tea and tincture should be consumed 30 minutes before eating. This allows for better absorption of the herb.

Devil's claw capsules

The anti-inflammatory properties of devil's claw are attributed to two constituents, harpagoside and beta sitoserol. If a person takes devil's claw capsules or tablets as a remedy, attention should be paid to the harpagoside content. The daily amount of harpagoside in capsules should total 50 mg.

Combinations

For arthritis treatment, devil's claw can be combined with anti-inflammatory or cleansing herbs. In addition, devil's claw can be combined with bogbean or meadowsweet. An herbalist, naturopathic doctor, or traditional healer can provide more information on herb combinations appropriate for a specific condition.

Precautions

Devil's claw is safe to use when proper dosage recommendations are followed, according to sources including the *PDR (Physician's Desk Reference) for Herbal Medicines*, the 1998 book based on the 1997 findings of Germany's Commission E.

Although devil's claw has not undergone the U.S. Food and Drug Administration (FDA) research required for approval as a remedy, other studies in Europe confirm that devil's claw is safe for most people. People with ulcers should be cautious because the herb stimulates the production of stomach acid.

Furthermore, it is not known if devil's claw is safe for people with major liver or kidney conditions. In addition, devil's claw could cause an allergic reaction.

There is some debate in the alternative medicine community about whether pregnant women can use devil's claw as a remedy. Some researchers say that the herb is safe to use; others say that not enough research has been done to prove that the herb is safe for pregnant women. There appears to be no scientific proof that using devil's claw could result in miscarriages.

Side effects

Devil's claw could cause an allergic reaction or mild gastrointestinal difficulties.

Interactions

No interactions between other medications and devil's claw have been reported according to the *PDR for Herbal Medicines*. However, the herb may possibly block the effect of medication taken to correct abnormal heart rhythms.

DHEA

Description

DHEA is the acronym for dehydroepiandrosterone, a hormone produced naturally from **cholesterol** in the adrenal glands of males and females. It is a precursor to the male sex hormone testosterone. It is also sold as an over-the-counter dietary supplement.

The human body produces very little DHEA until about the age of seven, when production soars. Production peaks in the mid-20s and starts to decline in the early 30s. By the mid-70s, DHEA production has dropped by about 80 to 90% of its maximum. At all ages, DHEA levels are slightly higher in men than women. The optimum DHEA level in a healthy adult is 750 to 1,250 milligrams per deciliter of blood (mg/dL) for men and 550 to 980 mg/dL for women.

DHEA was first identified in 1934 and was sold over the counter mainly as a weight loss aid until the late 1980s. Then the U.S. Food and Drug Administration (FDA) classified DHEA as a drug, making it available by prescription only. The FDA reversed itself in 1994, reclassifying DHEA as a dietary supplement obtainable without a prescription.

A 1994 study by researchers at the University of California, San Diego, looked at 30 middle-age men and women who took 50 mg of DHEA a day for three months. The test subjects generally reported an improved sense of well-being, increased energy, enhanced sex drive, and an improved ability to deal with **stress**. The results were widely reported by the mass media, with several referring to DHEA as the "fountain of youth hormone."

Despite hundreds of studies of DHEA between the late 1970s and the late 2000s, researchers remain unclear as to how the hormone works or exactly what it does in the body. Although it is known that DHEA decreases with age, it is not known whether this constitutes a deficiency or is because the body needs less DHEA as it ages.

So little is known about DHEA because the hormone is not patentable, so drug companies are unwilling to spend money doing further research on it. Much of the research as of 2008 is funded through universities and the National Institute on **Aging** (NIA) that maintains a skeptical attitude about DHEA supplementation. In one statement on the use of DHEA (January 19, 2007), NIA noted that it "does not recommend taking any supplement, including DHEA and **melatonin**, that is touted as an 'anti-aging' remedy because no supplement has been proven to serve this purpose."

General use

Originally marketed as a weight loss supplement, DHEA was later promoted as beneficial for treating a wide variety of medical conditions, including **cancer**, **heart disease**, Alzheimer's, and **AIDS**. It was also purported to have anti-aging qualities. Studies in rodents and test tubes showed that daily doses of DHEA seemed to prevent or to improve such conditions as cancer, heart disease, **osteoporosis**, diabetes, lupus, **obesity**, and viral **infections**. Far fewer long-term studies had been done on humans, and the results were often conflicting. In general, DHEA supplementation seemed to be more beneficial to men than women. In 2008, the Mayo Clinic Web site listed 28 uses for which DHEA has been recommended. It said that there was "good scientific evidence" for four of those uses (in the treatment of adrenal insufficiency, **depression**, obesity, and **systemic lupus erythematosus**), "fair scientific evidence against the use" of four other treatments (**fibromyalgia**, as an immune system stimulant, as a memory enhancer, and for muscle strength) and "unclear scientific evidence" on the other 20 uses.

Preparations

Most DHEA is derived from Mexican wild yams through a chemical process. Eating the yams will not produce the hormone. DHEA is generally taken once daily. Dosage recommendations vary. Allopathic physicians who support DHEA supplementation usually recommend 5 to 10 mg once a day. Some homeopathic health practitioners recommend 10 to 50 mg a day. Ray Sahelian, a physician and author of several books on dietary supplements, recommends "hormone holidays." With this approach, persons would take DHEA every other day, five days in a row and two days off, or go off it one or two weeks a month. DHEA commonly is sold in tablets of 5 mg, 10 mg, 25 mg, and 50 mg. It also is available as a cream, ointment, lozenge, and herbal tea.

Precautions

Several studies have shown DHEA may increase the risks of **prostate cancer** in men and endometrial cancer in women. Medical experts suggest that individuals have a blood test to determine existing DHEA and other hormone (testosterone or estrogen) levels before taking DHEA supplements. Also, men taking the supplement should have regular PSA tests and women should have periodic mammograms since DHEA may promote the growth of **breast cancer**.

There are several warnings associated with DHEA use. It should not be taken by men who have a history of prostate problems or by women with a history of breast, ovarian, or **uterine cancer**. It is not recommended for anyone under age 40 or by women who are pregnant, nursing, or who are of childbearing age. Women who are taking an estrogen replacement, who have a history of heart disease, and anyone with other significant health problems should consult their doctor before taking DHEA.

Side effects

Some side effects have been reported and are usually associated with doses of 5 mg a day or more. These include **acne**, body and facial hair growth in women, enlarged breasts in men, scalp **hair loss**, **anxiety**, **insomnia**, headaches, mood changes, and **fatigue**. DHEA can cause menstrual irregularities in women under age 50 and may decrease HDL (good cholesterol) in women. A

KEY TERMS

Adrenal glands—A pair of endocrine organs near the kidneys that produce steroids such as sex hormones, hormones associated with metabolic functions, and epinephrine.

Cholesterol—A fatty substance manufactured in the liver and carried throughout the body in the bloodstream.

Endometrial—Pertaining to the endometrium, a mucous membrane lining the uterus.

Estrogen—A hormone that stimulates development of female secondary sex characteristics.

Lupus—A group of diseases characterized by skin lesions.

Osteoporosis—A condition or disease characterized by low density and fragility of the bones.

Pregnenolone—A steroid ketone formed by the oxidation of other steroids, such as cholesterol, a precursor to the hormone progesterone.

PSA test—A blood test to determine prostate-specific antigen levels in men, which can help determine the risk for prostate cancer.

Testosterone—A male hormone produced in the testes or made synthetically that is responsible for male secondary sex characteristics.

few cases of irregular heart rhythm have been reported in people taking 25 to 50 mg a day of DHEA.

Interactions

DHEA functions similarly to pregnenolone, so the two should not be taken together in full doses. Natural Standard, an international organization that studies the risks and benefits of complementary and alternative therapies, suggests a number of possible interactions between DHEA and certain drugs, including triazolam (Halcion); carbamazepine; phenytoin; anticoagulants and antiplatelet drugs, such as warfarin (Coumadin), heparin, and clopidogrel (Plavix); diltiazem (Cardizem) and alprazolam (Xanax); clofibrate and tamoxifen; insulin; corticosteroids, such as dexamethasone; danazol; opiate painkillers; and estrogen-containing drugs. Interactions may also occur with certain herbal products, such as chasteberry (*Vitex agnus-castus*), **bitter melon** (*Momordica charantia*), **Ginkgo biloba**, **garlic** (*Allium sativum*), coenzyme Q10, Panax ginseng, **red clover** (*Trifolium pratense*), **hawthorn** (*Crataegus oxycantha*), **chromium** picolinate, and **carnitine**.

Diabetes mellitus

Definition

Diabetes mellitus is a disease in which the body is unable to properly use (metabolize) sugar (glucose). It arises from two causes. In type 1 diabetes (formerly called insulin-dependent, juvenile, or childhood-onset diabetes), the pancreas, a digestive organ, does not produce enough of the hormone insulin to allow the body to use glucose. Type 2 diabetes (formerly called noninsulin dependent or adult-onset diabetes) occurs when the pancreas produces insulin, but cells in the body stop responding to the hormone. In either case, the result is that glucose builds up in the blood because

Symptoms of diabetes mellitus

- Excessive thirst
- Increased appetite
- Increased urination
- Unexplained weight loss
- Fatigue
- Nausea
- Blurred vision
- Frequent vaginal infections in women
- Impotence in men
- Frequent yeast infections

(Illustration by Corey Light. Cengage Learning, Gale)

the body cannot use it. Gestational diabetes is transient diabetes that occurs during **pregnancy** and resolves after pregnancy.

Description

Diabetes mellitus is a chronic disease that contributes to serious health complications, including renal (kidney) failure, **heart disease**, **stroke**, and blindness. In 2007, diabetes affected an estimated 246 million people worldwide, with that number estimated to grow by 7 million per year. The highest rate of growth is expected to occur in developing countries. Of people with diabetes, 9 out of 10 have type 2 diabetes. The five countries with the largest numbers of people with diabetes are India, China, the United States, Russia, and Germany. Worldwide 3.8 million deaths are directly attributable to diabetes. The disease also is a contributing factor in many deaths due to cardiovascular disease.

In the United States in 2005, approximately 20.8 million people, or 7% of the population, had diabetes. Of these, 14.6 million were diagnosed with the disease, while another estimated 6.2 million remained undiagnosed. Another 54 million people have pre-diabetes. In pre-diabetes, blood glucose levels are higher than normal, but not so high as to justify a diagnosis of diabetes. The number of people with diabetes in the United States is increasing rapidly, especially among overweight and obese children.

Background

Every cell in the body needs energy to function. The body's primary energy source is glucose, a simple sugar that results from the digestion of foods containing carbohydrates (sugars and starches). Glucose from digested food circulates in the blood (blood glucose) as a ready energy source for cells. Insulin is a hormone produced by cells in the pancreas and released into the bloodstream. Insulin binds to receptor sites on the outside of cells and acts like a key to open a doorway into the cell through which glucose can enter. When not enough insulin is produced or when the doorway no longer recognizes the insulin key (a condition called **insulin resistance**), glucose stays in the blood instead of entering the cells. This results in high blood glucose levels, a condition called hyperglycemia.

For the body to function properly, the level of glucose in the blood must remain stable within fairly narrow limits. When the blood glucose level gets too high, the body attempts to dilute the concentration of glucose in the blood by drawing water out of the cells and into the bloodstream. The excess glucose, along with water, is then excreted in urine. It is common for people with undiagnosed or uncontrolled diabetes to be constantly thirsty, to drink large quantities of water, and produce large quantities of dilute, sweet-smelling urine as their bodies try to remove excess glucose from the blood.

At the same time that the body is trying to remove glucose from the blood, the cells are starving for glucose and sending signals to the body to eat more food, thus causing people with diabetes to be constantly hungry. To provide energy for the starving cells, the body also converts fats and proteins into glucose, an activity that does not require insulin. The breakdown of fats and proteins for energy causes acid compounds called ketones to form in the blood. These ketones cause the breath of an uncontrolled diabetic to smell like acetone (nail polish remover). Ketones are also excreted in urine. As ketones build up in the blood, the blood becomes more acidic and a condition called ketoacidosis can occur. If left untreated, ketoacidosis can lead to coma and death.

Types of diabetes mellitus

Type 1 diabetes begins most often during childhood or adolescence. In this type of diabetes, the pancreas produces little or no insulin. Type 1 diabetes is characterized by a sudden onset. It occurs more frequently in people of northern European ancestry than in those from southern European countries, the Middle East, or Asia. This form of diabetes also is

called insulin-dependent diabetes because people who develop type 1 diabetes need injections of insulin one or more times daily.

Brittle diabetics, sometimes called uncontrolled diabetics, are a subgroup of individuals with type 1 diabetes. These individuals, even when carefully complying with their insulin and diet regimen, have frequent and rapid swings of blood sugar levels moving between hyperglycemia (a condition in which there is too much glucose or sugar in the blood) and **hypoglycemia** (a condition in which there are abnormally low levels of glucose or sugar in the blood). These diabetics may require several injections of different types of insulin or an insulin pump during the day to keep their blood sugar within a fairly normal range.

The more common form of diabetes, type 2 diabetes, occurs in approximately 3 to 5% of Americans under age 50, and increases to 10 to 15% in those older than 50. More than 90% of the diabetics in the United States are type 2 diabetics. Symptoms of type 2 diabetes are milder than those of type 1 diabetes. As a result, many people (as many as 80% in some developing countries) with type 2 diabetes remain undiagnosed. This form of diabetes occurs most often in people who are overweight and who do not get adequate **exercise**. It also is more common in people of Native American, Hispanic, and African American descent. Type 2 diabetes appears to be somewhat linked to diet. People who have migrated to Western cultures from East India, Japan, and Australian Aboriginal cultures are more likely to develop type 2 diabetes than those who remain in their original countries.

Type 2 diabetes is initially a milder form of diabetes because of its slow onset (sometimes developing over the course of several years) and because it can often be controlled with diet, exercise, and oral medication instead of insulin injections. The consequences of uncontrolled and untreated type 2 diabetes, however, are just as serious as those for type 1. This form of diabetes also is called noninsulin-dependent diabetes, a term that is somewhat misleading. Many people with type 2 diabetes can control the condition with diet and oral medications; however, when this fails, insulin injections are necessary.

Another form of diabetes, called gestational diabetes, can develop during pregnancy. It usually resolves after the baby is delivered. This diabetic condition develops during the second or third trimester of pregnancy in about 2% of pregnancies. The condition usually is treated by diet; however, insulin injections may be required. Women who have diabetes during pregnancy are at higher risk for developing type 2 diabetes within 5 to 10 years.

Diabetes also can develop as a result of pancreatic disease, **alcoholism**, malnutrition, or other severe illnesses that **stress** the body and damage the pancreas.

Causes and symptoms

The causes of diabetes mellitus are unclear; however, there seem to be both complex hereditary (genetic factors passed on in families) and environmental factors involved. Research has shown that some people who develop diabetes have common genetic markers, but identical twins do not always both develop diabetes. In type 1 diabetes, an autoimmune response is believed to be triggered by a virus, other microorganism, or exposure to an environmental toxin. This causes the immune system to incorrectly identify its own insulin-producing cells as foreign material and to destroy them.

Ketoacidosis, a condition caused by starvation or uncontrolled diabetes, is common in type 1 diabetes. Ketones are acid compounds that form in the blood when the body breaks down fats and proteins. Symptoms include abdominal **pain**, **vomiting**, rapid breathing, extreme tiredness, and drowsiness. Patients with ketoacidosis will also have a sweet breath odor. Left untreated, this condition can lead to diabetic coma and death.

In type 2 diabetes, the pancreas may produce enough insulin; but cells have become resistant to the insulin produced, so that it does not work effectively. Symptoms of type 2 diabetes can begin so gradually that individuals may not know that they have it. Age, **obesity**, diet, and family history of diabetes all play significant roles in the development of type 2 diabetes.

Early signs of type 2 diabetes include tiredness, extreme thirst, and frequent urination. Other symptoms may include sudden weight loss, slow wound healing, urinary tract **infections**, **gum disease**, or blurred vision. It is common for type 2 diabetes to be detected while a patient is seeing a doctor about a health concern caused by the yet undiagnosed diabetes. Symptoms of type 1 diabetes are similar to those of type 2 diabetes, but often develop suddenly (over days or weeks) in previously healthy children or adolescents.

Individuals who are at high risk of developing type 2 diabetes mellitus include people who have the following characteristics:

- are obese (a body mass index [BMI] of 30 or higher)
- have a close relative with diabetes mellitus

- belong to a high-risk ethnic population (African American, Native American, Hispanic, or Native Hawaiian)
- have been diagnosed with gestational diabetes or have delivered a baby weighing more than 9 lbs (4 kg)
- have high blood pressure (140/90 mmHg or above)
- have a high density lipoprotein (HDL or "bad") cholesterol level less than or equal to 35 mg/dL and/or a triglyceride level greater than or equal to 250 mg/dL
- have had impaired glucose tolerance or impaired fasting glucose on previous tests

Several common drugs can impair the body's use of insulin, causing a condition known as secondary diabetes. These medications include treatments for high blood pressure (furosemide, clonidine, and thiazide diuretics), drugs with hormonal activity (oral contraceptives, thyroid hormone, progestins, and glucocorticorids), and the anti-inflammation drug indomethacin. Several drugs used to treat mood disorders also can impair glucose absorption. These drugs include haloperidol, lithium carbonate, phenothiazines, tricyclic antidepressants, and adrenergic agonists. Other drugs that can cause diabetes symptoms include isoniazid, nicotinic acid, cimetidine, and heparin.

Diagnosis

Diabetes is suspected based on symptoms. Urine tests and blood tests are used to confirm a diagnosis of diabetes. These tests measure the amount of glucose in the urine and blood. Urine tests also can detect ketones and protein in the urine, which may help to diagnose diabetes and assess how well the kidneys are functioning. These tests are also used to monitor the disease once the patient is under treatment.

Urine tests

Clinistix and Diastix are paper strips or dipsticks that change color when dipped in urine. The test strip is compared to a chart that shows the amount of glucose in the urine based on the change in color. The level of glucose in the urine lags behind the level of glucose in the blood. Testing the urine with a test stick, paper strip, or tablet is not as accurate as blood testing, but it can give a fast, simple, noninvasive reading.

Ketones in the urine can be detected using similar types of dipstick tests (Acetest or Ketostix). Ketoacidosis can be life-threatening in type 1 diabetics, so having a quick and simple test to detect ketones can assist in establishing a diagnosis rapidly.

Another dipstick test can determine the presence of protein or albumin in the urine. Protein in the urine can indicate problems with kidney function and can be used to track the development of renal failure. A more sensitive test for urine protein uses radioactively tagged chemicals to detect microalbuminuria, small amounts of protein in the urine, which may not show up on dipstick tests.

Blood tests

In a **fasting** plasma glucose test (FPT), blood is drawn from a vein in the patient's arm after the patient has not eaten for at least eight hours, usually in the morning before breakfast. The red blood cells are separated from the sample and the amount of glucose is measured in the remaining plasma. A plasma level of 99 mg/dL or below is normal. Readings of 100–125 mg/dL indicate pre-diabetes (impaired fasting glucose) and readings of 126 mg/dL or greater indicate diabetes. The fasting glucose test is usually repeated on another day to confirm the results. A postprandial glucose test in which blood is taken shortly after the patient has eaten a meal may also be done.

In the oral glucose tolerance test, blood samples are taken from a vein before and after a patient drinks a sweet syrup of glucose and other sugars. In a nondiabetic, the level of glucose in the blood goes up immediately after the drink and then decreases gradually as insulin is used by the body to metabolize, or absorb, the sugar. In a person with diabetes, the glucose in the blood goes up and stays high after drinking the sweetened liquid. A plasma glucose level after two hours that is 139 mg/dL is normal. Two-hour readings of 140 to 199 mg/dL indicate pre-diabetes and readings of 200 mg/dL or higher at two hours after drinking the syrup and at one other point during the two-hour test period confirms the diagnosis of diabetes.

In 2002, scientists announced that a simple blood test to screen for diabetes had been developed. Before that time, community-wide screening procedures had not proven cost-effective. The screening test was shown to be cost-effective if conducted in physician offices on patients with the three known risk factors of obesity, self-reported high blood pressure, and family history of diabetes.

Home blood glucose monitoring kits are available so diabetics can monitor their own levels. A small needle or lancet is used to prick the finger and a drop of blood is collected and analyzed by a monitoring device. Some patients may test their blood glucose levels several times during a day and use this information to adjust their diet or insulin dosage.

In the United States beginning in the early 2000s, a small number of service dogs, mostly Labrador retrievers, were trained to detect ketones in their diabetic human companions by smell. The dogs are trained to give a behavioral signal to the handler if they detect a smell that indicates the handler's metabolism is out of balance. Their acute sense of smell allows them to warn the diabetic handler of problems before the person can physically sense them. These dogs are permitted to travel in public places with their handlers under the Americans with Disabilities Act.

Treatment

There is no cure for diabetes. Treatment of diabetes focuses on two goals: keeping blood glucose within the normal range and preventing the development of long-term complications. Diet, exercise, medication, and careful monitoring of blood glucose levels are the keys to managing diabetes so that patients can live healthier lives. Diabetes can be life-threatening if not properly managed, so individuals should not attempt to treat this condition without medical supervision. Alternative treatments cannot replace the need for insulin, but they may enhance insulin's effectiveness and may lower blood glucose levels. In addition, alternative medicines may help to treat complications of the disease and improve quality of life.

Diet

Both conventional and alternative medicine practitioners agree that diet and moderate exercise are the first treatments to be implemented in diabetes. For overweight and obese type 2 diabetics, weight loss is an important goal to help them to control their blood glucose levels. A well-balanced, nutritious diet provides approximately 50 to 60% of calories from carbohydrates, approximately 10 to 20% of calories from protein, and less than 30% of calories from fat. The number of calories required depends on the patient's age, weight, and activity level. Calorie intake also needs to be distributed fairly evenly over waking hours so that surges of glucose entering the blood are kept to a minimum. Generally, whole grains and foods that provide large amounts of dietary fiber are helpful in controlling blood glucose levels and reducing glucose surges in people with type 2 diabetes.

Keeping track of the number of calories provided by different foods can be complicated, so patients are usually advised to consult a nutritionist or dietitian. An individualized, easy-to-manage diet plan can be set up for each patient. Both the American Diabetes Association and the American Dietetic Association recommend **diets** based on the use of food exchange lists. Each food exchange contains a known amount of calories in the form of protein, fat, or carbohydrate. A patient's diet plan will consist of a certain number of exchanges from each food category (meat or protein, fruits, breads and starches, vegetables, and fats) to be eaten at meal times and as snacks. Patients have flexibility in choosing the foods they eat as long as they do not exceed the number of exchanges prescribed. The food exchange system, along with a plan of moderate exercise, can help diabetics lose excess weight and improve their overall health. Certain foods will be emphasized over others to promote a healthy heart as well.

Supplements

Supplement use to control blood glucose levels is controversial, as many studies have either produced conflicting results or have been done using such a small number of patients that their general validity can be questioned. Patients should be sure to inform their healthcare provider of all herbal and dietary supplements and over-the-counter medications that they are taking because these remedies may enhance or diminish the effects of conventional drugs used to treat diabetes.

CHROMIUM PICOLINATE. Several studies have had conflicting results on the effectiveness of **chromium** picolinate supplementation for control of blood glucose levels. In one study, approximately 70% of the diabetics receiving 200 micrograms of chromium picolinate daily reduced their need for insulin and medications. While some studies have shown that supplementation caused significant weight loss and decreases in blood glucose and serum triglycerides, others have shown no benefit. Chromium supplementation may cause hypoglycemia and other side effects.

MAGNESIUM. Magnesium deficiency may interfere with insulin secretion and uptake and worsen the patient's control of blood sugar. Also, magnesium deficiency puts diabetics at risk for certain complications, especially **retinopathy** and cardiovascular disease.

VANADIUM. Vanadium has been shown to bring blood glucose to normal levels in diabetic animals. In human studies, people who took vanadium were able to decrease their need for insulin.

Traditional Chinese medicine

In one study, non-insulin dependent diabetics who practiced daily **qigong** for one year had decreases in fasting blood glucose and blood insulin levels. Qigong also provides general health benefits.

Acupuncture may relieve pain in patients with diabetic neuropathy, a condition in which the nerves of the spinal column degenerate due to diabetes. Some studies have suggested that acupuncture also may help to bring blood glucose to normal levels in diabetics who do not require insulin.

When used in consultation with a **traditional Chinese medicine** practitioner, some traditional Chinese herbal medicines are believed to alleviate symptoms of or complications from diabetes. However, none of these treatments eliminates the need for insulin in people with type 1 diabetes or weight and diet control (and possibly medications) in people with type 2 diabetes. These traditional Chinese medicines include:

- Xiao Ke Wan (Emaciation and Thirst Pill) for diabetics with increased levels of sugar in blood and urine.
- Yu Quan Wan (Jade Spring Pill) for diabetics with a deficiency of Yin.
- Liu Wei Di Huang Wan (Six Ingredient Pill with Rehmannia) for stabilized diabetics with a deficiency of Kidney Yin.
- Jin Gui Shen Wan (Kidney Qi Pill) for stabilized diabetics with a deficiency of Kidney Yang.

Herbs

Herbal medicines can have a positive effect on blood glucose and quality of life in diabetics. Herbs recommended by herbal practitioners to help control blood glucose levels include the following:

- ginseng (genus *Panax*), shown to moderately lower blood glucose levels in several well-designed clinical trials
- wormwood (*Artemisia herba-alba*), shown to decreased blood glucose
- gurmar (*Gymnema sylvestre*), thought to decrease blood glucose levels and the need for insulin
- *Coccinia indica*, believed to improved glucose tolerance
- fenugreek seed powder (*Trigonella foenum graecum*) shown to decrease blood glucose and improved glucose tolerance
- bitter melon (*Momordica charantia*) believed to decrease blood glucose and improved glucose tolerance
- cayenne pepper (*Capsicum frutescens*) to help relieve pain in the peripheral nerves (a type of diabetic neuropathy)

Other herbals that may treat or prevent diabetes and its complications include the following:

- bilberry (*Vaccinium myrtillus*) may lower blood glucose levels and maintain healthy blood vessels
- garlic (*Allium sativum*) may lower blood sugar and cholesterol levels
- onions (*Allium cepa*) may help lower blood glucose levels
- ginkgo (*Ginkgo biloba*) may improve blood circulation

Yoga

Studies of diabetics have shown that practicing **yoga** leads to decreases in blood glucose, increased glucose tolerance, decreased need for diabetes medications, and improved insulin processes. Yoga also enhances the sense of wellbeing and improves circulation and flexibility.

Biofeedback

Many studies have been performed to test the benefit of adding **biofeedback** to the diabetic's treatment plan. **Relaxation** techniques, such as visualization, usually were included. Biofeedback can have significant effects on diabetes, including improved glucose tolerance and decreased blood glucose levels. In addition, biofeedback can be used to treat diabetic complications and improve quality of life.

Allopathic treatment

Traditional treatment of diabetes begins with a well balanced diet and moderate exercise. Medications are prescribed only if the patient's blood glucose cannot be controlled by these methods.

Oral medications

Oral prescription medications are available to lower blood glucose in type 2 diabetics. Drugs first prescribed for type 2 diabetes are in a class of compounds called sulfonylureas and include tolbutamide, tolazamide, acetohexamide, chlorpropamide, glyburide, glimeperide, and glipizide. The way that these drugs work is not well understood; they seem to stimulate cells of the pancreas to produce more insulin. Other drugs available to treat diabetes include metformin, acarbose, and troglitizone. These medications are not a substitute for a well-planned diet and moderate exercise. Oral medications are not effective for type 1 diabetes, in which the patient produces little or no insulin.

Insulin

Patients with type 1 diabetes need daily injections of insulin to help their bodies use glucose. Some patients with type 2 diabetes may need to use insulin injections if their diabetes cannot be controlled. Injections are given subcutaneously—just under the skin, using a small needle and syringe. Insulin comes in many forms, including rapid-acting, short-acting, intermediate-acting, long-acting, and pre-mixed (several types in a specific ratio) insulin. Synthetic human insulin is commonly considered superior to bovine (cow) or porcine (pig) insulin. The type of insulin used varies with the age, health, and lifestyle of each diabetic. Different types of insulin can be mixed and given in one dose or split into two or more doses during a day. Patients who require multiple injections over the course of a day may be able to use an insulin pump that administers small doses of insulin on demand.

New drugs and new drug delivery systems to treat diabetes were active areas of research as of 2008. For example, in 2004, the United States Food and Drug Administration (FDA) approved a rapid-acting form of synthetic insulin, insulin glulisine (Apidra), to control hyperglycemia following meals. In 2007, the FDA approved a new delivery system for insulin glargine (Lantus) called LantusSoloStar, which consists of individual pre-loaded insulin pens to be used once daily at bedtime. Because the number of individuals with diabetes was expected to rise substantially between 2008 and 2018, research on new drugs, delivery systems, and blood glucose test kits is likely to remain vigorous.

Hypoglycemia, or low blood sugar, is a condition that can be caused by too much insulin, eating too little food, eating too late to coincide with the action of the insulin, alcohol consumption, or increased exercise. A patient with symptoms of hypoglycemia may be hungry, sweaty, shaky, cranky, confused, and tired. Left untreated, the individual can lose consciousness or have a seizure. This condition is sometimes called an insulin reaction or "insulin shock" and should be treated by giving the individual something sweet to eat or drink such as candy, sugar cubes, or juice.

Surgery

Transplantation of a healthy pancreas into a person with type 1 diabetes might seem like a successful treatment. Nevertheless, this transplant usually is done only if a kidney transplant is performed at the same time. Transplanted pancreases are rejected about half the time, so in many cases the potential benefits of transplantation are overshadowed by the risks of the surgery and subsequent immune system drug therapy.

Expected results

Individuals who can control their diabetes and keep their blood glucose levels constant within a normal range can, with care, lead a relatively healthy, normal life. Some diabetics have even been successful in playing professional sports (Bobby Clark, hockey player for the Philadelphia Flyers was one of the first professional sports figures to publicly discuss his diabetes). Uncontrolled diabetes is a leading cause of blindness, end-stage renal disease, and limb amputations. It also doubles the risk of heart disease and increases the risk of stroke. Eye problems, including **cataracts**, **glaucoma**, and retinopathy, also are more common in diabetics. Kidney disease is a common complication of diabetes and may require kidney dialysis or a kidney transplant. Babies born to diabetic mothers have an increased risk of birth defects and distress at birth.

Diabetic **peripheral neuropathy** is a condition in which nerve endings, particularly in the legs and feet, become less sensitive. Diabetic foot ulcers are a common problem since the patient does not feel the pain of a blister, callous, or other minor injury. Poor blood circulation in the legs and feet then contributes to slowing wound healing. The inability to sense pain along with the complications of delayed wound healing can result in minor injuries, **blisters**, or **calluses** becoming infected and difficult to treat. Severely infected tissue breaks down and rots, often necessitating amputation of toes, feet, or legs.

Prevention

Research continues on ways to prevent diabetes and to detect those at risk for developing diabetes. While the onset of type 1 diabetes is unpredictable, the risk of developing type 2 diabetes can be reduced by losing excess weight, exercising regularly, and eating a diet low in calories and high in fruits, vegetables, and whole grains. The Diabetes Prevention Program, a large well-designed clinical trial, found that people with pre-diabetes were substantially less likely to develop diabetes if they lost weight and exercised 150 minutes per week. People taking metformin (Glucophage) without lifestyle changes also reduced their

KEY TERMS

Body Mass Index (BMI)—A measurement of fatness that compares height to weight.

Cataracts—A condition in which the lens of the eye becomes cloudy.

Diabetic peripheral neuropathy—Dulled sensitivity of nerves to pain, temperature, and pressure particularly in the legs and feet.

Diabetic retinopathy—The tiny blood vessels to the retina, the tissues that sense light at the back of the eye, are damaged, leading to blurred vision, sudden blindness, or black spots, lines, or flashing light in the field of vision.

Glaucoma—A condition in which pressure within the eye causes damage to the optic nerve, which sends visual images to the brain.

Hyperglycemia—A condition of having too much glucose or sugar in the blood.

Hypoglycemia—A condition of having too little glucose or sugar in the blood.

Insulin—A hormone produced by the pancreas that is needed by cells of the body to use glucose (sugar), the body's main source of energy.

Ketoacidosis—A condition due to starvation or uncontrolled type 1 diabetes. Ketones are acid compounds that form in the blood when the body breaks down fats and proteins. Symptoms include abdominal pain, vomiting, rapid breathing, extreme tiredness, and drowsiness.

Kidney dialysis—A process by which blood is filtered through a dialysis machine to remove waste products that would normally be removed by the kidneys. The filtered blood is then circulated back into the patient; also called renal dialysis.

Pancreas—An organ located near the liver that produces the hormones insulin, glucagon, and somatostatin as well as digestive enzymes.

chance of developing diabetes, but less so than those who changed their eating and exercise habits.

The physical and emotional stress of surgery, illness, and alcoholism can increase the risks of diabetes, so stress reduction and maintaining a healthy lifestyle is important in preventing the onset of type 2 diabetes or reducing complications of the disease.

In early 2002, researchers announced that patients at high risk for developing diabetes who took an ACE inhibitor called ramipril (Altace) reduced their risk of developing diabetes by 30%. However, a large clinical trial reported in 2006 found that people who had impaired fasting glucose levels or impaired glucose tolerance and who used ramipril for three years developed diabetes and died at the same rate as people who did not take the drug, although of those people who did not develop diabetes, more returned to normal blood sugar levels while taking ramipril. These mixed results leave the effects of ACE inhibitors on diabetes unclear and open to more research as of 2008.

Diamond diet

Definition

The Diamond diet, popularly known as the Fit for Life Program, is a way of eating designed to be employed as a health lifestyle. Developed by Harvey and Marilyn Diamond, it is a set of dietary principles intended to serve as a blueprint for habits that can easily become routine, allowing individuals to take control of their health.

Origins

Harvey Diamond was an ill and underweight child with chronic and painful stomach problems. As a young adult, his health problems continued as he became overweight. After experiencing the dieting merry-go-round of losing and regaining his weight, Diamond decided that dieting does not work and that he needed to learn how to best care for his body. In 1970, Diamond found his answer in the concept of natural hygiene, an approach to the care and upkeep of the body that focuses on prevention of disease and healthful living. As described by Diamond, the concept of natural hygiene teaches that the body is self-cleansing, self-healing, and self-maintaining. Healing powers are contained within the body itself. He states "the body is always striving for health and . . . achieves this by continuously cleansing itself of deleterious waste material." In combination with an overall healthful lifestyle of adequate rest, **exercise**, sunshine, **stress** management, and interpersonal relationships, understanding how food impacts this cleansing process allows individuals to eliminate the cause of their health problems.

Almost immediately upon Diamond's introduction to this concept, his lifelong stomach pains ceased. Within one month, he had lost 50 pounds (a loss he was able to maintain). Diamond became a proponent of natural hygiene and, in 1981, began a seminar program known as The Diamond Method. In 1983, he earned a doctorate in nutritional science from the American College of Health Science, a non-accredited college in Austin, Texas. It is the basic fundamentals of natural hygiene that Harvey and Marilyn Diamond synthesized into the dietary and lifestyle principles of the Fit for Life Program.

Benefits

Although popularly discussed as a weight loss program, Fit for Life is not a diet. True to the tenets of natural hygiene, the approach to eating laid out in the Fit for Life books is designed to provide for optimal body functioning by internal cleansing of illness-producing toxins. Although weight loss and energy enhancements are positive results, the underlying goal is cleansing. Disease, as understood in this approach, is "nothing more than the body's own effort to cleanse itself of toxins." These toxins are the products of metabolic imbalance, or toxemia, resulting from wastes. Dead cells, food residue, and additives build up in the bodies and cannot be eliminated at the same rate they are produced. Understanding and minimizing this level of toxemia is the key to healthy longevity. The dietary guidelines of the Fit for Life program are designed to generate a minimum of toxic food residue within the body and to enable the body to continuously expel the toxic waste that is produced. An additional intent is that the dietary guidelines incorporate good food and enjoyable meals rather than strict, hard-to-follow regimens. If the program is stopped for any reason, according to Diamond, it can be re-started with almost immediate results.

Description

The Fit for Life program places an emphasis not only on what foods are eaten, but also in what combinations and at what time of day those foods are eaten. Three general principles guide Diamond's hygienic approach to eating.

The Principle of High-Water-Content Food

Water is vital to cleansing the inside of the body of accumulated wastes. Consuming sufficient high-water-content foods, fruits, and vegetables is crucial to accomplish this cleansing. Unlike drinking water, the water found in fruits and vegetables provides for the transport of the nutrients found in those foods. It then flushes waste matter from the body.

The Principle of Proper Food Combining

According to this principle, foods should be eaten in combinations that are most compatible with

digestive chemistry. Otherwise, the food will remain in the stomach longer than it should and cause digestive problems. Proteins and starches should not be eaten together because the stomach cannot digest both efficiently at the same time. For optimal digestion, proteins should be combined with vegetables at mealtime or a starch combined with vegetables.

The Principle of the Correct Consumption of Fruit

Fruit should be fresh and ripe when eaten. It should be eaten alone on an empty stomach, not with or after anything else. The reason is that fruit requires no digestion in the stomach and should be able to pass through the stomach quickly to help the body in its **detoxification** efforts. Additionally, because fruit requires so little digestive energy, it should be eaten in the morning to best work with natural body cycles of food utilization and elimination. The body needs to spend its energy on proper cleansing during the morning hours rather than diverting crucial energy to digestive processes. According to Diamond, the most beneficial habit a person can develop is consuming exclusively fresh fruit and fresh fruit juice from awakening until noon.

Research and general acceptance

Proponents, including some **nutrition** and medical professionals, claim benefits include weight loss, improved energy, and overall better health from following the program. Medical doctors, including Edward Taub, an Assistant Clinical Professor at the University of California, Irvine, and Kay S. Lawrence, contributed to the first Fit for Life book. Critics contend that the principles of the program disagree with much established nutritional advice such as that provided by the American Dietetic Association (ADA). The regimen does not, for example, advocate weight loss by counting calories, recommend the basic food groups, or call to attention the health benefits of milk. Although the emphasis on fresh fruits and vegetables is generally seen as positive, it is also called extreme by some reviewers. Reviewers in nutritional publications have raised concerns about inadequate protein intake, the possibility of deficiencies in **calcium**, **zinc**, some B vitamins (notably **riboflavin** and **thiamine**), and **iron** deficiency **anemia**. Some nutritionists have also argued that rigorously following the Fit for Life dietary guidelines could lead to inadequate nutrition for the proper development of growing children or fetuses. Critical reviews range from Environmental Nutrition's assessment that the Fit for Life regimen is "probably not dangerous, [but] has the potential to be unhealthy and therefore is not recommended" to the position of J. Lynne Brown, Ph.D., R.D. that if "followed rigorously, it could lead to serious health problems." Diamond rebuffs his critics, ADA guidelines and nutritional advice in particular, calling for a broader understanding of science, a quest for truth and less emphasis on credentials which are, he argues, the way organizations such as the ADA maintain power over dissenting opinions.

Diaper rash

Definition

Dermatitis of the buttocks, genitals, lower abdomen, or thigh folds of an infant or toddler is commonly referred to as diaper rash.

Description

The outside layer of skin normally forms a protective barrier that prevents infection. One of the primary causes of dermatitis in the diaper area is prolonged skin contact with wetness. Under these circumstances, natural oils are stripped away, the outer layer of skin is damaged, and there is increased susceptibility to infection by bacteria or yeast.

Male baby with severe diaper rash. *(Custom Medical Stock Photo. Reproduced by permission.)*

Diaper rash is a term that covers a broad variety of skin conditions that occur on the same area of the body. Some babies are more prone to diaper rash than others.

Causes and symptoms

Frequently, a flat, red rash is caused by simple chafing of the diaper against tender skin, initiating a friction rash. This type of rash is not seen in the skin folds. It may be more pronounced around the edges of the diaper, at the waist and leg bands. The baby generally does not appear to experience much discomfort. Sometimes the chemicals or detergents in the diaper are contributing factors and may result in **contact dermatitis**. These **rashes** should clear up easily with proper attention. Ignoring the condition may lead to a secondary infection that is more difficult to resolve.

Friction of skin against itself can cause a rash in the baby's skin folds, called intertrigo. This rash appears as reddened areas that may ooze, and is often uncomfortable when the diaper is wet. Intertrigo can also be found on other areas of the body where there are deep skin folds that tend to trap moisture.

Seborrheic dermatitis is the diaper area equivalent of **cradle cap**. It is scaly and greasy in appearance and may be worse in the folds of the skin.

Yeast, or candidal dermatitis, is the most common infectious cause of diaper rash. The affected areas are raised and quite red with distinct borders, and satellite lesions may occur around the edges. Yeast is part of the normal skin flora, and is often an opportunistic invader when simple diaper rash is untreated. It is particularly common after treatment with antibiotics, which kill the good bacteria that normally keep the yeast population in check. Usual treatments for diaper rash will not clear it up. Repeated or difficult to resolve episodes of **yeast infection** may warrant further medical attention, since this is sometimes associated with diabetes or immune problems.

KEY TERMS

Dermatitis—Inflammation of the skin.

Another infectious cause of diaper rash is **impetigo**. This bacterial infection is characterized by **blisters** that ooze and crust.

Diagnosis

The presence of skin lesions in the diaper area means that the baby has diaper rash. However, there are several types of rash that may require specific treatment in order to heal. It is useful to be able to distinguish them by appearance.

A baby with a rash that does not clear up within two to three days, or a rash with blisters or bleeding, should be seen by a healthcare professional for further evaluation.

Treatment

Good diaper hygiene will prevent or clear up many simple cases of diaper rash. Diapers should be checked very frequently and changed as soon as they are wet or soiled. Good air circulation is also important for healthy skin. Babies should have some time without wearing a diaper, and a waterproof pad can be used to protect the bed or other surface. Rubber pants, or other occlusive fabrics, should not be used over the diaper area. Some cloth-like disposable diapers promote better air circulation than plastic-type diapers. It may be necessary for mothers to experiment with diaper types to see if the baby's skin reacts better to cloth or disposable ones. If disposable diapers are used, the baby's skin may react differently to various brands. If the baby is wearing cloth diapers, they should be washed in a mild detergent and double rinsed.

The diaper area should be cleaned with something mild, even plain water. Some wipes contain alcohol or chemicals that can be irritating for some babies. Plain water may be the best cleansing substance when there is a rash. Using warm water in a spray bottle (or giving a quick bath) and then lightly patting the skin dry can produce less skin trauma than using wipes. In the event of suspected yeast, a tablespoon of cider vinegar can be added to a cup of warm water and used as a cleansing solution. This is dilute enough that it should

not burn, but acidifies the skin pH enough to hamper the yeast growth.

Barrier ointments can be valuable to treat rashes. Those that contain zinc oxide are especially effective. These creams and ointments protect already irritated skin from the additional insult of urine and stool, particularly if the baby has **diarrhea**. Cornstarch powder may be used on rashes that are moist, such as impetigo.

Nutrition

What the baby eats can make a difference in stool frequency and acidity. Typically, breast-fed babies will have fewer problems with rashes. When adding a new food to the diet, the baby should be observed closely to see whether rashes are produced around the baby's mouth or anus. If this occurs, the new food should be discontinued.

Babies who are taking antibiotics are more likely to get rashes due to yeast. To help bring the good bacterial counts back to normal, *Lactobacillus bifidus* can be added to the diet. It is available in powder form from most health food stores.

Herbal treatment

Some herbal preparations can be useful for diaper rash. **Calendula** reduces inflammation, tightens tissues, and disinfects. It has been recommended for seborrheic dermatitis as well as for general inflammation of the skin. The ointment should be applied at each diaper change. **Chickweed** ointment can also be soothing for irritated skin and may be applied once or twice daily.

Allopathic treatment

Antibiotics are generally prescribed for rashes caused by bacteria, particularly impetigo. This may be a topical or oral formulation, depending on the size of the area involved and the severity of the infection.

Over-the-counter antifungal creams, such as Lotrimin, are often recommended to treat a rash resulting from yeast. If topical treatment is not effective, an oral antifungal may be prescribed.

Mild steroid creams, such as 0.5-1% hydrocortisone, can be used for seborrheic dermatitis and sometimes intertrigo. Prescription strength creams may be needed for short-term treatment of more stubborn cases.

Expected results

Treated appropriately, diaper rash will resolve fairly quickly if there is no underlying health problem or skin disease.

Prevention

Frequent diaper changes are important to keep the skin dry and healthy. Application of powders and ointments is not necessary when there is no rash. Finding the best combination of cleansing and diapering products for the individual baby will also help to prevent diaper rash.

Diarrhea

Definition

To most persons, diarrhea means an increased frequency or softer consistency of bowel movements. The medical definition specifies that diarrhea correlates with an increase in stool weight; stool weights above 300 g per day generally indicate diarrhea. This is mainly due to excess water, which normally makes up 60 to 85% of fecal matter. In this way, true diarrhea is distinguished from diseases that cause only an increase in the number of bowel movements (hyperdefecation) or incontinence (involuntary loss of bowel contents).

Diarrhea is also classified by physicians into acute, which lasts one to two weeks, and chronic, which continues for longer than 23 weeks. Viral and bacterial **infections** are the most common causes of acute diarrhea.

Description

In many cases, acute infectious diarrhea is a mild, limited annoyance. However, acute infectious diarrhea has a huge impact worldwide, causing more than five million deaths per year. While most deaths are among children under five years of age in developing nations, the impact, even in developed countries, is considerable. For example, over 250,000 persons are admitted to hospitals in the United States each year

Causes of diarrhea

Causes	Examples
Viral infections	Rotavirus, Norwalk virus
Bacterial infections	*E. coli, Vibrio cholerae, Campylobacter, Shigella*
Parasites	*Giardia, Entamoeba*
Helminths (intestinal worms)	Strongyloides
Allergic	Lactose intolerance, celiac sprue, medication side effects
Autoimmune	Ulcerative colitis, Crohn's disease
Malabsorptive	Pancreatic deficiency, biliary disease
Nutritional	Zinc deficiency, vitamin A deficiency, enteral feedings consisting of liquid nutritional formulas delivered straight to the bowels
Functional	Irritable bowel syndrome, short bowel syndrome, cancer

(Illustration by GGS Information Services. Cengage Learning, Gale)

because of diarrhea. Rapid diagnosis and proper treatment can prevent much of the suffering associated with this illness.

Chronic diarrhea also has a considerable effect on health, as well as on social and economic well being. Patients with **celiac disease**, **inflammatory bowel disease**, and other prolonged diarrheal illnesses develop nutritional deficiencies, which diminish growth and immunity. They affect social interaction and result in the loss of many working hours.

Causes and symptoms

Diarrhea occurs because more fluid passes through the large intestine (colon) than can be absorbed. As a rule, the colon can absorb several times more fluid than is required on a daily basis. However, when this reserve capacity is overwhelmed, diarrhea occurs.

Diarrhea is caused by infections or illnesses that either lead to excess production of fluids or prevent absorption of fluids. Also, certain substances in the colon, such as fats and bile acids, can interfere with water absorption and cause diarrhea. In addition, rapid passage of material through the colon can cause diarrhea.

Symptoms related to diarrheal illness are often those associated with any injury to the gastrointestinal tract, such as **fever**, **nausea**, **vomiting**, and abdominal **pain**. All or none of these may be present depending on the cause of diarrhea. The number of bowel movements can vary with up to 20 or more per day. In some patients, blood or pus is present in the stool. Bowel movements may contain undigested food material.

The most common causes of acute diarrhea are infections (the cause of traveler's diarrhea), **food poisoning**, and medications. Medications are a frequent and often overlooked cause, especially antibiotics and antacids. Both prescription and over-the-counter medications can contain additives, such as lactose and sorbitol, that will produce diarrhea in sensitive persons. Less often, various sugar-free foods, which sometimes contain poorly absorbable materials, cause diarrhea. Review of **allergies** or skin changes may also point to a cause.

Rotavirus is a common cause of diarrhea in children. A study performed at the Baylor College of Medicine in Houston, Texas, found that children who have rotavirus in their intestine have a high likelihood of the presence of the disease in their bloodstream.

Chronic diarrhea is frequently due to many of the same conditions that cause the shorter episodes (e.g., infections, medications); symptoms just last longer. Some infections can become chronic. This occurs mainly with **parasitic infections** (such as *Giardia*) or in cases in which patients have altered immunity (such as **AIDS**).

The following are the more usual causes of chronic diarrhea:

- AIDS
- colon cancer and other bowel tumors
- endocrine or hormonal abnormalities (e.g., thyroid, diabetes mellitus)
- food allergy
- inflammatory bowel disease, or IBD (Crohn's disease and ulcerative colitis)
- lactose intolerance
- malabsorption syndromes (celiac and Whipple's disease)
- other (alcohol, microscopic colitis, radiation, surgery)

Complications

The major effects of diarrhea are dehydration, malnutrition, and weight loss. Signs of dehydration can be hard to notice but include thirst, **dry mouth**, weakness or lightheadedness (particularly if worsening on standing), urine darkening, or a decrease in urination. Severe dehydration leads to changes in the body's chemistry and could become life-threatening. Dehydration from diarrhea can result in kidney failure, neurological symptoms, arthritis, and skin problems. Dehydration in chronic diarrhea, such as that associated with inflammatory bowel disease, increases a person's risk for **kidney stones**.

Diagnosis

Most cases of acute diarrhea never need diagnosis or treatment, as many are mild and produce few problems. Patients with fever over 102°F (38.9°C), signs of dehydration, bloody bowel movements, severe abdominal pain, known immune disease, or recent use of antibiotics need prompt medical evaluation.

When diagnostic studies are needed, the most useful are stool culture and examination for parasites; however, these are often negative and a cause cannot be found in a large number of patients. The earlier cultures are performed, the greater the chance of obtaining a positive result. Stool samples of patients who had used antibiotics in the preceding two months need to be examined for the toxins that cause antibiotic-associated **colitis**. Tests are also available to check stool samples for microscopic amounts of blood and for cells that indicate severe inflammation of the colon. Examination with an endoscope is sometimes helpful in determining severity and extent of inflammation. Tests to check changes in blood chemistry (e.g., **potassium**, **magnesium**) and a complete blood count (CBC) may be performed.

Chronic diarrhea is quite different, and most patients with this condition will receive some degree of testing. Many exams are the same as for an acute episode, as some infections and parasites cause both types of diarrhea. A careful history to evaluate medication use, dietary changes, family history of illnesses, and other symptoms is necessary. Key points in determining the seriousness of symptoms are weight loss of over 10 lb (4.5 kg), blood in the stool, and nocturnal diarrhea (symptoms that awaken the patient from sleep). A combination of stool, blood, and urine tests may be needed in the evaluation of chronic diarrhea; in addition a number of endoscopic and x-ray studies are frequently required.

In some cases, appendectomy leads to a diagnosis of inflammatory bowel disease. The specimen removed during the procedure may contain signs of the disorder and may be the first clue that a patient has IBD.

Treatment

Diet

Treatment is ideally directed toward correcting the cause; however, the first aim is to prevent or treat dehydration and nutritional deficiencies. When possible, food intake should be continued even in patients with acute diarrhea. A physician should be consulted as to what type and how much food is permitted. Low-fat **diets** or more easily digestible fat is useful in some patients. The BRAT diet, which limits food intake to bananas, rice, applesauce, and toast, can help to resolve diarrhea. These foods provide soluble and insoluble fiber without irritation. If the toast is slightly burnt, the charcoal can help sequester toxins and pull them from the body.

The patient should drink plenty of fluids; however, in severe cases hospitalization to provide intravenous fluids may be necessary. A physician should be notified if the patient is dehydrated, and if oral replacement is suggested then commercial (Pedialyte and others) or homemade preparations can be used. The World Health Organization (WHO) has provided this easy recipe for home preparation, which can be taken in frequent small sips:

- table salt: 3/4 teaspoon
- baking powder: 1 teaspoon
- orange juice: 1 cup
- water: 1 quart or liter.

Supplements

Nutrient replacement also plays a role in preventing and treating diarrhea. **Zinc** especially appears to have an effect on the immune system, and deficiency of this mineral can lead to chronic diarrhea. Also, zinc replacement improves growth in young patients.

Dietary supplements that are generally beneficial in the treatment of digestive disorders include the following:

- vitamin C: 50-500 mg daily
- vitamin B_6: 50 to 150 mg daily
- magnesium aspartate: 400 mg daily
- vitamin E: 400 IU daily
- glutamine: 3,000 mg daily
- garlic, deodorized: 2,000 mg daily
- deghycirrhizinated licorice: chew as needed

Studies conducted at the Children's Hospital Oakland Research Institute (Oakland, California) and at the Heinrich Heine University (Dusseldorf, Germany), found that cocoa flavonoids in dark chocolate can limit the amount of fluid in the intestine, possibly relieving diarrhea. More research in the area was needed as of 2008; however, scientists noted that using chocolate as a diarrhea treatment dates back hundreds of years, although the mechanism was not known.

Probiotics

Probiotics refers to treatment with beneficial microbes either by ingestion or from a suppository. Studies and the clinical use of probiotics have shown

their utility in the resolution of diarrhea, especially antibiotic-associated diarrhea. Beneficial microbes include the bacteria *Lactobacillus acidophilus* and *L. bifidus* and the yeast *Saccharomyces boulardii*. To treat diarrhea, the patient can eat one cup of yogurt (containing active *Lactobacillus acidophilus* cultures) daily. Alternatively, one or two **acidophilus** capsules may be taken at each meal or at bedtime.

Researchers at Ohio State University found that treatment with probiotics lessened the chance of diarrhea in persons taking antibiotics. In the study, diarrhea was experienced by 20% of individuals not taking the probiotics. Only 8% of individuals taking probiotics had diarrhea.

Acupuncture

Shallow **acupuncture**, when the needles are inserted superficially and rapidly removed, was more therapeutic than drugs in children with acute or chronic diarrhea. In another study, acupuncture eliminated symptoms and normalized stools in children with chronic diarrhea who had not responded to conventional or Chinese medicines.

Herbals and Chinese medicines

Herbal remedies for diarrhea include meadowsweet, **goldenseal**, and **chamomile** taken as an infusion throughout the day.

Chinese patent medicines used for treating diarrhea include the following:

- Xiang Sha Liu Jun Wan (Six-Gentlemen Pill with Aucklandia and Amomum)
- Fu Zi Li Zhong Wan (Prepared Aconite Pill to Regulate the Middle)
- Si Shen Wan (Four-Miracle Pill)
- Wu Mei Wan (Mume Pill)
- Jian Pi Wan (Strengthen the Spleen Pill)
- Shen Ling Bai Zhu Wan (Ginseng, Poria, and Atractylodes Macrocephala Pill)

Allopathic treatment

Anti-motility agents, such as loperamide (Imodium AD) and diphenoxylate are useful for persons with chronic diarrhea; their use is limited or even contraindicated in patients with acute diarrhea, especially in those with high fever or bloody bowel movements. They should not be taken without the advice of a physician. Other treatments that are available, depending on the cause of diarrhea, include the bulk agent **psyllium** and the binder cholestyramine. Also, new antidiarrheal drugs that decrease excessive secretion of fluid by the intestinal tract are available.

A University of Tennessee study found promising results in treating certain types of traveler's diarrhea with the antibiotic Rifximin (Xafaxan). In the study, travelers to Mexico and Kenya who experienced traveler's diarrhea reduced the duration of the loose stools. The drug was found to be effective for certain strains of *E. coli* but is not effective if fever is present or if the stool contains blood.

KEY TERMS

Anti-motility medications—Medications such as loperamide (Imodium), diphenoxylate (Lomotil), or medications containing codeine or narcotics that decrease the ability of the intestine to contract. These can worsen the condition of a patient with dysentery or colitis.

Colitis—Inflammation of the colon.

Endoscope—A thin flexible tube with a lens or miniature camera that allows a doctor to view various internal organs, including the gastrointestinal tract. Both diagnosis and therapeutic procedures can be done with this instrument.

Endoscopy—The performance of an exam using an endoscope.

Lactose intolerance—An inability to properly digest milk and dairy products.

Probiotics—The use of beneficial microbes to treat various diseases, including diarrhea.

Rotavirus—The primary infectious cause of diarrhea in infants and children.

Expected results

Prognosis is related to the cause of the diarrhea; for most individuals in developed countries, a bout of acute, infectious diarrhea is at best uncomfortable. However, in both industrialized and developing areas, serious complications and death can occur.

Prevention

Proper hygiene and food handling techniques will prevent many cases. Traveler's diarrhea can be avoided by use of Pepto-Bismol and/or antibiotics, if necessary. The most important action is to prevent dehydration.

It was once planned to erect diathermy machines like the one in this photo in New York in 1946. In diathermy, high-frequency electrical currents are used to heat deep muscular tissues. *(Black Star / Alamy)*

Diathermy

Definition

In diathermy, high-frequency electrical currents are used to heat deep muscular tissues. The heat increases blood flow, speeding up recovery. Doctors also use diathermy in surgical procedures by sealing blood vessels with electrically heated probes.

The term diathermy is derived from the Greek words *therma,* meaning heat, and *dia,* meaning through. Diathermy literally means heating through.

Origins

The therapeutic effects of heat have long been recognized. More than 2,000 years ago, the Romans took advantage of heat therapies by building hot-spring bathhouses. Since then, various methods of using heat have evolved. In the early 1890s, French physiologist Arséne d'Arsonval began studying the medical application of high-frequency currents. The term diathermy was coined by German physician Carl Franz Nagelschmidt, who designed a prototype apparatus in 1906. Around 1925, United States doctor J. W. Schereschewsky began studying the physiological effects of high-frequency electrical currents on animals. It was several years, however, before the fundamentals of the therapy were understood and put into practice.

Benefits

Diathermy can be used to treat arthritis, **bursitis**, and other conditions involving stiff, painful joints. It is also used to treat pelvic **infections** and sinusitis. A benefit of diathermy is that it is a painless procedure that can be administered at a clinic. Also, if the treatment relieves **pain**, then patients can discontinue pain killers and escape their high cost and side effects.

Description

Diathermy involves heating deep muscular tissues. When heat is applied to the painful area, cellular metabolism speeds up and blood flow increases. The increased metabolism and circulation accelerates tissue repair. The heat helps the tissues relax and stretch, thus alleviating stiffness. Heat also reduces nerve fiber sensitivity, increasing the patient's pain threshold.

KEY TERMS

Bursitis—Pain and swelling in a joint, often the elbow, hip, knee or shoulder. In bursitis, the bursa (a sac-like membrane that acts as a pillow between the bones and tissues) becomes inflamed.

Capacitor plates—An apparatus that can carry electricity and stores an electrical charge.

Hemophilia—A blood-clotting disorder that can lead to serious hemorrhage from minor cuts and injuries.

There are three methods of diathermy. In each, energy is delivered to the deep tissues, where it is converted to heat. The three methods are:

- Shortwave diathermy. The body part to be treated is placed between two capacitor plates. Heat is generated as the high-frequency waves travel through the body tissues between the plates. Shortwave diathermy is most often used to treat areas like the hip, which is covered with a dense tissue mass. It is also used to treat pelvic infections and sinusitis. The treatment reduces inflammation. The Federal Communications Commission regulates the frequency allowed for short-wave diathermy treatment. Most machines function at 27.33 megahertz.
- Ultrasound diathermy. In this method, high-frequency acoustic vibrations are used to generate heat in deep tissue.
- Microwave diathermy. This method uses radar waves to heat tissue. This form is the easiest to use, but the microwaves cannot penetrate deep muscles.

Diathermy is also used in surgical procedures. Many doctors use electrically heated probes to seal blood vessels to prevent excessive bleeding. This is particularly helpful in neurosurgery and eye surgery. Doctors can also use diathermy to kill abnormal growths, such as tumors, **warts**, and infected tissues.

Preparations

To keep patients from sweating, patients are usually asked to remove clothing from the body part being treated. If a patient sweats, the electrical currents may pool in the area, causing **burns**. Also, clothing containing metal must be removed, as must earrings, buttons, barrettes, or zippers that contain metal. Watches and hearing aids should be removed because the therapy may affect their function.

Practitioners of surgical diathermy should steer clear of alcohol-based solutions to prepare and cleanse the skin. These preparations can create a flammable vapor and cause burns and fires.

Precautions

Patients with metal implants should not undergo diathermy treatment because the metal can act as a conductor of heat and result in serious internal burns. Female patients with metallic uterine implants, such as an IUD, should avoid treatment in the pelvic area. Diathermy should not be used in joints that have been replaced with a prosthesis or in those with sensory impairment who may not be able to tell if they are burning. Furthermore, pulsed shortwave diathermy should be avoided during **pregnancy**, as it can lead to abnormal fetal development.

Patients with hemophilia should avoid the treatment because the increased blood flow could cause them to hemorrhage.

Side effects

Some patients may experience superficial burns. Since the therapy involves creating heat, care must be taken to avoid burns, particularly in patients whose injuries have caused decreased sensitivity to heat. Also, diathermy may affect pacemaker function.

Female patients who receive treatment in the lower back or pelvic area may experience an increased menstrual flow.

Research and general acceptance

For years, physiotherapists and physical therapists have used diathermy as a routine part of physical rehabilitation.

Training and certification

It is recommended that those who treat patients with diathermy complete a course in shortwave therapy and should retake courses every five years to stay updated on procedures. Physiotherapists should also stay updated by reading appropriate medical journals.

Diets

Definition

Humans may alter their usual eating habits for many reasons, including weight loss, disease prevention or treatment, removing toxins from the body, or to achieve a general improvement in physical and mental health. Others adopt special diets for religious reasons. In the case of some vegetarians and vegans, dietary changes are made out of ethical concerns for the rights of animals.

Origins

The practice of altering diet for special reasons has existed since antiquity. For example, Judaism has included numerous dietary restrictions for thousands of years. One ancient Jewish sect, the Essenes, is said to have developed a primitive **detoxification** diet aimed at preparing the bodies, minds, and spirits of its members for the coming of a "messiah" who would deliver them from their Roman captors. Preventative and therapeutic diets became quite popular during the late twentieth century. Books promoting the latest dietary plan continue to make the bestseller lists, although not all of the information given is considered authoritative.

Benefits

People who are moderately to severely overweight can derive substantial health benefits from a weight-loss diet. A weight reduction of just 10 to 20 lbs (5-10 kg) can result in reduced **cholesterol** levels and lower blood pressure. Weight-related health problems include **heart disease**, diabetes, high blood pressure, and high levels of blood sugar and cholesterol.

In individuals who are not overweight, dietary changes may also be useful in the prevention or treatment of a range of ailments including acquired immunodeficiency syndrome (**AIDS**), **cancer**, **osteoporosis**, **inflammatory bowel disease**, chronic pulmonary disease, renal disease, **Parkinson's disease**, seizure disorders, and food **allergies** and intolerances.

Description

The idea of a healthful diet is to provide all of the calories and nutrients needed by the body for optimal performance, at the same time ensuring that neither nutritional deficiencies nor excesses occur. Diet plans that claim to accomplish those objectives are so numerous they are virtually uncountable. These diets employ a variety of approaches, including the following:

- Fixed-menu: Offers little choice to the dieter. Specifies exactly which foods will be consumed. Easy to follow, but may be considered "boring" to some dieters.
- Formula: Replaces some or all meals with a nutritionally balanced liquid formula or powder.
- Exchange-type: Allows the dieter to choose between selected foods from each food group.
- Flexible: Doesn't concern itself with the overall diet, simply with one aspect such as fat or energy.

Diets may also be classified according to the types of foods they allow. For example, an omnivorous diet consists of both animal and plant foods, whereas a lacto-ovo-vegetarian diet permits no animal flesh, but does include eggs, milk, and dairy products. A vegan diet is a stricter form of **vegetarianism** in which eggs, cheese, and other milk products are prohibited.

A third way of classifying diets is according to their purpose: religious, weight-loss, detoxification, lifestyle-related, or aimed at prevention or treatment of a specific disease.

Precautions

Dieters should be cautious about plans that severely restrict the size of food portions, or that eliminate entire food groups from the diet. It is highly probable that they will become discouraged and drop out of such programs. The best diet is one that can be maintained indefinitely without ill effects, that offers sufficient variety and balance to provide everything needed for good health, and that is considerate of personal food preferences.

Fad diets for quick weight loss are coming under increasing fire, since dieters seldom maintain the weight loss. In 2001, researchers found that three times as many people on moderate fat weight loss diets stuck to their plan compared to those on traditional low-fat diets. Not only do many diets offer only short-term and rapid weight loss, some can be bad for the dieter's health. For instance, the American Heart Association made a statement in late 2001 questioning

Unhealthy food additives

Name	Description	Example products
Aspartame	An artificial sweetener associated with rashes, headaches, dizziness, depression, and insomnia, and can also affect calcium metabolism	Diet sodas, sugar substitutes, gelatin desserts, low-calorie frozen desserts, etc.
Brominated vegetable oil (BVO)	Used as an emulsifier and clouding agent. Its main ingredient, bromate, is a poison.	Sodas, etc.
Butylated hydroxyanisole (BHA)/butylated hydroxytoluene (BHT)	Prevents rancidity in foods and is added to food packagings. It slows the transfer of nerve impulses, effects sleep, aggressiveness and weight in test animals, and may be carcinogenic.	Cereals, cheese packaging, chewing gum, potato chips, oils, etc.
Citrus red dye #2	Used to color the skin of oranges, it is a probable carcinogen. The FDA has recommended it to be banned.	Oranges
Monosodium glutamate (MSG)	A flavor enhancer that can cause headaches, heart palpitations and nausea.	Restaurant and fast food, processed and packaged food
Nitrates	Used as preservatives, nitrates form cancer-causing compounds in the gastrointestinal tract and have been associated with cancer and birth defects.	Cured meats and wine
Saccharin	An artificial sweetener that may be carcinogenic.	Diet sodas and sugar substitutes
Sulfites	Used as a food preservative, sulfites have been linked to at least four deaths reported to the FDA in the United States. They destroy vitamin B-1, and can also cause severe allergic reactions, especially in asthmatics.	Dried fruits, shrimp, frozen potatoes, and wine
Tertiary butyhydroquinone (TBHQ)	It is extremely toxic in low doses and has been linked to childhood behavioral problems.	Candy bars, baking sprays, butter/ margarine blends and other animal fats, and fast foods
Yellow dye #6	Increases the number of kidney and adrenal gland tumors in lab rats. It has been banned in Norway and Sweden.	Candy, sodas, gelatin, baked goods, and sausages

(Illustration by Corey Light. Cengage Learning, Gale)

the value of high-protein, low-carbohydrate diets. The association said that the diets do not work over the long term and that they can pose some health risks to dieters. In 2003, these statements were largely supported. Though clinical trials showed that these types of diets worked in lowering weight without raising cholesterol for the short-term, many of the participants gained a percentage of the weight back after only one year. A physician group also spoke out about high protein diets' dangers for people with decreased kidney function and the risk of bone loss due to decreased **calcium** intake.

Low-fat diets are not recommended for children under the age of two. Young children need extra fat to maintain their active, growing bodies. Fat intake may be gradually reduced between the ages of two and five, after which it should be limited to a maximum of 30% of total calories through adulthood. Saturated fat should be restricted to no more than 10% of total calories.

Weight-loss dieters should be wary of the "yo-yo" effect that occurs when numerous attempts are made to reduce weight using high-risk, quick-fix diets. This continued "cycling" between weight loss and weight gain can slow the basal metabolic rate and can sometimes lead to eating disorders. The dieter may become discouraged and frustrated by this success/failure cycle. The end result of yo-yo dieting is that it becomes more difficult to maintain a healthy weight.

Caution should also be exercised about weight-loss diets that require continued purchases of special prepackaged foods. Not only do these tend to be costly and over-processed, they may also prevent dieters from learning the food-selection and preparation skills essential to maintenance of weight loss. Further, dieters should consider whether they want to carry these special foods to work, restaurants, or homes of friends.

Concern has been expressed about weight-loss diet plans that do not include **exercise**, considered essential to long-term weight management. Some diets and supplements may be inadvisable for patients with special conditions or situations. In fact, use of the weight loss supplement **ephedra** was found to cause serious conditions such as **heart attack** and **stroke**. In 2004, the U.S. Food and Drug Administration (FDA) banned the sale of supplements containing ephedra. In short, most physician organizations see fad diets as distracting from learning how to achieve weight control over the long term through healthy lifestyle changes such as eating smaller, more balanced meals and exercising regularly.

Certain fad diets purporting to be official diets of groups such as the American Heart Association and the Mayo Clinic are in no way endorsed by those institutions. Patients thinking of starting such a diet should check with the institution to ensure its name has not been misappropriated by an unscrupulous practitioner.

Side effects

A wide range of side effects (some quite serious) can result from special diets, especially those that are nutritionally unbalanced. Further problems can arise if the dieter is taking high doses of dietary supplements. Food is essential to life, and improper **nutrition** can result in serious illness or death.

Research and general acceptance

It is agreed among traditional and complementary practitioners that many patients could substantially benefit from improved eating habits. Specialized diets have proved effective against a wide variety of conditions and diseases. However, dozens of unproved but widely publicized "fad diets" emerge each year, prompting widespread concerns about their usefulness, cost to the consumer, and their safety.

Training and certification

A wide variety of practitioners provide advice on dietary matters. These range from unregulated, uncertified alternative practitioners, to registered dietitians, medical doctors, and specialists. Nutritional advice can also be obtained from home economists and from college or university nutrition departments.

Digestive enzymes

Description

Enzymes are catalysts for virtually every biological and chemical reaction in the body, and digestive enzymes are crucial for the breakdown of food into nutrients that the body can absorb. Digestive enzymes, among which are a variety are herbs, are used to treat a number of digestive problems and other conditions.

General use

Digestive enzymes are used for relief of a number of digestive symptoms and conditions:

- flatulence
- heartburn
- diarrhea
- spasms
- inflammation
- constipation
- gastroesophageal reflux
- peptic ulcers
- indigestion
- age-related digestive problems

Digestive enzymes also may be used to treat and to provide relief to other conditions, such as anorexia, **Crohn's disease**, ulcerative **colitis**, **parasitic infections**, cystic fibrosis, and **pancreatitis**. Potential systemic benefits of digestive enzymes include increasing healing and reducing water retention after surgery, reducing inflammation, enhancing the immune system, and reducing the risk of malnutrition. **Enzyme therapy** also has been shown to reduce the adverse effects of radiotherapy and chemotherapy in **cancer** treatment due to its anti-inflammatory properties.

In Europe, supplemental oral enzymes have been used as substitutes for nonsteroidal anti-inflammatory drugs to treat inflammation-related conditions such as **osteoarthritis** and **rheumatoid arthritis**.

Preparations

Pancreatin, also called pancreatinum, is an animal-based enzyme mixture of several enzymes released by the pancreas, including *proteases* to break down proteins into **amino acids**; *amylase* to break down complex carbohydrates; and *lipase* to break down lipids (fats). Pancreatin has been shown to reduce bloating, **gas**, and the feeling of fullness, particularly after eating high-fat meals.

Lactase aids the digestion of lactose (milk sugar found in dairy products) when taken just before eating lactose-containing foods. Lactase supplements are available over-the-counter in caplet and chewable tablet form and are commonly used to treat lactose intolerance. Two common brands are Lactaid and Lactrase. A variety of lactose-reduced products, such as Lactaid and Dairy Ease, are available at many grocery stores.

Beano is an over-the-counter dietary supplement that can help prevent gas by aiding the digestion of the gas-producing sugars in complex carbohydrates that are found in beans and many vegetables. The supplement is available in liquid and tablet form, and the recommended dose is five drops or one tablet taken just before eating.

Herbal preparations

Carminative herbs are considered to be mild and are rich in volatile oils, which have antibacterial properties. These herbs include **peppermint** (*Mentha spicata*), **ginger** (*Zingiber officinale*), **fennel** (*Foeniculum vulgare*), **anise** (*Pimpinella anisum*), and **lemon balm** (*Melissa officinalis*). Carminative herbs help to stimulate peristalsis, which is the wave-like action that pushes food through the digestive tract. These herbs can also help to relax the smooth muscle of the digestive tract, helping to reduce spasms. The antibacterial properties of the volatile oils aid in reducing gas pains that result from bacteria in the intestines acting on pieces of food that have not been digested fully.

Peppermint is one of the oldest medicinal herbs. Peppermint has three major actions in the body: it reduces **nausea** and **vomiting**, it encourages the liver to produce bile, and it clears the stomach of imbalanced bacteria. It is particularly useful for treating spastic colon, **irritable bowel syndrome**, and **diarrhea**. Peppermint is also useful for reducing gas **pain** and **indigestion**.

Demulcent herbs can help ease **heartburn**, another bothersome digestive condition. These herbs are rich in mucilage, soothing irritated or inflamed

tissue. Examples of demulcent herbs are **marsh mallow** root (*Althaea officinalis*), Irish moss (*Chondrus crispus*), and **slippery elm** (*Ulmus rubra*).

Herbs, known as **bitters**, can relieve **constipation** and assist the stomach in acid digestion. Bitter herbs stimulate bile production, and bile is the body's natural laxative. Taking bitters in a capsule or pill form will not work because in order for the liver to produce bile, the bitters must be tasted, not just ingested. Some examples of a bitter herb are **dandelion** root (*Taraxacum officinale*), ginger, and **aloe** (*Aloe vera*).

Ginger has been found to be particularly useful in treating nausea. Ginger has stimulating and antiemetic properties that warm the stomach to reduce intestinal and gas pain.

Aloe can be a powerful laxative when used internally. It takes 10 to 15 hours to work in the body, so it is best used in the evening before bedtime. People should not use aloe for an extended period of time, or dependency can develop. Overuse of aloe can result in loss of intestinal tone. Overdoses of aloe can result in diarrhea, intestinal distress, and kidney problems, so caution should be taken when using this herb.

Papain, also known as papaya extract, aids with the digestion of protein. It has also been used to treat **burns** and to help treat cancer.

Astringent herbs are beneficial in slowing down diarrhea. These herbs contain tannin, a substance that causes protein in body tissues to tighten up. When an astringent herb is taken, the proteins in the digestive tract tighten up to form a protective barrier that reduces fluid and electrolyte loss.

Many of these herbs make delicious teas and are commonly available as packaged teas. Those who wish to make their own tea should try steeping one teaspoon of dry herb per cup of boiled water for five to 10 minutes. They should be sure to cover the tea so that the volatile oils do not evaporate. An Indian custom that is also helpful for digestion is to keep fennel or anise seed available at the table to pass around following a meal.

Precautions

A few suggestions apply before using any of the various herbal supplements to aid digestion. It is best not to overeat, and snacking between meals on anything other than fruit should be avoided. Individuals should increase their consumption of fruit, vegetables, and whole grains and try to decrease the amount of fatty foods, red meat, dairy products, nuts, and nut butters from the diet. People should try to relax while eating, chew food 10 to 20 times, and avoid distractions while eating, such as reading or watching television. They should also drink at least eight glasses of water each day. Care should be taken not to exceed the recommended dosage as indicated on the product label.

There have been very few scientific studies to prove either the adverse or the beneficial health effects of the 1,500-plus herbal products that are available throughout the United States. Furthermore, under the Dietary Supplement Health and Education Act of 1994, herbal products are not required to be proven safe before they are marketed. After the product is marketed, the U.S. Food and Drug Administration (FDA) must prove the dietary supplement unsafe before it can be removed from the shelves. Many people associate the term natural with safe, and that is not always the case. Anyone taking herbal products of any kind should be certain to read labels carefully and discuss the products with a physician to evaluate potential interactions with other medical conditions and/or prescription medications. As is the case with some prescription medications, dependency on some herbal supplements is possible.

Herbal preparations can vary widely from one brand to another and within the same brand from one purchase to the next, making inconsistency in the concentration of ingredients a potential risk. Anyone using herbal products should be careful and try to use well-known brands, because these products are largely unregulated.

Side effects and interactions

Side effects such as breathing problems or tightness in the throat or chest, chest pain, skin **hives**, rash, or itchy or swollen skin may be the signs of an allergic reaction. The product should be discontinued and the patient should seek the advice of a physician.

Persons wishing to take digestive enzymes should consult a physician. Herbs have the potential to interact with any prescription medication, as well as with other herbs. Patients taking the prescription medications acarbose (Precose), anisindione (Miradon), or miglitol (Glyset) should consult their physician before using pancreatin. The use of digestive enzymes has not been extensively studied in pregnant women, so the use of these supplements during **pregnancy** is not recommended. Patients taking the anticoagulant warfarin (Coumadin) should consult their doctor before using papain digestive enzymes.

KEY TERMS

Cellulose—A material derived from the cell walls of certain plants. It is used in the production of many vegetable fibers and is a major raw material component in the production of manufactured fibers including acetate, rayon, and triacetate.

Digestion—The body's process of breaking down food, extracting energy and nutrients, and eliminating unusable components.

Microflora—Beneficial bacteria in the intestines that produce enzymes to aid digestion.

Peristalsis—The wave-like action that pushes food through the digestive tract.

Digitalis

Definition

Digitalis is the name of a genus of plants in the Plantaginaceae family. The genus, also known as foxgloves, contains about 20–30 species, perhaps the best

Digitalis. *(© Michael P. Gadomski/Photo Researchers, Inc. Reproduced by permission.)*

known of which is *Digitalis purpurea*, the common **foxglove**. The plant's common name comes from the fact that its flowers often fit neatly over a human finger, like a tiny glove. The term *digitalis* also refers to a class of cardiac glycosides obtained from the plant. A glycoside is a chemical compound consisting of two parts, one of which is always a sugar. Cardiac glycosides are glycosides that stimulate the heart, and that have important medical applications in coronary diseases and disorders.

Description

Digitalis is usually a biennial, although it may survive as a perennial. In its first year, the plant sends up a rosette of smallish leaves; in its second year, it has long (3–4 feet in length) flowering stems that carry pink, white, purple, or even yellow flowers that are very attractive to bees and other insects. The plant is tolerant of poor soil, although it prefers a loose, well–drained habit. It fluorishes in Europe (where it is especially popular among British gardeners), western and central Asia, and northwestern Africa.

An English physician, William Withering (1741–1799) is usually given credit for having discovered the medical benefits of the digitalis plant. The story is told that one of Withering's patients was cured of a potentially fatal heart condition after taking a secret concoction that he received from a local gypsy. Withering convinced the gypsy to reveal her secret: The concoction consisted of a mixture of herbs, the most important of which was leaves of *D. purpurea*.

The cardiac effects of digitalis had been known long before Withering's time, but within a different context. The plant had frequently been used as a poison. The essential discovery Withering made was that, in addition to being poisonous, digitalis could have beneficial effects if used in less concentrated, smaller amounts. A typical dose of digitalis used for therapeutic treatment is less than 0.5 mg per day. The drug is widely used to treat heart failure and arrhythmias (irregular heartbeat).

Probably the best known and most widely used cardiac glycosides extracted from the digitalis plant are digoxin (Lanoxin®, Stillicor®, Vanoxin®) and digitoxin (Crystodigin®, Unidigin®, Tardigal®), both obtained from *D. purpurea*. A second member of the digitalis genus, *D. lanata* also contains medically useful glycosides, deslanoside (Cedilanid–d®, Deacetyllanatoside C®) and lanatoside C (Isolanide®). Cardiac glycosides are also extracted from a number of non–digitalis plants, including:

- Adonitoxin, from *Adonis vernalis*, false hellebore
- Convallatoxin, from *Convallaria majalis*, lily of the valley
- Neriantin, from *Nerium oleander*, common oleander
- Proscillaridin, from *Scilla maritima*, squill
- Sarveroside, from *Strophanthus sarmentosus*

Mechanism of action

The cardiac effects produced by digoxin, digitoxin, and other cardiac glycosides are the result of their inhibitory action on a critical enzyme in the central nervous system, Na^+/K^+–ATPase (the so–called "sodium–potassium pump"). This enzyme facilitates the flow of **sodium** ions (Na^+) and **potassium** ions (K^+) across cell membranes, maintaining the proper electrical potential in cells. The flow of sodium ions is also associated with the flow of **calcium** ions into and out of heart muscle cells by a mechanism that is not yet completely understood by scientists. Since calcium ions are needed for the contraction of heart muscle, any change in their concentration affects and may inhibit normal heart rhythms. Such inhibition may have beneficial effects, as in controlling arrhythmias or harmful effects, as in stopping heart contractions entirely, resulting in heart failure and death.

Uses

In allopathic medicine, digoxin, digitoxin, and other cardiac glycosides have relatively limited and specific applications in the treatment of coronary disorders, primarily arrhythmias and heart failure. Alternative healers have not suggested other uses beyond these applications. Some early studies suggest that cardiac glycosides may have some benefit in the treatment of **cancer**, although much more research is needed to confirm this hypothesis.

Side effects

The most serious side effect of the cardiac glycosides is the induction of cardiac arrhythmia, which, in turn, leads to death. The use of digitalis drugs is contraindicated with individuals who are hypokalemic (deficient in potassium), who have an atrioventricular block (a dysfunctional electrical function of cardiac muscle), or who have Wolff–Parkinson–White (WPW) syndrome (a condition caused by abnormal electrical function in the heart). Individuals with abnormal or deficient renal function are also not candidates for digitalis therapy since the drug is not excreted normally by such individuals and serum levels of the drug may accumulate to hazardous or toxic levels.

KEY TERMS

Arrhythmia—An irregular heartbeat.

Atrioventricular block—A dysfunctional electrical function of cardiac muscle.

Cardiac glycoside—A chemical compound, often derived from a plant, consisting of a sugar joined to another chemical group, with biological effects on the heart.

Hypokalemia—A deficiency of potassium in the bloodstream.

Sodium–potassium pump—A system responsible for the diffusion of sodium ions and potassium ions across cell membranes.

Wolff–Parkinson–White (WPW) syndrome—A condition caused by abnormal electrical function in the heart.

Interactions

Digitalis interacts with a number of commonly used allopathic medications, including non–steroidal anti–inflammatory drugs (NSAIDs), calcium–channel blockers, beta–blockers, and the antiarrhythmic medication quinidine. All of these drugs operate directly on the cardiac system and, thus, amplify the effects of cardiac glycosides. Other drugs interact with digitalis indirectly. Diuretics, for example, tend to reduce the concentration of potassium in the blood, disrupting the normal sodium/potassium levels needed for operation of the sodium–potassium pump.

Alternative healers list a number of possible interactions with herbs and other supplements used in their practice, including interactions with:

- Potassium and magnesium supplements
- Buckthorn (*Rhamnus catharticus*)
- Cascara (*Rhamnus purshiani cortex*)
- Hawthorne (*Crataegus oxyacantha/monogyna*)
- Licorice (*Glycyrrhiza glabra*)
- Sarsaparilla (*Smilax spp.*)
- Senna (*Cassia senna/angustifolia*)
- St. John's wort (*Hypericum perforatum*)

Diverticulitis

Definition

Diverticulitis refers to the development of inflammation and infection in one or more *diverticula*. Diverticula are outpouchings or bulges that occur when the inner lining layer of the large intestine (colon) bulges out (herniates) through the outer muscular layer. The presence of diverticula indicates a condition called diverticulosis.

Description

Diverticula tend to occur in the last segment of the large intestine, the sigmoid colon. They occur with decreasing frequency toward the beginning of the large intestine. The chance of developing diverticula increases with age, so that by the age of 50, about 20 to 50% of all people have some diverticula. By the age of 90, virtually everyone has developed some diverticula. Most diverticula measure 3 to 30 mm in diameter. Larger diverticula, termed giant diverticula, are quite infrequent but may measure as large as 15 cm in diameter.

The great majority of people with diverticulosis remain symptom-free. Many diverticula are quite accidentally discovered during examinations for other conditions of the intestinal tract.

Causes and symptoms

Diverticula are believed to be caused by overly forceful contractions of the muscular wall of the large intestine. As areas of this wall spasm, they become weaker and weaker, allowing the inner lining to bulge through. The anatomically weakest areas of the intestinal wall occur next to the blood vessels that course through the wall, so diverticula commonly occur in these locations.

Diverticula are most common among the populations of the developed countries of the West (North America, Great Britain, and northern and western Europe). Experts believe that this pattern is due to **diets** in these countries, which tend to be quite low in fiber. A diet low in fiber results in the production of smaller volumes of stool. In order to move this smaller stool along the colon and out of the rectum, the colon must narrow itself significantly and does so by contracting down forcefully. This causes an increase in pressure, which, over time, weakens the muscular wall of the intestine and allows diverticular pockets to develop.

Diverticulitis is believed to occur when a hardened piece of stool, undigested food, and bacteria (called a fecalith) becomes lodged in a diverticulum. This blockage interferes with the blood supply to the area, and infection sets in.

Diverticulitis is three times more likely to occur in the left side of the large intestine. Since most diverticula are located in the sigmoid colon (the final segment of the large intestine that empties into the rectum), most diverticulitis also takes place in the sigmoid. The elderly have the most serious complications from diverticulitis, although very severe **infections** can also occur in patients under the age of 50. Men are three times more likely than women to be stricken with diverticulitis.

An individual with diverticulitis experiences **pain** (especially in the lower left side of the abdomen) and **fever**. In response to the infection and the irritation of nearby tissues within the abdomen, the abdominal muscles may begin to spasm. About 25% of all patients with diverticulitis have some rectal bleeding, although this condition rarely becomes severe. Walled-off pockets of infection, called abscesses, may appear within the wall of the intestine or even on the exterior surface of the intestine. When a diverticulum weakens sufficiently and is filled to bulging with infected pus, a perforation in the intestinal wall may develop. When the infected contents of the intestine spill into the abdomen, a severe infection called peritonitis occurs. Peritonitis is an infection and inflammation of the lining of the abdominal cavity, the peritoneum. Other complications of diverticulitis include the formation of abnormal connections, called fistulas, between two organs that normally do not connect (for example, the intestine and the bladder), and scarring outside the intestine that squeezes off and obstructs a portion of the intestine.

Diagnosis

When diverticula are suspected because a patient begins to have sudden rectal bleeding, the location of the bleeding can be studied by performing angiography. Angiography involves the insertion of a tiny tube (catheter) through an artery in the leg and moving it up into one of the major arteries of the gastrointestinal system. A dye (contrast medium) that will show up on x-ray films is injected into the catheter, and the area of bleeding is located by looking for an area where the contrast is leaking into the interior (lumen) of the intestine.

A procedure called colonoscopy provides another method for examining the colon and locating the site of bleeding. In colonoscopy, a small, flexible scope (colonoscope) is inserted through the rectum and into the intestine. A fiber-optic camera that projects to a nearby television screen is mounted in the colonoscope, which allows the physician to view the interior of the colon and locate the source of bleeding.

Diagnosis of diverticulitis is not difficult in patients with previously diagnosed diverticulosis. The presence of abdominal pain and fever in such an individual would make the suspicion of diverticulitis quite high. Examination of the abdomen usually reveals tenderness to touch, with the patient's abdominal muscles contracting strongly to protect the tender

area. During a rectal exam, a doctor may be able to feel an abnormal mass. Touching this mass may prove painful to the patient.

When doctors suspect diverticulitis as the cause for the patient's symptoms, they most likely avoid the types of tests usually used to diagnose gastrointestinal disorders. These tests include barium enema and colonoscopy (although colonoscopy may have been used earlier to diagnose the diverticulosis). The concern is that the increased pressure exerted on the intestine during these exams may increase the likelihood of intestinal perforation. After medical treatment for the diverticulitis, these examinations may be performed in order to learn the extent of the patient's disease.

Treatment

Treatment for uncomplicated diverticulitis usually requires hospitalization, but some physicians try treatment at home for very mildly ill patients. These patients are put on a liquid diet and receive oral antibiotics. Although **relaxation**, **guided imagery**, and **acupuncture** treatment may be helpful in alleviating pain symptoms, a course of antibiotics is necessary to treat the infection itself.

An infusion of herbs with anti-inflammatory and soothing properties, such as **Mexican yam** (*Dioscorea villosa*), German **chamomile** (*Matricaria recutita*), **marsh mallow** (*Althaea officinalis*), and calamus (*Acorus calamus*, or sweet flag) may be helpful in treating the inflammation of diverticulitis. **Ginger** (*Zingiber officinale*) can also be helpful in relieving gastrointestinal **gas** that may be symptomatic of the disorder.

Allopathic treatment

Resting the bowel is a mainstay of treatment and involves keeping the patient from eating or sometimes even drinking anything by mouth. Therefore, a patient hospitalized for diverticulitis receives fluids through a needle in the vein (intravenous or IV fluids). Antibiotics are also administered through the IV. In cases of severe bleeding (hemorrhaging), blood transfusion may be necessary. Medications that encourage clotting may also be required.

While there are almost no situations in which uncomplicated diverticulosis requires surgery, giant diverticula always require removal. This procedure is necessary because of the very high chance of infection and perforation of these diverticula. When giant diverticula are diagnosed, the usual treatment involves removing that portion of the intestine in which they are located.

The various complications of diverticulitis need to be treated aggressively because the death rate from problems such as perforation and peritonitis is quite high. Abscesses can be drained of their infected contents by inserting a needle through the skin of the abdomen and into the **abscess**. When this procedure is unsuccessful, open abdominal surgery is required to remove the piece of the intestine containing the abscess. Fistulas require surgical repair, including the removal of the length of intestine containing the origin of the fistula, followed by immediate reconnection of the two free ends of intestine. Peritonitis requires open surgery. The entire abdominal cavity is cleaned by being irrigated (washed) with a warmed sterile salt-water solution, and the damaged piece of intestine is removed. Obstructions require immediate surgery to prevent perforation. Massive, uncontrollable bleeding, while rare, may require removal of part or all of the large intestine.

During any of these types of operations, the surgeon must make an important decision regarding the quantity of intestine that must be removed. When the amount of intestine removed is great, it may be necessary to perform a colostomy. A colostomy involves pulling the end of the remaining intestine through the abdominal wall to the outside. This bit of intestine is then fashioned so that a bag can be fit over it. The patient's waste (feces) collects in the bag because the intestine no longer connects with the rectum. This colostomy may be temporary, in which case another operation is required to reconnect the intestine, after some months of substantial healing has occurred. Other times, the colostomy needs to be permanent, and the patient has to adjust to living permanently with the colostomy bag. Most people with colostomies are able to have active lives.

Occasionally, a patient has such severe diverticular disease that a surgeon recommends planning ahead and schedules removal of a portion of the colon. This procedure is done to avoid the high risk of surgery performed after a complication has set in. Certain developments identify those patients who are at very high risk of experiencing dangerous complications, such as those with a history of diverticulitis.

Surgery for chronic (recurring) diverticulitis remains controversial. Some surgeons say that surgery prevents recurrence of problems, while others say it does not. The guidelines of the Society for Surgery of the Alimentary Canal (2007) suggest that "elective sigmoid resection may not be necessary after any specific number of episodes of uncomplicated diverticulitis, or with any definite age thresholds."

KEY TERMS

Angiography—X-ray imaging of the arteries in a particular part of the body. Angiography is often performed in order to determine the location of internal bleeding.

Bowel obstruction—A blockage in the intestine that prevents the normal flow of waste down the length of the intestine.

Colonoscopy—Examination of an area of the gastrointestinal tract by putting a lighted scope, usually bearing a fiber-optic camera, into the rectum and passing it through the intestine.

Colostomy—A procedure performed when a large quantity of intestine is removed. The end piece of the intestine leading to the rectum is closed.

Fistula—An abnormal connection formed between two organs which usually have no connection at all.

Sigmoid colon—The final portion of the large intestine which empties into the rectum.

Expected results

The prognosis for people with diverticula is excellent, with only 20% of such patients ever seeking any medical help for their condition.

While diverticulitis can be a difficult and painful disease, it is usually quite treatable. Prognosis is worse for individuals who have other medical problems, particularly those requiring the use of steroid medications, which increase the chances of developing a serious infection. Prognosis is also worse in the elderly.

Prevention

While there is no certain way to prevent the development of diverticula, experts believe that high-fiber diets may help. Foods that are recommended for their high fiber content include whole grain breads and cereals and all types of fruits and vegetables. Most experts suggest that individuals take in 20 to 35 grams of fiber daily. If this is not possible to achieve through diet, an individual may supplement with fiber products that are mixed into juice or water.

Dizziness

Definition

Dizziness is classified into three categories—vertigo, syncope, and nonsyncope nonvertigo. Each category has a characteristic set of symptoms, all related to the sense of balance. In general, syncope is defined by a brief loss of consciousness (fainting) or by dimmed vision and feeling uncoordinated, confused, and lightheaded. Many people experience a sensation like syncope when they stand up too fast. Vertigo is the feeling that either the individual or the surroundings are spinning. This sensation is like being on a spinning amusement park ride. Individuals with nonsyncope nonvertigo dizziness feel as though they cannot keep their balance. This sensation may become worse with movement.

Description

The brain coordinates information from the eyes, the inner ear, and the body's senses to maintain balance. If any of these sources of information is disrupted,

the brain may not be able to compensate. For example, people sometimes experience **motion sickness** because the information from their body tells the brain that they are sitting still, but information from the eyes indicates that they are moving. The messages do not correspond and dizziness results.

Vision and the body's senses are the most important systems for maintaining balance, but problems in the inner ear are the most frequent cause of dizziness. The inner ear, also called the vestibular system, contains fluid that helps to fine tune the information the brain receives from the eyes and the body. When fluid volume or pressure in the inner ear changes, information about balance is altered. The discrepancy gives conflicting messages to the brain about balance and induces dizziness.

Certain medical conditions can cause dizziness because they affect the systems that maintain balance. For example, the inner ear is very sensitive to changes in blood flow. Because such medical conditions as high blood pressure or low blood sugar can affect blood flow, these conditions are frequently accompanied by dizziness. Circulation disorders are the most common causes of dizziness. Other causes are head injuries, ear **infections**, **allergies**, and nervous system disorders.

Dizziness often disappears without treatment or with treatment of the underlying problem, but it can be long-term or chronic. According to the National Institutes of Health, 42% of Americans will seek medical help for dizziness at some point in their lives. The costs may exceed a billion dollars and account for five million visits to physicians annually. Episodes of dizziness increase with age. Among people aged 75 or older, dizziness is the most frequent reason for seeing a doctor.

KEY TERMS

Acoustic neuroma—A benign tumor that grows on the nerve leading from the inner ear to the brain. As the tumor grows, it exerts pressure on the inner ear and causes severe vertigo.

Autonomic nervous system—The part of the nervous system that controls such involuntary body functions as breathing and heart beat.

Electronystagmography—A method for measuring the electricity generated by eye movements. Electrodes are placed on the skin around the eye and the individual is subjected to a variety of stimuli so that the quality of eye movements can be assessed.

Ménière's disease—A disease of the labyrinth in the ear, characterized by dizziness, hearing loss, ringing in the ears, and nausea.

Syncope—Dizziness or brief loss of consciousness resulting from an inadequate flow of oxygenated blood to the brain.

Vertigo—Dizziness associated with a sensation of whirling or spinning.

Vestibular system—The area of the inner ear that helps maintain balance.

Causes and symptoms

Careful attention to symptoms can help determine the underlying cause of the dizziness. The underlying problems may be benign and easily treated, or they may be dangerous and require intensive therapy. Not all cases of dizziness can be linked to a specific cause. More than one type of dizziness can be experienced at the same time and symptoms may be mixed. Episodes of dizziness may last for a few seconds or for days. The length of an episode is related to the underlying cause.

The symptoms of syncope include dimmed vision, loss of coordination, confusion, lightheadedness, and sweating. These symptoms can lead to a brief loss of consciousness or fainting. They are related to a reduced flow of blood to the brain; they often occur when a person is standing up and can be relieved by sitting or lying down. Vertigo is characterized by a sensation of spinning or turning, accompanied by **nausea**, **vomiting**, ringing in the ears, **headache**, or **fatigue**. An individual may have trouble walking, remaining coordinated, or keeping balance. Nonsyncope nonvertigo dizziness is characterized by a feeling of being off balance that becomes worse if the individual tries moving or performing detail-intense tasks.

A person may experience dizziness for many reasons. Syncope is associated with low blood pressure, heart problems, and disorders in the autonomic nervous system, which controls such involuntary functions as breathing. Syncope may also arise from emotional distress, **pain**, and other reactions to outside stressors. Nonsyncope nonvertigo dizziness may be caused by rapid breathing, low blood sugar, or **migraine headache**, as well as by more serious medical conditions.

Vertigo is often associated with inner ear problems called vestibular disorders. A particularly intense vestibular disorder, **Ménière's disease**, interferes with the volume of fluid in the inner ear. This disease, which affects approximately one in every 1,000 people, causes intermittent vertigo over the course of weeks, months, or years. Ménière's disease is often accompanied by

ringing or buzzing in the ear, **hearing loss**, and a feeling that the ear is blocked. Damage to the nerve that leads from the ear to the brain can also cause vertigo. Such damage can result from head injury or a tumor. An acoustic neuroma, for example, is a benign tumor that wraps around the nerve. Vertigo can also be caused by disorders of the central nervous system and circulation, such as hardening of the arteries (arteriosclerosis), **stroke**, or **multiple sclerosis**.

Some medications cause changes in blood pressure or blood flow. These medications can cause dizziness in some people. Prescription medications carry warnings of such side effects, but common drugs such as **caffeine** or nicotine can also cause dizziness. Certain antibiotics can damage the inner ear and cause hearing loss and dizziness.

Diet may cause dizziness. The role of diet may be direct, as through alcohol intake. It may also be indirect, as through arteriosclerosis caused by a high-fat diet. Some people experience a slight dip in blood sugar and mild dizziness if they miss a meal, but this condition is rarely dangerous unless the person is diabetic. Food sensitivities or allergies can also be a cause of dizziness. Such chronic conditions as **heart disease** and serious acute problems such as seizures and strokes can cause dizziness. These conditions, however, usually exhibit other characteristic symptoms.

Diagnosis

During the initial medical examination, an individual with dizziness should provide a detailed description of the type of dizziness experienced, when it occurs, and how often each episode lasts. A diary of symptoms may help to track this information. The patient should report any symptoms that accompany the dizziness, such as ringing in the ear or nausea, any recent injury or infection, and any medication taken.

The examiner will check the patient's blood pressure, pulse, respiration, and body temperature as well as the ear, nose, and throat. The sense of balance is assessed by moving the individual's head to various positions or by tilt-table testing. In tilt-table testing, the person lies on a table that can be shifted into different positions and reports any dizziness that occurs.

Further tests may be indicated by the initial examination. Hearing tests help assess ear damage. X rays, computed tomography scan (CT scan), and magnetic resonance imaging (MRI) can pinpoint evidence of nerve damage, tumors, or other structural problems. If a vestibular disorder is suspected, a technique called electronystagmography (ENG) may be used. ENG measures the electrical impulses generated by eye movements. Blood tests can determine diabetes, high **cholesterol**, and other diseases. In some cases, a heart evaluation may be useful. Despite thorough testing, however, an underlying cause cannot always be determined.

Doctors caution that childhood syncope (fainting), although rarely serious, can indicate a serious cardiac condition. If the fainting is abrupt or happens with exertion, it may indicate a more serious problem.

Treatment

Because dizziness may arise from serious conditions, it is advisable to seek medical treatment. Alternative treatments can often be used alongside conventional medicine without conflict. Potentially beneficial therapies include nutritional therapy, herbal remedies, **homeopathy**, **aromatherapy**, **osteopathy**, **acupuncture**, **acupressure**, and **relaxation** techniques.

Nutritional therapy

To prevent dizziness, nutritionists often advise eating smaller but more frequent meals and avoiding caffeine, nicotine, alcohol, foods high in fat or sugar, or any substances that cause allergic reactions. A low-salt diet may also be helpful to some people. Nutritionists may also recommend certain dietary supplements:

- Magnesium citrate, aspartate or maleate: for dizziness caused by magnesium deficiency.
- B-complex vitamins, especially vitamin B_{12}: for dizziness caused by deficiency of these essential vitamins.

Herbal remedies

The following herbs have been used to treat dizziness symptoms:

- Ginger: for treatment of dizziness caused by nausea.
- *Ginkgo biloba*: may decrease dizziness by increasing blood flow to the brain.

Homeopathy

Homeopathic therapies can work very effectively for dizziness, and are especially applicable when no organic cause can be identified. They are chosen according to the patient's specific symptom profile:

- Aconite: for feeling light-headed from postural hypotension (getting up too quickly).
- Coccolus: for motion sickness or syncope.
- Conium maculatum: for feeling dizzy while looking at rapidly-moving images.

- Gelsemium: for feeling light-headed and out of balance, often associated with influenza or stage fright.
- Petroleum: for dizziness upon standing up too fast and headache before and after a storm.

Aromatherapy

Aromatherapists recommend a warm bath scented with **essential oils** of **lavender**, geranium, and sandalwood as treatment for dizziness. This therapy can have a calming effect on the nervous system.

Osteopathy

An osteopath or chiropractor may suggest manipulations or adjustments of the head, jaw, neck, and lower back to relieve pressure on the inner ear.

Acupressure

Acupressure may be able to improve circulation and decrease the symptoms of vertigo. The Neck Release, which involves pressing on five pairs of points on the shoulder blades and neck, is helpful for dizziness associated with migraine headaches.

Relaxation techniques

Relaxation techniques, such as **yoga**, **meditation**, and **massage therapy** for relieving tension, are popularly recommended methods for reducing **stress**.

Allopathic treatment

Treatment of dizziness is determined by the underlying cause. If an individual has a cold or **influenza**, a few days of bed rest is usually adequate to resolve dizziness. Other causes of dizziness, such as mild vestibular system damage, may resolve without medical treatment. If dizziness continues, drug therapy may be required to treat such underlying illnesses as high blood pressure, arteriosclerosis, nervous conditions or diabetes. A physician may also prescribe antibiotics if ear infections are suspected. Selective serotonin reuptake inhibitors (SSRIs) have recently been shown to relieve dizziness in patients who have psychiatric symptoms. When other measures have failed, surgery may be suggested to relieve pressure on the inner ear. If the dizziness is not treatable by drugs, surgery, or other means, physical therapy may be used and the patient may be taught coping mechanisms for the problem.

Expected results

The outcome of treatment depends on the cause of dizziness. Controlling or curing the underlying factors usually relieves the dizziness itself. In some cases, the symptoms disappear without treatment. In a few cases, dizziness can become a permanent disabling condition.

Prevention

Most people learn through experience that certain activities will make them dizzy and they learn to avoid them. For example, if reading in a car produces motion sickness, reading should be postponed until after the trip. Changes in diet can also cut down on episodes of dizziness in susceptible people. For example, persons with Ménière's disease may avoid episodes of vertigo by leaving salt, alcohol, and caffeine out of their **diets**. Reducing blood cholesterol can help diminish arteriosclerosis and indirectly treat dizziness. Daily multiple vitamin and mineral supplements may help prevent dizziness caused by deficiencies of these essential nutrients. Relaxation techniques can help ward off tension and **anxiety** that can cause dizziness.

Some cases of dizziness cannot be prevented. Acoustic neuromas, for example, are not predictable or preventable. Alternative approaches designed to rebalance the body's energy flow, such as acupuncture and constitutional homeopathy, may be helpful in cases where the cause of dizziness cannot be pinpointed.

Dolomite

Description

Physical characteristics

Dolomite is a common mineral. Chemically, dolomite is **calciummagnesium** carbonate $CaMg(CO_3)_2$, a type of compact limestone. In combination with calcite and aragonite, dolomite makes up approximately 2% of the earth's crust. The mineral was first described by and then named after the French mineralogist and geologist Deodat de Dolomieu (1750–1801).

Dolomite is a fairly soft mineral that occurs as crystals as well as in large sedimentary rock beds several hundred feet thick. The crystals—usually rhombohedral in shape—are transparent to translucent and are colorless, white, reddish-white, brownish-white, gray, or sometimes pink. In powdered form, dolomite dissolves readily with effervescence in warm acids.

Although rock beds containing dolomite are found throughout the world, the most notable quarries are located in the Midwestern United States; Ontario, Canada; Switzerland; Pamplona, Spain; and Mexico.

Formation

Although dolomite does not form on the surface of the earth at the present time, massive layers of dolomite can be found in ancient rocks. Dolomite is one of the few sedimentary rocks that undergoes a significant mineralogical change after it is deposited. Dolomite rocks are originally deposited as calcite/aragonite–rich limestone, but during a process called diagenesis, the calcite and/or aragonite is transformed into dolomite. Magnesium-rich ground water containing a significant amount of salt is thought to be essential to dolomite formation. Thus, warm, tropical marine environments are considered the best sources of dolomite formation.

Close-up view of the mineral dolomite. In combination with calcite and aragonite, dolomite makes up approximately two percent of the earth's crust. *(GC Minerals / Alamy)*

Chemical components

Dolomite is composed of 52.06% oxygen, 13.03% carbon, 13.18% magnesium, and 21.73% calcium. **Iron** and **manganese** carbonates, barium, and lead are sometimes present as impurities.

General use

Dolomite is commonly used in a variety of products. A few of these are listed below:

- antacids (neutralizes stomach acid)
- base for face creams, baby powders, or toothpaste
- calcium/magnesium nutritional supplements for animals and humans
- ceramic glazes on china and other dinnerware (dolomite is used as source of magnesia and calcia)
- fertilizers (dolomite added as soil nutrient)
- glass (used for high refractive optical glass)
- gypsum impressions from which dental plates are made (magnesium carbonate)
- mortar and cement
- plastics, rubbers, and adhesives

Although calcium carbonate (as found in dolomite) has a high percentage of calcium by weight (40%) and is the most common preparation available, this form of calcium is relatively insoluble and can be difficult to break down in the body. In contrast, calcium citrate, although containing about half as much calcium by weight (21%), is a more soluble form. Since calcium citrate does not require gastric acid for absorption, it is considered a better source of supplemental calcium, particularly for the elderly, whose stomach acid secretions are decreased.

Calcium supplements offer many benefits and research indicates that calcium supplements can help prevent formation of **kidney stones** when combined with a fairly low animal protein-low salt diet. Doctors once advised a low-calcium diet to prevent kidney stones.

Preparations

Dolomite is generally ground into coarse or finely grained powder and made into calcium/magnesium capsules or antacids for human consumption. The powdered form is also used in animal feed, fertilizers, and a variety of other applications.

Precautions

Nutritional supplements

Concern about heavy-metal contamination of calcium supplements first arose in the early 1980s. Natural sources of dolomite sometimes contain small amounts of lead and other heavy metals that remain after being processed for human use. As late as 2005, *Consumer Reports* magazine reported that some calcium supplements still contain very small amounts of lead. Most experts believe that such supplements are generally safe and their benefits far outweigh the small risks they pose to human health.

When purchasing calcium supplements, products marked as purified (especially those made from dolomite, bone meal, or oyster shells) or those containing the USP (*United States Pharmacopoeia*) symbol are considered the safest. The symbol means that the vitamin and mineral manufacturer's product has voluntarily met the USP criteria for quality, strength, and purity.

Research also encourages consumers to tell their doctors when they take antacids and calcium supplements so that physicians can watch for possible side effects or interactions with medications. Some antacids can cause side effects that eventually put patients at risk for serious problems. If patients have a complicating problem such as renal dysfunction, they can suffer from aluminum toxicity from certain antacids.

Ceramic glazes

Another potential health risk associated with dolomite arises from storing food in or eating or drinking from dinnerware or cups made with glazes containing dolomite. Although it is not possible to detect a lead glaze on china with the naked eye, corroded glaze, or a dusty or chalky, gray residue on the glaze after the piece has been washed is a good indication of lead content. Although high lead toxicity is rare, trace amounts may be present. If possible, it is best to purchase dinnerware that is labeled lead-free. Also, stoneware, unless painted with decorations on the surface, are normally coated with a material that contains no lead. Glass dishes, with the exception of leaded glass and glass painted with decorations or decals, are also considered safe.

The problem is intensified if the food or beverage consumed is acidic, since acid increases lead leaching. Although other additives in glazes may contribute to the lead content (such as lead oxide

or cadmium) leaching out, dolomite is a potential cause for lead toxicity.

Glazes on bathtubs also may contain harmful amounts of lead, which may leach out into the bathwater, especially if the glaze is worn. Information regarding lead content can be obtained from the manufacturer. Lead testing kits are also available by mail order or at most home and garden centers.

Fertilizers and animal feed

Dolomite and bone meal in fertilizers and animal feed may contaminate the soil, animals, and humans with lead and other toxic metals.

Side effects

Indirect side effects may occur if more than the recommended dosage of any calcium supplement is taken over an extended period of time. If an individual consumes more than 2,000 mg/day of calcium, gastrointestinal problems can occur.

Some of the short-term symptoms of low-level lead exposure (which is particularly harmful to the young and elderly) are:

- decreased appetite
- stomachache
- sleeplessness
- constipation
- vomiting
- diarrhea
- fatigue
- irritability
- headaches

Some of the long-term effects of low-level lead exposure are:

- learning disabilities
- brain damage
- loss of IQ points
- attention deficit disorder
- hyperactive behavior
- criminal or antisocial behavior
- neurological problems

Interactions

Research on the interactions of dolomite with other drugs, vitamins, minerals, or foods as of 2008 was limited.

KEY TERMS

Calcium citrate—A chemical compound made from calcium and citric acid.

Diagenesis—Changes that occur in sediment or a sedimentary rock after deposition.

Rhombohedral—A parallelepiped whose edges are all of equal length.

Sedimentary—Formed by deposits of sediment, or material that settles on the bottom in a body of water.

Dong quai

Description

Dong quai, *Angelica sinensis*, also called Chinese **angelica**, is a member of the Umbelliferae (Apiaceae), or carrot family. This Oriental medicinal herb is sometimes called the empress of herbs, or female ginseng.

Dong quai grows best in such damp places as moist meadows, river banks, and mountain ravines. It may be biennial or perennial. The bitter-sweet root,

described by some herbalists as resembling carved ivory, is used medicinally. Dong quai, variously known as dang gui or tang kuei, produces a round, hollow, grooved stem that grows as high as 7 ft. The lower leaves are large and tri-pinnate, each further divided into two or three leaflets. The smaller upper leaves are pinnate, which means that the leaflets are arranged in opposite rows along the leaf stalk. The leaves of dong quai resemble those of carrot, celery, or **parsley** and emerge from dilated sheaths surrounding a bluish-colored stem that is branched at the top. Honey-scented, greenish-white flowers grow in large compound flat-topped clusters and bloom from May to August.

KEY TERMS

Decoction—A medication or herbal preparation made by boiling.

Infusion—A medicine or herbal preparation made by steeping plant parts or other substances in water to extract their medicinal principles.

Volatile—Evaporating readily at room temperature. The essential oils of a plant are sometimes called volatile oils for this reason.

General use

Dong quai is one of the most extensively researched Chinese medicinal herbs. It is well known as a female remedy thought to benefit women throughout the menstrual cycle and during the transition to **menopause**. A recent study indicates that dong quai is a popular herbal remedy among women being treated for **ovarian cancer**. Dong quai has been used in China for thousands of years to treat ailments of the female reproductive system and as a tonic herb to treat **fatigue**, mild **anemia**, high blood pressure and poor circulation in both men and women. Chinese herbalists prepare dong quai in combination with other herbs, including **astragalus** (*Astragalus membranaceus*) as a fatigue tonic, **mugwort** (*Artemesia vulgaris*), bai shao (white peony), chai hu (bupleurum root), and rou gui (**cinnamon bark**) in medicinal formulas for women. Secondary herbs are used to enhance the action of the primary ingredient or to provide additional properties that work synergistically with the primary ingredient. Research in the United States indicates that dong quai has no demonstrable estrogen-like effect on menopausal women when it is used alone. However, other research has shown that dong quai, when used in combination with other herbs, resulted in a reduction of the severity of **hot flashes**, vaginal dryness, **insomnia**, and mood changes. Dong quai should not be regarded as a replacement for natural estrogen. Its unique mechanism of action reportedly promotes the synthesis of natural progesterone, a hormone whose production declines during menopause. Dong quai's ability to relieve menstrual problems has been attributed to its muscle-relaxing properties and its ability to quiet spasms in the internal organs. Dong quai has a tonic effect on all female reproductive organs and increases blood flow to the uterus. It acts to increase vaginal secretions and to nourish vaginal tissue. Dong quai root's analgesic properties help diminish uterine **pain** and have been found to be as much as 1.7 times as effective as aspirin. The herb has also been useful in the treatment of migraine headaches.

One recent Western study has called into question the value of dong quai for treating menopausal symptoms. The authors of the study found that **black cohosh** appears to be a more effective herbal remedy for hot flashes and other symptoms associated with menopause.

Research in China indicates that dong quai stimulates production of the red blood cells that carry oxygen throughout the body. Its sedative properties relieve emotional distress and irritability. It is used to treat mild anemia and as a liver tonic. The herb is beneficial to the endocrine and circulatory systems, promoting healthful blood circulation. Its laxative properties ease **constipation**, particularly in the elderly. This beneficial herb has also been proven effective against certain fungi, such as *Candida albicans*, the primary cause of vaginal **yeast infection**. Dong quai also helps to dissolve **blood clots**.

Dong quai contains high amounts of **vitamin E**, **iron**, cobalt, and other vitamins and minerals important to women, including **niacin**, **magnesium**, **potassium**, and vitamins A, C, and B_{12}. The plant contains numerous phytochemicals, including coumarins, phytosterols, polysaccharides, and flavonoids.

European angelica (*A. archangelica*) stimulates secretion of gastric juices and has been used to treat digestive problems, flatulence, and loss of appetite. The root of European angelica has sometimes been used in cases of prolonged labor or to treat problems with retention of the placenta after **childbirth**.

American angelica (*A. atropurpurea*) has also been used by some herbalists for menstrual complaints, though the Chinese dong quai is most often used in formulas for women.

Preparations

The medicinal part of the angelica plant is the root. Dong quai root can be prepared as an infusion or decoction, tincture, tablet, or capsule. It is also available dried, either whole, diced, or sliced. The herb is nontoxic, but recent findings suggest caution in using it over an extended period of time. The dried root may be chewed in quarter inch segments two to three times daily, up to 3-4 g grams per day.

Infusion or decoction: Research indicates that extracts of dong quai that retain the volatile constituents act to raise blood pressure and relax uterine muscles. An infusion of the root, steeped in hot water, retains the volatile constituents and is useful to treat **dysmenorrhea** and to quiet uterine spasm. For **amenorrhea**, where stimulation of the uterine muscles is sought, a decoction is indicated. Simmer the root in water to evaporate the volatile constituents. Most Chinese herbalists use dong quai in combination with other herbs depending on the problems being addressed and these are prepared together.

Alcohol tincture: Combine fresh or dry, chopped root with enough alcohol to cover in a glass container. Alcohol should be of good quality. A 50/50 alcohol/water ratio is optimal. If the alcohol is not 100 proof, add pure water to obtain a 50/50 ratio. Brandy, vodka, and gin are often used. Seal the mixture in an air-tight container and set aside in a dark place for about two weeks. Shake daily. Strain through cheesecloth or muslin and store in dark containers for up to two years. Dosage: 10-40 drops of the fresh root tincture one to three times daily.

Precautions

Pregnant or lactating women are advised not to use dong quai. Menstruating women who are experiencing unusually heavy bleeding should discontinue use of dong quai without advice of a qualified herbal practitioner, because in certain preparations the herb may act to increase the blood flow. Consult a qualified herbalist before use if fibroids are present, or when there is unusual breast tenderness.

Dong quai should not be used as a substitute for hormonal replacement therapy, or HRT. Women who are concerned about the possible side effects of HRT should consider fo-ti or such other herbs as **licorice** and **hops**.

Side effects

Dong quai has been considered quite safe; however, it may cause minor gastric upset in sensitive individuals. Stomach upset can be eliminated if dong quai is combined with other herbs in preparation. The herb may also increase sensitivity to the sun and other ultraviolet exposure in fair-skinned individuals.

More seriously, a study published in 2002 reported that dong quai appears to encourage the growth of **breast cancer** cells independent of its estrogenic activity. The researchers recommend cautious use of dong quai until definitive studies can be performed. Interestingly, two teams of researchers in the United States and China respectively reported in 2003 that dong quai appears to suppress the growth of human **prostate cancer** cells.

Interactions

Some herbalists suggest that fruit consumption be decreased when using dong quai.

As of 2003, dong quai has been reported to interact with some prescription medications, particularly anticoagulant and antiplatelet drugs. Dong quai appears to have an additive effect with these medications, increasing bleeding time. In May 2002 the U.S. Food and Drug Administration added dong quai to the list of herbal products not to be used together with sodium warfarin (Coumadin).

Dong quai has also been reported to interact with bleomycin (Blenoxane), an anticancer drug used to treat tumors of the cervix, uterus, testicle, and penis, as well as certain types of lymphoma.

Dry mouth

Definition

Dry mouth, known medically as xerostomia, is the abnormal reduction of saliva due to medication, disease, or medical therapy.

KEY TERMS

Salivary duct—Tube through which saliva is carried from the salivary gland to the mouth.

Salivary gland—Gland in which saliva is formed.

Sjögren's syndrome—An autoimmune disorder in which the body's white cells attack the glands that produce saliva and tears. Dry mouth is a core symptom of Sjögren's syndrome.

Xerostomia—The medical term for dry mouth.

Description

Dry mouth due to the lack of saliva can be a serious medical problem. Decreased salivation can make swallowing difficult, decrease taste sensation, and promote tooth decay.

Causes and symptoms

Dry mouth, resulting from thickened or reduced saliva flow, can be caused by a number of factors: medications, both prescription and over-the-counter; systemic diseases, such as **anemia** or diabetes, manifestations of syndromes such as **rheumatoid arthritis**, lupus, chronic hardening and thickening of the skin, or chronic and progressive inflammation of skeletal muscles; **infections** of the salivary glands; blockage of the salivary ducts caused by stones or tumors forming in the ducts through which the saliva passes; dehydration; medical therapies, such as local surgery or radiation; secretion reduction due to the normal **aging** process; and emotional **stress**.

Dry mouth, together with dry eyes, is a core symptom of **Sjögren's syndrome**, named for the Swedish physician who first described it. Sjögren's syndrome is an autoimmune disorder in which the body's white cells attack the glands that produce saliva and tears. It is a common cause of dry mouth in the elderly.

Although psychiatric disorders involving dry mouth are unusual, several cases have been reported of somatoform disorders in which dry mouth is a central symptom. Somatoform disorders are psychiatric disturbances characterized by external physical symptoms or complaints that are related to psychological problems rather than organic illness.

Diagnosis

The diagnosis of dry mouth is not difficult. The patient will state that his or her saliva is very thick or

non-existent. Finding the cause of the dry mouth may be more difficult and require some laboratory testing. Salivary gland biopsy for stones or tumors should be performed if indicated.

Treatment

To treat dry mouth, the use of caffeine-containing beverages, alcoholic beverages, and mouthwashes containing alcohol should be minimized. Drinking water and fruit juices will decrease dry mouth problems. Chewing gum and lemon drops can be used to stimulate saliva flow. **Bitters** also can initiate salivary flow as long as the salivary glands and ducts are functional. Commercial saliva substitutes are available without prescription and can be used as frequently as needed. Use of a humidifier in the bedroom reduces nighttime oral dryness.

Herbal therapy

There are several herbal remedies that may be effective in increasing saliva production and preventing dry mouth. Drinking **ginger**, **chamomile**, or Chinese **green tea** at frequent intervals stimulates salivary flow. A Chinese herbal mix of ophiopogois, pinelliae tuber, zizyphi fructus, glycyrrhiaze, ginseng radix, and oryzae semen has been evaluated as treatment for dry mouth. Studies have shown this formula is effective in relieving dry mouth in half of those tested, including severe cases, such as **cancer** patients undergoing radiation therapy.

Nutritional therapy

Because dry mouth often causes **gum disease**, patients should take **vitamin C** and beta-carotene supplements as a preventive measure.

Acupuncture

Acupuncture has been tried since the late 1990s as a treatment for dry mouth caused by cancer treatments. Practitioners at a California clinic that offers acupuncture to cancer patients use a total of eight needles, to stimulate three points on each ear and one on each index finger. Of the 50 patients who have been treated with acupuncture in this clinic, 35 reported significant improvement in their salivation, and 13 reported that the improvement lasted for over three months before they required another treatment.

Allopathic treatment

Treatment of dry mouth involves management of the underlying condition. If dry mouth is caused by medication, the medication should be changed. If dry mouth is caused by blockage of the salivary ducts, the cause of the blockage should be investigated. When such systemic diseases as diabetes and anemia are brought under control, dry mouth problems may decrease.

Some new medications have been developed to treat dry mouth associated with cancer therapy and Sjögren's syndrome. Amifostine (Ethyol), a medication that protects the cells of the mouth against radiation and chemotherapy agents, has been approved by the U.S. Food and Drug Administration (FDA) as a treatment for dry mouth related to cancer therapy. Pilocarpine hydrochloride (Salagen) is a drug that was approved in 1998 for treating dry mouth associated with Sjögren's syndrome; it works by stimulating the salivary glands to produce more moisture. A study published in 2002 indicates that pilocarpine also relieves dry mouth in cancer patients. Cevimeline (Evoxac) is a newer drug that was approved by the FDA in February 2000 for the treatment of dry mouth associated with Sjögren's syndrome. All three medications appear to give good results and to be well tolerated by patients.

Expected results

The prognosis for patients with xerostomia due to medication problems is good, if the offending agent can be changed. Dry mouth due to systemic problems may be eliminated or improved once the disease causing the dry mouth is under control. Persistent xerostomia can be managed well with saliva substitutes.

Prevention

A patient needs to ask his or her health care provider if any medication to be prescribed will cause dry mouth. Patients with persistent xerostomia need to practice good oral hygiene and visit a dentist on a regular basis; the lack of adequate saliva can cause severe dental decay. The salivary glands are very sensitive to radiation, so any patient scheduled for radiation therapy of the head and neck should discuss minimizing exposure of the salivary glands to radiation with the radiation therapy provider.

Dysbosis

Definition

Dysbiosis typically refers to a disorder of the gastro-intestinal tract occurring when there is a disturbance of the complex ecological balance between the microbial organisms in the gut and their human host.

Russian scientist and Nobel Prize winner Elie Metchniko (Llya Llyich Metchniko, 1845–1916), a colleague of Louis Pasteur (1822–1895), devised the term in the early twentieth century to denote the condition when healthy symbiosis of intestinal flora is disrupted bringing about a harmful relationship between the human host and the gastro-intestinal bacteria. Researchers afterward determined that such a non-infectious microbial overgrowth can occur in various locations inside the body, on the skin surface, or in the external environment.

Alex Vasquez, a widely published **chiropractic** and naturopathic doctor, writing in the *Journal of the Council on Nutrition of the American Chiropractic Association*, uses a broad definition of dysbiosis as "a relationship of non-infectious host-microorganism interaction that adversely affects the human host." He specifies the subtype of dysbiosis based on the location: "gastrointestinal, oral, sinus, genitourinary, dermatologic, or environmental." According to Vasquez, with multifocal dysbiosis in general the adverse physiologic and clinical consequences are "additive and synergistic."

Although it is difficult to obtain a culture of intestinal microorganisms and separate and count the various types of protozoa, bacteria, and fungi in a laboratory environment, using these methods, researchers identified as many as 500 different species. However, subsequent advances in DNA sequence-based technologies permitted a genetic analysis without the need for prior cultivation. This process, known as metagenomics, enabled a detailed ecological analysis of the gastrointestinal tract. Researchers Daniel N. Frank and Norman R. Pace, writing in 2008 in the journal *Current Opinion in Gastroenterology* reported that there may be as many as 40,000 bacterial species comprising the "collective gastrointestinal microbiome."

According to researchers Jason A. Hawrelak and Stephen P. Meyers, reporting in a 2004 review of the scientific literature on dysbiosis, intestinal microflora are involved with the synthesis of vitamins, stimulation of the immune system, digestion and absorption of nutrients, metabolism of drug and plant compounds, and in improving the function and motility of the gastro-intestinal system. Microflora also act to inhibit pathogens and aid in the production of short-chain fatty acids and polyamines. Beneficial lactic-acid producing lactobacilli and bifidobacteria, which constitute a major part of healthy human intestinal microflora, help increase bioavailability and absorption of minerals such as **calcium**, **copper**, **iron**, **magnesium**, and **manganese**.

Researchers concur that dysbiosis is a contributing factor in many chronic and degenerative diseases, including **irritable bowel syndrome** (IBS), **inflammatory bowel disease** (IBD), autoimmune disorders, **rheumatoid arthritis** and **ankylosing spondylitis**, atopic **eczema**, and mental and emotional disorders.

Eliminating toxins in the intestinal tract has been seen as a vital component of health maintenance for as

long as 5,000 years. In **Ayurvedic medicine**, intestinal toxins were understood to be at the root of all disease.

There are differences in both quality and quantity of the commensal bacteria present in non-harmful relationship throughout the healthy gastro-intestinal tract. These bacteria are an integral part of the immune system and form a front-line defense. As many as 80% of the body's immune cells (lymphocytes) are present in the intestinal lining, positioned there to protect the system from the toxins, bacteria, viruses, and allergens found in the bowel contents.

Causes and symptoms

There are four patterns of intestinal dysbiosis, according to Leo Galland, MD, and Stephen Barrie, ND. These patterns are: putrefacation, deficiency, fermentation, and sensitization. Researchers have identified various factors that contribute to development of the patterns of dysbiosis:

- prolonged and repeated antibiotic drug use
- diets of high-fat, animal protein, and low-fiber
- psychological and physical stress
- immune system dysfunction
- processed foods, refined sugars, and food additives
- oral contraceptives
- long-term use of pharmaceutical pain medications
- geriatric deficiency of gastric hydrochloric acid

Common symptoms of dysbiosis include abdominal cramps and bloating, chronic **fatigue**, food **allergies** and intolerance, fluid retention, headaches, **tinnitus**, vertigo, unclear thinking, weight gain, **diarrhea** and/or **constipation**, flatulence, and gastro-intestinal disturbances such as irritable bowel syndrome (IBS).

Serious conditions such as **autism** and attention deficit hyperactivity disorder (ADHD) have been linked to overgrowth of the gastro-intestinal yeast, candida *(Candida albicans)*.

According to Marcelle Pick, an OB/GYN physician, women in the United States seek medical help for digestive disorders two to three times as often as men. Some research suggests that the hormones estrogen and progesterone may influence digestion. A decline in these ovarian hormones is strongly linked to symptoms of gastro-intestinal distress.

Diagnosis

Though there is not much scientific literature establishing diagnostic criteria for dysbiosis, some health practitioners suggest a comprehensive diagnostic stool analysis (CDSA) to determine the dysbiosis risk index based upon gut microbiology, pH, and short-chain fatty acids. Many studies of microbiota in the human GI tract have used fecal samples, but these samples may not accurately detect the micro flora along the entire GI tract, according to researchers. More accurate diagnostic tools may be required to distinguish the particular pattern of intestinal dysbiosis. This determination is crucial to developing and effective treatment plan.

Treatment

Dietary and nutritional therapies

The first and most important treatment is a change in the diet. Care must be taken to eliminate the foods that feed the unhealthy bacteria. A diet eliminating simple sugars and refined carbohydrates and low in fruit and starchy vegetables may help to keep yeast growth in check and eliminate the toxins created from fermentation. To assure lasting results, the diet should be adhered to for as long as one year, though relief from symptoms of various patterns of dysbiosis may be observed much earlier.

When it is determined that the dysbiosis is caused by bacteria and/or yeast, a supplementation with friendly probiotic organisms such as Lactobacillus and Bifidobacterium may be indicated. The best food sources of these bacteria are organic yogurt with live cultures and kefir. Some additional food sources are: **garlic**, onions, asparagus, artichokes, **chicory**, bananas, wheat, barley and rye, miso, tempeh, tamari, pickled daikon, and sauerkraut. **Probiotics** are also available in capsule form.

Prebiotics are non-digestible food ingredients that help promote and stimulate the growth and/or activity of beneficial bacteria. These include **fructooligosaccharides** (FOS), inulin, and galactooligosaccharides.

Herbal remedies

Some recommended herbal remedies include:

- An extract of the inner rind and seeds of grapefruit *(Citrus racemosa)* acts as a broad-spectrum natural antibiotic that is highly active against protozoa, bacteria, yeast, and some viruses.
- An extract of the western larch tree *(Larix occidentalis)*, which contains the water-soluble polysaccharide arabinogalactan with immune-enhancing properties. Arabinogalactans are also found in other plants and herbs, including echinacea (*Echinacea purpurea*) and tumeric *(Curcuma longa)*.
- Berberine, containing medicinal plants such as goldenseal *(Hydrastis canadensis)*, and Barberry (*Berberis vulgaris*), which studies have shown fight bacterial,

KEY TERMS

Ankylosing spondylitis—A systemic rheumatic disease causing chronic inflammation (spondylitis) and stiffness in the spine, the lower back, and inflammation of other tissues throughout the body such as the eyes, heart, lungs, and kidneys. Over time, the inflamation may lead to a complete fusion of the vertebrae and loss of spinal mobility (ankylosis).

Autoimmune—An abnormal, overactive and misdirected immune response against substances and tissues in the body that are normally not recognized as a threat.

Candidiasis—A systemic infection caused by an imbalance of intestinal bacteria with an overgrowth of the yeast *Candida albicans*.

Leaky gut—Intestinal permeability caused by damage to the intestinal mucosa, which leads to increase in the toxic load placed on the liver.

Probiotics—Beneficial bacteria in the gastrointestinal tract essential to healthy digestion. Probiotics produce certain essential vitamins and provide protection from bacteria, parasites, viruses, yeasts, and fungi while promoting the breakdown of waste and toxins. The lactobacillus species is the best known of the many probiotics.

Short-chain fatty acids—End products of bacterial fermentation derived from the breakdown of complex carbohydrates by anaerobic micro-organisms in the large intestine.

viral, fungal, and parasitic infections with the alkaloid berberine.

- Kombucha (*Fungus japonicus*) tea, a fermented drink containing a colony of yeast and bacteria, helps correct the intestinal flora imbalance.
- Vitamin and mineral supplementation may help counteract the effects of malabsorption, maldigestion, and hypermetabolism that may be factors contributing to dysbiosis.
- Time-released capsules of oregano, and the extract hyperforin from St. John's Wort *(Hypericum perforatum)*, myrrh *(Commiphora molmol)* and thyme, clove, and anise may also help.

Prevention

Prevention of dysbiosis may involve lifestyle change that reduces physical and mental **stress**, adoption of a healthy diet, body cleansing, including periodic **fasting**, physical exercises, vitamin and mineral supplementation, and traditional and natural therapies that maximize general health and wellbeing.

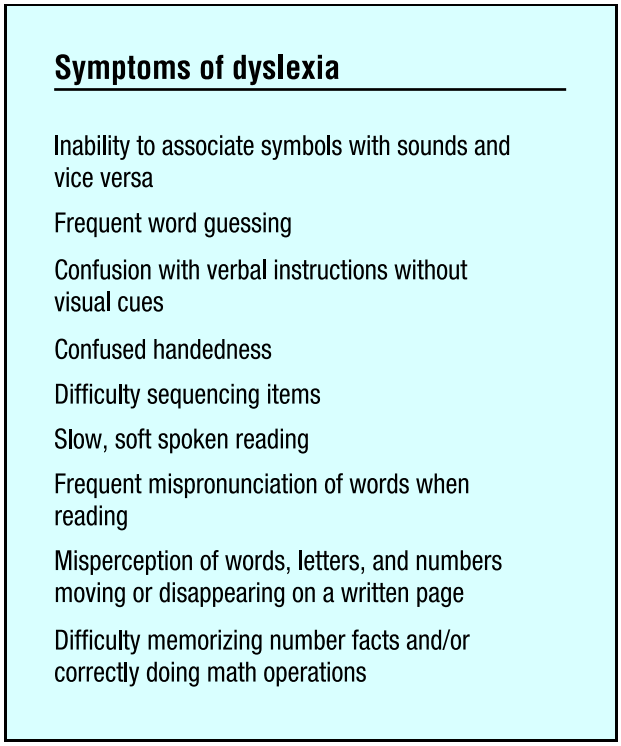
Dyslexia

Definition

Dyslexia is a kind of learning disability noted for spatial reversals and shifts and is sometimes described as a neurological disorder. It manifests as difficulties with reading, writing, spelling and sometimes math. Occasionally, balance, movement, and rhythm are affected. Persons with dyslexia frequently display above average to superior intelligence, gifted creativity and genius. Leonardo da Vinci, Albert Einstein, Walt Disney, and the Olympic multi-Gold Medal diving champion, Greg Louganis, are noted examples of persons with dyslexia.



(Illustration by Corey Light. Cengage Learning, Gale)

Description

Genetics is believed to be a deciding factor in whether or not a person develops dyslexia. The condition may appear as early as three months. One report suggested that as many as 5–15% of Americans are affected. The National Institute of Health (NIH) reports that up to 8% of American elementary school children may have the unique characteristics described originally in 1920 by Dr. Samuel Torrey Orton. Believing it first a condition of "cross lateralization of the brain," by which he meant that functions normally processed on the right side of the brain are processed on the left side in the person with dyslexia, Orton later modified his description of the condition as being a "mixed hemispheric dominance," by which he meant that the alteration of functions to the opposite side of the brain occurred sometimes, but not all the time.

Since the advent of magnetic resonance imaging (MRIs), scientists have been able to view dyslexia from another vantage point, ironically, a process imitating what happens inside the mind of a dyslexic individual, according to one educator with dyslexia, Ronald D. Davis. He describes the ordinary ability of the person with dyslexia to visualize an object from multiple points of view, a process which has a moving point of view and which is spatially unanchored. When presented with a word that is easily visualized as a known object, like horse, the dyslexic mind easily imagines the horse from multiple perspectives, and, so rapidly—somewhere between 400 to 2,000 times faster than those without dyslexia—visual cues are processed 'almost intuitively,' demonstrating great mastery of the objectified visual world. However, when it comes to processing sound, language, speaking, handwriting and understanding verbalized communication not associated with an object, like the words "the" or "and", a series of non-image disconnections leads to confusion, disorientation, and an inability to adequately make sense of key pieces of visual information. To the person with dyslexia, a simple seven word sentence may look like a three word sentence with four blank spaces here and there.

Causes and symptoms

Although an exact cause has not been identified, studies have identified differences in the way sound and visual information are processed between persons with and without dyslexia. In the dyslexic individual these differences create what one NIH scientist refers to as a "physiologic signature"—a unique brain pattern—perhaps the result of emphasized activity along dopamine related neuro-pathways. Dopamine is a neurotransmitter, a chemical substance acting in the brain that facilitates certain kinds of messages. According to one author, when dopamine levels are high, the person with dyslexia experiences time as moving very slowly outside themselves, and very fast inside; as if time stands still. This author also notes that when the person with dyslexia experiences episodes of disorientation, when words or sounds do not create a visual picture for them and their mind continues to try and solve the confusion visually, dopamine levels shift and change. This would seem to be consistent with some of the symptoms of dyslexia, such as inaccurate perceptions of time and a lot of day dreaming.

Symptoms may include:

- poor ability to associate symbols with sounds and vice versa
- frequent word guessing when reading, and an inability to retain meaning
- confusion when given verbal instructions unaccompanied by visual cues
- confused sense of spatial orientation, especially by reversing letters and numbers, and losing one's place frequently while reading, or skipping lines

KEY TERMS

Acetylcholine—A chemical of nerve transmission involved with movement.

Attention Deficit Disorder (ADD)—A learning disability characterized by an inability to pay attention. It may be different from dyslexia in that dyslexic individuals are highly aware and able to pay attention, but unable to make sense of their perceptions.

Attention Deficit with Hyperactivity Disorder (ADHD)—A learning disability characterized by an inability to sit still or concentrate well. It has been demonstrated to be diagnostically different from dyslexia by speech and vocalization patterns.

Cross lateralization—A term used to describe what was believed to be a difference in the way the mind works in persons with and without dyslexia. It was believed that functions processed in the right half of the brain by a person without dyslexia were processed in the left half by a person with dyslexia.

Dopamine—A chemical of nerve transmission involved with pleasure and pain and some forms of movement.

Dyslexia—A term applied to a kind of learning disability particularly noted for reversals and spatial shifts, making reading, writing, spelling and math very difficult.

Koosh ball—A lightweight, "furry" ball of rubber band material used in Davis technique exercises for retraining neuropathways in the brain of a person with dyslexia.

Mind's eye—A term referring to an imaginary point from which the mind views what the eyes look at or what the imagination presents. In dyslexia, the mind's eye is unanchored to one location, and sends many signals to the brain about what it sees, which causes disabling confusion.

Mixed hemispheric dominance—A term later used to describe what was believed to be a difference in the way the mind works in persons with and without dyslexia. It was believed that functions processed in the right half of the brain by a person without dyslexia were sometimes processed in the left half by a person with dyslexia.

Monoamine oxidase (MAO) inhibitors—A group of anti-depressant drugs.

Neurotransmitter—A chemical substance that facilitates the passing of messages along nerve pathways. There are several different neurotransmitters used in the human nervous system, each with distinct effects on mood, movement and perception.

Point of view—In a person with dyslexia, this term is used to describe the angle from which their mind's eye views an object. This point of view may be unanchored and moving about, as if several different people were telling what they see all at the same time.

- having the perception that words, letters and numbers move around, disappear, or get bigger or smaller
- overlooking punctuation marks or other details of language
- slow, labored reading and speech may be difficult to understand, words often mispronounced and softly spoken
- confused sense of right and left handedness
- math concepts are difficult to learn, excessive daydreaming, and difficulty with time
- difficulty sequencing items
- difficulty with jigsaw puzzles, walking a chalk line straightly or other fine motor skill tasks.

Other more positive characteristics common with dyslexia include:

- primary ability of the brain to alter and create perceptions
- highly aware of their environment, intelligent, and above average curiosity
- intuitive, insightful, and having the extraordinary ability of thinking in pictures
- multi-dimensional perception (from various viewpoints almost simultaneously)
- vivid imagination
- experiencing thought as reality (confusing what they see with what they think they see), thereby being abundantly creative

Diagnosis

Diagnosis is difficult in part because symptoms can also result from other conditions and because no two individuals display the same symptoms. As a result, dyslexia can be viewed as a developmental condition, a "self-created condition," rather than as a disease. As each individual baby interprets visual data, and adapts to the environment accordingly,

they develop their own individual and unique brain patterns. It is that developmental pattern that is consistent among people with dyslexia. When the individual's mind cannot make sense of the data, confusion and disorientation result; incorrect data is incorporated, causing the individual to make mistakes that leads to emotional reactions, primarily frustration. A behavior is adopted that constitutes a learning disability because it disables future learning and, ultimately, affects self esteem.

Sometimes the learning disorder of dyslexia is inaccurately paralleled to Attention Deficit Disorder (ADD) or Attention Deficit Hyperactivity Disorder (ADHD). In a 2003 study, distinguishable differences between the two **learning disorders** were readily apparent. Comparing 105 boys between the ages of eight and ten, from three different schools and cross divided into three different groups—35 boys diagnosed with ADHD not taking stimulant medication, 35 boys with dyslexia, and 35 boys without learning disabilities—the study found clear and diagnostically useful differences in speech related patterns between all groups. Since diagnosis of a learning disability may be made between parents and teachers or other school administrators on the basis of symptoms rather than clinical diagnostic testing, careful diagnosis is advisable.

Treatment

Ronald D. Davis, writing in *The Gift of Dyslexia* outlines an alternative and complementary treatment consistent with the "moving point of view" model. According to this model, and the reason why letters seem to change shape and float, why lines of print appear to move, and why words appear to be other than they are is that the dyslexic individual sees the world predominantly through his or her "mind's eye," rather than through his or her physiologic eye. In other words, the person with dyslexia more than all others, sees what he or she 'thinks' they see, rather than what their eyeballs see. To further complicate matters, they do this so quickly, they easily become confused when the multiple facets do not produce a solid view. The object of treatment proposed by Davis, a dyslexic individual himself, is to train the mind's eye to return to a learned, anchored, viewpoint when they realize they are seeing with their mind, and not with their eyeballs. This is accomplished with assessment testing, followed by one-on-one exercises that retrain mental perception pathways. Using the gifts of the dyslexic individual—their imagination and curiosity—these exercises involve creative physical activities, including the use of modeling clay, "koosh" balls, and movement training. Davis founded the Reading Research Council's Dyslexia Correction Center in 1982, and the Davis Dyslexia Association International, which trains educators and therapists, in 1995.

Another alternative treatment option seeks to address unmastered learning skills needed for reading and math. This system, called Audioblox, may be used one-on-one (especially for children) or in groups, and involves a series of mental exercises that address learning, focusing on the "deficits" of dyslexia. Treatment involves the purchase of a kit online that contains a book entitled *The Right to Read,* a supplementary manual, a computer program on CD to supplement Audioblox training, and teaching materials. The book is in two parts; first, an explanation of theory; second, the program itself, with exercises. The supplementary manual contains specialized programs for areas of deficit, including handwriting, spelling, math, preschool readiness, and high school or adult learning. The teaching materials include 96 colored blocks, representing each of six colors on each of the six sides of the block; a view blocking screen; colored cards with preprinted patterns; letter cards; a reading book with a story written in the 800 most common English words, and word cards; and, a demonstration video. The kit originates in England; pricing in America ranges approximately between $135 and $150.

Special education recommendations include helping a child stay organized and on task by keeping their desk and workplace free of extraneous, distracting materials; making more frequent, shorter assignments to increase confidence; providing positive, "immediate gratification" feedback; and short conferences or work contracts as needed.

Allopathic treatment

Allopathic medical treatment for dyslexia includes use of anti-motion drugs, addressing the symptoms of balance and coordination that results from visual perception alterations; stimulant drugs, such as Cylert or Ritalin, to address symptoms of low self esteem, restlessness, and distractibility, and 'nootropics' drugs, a class of drugs believed to improve cognitive function. The stimulant drugs may be more effective for learning disorders related to ADHD or ADD than for dyslexia. The drug Piracetam, a nootropic, although reported as a possible treatment for dyslexia, is also reported to have legal issues because it has not been approved for use in the United States by the Food and Drug Administration (FDA). Reported potential side effects of the stimulants include nervousness and **insomnia**, and are

contra-indicated with **epilepsy**, **allergies**, blood pressure problems, or with use of monoamine oxidase (MAO) inhibitors. Long-term use of stimulants in children are reported to adversely affect growth, and may ironically depress the nervous system or lead to loss of consciousness. By reducing natural levels of stimulants in the brain, they may also cause dependence. The stimulants and nootropics are said to increase the effects of alcohol and amphetamines. Other possible interactions include use of anti-convulsants or anti-epileptics; tricyclic anti-depressants; anti-coagulants, like Coumadin; and atropine-like drugs that blocks the neurotransmitter acetylcholine.

Prognosis

If left unaddressed, a person with dyslexia may become functionally illiterate, able to function limited by their ability to read, spell, have their handwriting understood, or do arithmetic. Recognizing that dyslexia is a developed learning disorder affecting people of extraordinary curiosity, imagination and intelligence—people of genius, often—from a productive or functional point of view, dyslexia may contribute significantly, positively or negatively, to performance levels. From an emotional or psychological point of view, dyslexia affects self esteem, and promotes confusion and frustration that may contribute to under achievement.

Prevention

No method of preventing dyslexia is currently known. However, existing methods of treatment may prevent or reduce the secondary or indirect losses to individuals, society and culture that might otherwise occur. As the genetic aspects of dyslexia are revealed, genetic chromosomal modifications may prevent the expression of dyslexia in future generations. Wise use of present and future understandings will allow individuals with dyslexic gifts, individuals such as Leonardo daVinci, Albert Einstein, Walt Disney and Greg Louganis, to continue to contribute their genius and talents.

Dysmenorrhea

Definition

Dysmenorrhea is the occurrence of painful cramps during **menstruation**.

Description

More than half of all girls and women have dysmenorrhea (cramps), a dull or throbbing **pain** that usually centers in the lower mid-abdomen, radiating toward the lower back or thighs. Menstruating women of any age can experience cramps.

While the pain may be only mild for some women, others experience severe discomfort that can significantly interfere with everyday activities for several days each month. In fact, about 43% of women in the United States have pain so severe that it disrupts their daily lives and about 18% miss one or more days or work, school, or other activities each year because of menstrual cramps.

Causes and symptoms

Dysmenorrhea is called "primary" when there is no specific abnormality, and "secondary" when the pain is caused by an underlying gynecological problem. It is believed that primary dysmenorrhea occurs when

KEY TERMS

Endometriosis—The growth of uterine tissue outside the uterus.

Hormone—A chemical messenger secreted by a gland and released into the blood, where it travels to distant cells to exert an effect.

Ovary—One of the two almond-shaped glands in the female body that produces the hormones estrogen and progesterone.

Ovulation—The monthly release of an egg from an ovary.

Progesterone—The hormone produced by the ovary after ovulation that prepares the uterine lining for a fertilized egg.

Uterus—The female reproductive organ that contains and nourishes a fetus from implantation until birth.

prostaglandins, hormone-like substances produced by uterine tissue, trigger strong muscle contractions in the uterus during menstruation. However, the level of prostaglandins does not seem to correlate with the strength of a woman's cramps. Some women have high levels of prostaglandins and no cramps, whereas other women with low levels have severe cramps. This is why experts assume that cramps must also be related to other causes, such as **diets**, genetics, **stress**, and different body types, in addition to prostaglandins. The first year or two of a girl's periods are not usually very painful. However, once ovulation begins, the blood levels of the prostaglandins rise, leading to stronger contractions.

Secondary dysmenorrhea may be caused by **endometriosis**, fibroid tumors, or an infection in the pelvis.

The likelihood that a woman will have cramps increases if she:

- has a family history of painful periods
- leads a stressful life
- does not get enough exercise
- uses caffeine
- has pelvic inflammatory disease (PID)

Symptoms include a dull, throbbing cramping in the lower abdomen that may radiate to the lower back and thighs. In addition, some women may experience **nausea** and **vomiting**, **diarrhea**, irritability, sweating, or **dizziness**. Cramps usually last for two or three days at the beginning of each menstrual period. Many women often notice their painful periods disappear after they have their first child, probably due to the stretching of the opening of the uterus or because the birth improves the uterine blood supply and muscle activity, although others do not notice a change.

Diagnosis

A doctor should perform a thorough pelvic exam and take a patient history to rule out any underlying condition that could cause cramps.

Treatment

Nutritional therapy

The following dietary changes may help prevent or treat menstrual pain:

- Increased dietary intake of foods such as fiber, calcium, soy foods, fruits and vegetables.
- Decreased consumption of foods that exacerbate PMS. They include caffeine, salt and sugar.
- Quitting smoking. Smoking has been found to worsen cramps.
- Taking daily multi-vitamin and mineral supplements that contain high doses of magnesium and vitamin B_6 (pyridoxine), and flaxseed or fish oil supplements. Recent research suggests that vitamin B supplements, primarily vitamin B_6 in complex, magnesium, calcium, zinc, vitamin E, and fish oil supplements (omega-3 fatty acids) also may help relieve cramps.

Herbal therapy

An herbalist may recommend one of the following herbal remedies for menstrual pain:

- Chasteberry (*Vitex agnus-castus*) for women who also experience breast pain, irregular periods, and ovarian cysts.
- Dong quai (*Angelica sinensis*) for women with typical menstrual pain.
- Licorice (*Glycyrrhiza glabra*) for abdominal bloating and cramping.
- Black cohosh (*Cimifuga racemosa*) for relief of menstrual pain as well as mood swing and depression.

Yoga

Several **yoga** positions are popular as methods to ease menstrual pain. In the "cat stretch" position, the woman rests on her hands and knees, slowly arching the back. The pelvic tilt is another popular yoga position, in which the woman lies with knees bent, and then lifts the pelvis and buttocks.

Exercise

Exercise may be a way to reduce the pain of menstrual cramps through the brain's production of endorphins, the body's own painkillers.

Other remedies

Acupuncture and Chinese herbs are other popular alternative treatments for cramps. There are particular formulas depending on the pattern of imbalance. **Aromatherapy** and massage may ease pain for some women. Transcutaneous Electrical Nerve Stimulation (TENS) has been touted as a safe and practical way to relieve the pain of dysmenorrhea. It works by using electrodes to stimulate nerve fibers. Some women find relief through visualization, concentrating on the pain as a particular color and gaining control of the sensations. Others find that imagining a white light hovering over the painful area can actually lessen the pain for brief periods. Simply changing the position of the body can help ease cramps. The simplest technique is assuming the fetal position with knee pulled up to the chest while hugging a heating pad or pillow to the abdomen. Also, orgasm can make a woman feel more comfortable by releasing tension in the pelvic muscles.

Allopathic treatment

Several drugs can lessen or completely eliminate the pain of primary dysmenorrhea. Most popular are the non-steroidal anti-inflammatory drugs (NSAIDs), which prevent or decrease the formation of prostaglandins. These include aspirin, ibuprofen (Advil), and naproxen (Aleve). For more severe pain, prescription strength ibuprofen (Motrin) is available. These drugs are usually begun at the first sign of the period and taken for a day or two.

If an NSAID is not available, acetaminophen (Tylenol) may also help ease the pain. Heat applied to the painful area may bring relief, and a warm bath twice a day also may help.

Studies of a drug patch containing glyceryl trinitrate to treat dysmenorrhea suggest that it also may help ease pain. This drug has been used in the past to ease preterm contractions in pregnant women.

In 2002, an intrauterine device (IUD) was introduced to help eliminate the pain of menstrual cramps related to endometriosis. The IUD, known as Mirena, is approved for use in the Untied States as a contraceptive.

Expected results

Treatments should lessen or eliminate pain.

Prevention

Avoidance of **caffeine**, alcohol, and sugar prior to onset of period and NSAIDs taken a day before the period begins should eliminate cramps for some women.

Ear infection

Definition

Otitis media is an infection of the middle ear space, which lies behind the eardrum (tympanic membrane). It is characterized by **pain**, **dizziness**, and partial loss of hearing.

Description

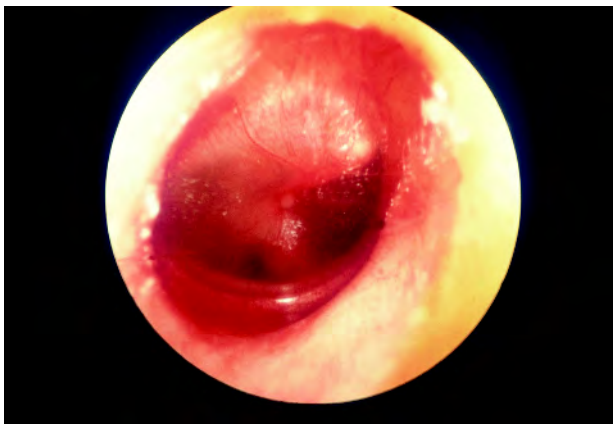
A little knowledge of the basic anatomy of the middle ear will be helpful for understanding the development of otitis media. The external ear canal is a tube that leads from the outside opening of the ear to a structure called the tympanic membrane. Behind the tympanic membrane is the space called the middle ear. Within the middle ear are three tiny bones called ossicles. These are the malleus, the incus, and the stapes. Their shapes are often described as a hammer, an anvil, and a stirrup. Sound in the form of vibration causes movement in the eardrum, and then in the chain of ossicles. The ossicles transmit the sound to the cochlea within the inner ear, which sends it to the brain for processing.

The nasopharynx is the passageway behind the nose that takes inhaled air into the breathing tubes leading to the lungs. The eustachian tube is a canal that runs between the middle ear and the nasopharynx. One of the functions of the eustachian tube is to keep the air pressure in the middle ear equal to that outside. This equalization of the air pressure allows the eardrum and ossicles to vibrate appropriately, so that hearing is normal.

By age three, almost 85% of all children will have had otitis media at least once. It is the most common pediatric complaint. Babies and children between the ages of six months and six years are most likely to develop otitis media. Children at higher risk for otitis media include boys, children from poor families, those with **allergies**, Native Americans, Native Alaskans, children born with cleft palate or other defects of the structures of the head and face, and children with Down syndrome. Babies whose first ear infection occurs prior to six months of age are more prone to chronic problems with otitis media. There also appears to be some genetic predisposition towards otitis media, which may be related to the structure and function of the area in and around the middle ear. Exposure to cigarette smoke significantly increases the risk of ear **infections**, as well as other problems affecting the respiratory system. In addition, children who enter daycare at an early age have more upper respiratory infections (URIs or colds), and thus more cases of otitis media. Although the ear infection itself is not contagious, the URIs that predispose children to them certainly are. The most common times of year for otitis media to strike are winter and early spring, which are the same times that URIs are most common.

Otitis media is an important medical problem because it often results in fluid accumulation within the middle ear. This is known as otitis media with effusion (OME). The effusion can last for weeks to months. Effusion within the middle ear can cause significant hearing impairment. When such hearing impairment occurs in a young child, it may interfere with the development of normal speech and language processing. A chronic effusion also increases the risk for subsequent infections, as the fluid provides a growth medium for bacteria.

In adults, acute otitis media can lead to such complications as paralysis of the facial nerves. Recovery from these complications may take from two weeks to as long as three months.



A photograph of the eardrum, through the ear using an otoscope, in a patient with otitis media, an ear infection. *(© Medical-on-Line / Alamy)*

KEY TERMS

Adenoid—A collection of lymph tissue located in the nasopharynx.

Effusion—A collection of fluid that has leaked out into some body cavity or tissue.

Eustachian tube—A small tube that runs between the middle ear space and the nasopharynx.

Fomite—An inanimate object that can transmit infectious organisms.

Myringotomy—A surgical procedure performed to drain an infected middle ear. A newer type of myringotomy uses a laser instead of a scalpel.

Nasopharynx—The part of the airway leading into the nose.

Ossicles—Tiny bones located within the middle ear that convey the vibrations of sound through to the inner ear.

Perforation—A hole that develops in a body tissue. In otitis media, the eardrum sometimes perforates because of the pressure of fluid behind it.

Topical—Referring to a medication applied to the skin or outward surface of the body. Ear drops are one type of topical medication.

Causes and symptoms

The first precondition for the development of acute otitis media is exposure to an organism capable of causing the infection. Otitis media can be caused by either viruses or bacteria. Virus infections account for about 15% of cases. The three most common bacterial pathogens are *Streptococcus pneumoniae*, *Haemophilus influenzae*, or *Moraxella catarrhalis*. About 75% of ear infections caused by *S. pneumoniae* are reported to be resistant to penicillin.

Otitis media may also be caused by other disease organisms, including *Bordetella pertussis*, the causative agent of **whooping cough**, and *Pneumocystis carinii*, which often causes opportunistic infections in patients with **AIDS**.

There are other factors that make the development of an ear infection more likely. Because the eustachian tube has a more horizontal orientation and is considerably shorter in early childhood, material from the nasopharynx can easily reach the middle ear. Discharges from the nasopharynx include infection-causing organisms. Children also have a lot of lymph tissue, some of which makes up the adenoids, in the area of the eustachian tube. The adenoids may enlarge with repeated respiratory tract infections, ultimately blocking the eustachian tubes. When the eustachian tube is blocked, the middle ear is more likely to fill with fluid. This fluid increases the risk of infection, and the corresponding risks of **hearing loss** and delayed speech development.

Recent advances in gene mapping have led to the discovery of genetic factors that increase a child's susceptibility to otitis media. Researchers are hoping to develop molecular diagnostic assays that will help to identify children at risk for severe ear infections.

Most cases of acute otitis media occur during the course of a URI. Symptoms may include cold symptoms, **fever**, ear pain, irritability, and problems with hearing. Babies may have difficulty feeding. When significant fluid is present within the middle ear, pain can increase depending on position. Lying down may cause an increase in painful pressure within the middle ear, so that babies often fuss if not held upright. Older children sometimes complain of a full sensation in the affected ear. If the fluid build-up behind the eardrum is sufficient, the eardrum may develop a hole (perforate), causing bloody fluid or greenish-yellow pus to drip from the ear. Although the pain may be severe before the eardrum perforates, the pain is usually relieved by the reduction of pressure brought on by a perforation.

Diagnosis

Diagnosis is usually made simply by looking at the eardrum through a special lighted instrument called an otoscope. The eardrum will appear red and swollen,

and may appear either abnormally drawn inward, or bulging outward. Under normal conditions, the ossicles create a particular pattern on the eardrum, referred to as "landmarks." These landmarks may be obscured in the course of an infection. Normally, the light from the otoscope reflects off the eardrum in a characteristic fashion. This is called the "cone of light." In an infection, this cone of light may be shifted or absent.

A special attachment to the otoscope allows the examiner to blow a puff of air gently into the ear. Normally, this should cause movement of the eardrum. In an infection, or when there if fluid behind the eardrum, this movement may be decreased or absent. Movement of the eardrum can also be assessed by a tympanogram. A tympanogram is a quick, painless test. If there is fluid in the middle ear, the tympanogram reading will be flat. If the middle ear is filled with air, as it is normally, the test will also show whether it is at higher or lower pressure than it should be. This measurement could be an indicator of abnormal function of the eustachian tube.

Hearing tests, or audiograms, are sometimes used to determine whether hearing loss has occurred because of infection or persistent fluid, and whether the loss is severe. A hearing screen for children old enough to describe their own hearing reliably can be performed in schools or at the pediatrician's office. More accurate testing is done in a soundproof booth by an audiologist. This method can also be modified for use with children who can not give a verbal indication that they have heard a sound, but are old enough to turn their heads to see the source of a noise.

Fluid or pus draining from the ear can be collected. This sample can then be processed in a laboratory to allow any organisms present to multiply sufficiently (cultured) to permit the organisms to be viewed under a microscope and identified. Cultures are also used to determine the sensitivity of the organisms to specific antibiotics.

Treatment

Chiropractic

One particular **chiropractic** procedure, known as the endonasal technique, is thought to help the eustachian tube to open and thus improve drainage of the middle ear. The tube is sometimes blocked off due to exudates or inflammatory processes. The endonasal technique can offer significant relief from **earache**.

Craniosacral therapy and osteopathy

Craniosacral therapy uses gentle manipulation of the bones of the skull to relieve pressure and improve eustachian tube function. This treatment may also help the eustachian tubes to assume a position in which they can drain on their own. The pressure exerted on a baby's head during the birth process sometimes contributes to the tubes being in a position in which it is hard for them to drain. Osteopaths practice a similar gentle manipulation of the bones of a child's head. One osteopathic study of children from kindergarten through third grade in a Missouri school district found a direct correlation between abnormal head shape at birth and susceptibility to otitis media during the early elementary school years. Pediatric osteopaths specialize in cranial work in children.

Herbal therapy

A number of herbal treatments for otitis media have been recommended, including eardrops made with **goldenseal** (*Hydrastis canadensis*), **mullein** (*Verbascum thapsus*), **St. John's wort** (*Hypericum perforatum*), and **echinacea** (*Echinacea* spp.). Tinctures of echinacea, **thyme** (*Thymus vulgaris*), and elderflower (*Sambucus nigra*) are often recommended for oral treatment of otitis media due to chronic congestion. Warm **garlic** oil can be instilled directly into the ear. Steam inhalation infused with **eucalyptus** or **chamomile** may reduce the congestion of the URIs that often accompany otitis media.

Homeopathy

Homeopathic remedies that may be prescribed for middle ear infections include **aconite**, ferrum phosphoricum, **belladonna**, chamomilla, **lycopodium**, **pulsatilla**, or **silica**.

Nutrition

Some practitioners believe that food allergies may increase the risk of ear infections, and they suggest eliminating suspected food allergens from the diet. The top food allergens are wheat, dairy products, corn, peanuts, citrus fruits, and eggs. Elimination of sugar and sugar products can allow the immune system to work more effectively. Other nutritionists have noted that children who were breastfed as babies are less susceptible to ear infections.

Acupuncture

Acupuncture can help to reestablish a normal flow of fluids within the head. This form of treatment may also enhance the immune system.

Allopathic treatment

Medications

Antibiotics are the treatment of choice for acute otitis media (AOM). Different antibiotics are used depending on the type of bacteria most likely to be causing the infection. This decision involves knowledge of the types of antibiotics that have worked on other ear infections occurring within a particular community at a particular time. Options include sulfa-based antibiotics, as well as a variety of penicillins, cephalosporins, and others. The patient's sensitivity to certain medications, as well as previously demonstrated resistant **strains**, also contributes to the choice of antibiotic. An 0.3% topical solution of ofloxacin has been recommended as a more effective medication than other oral or topical antibiotics.

Following a course of antibiotic treatment, approximately 40% of children will continue to have fluid behind the eardrum, resulting in otitis media with effusion (OME). The eardrum is no longer red or infected. The fluid may take weeks to months to resolve. Generally, it is safe to allow this condition to continue with observation for up to 12 weeks. At that time, hearing should be tested. If hearing loss is insignificant or only in one ear, observation can continue for up to a total of 4–6 months, at which time placement of ventilation tubes in the eardrum is often recommended. The tube functions as an accessory eustachian tube until it falls out. If hearing loss is significantly affecting both ears at any time after six weeks from diagnosis of OME, antibiotic treatment or tube placement should be considered.

The overuse of antibiotics is contributing to some strains of bacteria—particularly *S. pneumoniae*—developing resistance and becoming more difficult to treat. Research is being done to try to help determine whether there may be some ear infections that would resolve without antibiotic treatment. One pediatrician has suggested some changes in usage of antibiotics for otitis media. He describes five factors to use to determine whether antibiotic treatment can be limited to five days or perhaps avoided altogether. The factors to consider are the age of the child; time of year; severity of the infection; frequency of infection; and rapidity of response to antibiotics. Generally, otitis media clears more readily when it occurs in an older child, in the summer, and causes relatively mild symptoms in a child who has not experienced frequent infections in the past. Given these factors, it may be possible to avoid antibiotic use. The patient must be monitored to be sure the infection clears without complication. If antibiotic treatment is initiated and the infection clears quickly, a five-day course of medication may be all that's needed.

Whether or not antibiotics are used, such pain relievers as Tylenol or Motrin can be very helpful in reducing the pain and inflammation associated with otitis media.

The use of decongestants and antihistamines does not appear to shorten the course of infection.

Surgery

In a few rare cases, a surgical perforation to drain the middle ear of pus may be performed. This procedure is called a myringotomy. The hole created by the myringotomy generally heals itself in about a week. In 2002 a minimally invasive procedure was introduced that uses a laser to perform the myringotomy. It can be performed in the doctor's office and heals more rapidly than the standard myringotomy.

Although some doctors have recommended removing the adenoids to prevent recurrent otitis media in young children, recent studies indicate that surgical removal of the adenoids does not appear to offer any advantages over a myringotomy as a preventive measure.

Expected results

With treatment, the prognosis for acute otitis media is very good. Long-lasting accumulations of fluid within the middle ear, however, place the patient at risk both for difficulties with hearing and speech, and for the repeated development of ear infections. Without treatment, otitis media occasionally leads to serious complications, including an infection within the nearby mastoid bone, called mastoiditis.

Prevention

Although otitis media seems inevitable in childhood, some measures can be taken to decrease the chance of repeated infections and fluid accumulation. Breastfeeding provides some protection against URIs, which in turn protects against the development of otitis media. If a child is bottle-fed, parents should be advised to feed him or her upright, rather than allowing the baby to lie down with the bottle. General good hygiene practices (especially hand washing) help to decrease the number of upper respiratory infections in a household or daycare center. Hand sanitizers are preferable to antibacterial soaps, which may contribute to bacterial resistance.

The use of pacifiers should be avoided or limited. They may act as fomites, particularly in a daycare setting. In children who are more susceptible to otitis media, pacifier use can increase by as much as 50% the number of ear infections experienced.

Two vaccines can prevent otitis media associated with certain strains of bacteria. One is designed to prevent **meningitis** and other diseases, including otitis media, that result from infection with *Haemophilus influenzae* type B. Another is a vaccine against *Streptococcus pneumoniae*, a very common cause of otitis media. Children who are at high risk or have had severe or chronic infections may be good candidates for these vaccines; in fact, a recent consensus report among pediatricians recommended routine administration of the pneumococcal conjugate vaccine to children younger than two years, as well as those at high risk for AOM. Parents should consult a health care provider concerning the advisability of this treatment.

Another vaccine that appears to lower the risk of AOM in children is the intranasal vaccine that was recently introduced for preventing **influenza**. Although the flu vaccine was not developed to prevent AOM directly, one team of researchers found that children who were given the vaccine before the start of flu season were 43% less likely to develop AOM than children who were not vaccinated.

As of early 2003, there was no vaccine effective against *M. catarrhalis*. Researchers are working on developing such a vaccine, as well as a tribacterial vaccine that would be effective against all three pathogens that commonly cause otitis media.

A nutrition-based approach to preventive treatment is undergoing clinical trials as of late 2002. This treatment involves giving children a dietary supplement of lemon-flavored cod liver oil plus a multivitamin formula containing **selenium**. The pilot study found that children receiving the supplement had fewer cases of otitis media, and that those who did develop it recovered with a shorter course of antibiotic treatment than children who were not receiving the supplement.

After a child has completed treatment for otitis media, a return visit to the practitioner should be scheduled. This visit should occur after the course of antibiotic has been completed. It allows the practitioner to evaluate the patient for the persistent presence of fluid within the middle ear. In children who have a problem with recurrent otitis media, a small daily dose of an antibiotic may prevent repeated full attacks of otitis media. In children who have frequent bouts of otitis media or persistent fluid, a procedure to place ventilation tubes within the eardrum may help to equalize pressure between the middle ear and the outside, thus preventing further fluid accumulation.

Earache

Definition

An earache is a commonly used term for ear **pain** or discomfort that is a symptom of disease or injury.

Description

An earache itself is not a disease, but it is a symptom of disease or injury in the external or middle ear. It may also be a symptom of problems in the mouth, nose, or throat. Infants or very young children may be unable to say that they are in pain. Increased irritability or pulling at the ears is often a sign of ear pain in infants.

Causes and symptoms

The most common cause of an earache is a buildup of pressure in the eustachian tube. Among other functions, the eustachian tube drains fluids out of the middle ear via the back of the throat. A cold, allergy, or **sore throat** can cause the eustachian tube to swell shut. Infants and young children are especially susceptible to earaches caused by problems with the eustachian tube, since the structure is still underdeveloped in that age group. When the normal drainage of fluid is prevented, it can accumulate in the middle ear, causing pressure, pain, stagnation, and possibly infection.

An earache may be due to a perforated, or broken, eardrum. The eardrum can be broken as a result of a blow to the head, infection in the inner ear, suction applied to the ear, or the insertion of a foreign object into the ear. **Infections** of the middle and outer ears are often associated with earaches. Other causes of an earache may be the obstruction of the ear canal with a foreign object or excessive ear wax, **boils** in the ear canal, a herpes zoster infection of the ear, keratosis of the ear, tumors, an infection of the mastoid process, "swimmer's ear," and the aftermath of surgical procedures. Ear pain can also be caused by a rapid descent from high altitudes, during air travel or travel in the mountains. A **sinus infection**, arthritis of the jaw, sore throat, **tonsillitis**, and dysfunction of the temporomandibular joint (TMJ) may be the source of referred pain to the ears.

Diagnosis

A history of the illness should be obtained, including information about the symptoms accompanying the earache. A physical exam should be performed, which may include an examination of the ears, the nasal passages and sinuses, and the throat. An otoscope may be used to see more deeply into the ears, nose, and throat. In addition, the teeth, tongue, tonsils, salivary glands, and TMJ should be examined for problems that might be causing referred pain to the ears. A culture and sensitivity test should be done if there is any discharge from the ears. X rays or a computed tomography (CT) scan may be required to diagnose the problem. Hearing and balancing tests are important to the diagnosis of an earache.

Treatment

Three to five drops of the warmed oil extract of **mullein** flowers (*Verbascum thapsus*), **garlic** (*Allium sativa*), or **St. John's wort** (*Hypericum perforatum*), or a combination of any of the three should be placed into the affected ear. The oil of *Calendula officinalis* may be used in the same manner. If there is a persistent **ear infection**, **goldenseal** (*Hydrastis canadensis*) salve or tincture can be placed directly onto the outer ear or into the ear canal three to four times per day. Glycerin can be introduced into the ear if it is suspected that excessive earwax or water in the ear is causing the problem.

Food and environmental **allergies** should be considered as contributors to the development of ear pain and infections, especially if the earache is chronic or

KEY TERMS

Computed tomography (CT) scan—A medical procedure where a series of x rays are taken and put together by a computer in order to form detailed pictures of areas inside the body.

Eustachian tube—A canal extending from the middle ear to the pharynx.

Mastoid process—The rounded protrusion of bone that can be felt just behind the ear.

Middle ear—The inner portion of the ear made up of an air-filled chamber, which is separated from the outer ear by the tympanic membrane.

Otoscope—A lighted medical instrument that can be used to visualize the ear canal and the tympanic membrane.

Swimmer's ear—An inflammation or infection of the ear canal due to overexposure to water.

Temporomandibular joint (TMJ)—The joint responsible for movement of the jawbone.

recurrent. Allergy testing should be done, and then the allergens should be avoided. Alcohol, dairy products, **smoking**, **caffeine**, sugary foods, and processed foods should also be avoided to keep from stressing the immune system. One or two cloves of raw garlic daily may help end chronic episodes of earache, since garlic can kill many of the pathogens that cause earaches. If there is trouble tolerating raw garlic, a daily garlic supplement can be taken instead. Daily supplementation of **vitamin C**, **bioflavonoids**, **zinc**, and **beta carotene** is recommended to treat some of the underlying conditions causing ear pain and bolster general immune function.

Several homeopathic remedies may also be helpful in treating earaches. Depending upon the symptoms, a 6C or 12C dose of **Pulsatilla**, Mercurius, or Hepar sulphuris, or a 30C dose of **Belladonna** can be taken for up to four doses. If there is no symptom relief, a homeopath or other healthcare practitioner should be consulted.

Hydrotherapy treatment for earaches includes the use of hot compresses. To make a compress, a large cloth soaked in hot water should be placed over both ears and the throat for about five minutes. A hot water bottle or smaller compress can also be used. A new hot compress can be used every three to five minutes until the earache is relieved for a maximum of 30 minutes. This treatment is best when the feet are in a hot footbath while the compresses are being applied. Hot water can be added as needed to keep the water comfortably hot. The soak can be repeated two or three times a day as needed.

Massage such as tui na or **reflexology** can be helpful in clearing up ear pain, congestion, and TMJ dysfunction. A knowledgeable practitioner should be consulted.

Allopathic treatment

If an earache is accompanied by any of the following symptoms, a healthcare provider should be consulted as soon as possible:

- severe pain
- discharge from the ear
- a fever of 102°F (38.8°C) or higher
- a sudden change in hearing
- a sudden onset of dizziness
- an inability to concentrate
- facial muscle weakness
- the earache lasts for more than a few days
- the earache is worse during chewing
- there is sudden or severe ear pain without any other accompanying symptoms
- the earache does not respond to home treatment
- the earache appears to be getting worse
- pain, tenderness, or redness of the over the area of the mastoid process, which often indicates a serious infection

Antibiotics, decongestants, and antihistamines are often prescribed to halt the infection and inflammation that may be the cause of ear pain. The insertion of ear tubes may be recommended for children who have persistent ear infections to reestablish proper functioning of the middle ear. However, the effectiveness of this treatment is still widely debated. Repeated swallowing or gum-chewing can relieve ear pain caused by changes in pressure secondary to changes in altitude. Allowing infants and young children to suck on a bottle during descent can help relieve popping and ear pain. TMJ dysfunction should be evaluated by a dentist. Anti-inflammatory medication, tranquilizers, or muscle relaxants may be prescribed for temporary relief. Other treatments for TMJ problems include braces to correct the bite or a bite plate to wear when sleeping.

Expected results

Earaches can generally be relieved by attending to the underlying problem. Untreated problems may lead

to serious ear damage and possible **hearing loss**. Most children with chronic earaches due to infections tend to outgrow the condition.

Prevention

A hair dryer or other method should be used after swimming if there is a tendency for the ears to retain water. Earplugs should be worn while swimming and cotton or wool should be loosely inserted into the outer ear canal during showers or when the hair is being washed. Objects such as cotton swabs should not be inserted into the ear canal. A healthy immune system should be maintained to reduce the opportunity for infections.

Echinacea

Description

Echinacea, commonly known as purple coneflower, is a perennial herb of the Composite family, commonly known as the daisy family. In addition to being known as purple coneflower, this hardy plant is also sometimes called Sampson root, Missouri snakeroot, coneflower, American coneflower, and rudbeckia. The prominent, bristly seed head inspired the generic name of the plant, taken from the Greek word, *echinos* meaning hedgehog.

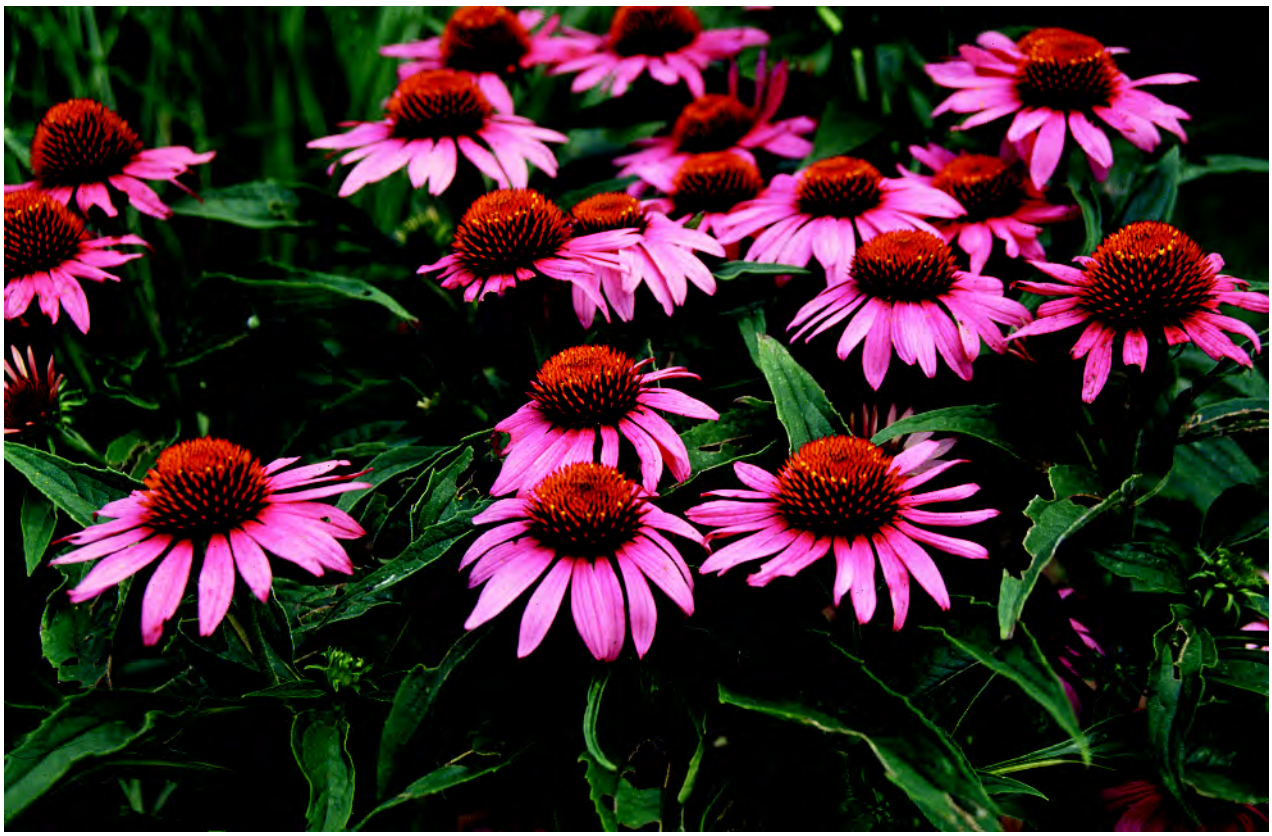
Echinacea is a North American prairie native, abundant in the mid west and cultivated widely in ornamental and medicinal gardens. The purple-pink rays of the blossom droop downward from a brassy hued center cone composed of many small, tubular florets. The conspicuous flowers bloom singly on stout, prickly stems from mid-summer to autumn. Flower heads may grow to 4 in (10 cm) across. The dark green leaves are opposite, entire, lanceolate, toothed, and hairy with three prominent veins. The narrow upper leaves are attached to the stem with stalks. The lower leaves are longer, emerging from the stem without a leaf stalk, and growing to 8 in (20 cm) in length. The plant develops deep, slender, black roots. Echinacea propagates easily from seed or by root cuttings. However, due to its increasing popularity as an herbal supplement, echinacea is numbered among the 19 medicinal plants considered at risk by the nonprofit organization United Plant Savers.

General use

Three species of echinacea are used medicinally: *Echinacea augustifolia, E. purpurea*, and *E. pallida*. The entire plant has numerous medicinal properties that act synergistically to good effect.

Native American plains Indians relied on echinacea as an all-purpose antiseptic. The Sioux valued the root as a remedy for snake bite, the Cheyenne chewed the root to quench thirst, and another tribe washed their hands in a decoction of echinacea to increase their tolerance of heat. European settlers learned of the North American herb's many uses, and soon numerous echinacea-based remedies were commercially available from pharmaceutical companies in the United States. Echinacea was a popular remedy in the United States through the 1930s. It was among many medicinal herbs listed in the *U.S. Pharmacopoeia*, the official U.S. government listing of pharmaceutical raw materials and recipes. The herb fell out of popular use in the United States with the availability of antibiotics. In West Germany, more than 200 preparations are made from the species *E. purpurea*. Commercially prepared salves, tinctures, teas, and extracts are marketed using standardized extracts. Echinacea is regaining its status in the United States as a household medicine-chest staple in many homes. It is one of the bestselling herbal supplements in the United States.

In the early twenty-first century, echinacea is most often used to boost the immune system and fight infection. Research has shown that echinacea increases production of interferon in the body. It is antiseptic and antimicrobial, with properties that act to increase the number of white blood cells available to destroy bacteria and slow the spread of infection. As a depurative, the herbal extract cleanses and purifies the bloodstream and has been used effectively to treat **boils**. Echinacea is vulnerary, promoting wound healing through the action of a chemical substance in



Echinacea, close-up of deep pink and purple coneflowers, used in herbal medicine. *(© Photo Researchers, Inc. Reproduced by permission.)*

the root known as caffeic acid glycoside. As an alterative and an immuno-modulator, echinacea acts gradually to promote beneficial change in the entire system. It has also been used to treat urinary infection and *Candida albicans* **infections**. Echinacea is a febrifuge, useful in reducing fevers. It is also useful in the treatment of **hemorrhoids**. A tincture, or a strong decoction, of echinacea serves as an effective mouthwash for the treatment of pyorrhea and gingivitis.

The various uses of echinacea were the subject of clinical research in the 2000s. Echinacea appears to be a complex plant, containing many different active substances. A study published in January 2008 stated that two different substances found in echinacea appeared to have opposite effects when applied to a certain type of human cells. Many other studies, instead of focusing on certain compounds applied to only one type of human cell, tried to evaluate echinacia's effectiveness in treating diseases and conditions for which it is commonly taken. One such study, published in 2002 in the *Annals of Internal Medicine* found that taking echinacea had no significant effect on the **common cold**. However, another study, published in 2007 found that taking echinacea reduced the likelihood of getting a common cold by 58% and decreased the average duration of the cold by 1.4 days. These types of seemingly contradictory results make echinacea research an active and strongly debated field.

In addition to investigating its effects on the common cold, researchers have studied echinacea's possible benefits for upper respiratory infections. The National Institutes of Health's National Center for Complementary and Alternative Medicine stated that research in this area was promising enough that they sponsored ongoing clinical trials of echinacea to treat upper respiratory infections. Research is also being done on the effects of echinacea on the gastrointestinal tract and its possible use to help protect the immune system during **cancer** treatment with chemotherapy.

Preparations

Decoction is the best method to extract the mineral salts and other healing components from the

coarser herb materials, such as the root, bark, and stems. It is prepared by adding 1 oz (28 g) of the dried plant materials, or 2 oz (56 g) of fresh plant parts, to one pint of pure, chlorine-free, boiled water in a non-metallic pot. The mixture is simmered for about one half hour, then strained and covered. A decoction may be refrigerated for up to two days and retain its healing qualities.

An infusion is the method used to derive benefits from the leaves, flowers, and stems in the form of an herbal tea. Twice as much fresh, chopped herb as dried herb should be used. It is steeped in one pint of boiled, chlorine-free water for 10–15 minutes. Next, it is strained and covered. The infusion is drunk warm and sweetened with honey if desired. A standard dose is three cups per day. An infusion will keep for up to two days in the refrigerator and retain its healing qualities.

A tincture is the usual method for preparing a concentrated form of the herbal remedy. Tinctures, properly prepared and stored, will retain medicinal potency for two years or more. Combine 4 oz (113 g) of finely cut fresh or powdered dry herb with one pint of brandy, gin, or vodka, in a glass container. The alcohol should be enough to cover the plant parts and have a 50/50 ratio of alcohol to water. The mixture should be placed away from light for about two weeks and shaken several times each day. It should be strained and stored in a tightly capped, dark glass bottle. A standard dose is 4 ml of the tincture three times a day.

Precautions

Echinacea is considered safe in recommended doses. Women who are pregnant or breastfeeding are generally advised not to take echinacea in injection form. Because the plant has proven immuno-modulating properties, individuals with systemic lupus erythmatosus, **rheumatoid arthritis**, **tuberculosis**, **leukemia**, **multiple sclerosis**, or **AIDS** should consult their physician before using echinacea. Echinacea should not be given to children under two years of age, and it should only be given to children over two in consultation with a physician. Research indicates that echinacea is most effective when taken at first onset of symptoms of cold or flu and when usage is continued no longer than eight weeks. There is some indication that the herb loses its effectiveness when used over a long period of time. Echinacea is believed to be more effective when use is discontinued for a period after every eight weeks of use.

Studies investigating the active ingredients in echinacea preparations available commercially have found widely varying potencies. In many cases the amount and type of echinacea contained in the product was not that specified on the label. One study even found that 10% of brands investigated contained no echinacea at all. Individuals should be sure to obtain echinacea from a trusted, reputable brand, preferably one that guarantees the amount, type, and potency of the echinacea contained in it.

KEY TERMS

Alterative—A medicinal substance that acts gradually to nourish and improve the system.

Antimicrobial—A plant substance that acts to inhibit the growth of harmful microorganisms or acts to destroy them.

Febrifuge—A plant substance that acts to prevent or reduce fever.

Glycoside—An herbal carbohydrate that exerts powerful effect on hormone-producing tissues. The glycoside breaks down into a sugar and a non-sugar component.

Lanceolate—Narrow, leaf shape that is longer than it is wide and pointed at the end.

Macrophage—Specialized cells present throughout the lymphoid tissues of the body that circulate in the bloodstream. Macrophages have a surface marker that stimulates other cells to react to an antigen.

Side effects

Most people experience no side effects when taking echinacea at recommended dosage levels. Some instances of side-effects have been reported however, including rash, temporary numbing of the tongue, and gastrointestinal problems. Echinacea may cause allergic reaction in some people. It is believed to be more likely to cause an allergic reaction in individuals who are allergic to other members of the daisy family, including daisies, marigolds, chrysanthemums, and ragweed. Individuals who have **asthma** may also be at increased risk.

Interactions

Individuals taking drugs that suppress the immune system should check with their doctor before taking echinacea. It is believed that echinacea might interact with immunosuppressant drugs, making them less effective.

Eczema

Definition

Eczema, also called atopic **dermatitis** (AD), is a noncontagious inflammation of the skin that is characteristically very dry and itchy. The condition is frequently related to some form of allergy, which may include foods or inhalants.

Description

Atopic dermatitis is sometimes described as "the itch that rashes"—the scratching of the irritated areas may very well initiate the rash in some patients. The skin of those affected by AD is abnormally dry because of excessive loss of moisture. Chronic or severe cases of it can cause the affected areas to form thick plaques (patches of slightly raised skin), develop serous (watery) exudates, or become infected.

The areas of the body that are affected by AD tend to vary with age. Children under five years old most commonly have AD, but it can occur at any age. It can be mild and intermittent, or severe and chronic. Infants frequently experience it on the face and other areas of the head. They frequently rub their heads with their hands or on the crib bedding. The stomach and limbs may also become involved. Older children commonly have the worst spots on flexor surfaces, namely the inner wrists and elbows, backs of knees, and tops of ankles. The hands and feet are other common sites. The knees, elbows, hands, and feet may continue to be a problem into adulthood.

KEY TERMS

Atopy—A group of diseases, including eczema, that develop in people with an inherited tendency to develop immediate antibodies to common environmental allergens.

Corticosteroids—A group of synthetic hormones that are used to prevent or reduce inflammation. Toxic effects may result from rapid withdrawal after prolonged use or from continued use of large doses.

Dermatitis—An irritation or imflammation of the skin.

Nummular dermatitis—A skin infection in which the areas of irritated skin are coin-shaped.

Causes and symptoms

Genetic predisposition plays a large role in who will get AD or other **allergies**. The condition is not contagious. A child who has one parent with some form of allergic, or atopic, disease has somewhere between a 25–60% chance of also experiencing allergies, whether AD or some other form. There is approximately a 50–80% chance that a child of two parents with allergies will also develop some form of atopy. The genetic predisposition of the individual, combined with such factors such as early exposure to strong antigens, will determine whether and to what extent that person will develop allergies. Aside from a predisposition to eczema, increased use of soapy detergents and baby wipes is probably responsible for higher incidence of childhood eczema as well.

The hallmark sign of AD is a red, itchy rash. The age of the patient determines what regions are most likely affected, but exceptions do occur.

Diagnosis

No laboratory test can reliably diagnose AD, although some patients will be reactive to tests

designed to diagnose allergy. These would include skin tests by intradermal injection, scratch, or patch tests. There is also a blood test available that measures levels of antibodies to suspected allergens. Diagnosis is generally made by the appearance and location of the rash. A personal or family history of allergy of any type, including food allergy, **asthma**, or **hay fever** also supports the diagnosis of AD.

Other types of dermatitis that may be described as eczematous include **contact dermatitis**, nummular dermatitis, and stasis dermatitis. The stasis type is related to poor circulation, which may also be a factor in nummular dermatitis. These forms generally occur in older adults, whereas AD is primarily a disease of children. Contact dermatitis can occur at any age. It results from skin contact with either an irritant or an allergen. The area affected is limited to the area in contact with the offending substance.

Treatment

The basis of treatment for AD is keeping the skin moist and clean, as well as avoiding irritants and known allergens as much as possible. Further measures become necessary if the case is particularly severe, or if the skin becomes infected.

Conventional wisdom has been that minimal bathing of the patient with AD is ideal. The rationale was that bathing would break down the natural oil barrier of the skin and cause further drying. It actually appears now that frequent long, tepid soaks are beneficial to hydrate the very dry skin that this condition produces. Adding a muslin bag filled with milled oats or the commercially available preparation Aveeno bath to the water can be soothing. The bath water should cover as much of the skin as possible. Wet towels may be draped around the shoulders, upper trunk, and arms if they are above the water level. The face should be dabbed frequently during bathing to keep it moist. The use of soap should be minimized, and limited to very mild agents such as Cetaphil. The bath must be followed within two or three minutes by a gentle patting dry, and a thick application of a water barrier ointment, such as Aquaphor, Unibase, or Vaseline. Lotions are not generally recommended as they almost universally contain alcohol, which is drying and may burn when applied. Soaking in plain water can be painful during severe episodes of AD. Adding one-half cup of table salt to one-half tub of water creates a normal saline solution, similar to what is naturally present in the tissues, and may relieve the burning. Commercial Domeboro powder may also be helpful.

One alternative to bathing is to use soaking wraps. For this method, cotton towels or other cloths are soaked in tepid water, with table salt or Domeboro powder added for comfort if desired. The patient's bed is covered with something waterproof, and the bare skin is covered as thoroughly as possible with the wet wrappings. The body should then be covered by a waterproof covering to slow evaporation. Vinyl sheeting and plastic wrap are two alternatives. The wraps should be left in place for as long as possible, but at least for 30 minutes, before the water barrier and any topical medications are applied.

Environmental improvement affords some relief for many patients. Pet dander and cigarette smoke are potential aggravating factors. Keeping these out of the home is probably for the best, but at minimum, they should not be allowed in the room of the allergic person. Clothing and bedding should be 100% soft cotton, and laundered in detergent with no perfumes. These items should also be washed before the initial use in order to rid them of potentially irritating residues. Clothes should fit loosely to prevent irritation from rubbing. Washing bedding in hot water will help to kill dust mites. Running laundry through a double rinse cycle will help to remove any vestiges of detergent. Avoiding the use of fabric softener or dryer sheets helps, as these are frequently scented and may be irritating. Drying clothes or bedding outdoors should be avoided, because pollen and other potential allergens are likely to cling to them. Mattresses and pillowcase can be covered by special casings that are impervious to the microscopic dust mites that infest them. Under normal circumstances, these mites cause no problem, but they can be a major irritant for the individual with asthma or AD.

Temperature extremes can make AD worse, so heating and cooling should be employed as appropriate, along with adding humidity if needed. Patients tend to have abnormal regulation of body temperature, and sometimes feel warmer or colder than other people in similar circumstances. Sweating will frequently aggravate AD. Room temperature should be adjusted for comfort. Central air conditioning is the best option for cooling the home. Evaporative cooling brings a large amount of potential irritants into the house, as do open windows. Air conditioning rather than open windows should also be used to cool the car. Electrostatic filters and vent covers are available to remove irritants from the air in the house. These should be frequently changed or cleaned as recommended by the manufacturer.

In the patient's room, dust-collecting items such as curtains, carpeting, and stuffed animals are best

minimized. Vacuuming and dusting should be done regularly when the affected person is not in the room. A HEPA filter unit, and a vacuum with a built-in HEPA filter remove a high percentage of dust and pollen from the environment.

Some simple mechanical measures will reduce the amount of skin damage done by scratching. It is important to keep fingernails short. Using a nail file will produce a smoother nail edge than scissors or clippers. It is particularly difficult to keep children from scratching irritated and itchy skin, but using pajamas and clothing with maximum skin coverage will help to protect the bare skin from fingernails. Mittens or socks may be used to cover the hands at night to reduce the effects of scratching. Infant gowns with hand coverings are useful for the very young patient.

In addition to the skin care and environmental measures to relieve eczema, there are some complementary therapies that may prove helpful.

Acupuncture

Any type of therapy that relieves **stress** can also help to manage AD. Acupuncturists also claim to be able to treat blood and energy deficiencies, and to counteract the effects of detrimental elements, including heat, dampness, and wind.

Autogenic training

Autogenic training is similar to methods of **meditation** and self-hypnosis. Instructors help the patient to achieve and maintain a relaxed state of positive concentration. This is eventually done independently. Even ten minutes of practice per day can produce beneficial results for mind and body. Research has shown AD to be one of the conditions that is improved by this technique.

Aromatherapy/massage

Massage is another therapy that can be effective in reducing stress. The oils that are used in the treatment can also make a difference in AD. Some patients get relief from the topical use of **evening primrose oil** (EPO) diluted in carrier oil. Aromatherapists may use small amounts of **essential oils** from **lavender**, bergamot, and geranium. These are promoted to decrease both **itching** and inflammation. Improper dilutions, however, can worsen the condition.

Herbal therapy

Some herbal therapies can be useful for skin conditions. Among the herbs most often recommended are:

- Calendula (*Calendula officinalis*) ointment, for anti-inflammatory and antiseptic properties.
- Chickweed (*Stellaria media*) ointment, to soothe itching.
- Evening primrose oil (*Oenograceae*) topically to relieve itching, and internally to supplement fatty acids.
- German chamomile (*Chamomilla recutita*) ointment, for anti-inflammatory properties.
- Nettle (*Urtica dioica*) ointment, to relieve itching.
- Peppermint (*Menta piperita*) lotion, for antibacterial and antiseptic properties.
- Chinese herbal medicine. In traditional Chinese medicine, there are formulas used to treat eczema that nourish the blood, moisten the skin, stop itching, and encourage healing. Some formulas are used topically and others taken internally.

There is individual variation in the effectiveness of the topical treatments. Some experimentation may help to find the combination that most benefits an individual. When the condition is chronic, severe, or infected, guidance from a health care professional should be sought before attempting self-treatment.

Hypnotherapy

Hypnotherapy has the potential to improve AD through using the power of suggestion to reduce itching. Since mechanical damage to the skin done by scratching may irritate, or actually cause, the rash, any measure that reduces scratching can prove helpful.

Nutritional supplements

There are several nutrients that can prove helpful for treating AD. Oral doses of EPO, which contains gamma-linolenic acid, have been shown to significantly reduce itching. The amount used in studies was approximately 6 g of EPO per day. **Fish oil** has also been shown to improve AD, at an approximate dose of 1.8 g per day. **Vitamin C** can affect both skin healing and boost the immune system. Doses of 50–75 mg per kilogram of body weight have been proven to relieve symptoms of AD. Additional **copper** may be required in supplemental form when high doses of vitamin C are taken. **Vitamin E** is reportedly useful, but there are no documented studies of its benefits.

Reflexology

The areas of the foot that receive attention from a reflexologist when a patient has AD include the ones relating to the affected areas of the body, as well as

those for the solar plexus, adrenal glands, pituitary gland, liver, kidneys, gastrointestinal tract, and reproductive glands.

Allopathic treatment

Allopathic treatment involves use of oral antihistamines to decrease itching, topical water barriers, mild topical corticosteroids when indicated, and topical antibiotics if needed. The water barrier should be applied generously; the corticosteroids and antibiotics used sparingly, and only on areas where indicated. The person applying the topical medications can wear gloves to minimize exposure to the steroids and antibiotics. Oral antibiotics may also be used when widespread infection is present. On rare occasions, oral corticosteroids are prescribed to reduce severe itching and inflammation, but this course is best avoided due to its potential side effects. In 2001, the U.S. Food and Drug Administration (FDA) approved a new nonsteroid prescription cream for patients age two and older called Elidel.

Expected results

There is no cure for AD, although most patients will experience improvement with age. Perhaps half of children will have no further trouble past the age of five years. However, as many as 75% of those who have AD in childhood will go on to have other allergic manifestations such as asthma, food allergies, and hay fever. Diligent daily care of the skin and avoidance of known triggers will control most cases of AD to a large extent.

Prevention

One of the best things a mother can do to help keep her child from getting AD is to breastfeed. It is best for the baby to have breast milk exclusively for at least six months, particularly when there is a family history of AD or other types of allergy. There also appears to be an advantage to the breastfeeding mother avoiding foods known to be commonly allergenic, particularly if there is a family history. This would include wheat, eggs, products made from cow's milk, peanuts, and fish. If breastfeeding is not possible, a hypoallergenic formula should be used if there is family history of allergy. Consult a health care provider for help with determining the best type.

The patient already diagnosed with AD can minimize flare-ups by avoiding known triggers and following the skin care program outlined above. It is important to continue to follow guidelines for a daily emollient routine (moistening skin twice daily) even when skin is under control to prevent flare-ups. Eczematous skin is also more susceptible to **infections**. Patients should try to stay away from people with chicken pox, cold sores, and other contagious skin infections.

Edema

Definition

Edema is a condition of abnormally large fluid volume in the circulatory system or in tissues between the body's cells (interstitial spaces).

Description

Normally the body maintains a balance of fluid in tissues by ensuring that the same amount of water entering the body also leaves it. The circulatory system transports fluid within the body via its network of blood vessels. The fluid, which contains oxygen and nutrients needed by the cells, moves from the walls of the blood vessels into the body's tissues. After its

nutrients are used up, fluid moves back into the blood vessels and returns to the heart. The lymphatic system (a network of channels in the body that carry lymph, a colorless fluid containing white blood cells to fight infection) also absorbs and transports this fluid. In edema, either too much fluid moves from the blood vessels into the tissues, or not enough fluid moves from the tissues back into the blood vessels. This fluid imbalance can cause mild to severe swelling in one or more parts of the body.

KEY TERMS

Digitalis—A naturally occurring compound used in the preparation of the medication digoxin, prescribed to increase the heart rate and strengthen the force of the heart's contractions.

Diuretics—Medications used in the treatment of fluid overload to promote excretion of sodium and water.

Interstitial spaces—Areas of the body occurring outside the vessels or organs, between the cells.

Pitting edema—A swelling in the tissue under the skin, resulting from fluid accumulation, that is measured by the depth of indentation made by finger pressure over a boney prominence.

Causes and symptoms

Many ordinary factors can upset the balance of fluid in the body to cause edema, including:

- Immobility. The leg muscles normally contract and compress blood vessels to promote blood flow with walking or running. When these muscles are not used, blood can collect in the veins, making it difficult for fluid to move from tissues back into the vessels.
- Heat. Warm temperatures cause the blood vessels to expand, making it easier for fluid to cross into surrounding tissues. High humidity also aggravates this situation.
- Medications. Certain drugs, such as steroids, hormone replacements, nonsteroidal anti-inflammatory drugs (NSAIDs), and some blood pressure medications may affect how fast fluid leaves blood vessels.
- Intake of salty foods. The body needs a constant concentration of salt in its tissues. When excess salt is taken in, the body dilutes it by retaining fluid.
- Menstruation and pregnancy. The changing levels of hormones affect the rate at which fluid enters and leaves the tissues.

Some medical conditions may also cause edema, including:

- Heart failure. When the heart is unable to maintain adequate blood flow throughout the circulatory system, the excess fluid pressure within the blood vessels can cause shifts into the interstitial spaces. Left-sided heart failure can cause pulmonary edema, as fluid shifts into the lungs. The patient may develop rapid, shallow respirations, shortness of breath, and a cough. Right-sided heart failure can cause pitting edema, a swelling in the tissue under the skin of the lower legs and feet. Pressing this tissue with a finger tip leads to a noticeable momentary indentation.
- Kidney disease. The decrease in sodium and water excretion can result in fluid retention and overload.
- Thyroid or liver disease. These conditions can change the concentration of protein in the blood, affecting fluid movement in and out of the tissues. In advanced liver disease, the liver is enlarged and fluid may build up in the abdomen.
- Malnutrition. Protein levels are decreased in the blood, and in an effort to maintain a balance of concentrations, fluid shifts out of the vessels and causes edema in tissue spaces.

Some conditions that may cause swelling in just one leg include:

- Blood clots. Clots can cause pooling of fluid and may be accompanied by discoloration and pain. In some instances, clots may cause no pain.
- Weakened veins. Varicose veins, or veins whose walls or valves are weak, can allow blood to pool in the legs. This is a common condition.
- Infection and inflammation. Infection in leg tissues can cause inflammation and increasing blood flow to the area. Inflammatory diseases, such as gout or arthritis, can also result in swelling.
- Lymphedema. Blocked lymph channels may be caused by infection, scar tissue, or hereditary conditions. Lymph that can not drain properly results in edema. Lymphedema may also occur after cancer treatments, when the lymph system is impaired by surgery, radiation, or chemotherapy.
- Tumor. Abnormal masses can compress leg vessels and lymph channels, affecting the rate of fluid movement.

Symptoms vary depending on the cause of edema. In general, weight gain, puffy eyelids, and swelling of the legs may occur as a result of excess fluid volume. Pulse rate and blood pressure may be elevated. Hand and neck veins may be observed as fuller.

Diagnosis

Edema is a sign of an underlying problem, rather than a disease unto itself. A diagnostic explanation should be sought. Patient history and presenting symptoms, along with laboratory blood studies, if indicated, assist the health professional in determining the cause of the edema.

Treatment

Simple steps to lessen fluid build-up may include:

- reducing sodium intake
- maintaining proper weight
- exercise
- elevation of the legs
- use of support stockings
- massage
- travel breaks

Nutritional therapy

A naturopath or a nutritionist may recommend the following dietary changes:

- Reduction of salt intake, including salty foods such as olives, soy sauce, or pickles. Cutting back the amount of sodium eaten may help reduce edema.
- Limited use of alcohol, caffeine, sugar, and dairy products.
- Increased consumption of whole grain foods, cucumbers, apples, potatoes, grapes, onions, cabbage, and oranges.
- Daily vitamin and mineral supplements.

Herbal therapy

Diuretic herbs can also help relieve edema. One of the best herbs for this purpose is **dandelion** (*Taraxacum mongolicum*), since, in addition to its diuretic action, it is a rich source of **potassium**. (Diuretics flush potassium from the body, and it must be replaced to avoid potassium deficiency.)

Hydrotherapy

Hydrotherapy using daily contrast applications of hot and cold (either compresses or immersion) may also be helpful.

Other alternative treatments

Other alternative therapies may also reduce edema. They include **traditional Chinese medicine**, Ayurveda, juice therapy, and bodywork. Traditional Chinese medicine and **acupuncture** have an elaborate diagnostic system to determine the pattern causing the edema. Thus treatment, if done correctly, results not only in the removal of fluid, but also with the correction of the problem.

Allopathic treatment

The three "Ds"—diuretics, **digitalis**, and diet—are frequently prescribed for medical conditions that result in excess fluid volume. Diuretics are medications that promote urination of **sodium** and water. Digoxin is a digitalis preparation that is sometimes needed to decrease heart rate and increase the strength of the heart's contractions. One dietary recommendation includes less sodium in order to decrease fluid retention. Consideration of adequate protein intake is also made.

For patients with lymphedema, a combination of therapies may prove effective. Combined decongestive therapy includes the use of manual lymph drainage (MLD), compression bandaging, garments and pumps, and physical therapy.

Elder

Description

Gaining popularity in modern times as a cold and flu medicine, elder flower has been an important folk remedy for centuries. The Roman naturalist Pliny wrote about the therapeutic value of this flowering tree in the first century A.D. Native Americans used elder as a treatment for respiratory **infections** and **constipation** as well as an herbal pad for healing **wounds**. Black elder (*Sambucus nigra*) is the most popular variety of the plant, though there are other species known to have similar chemical ingredients. Elder grows in Europe, Asia, North Africa, and the

Elderflowers. *(©PlantaPhile, Germany. Reproduced by permission.)*

United States. Most medicinal elder is obtained from the former Soviet Union, Eastern Europe, and the United Kingdom. The Latin word *sambucus* is thought to be derived from the Greek *sambuca*, which refers to a stringed musical instrument popular among the Ancient Romans. In fact, some modern day Italians still make a primitive pipe called a *sampogna* from the branches of the tree, which also produces fragrant, cream-colored flowers and deep-violet berries. The flowers and berries are used most often in the drug of commerce, though the leaves, bark, and roots are also considered to have therapeutic effects. The berries traditionally have been used to make elderberry wine as well as pies and jellies, although no value has yet been found in these products.

The German Commission E, considered an authoritative source of information on alternative remedies, determined that elder has the ability to increase bronchial secretions as well as perspiration. These properties can be useful in helping to alleviate symptoms of the **common cold** or the flu. Even more interesting is the possibility that elder, like another herbal remedy called **echinacea**, may have the power to shorten the duration of colds by up to a few days. While it is not known exactly how elder produces its therapeutic effects, study has focused on several naturally occurring chemicals in the plant. Elder's flavonoids and phenolic acids are thought to be responsible for its ability to increase perspiration. The triterpenes in elder may also be potential active ingredients, though more study is required to confirm this. The remaining chemical constituents of medicinal elder usually include **potassium** and other minerals; sterols; volatile oils containing linoleic, linolenic, and palmitic acid; mucilage; pectin; protein; sugar; and tannins.

A number of other properties have been ascribed to elder as well, including anti-inflammatory, diuretic, antiviral, and antispasmodic activities. A 1997 study published in the *Journal of Ethnopharmacology*, which studied black elder in the test tube, indicates that the herb has some activity as an anti-inflammatory. While this may help to partially explain elder's success in treating colds, it also suggests that the herb may have potential as a treatment for inflammatory diseases such as rheumatism. Elder has also been described in the history of folk medicine as a laxative and a sedative.

General use

While not approved by the U.S. Food and Drug Administration (FDA), black elder flower is primarily used in the United States and Europe for colds and the flu. When taken internally, elder flower is approved by the Commission E for colds. In Germany, elder flower tea is licensed by the government to treat the common cold and other upper respiratory problems. By increasing bronchial secretions as well as perspiration, elder is believed to help ease symptoms such as **cough** and **fever** and may even shorten a cold's duration. In the United States and Canada, elder is often combined with **peppermint** leaf and **yarrow** flower in preparations intended to alleviate cold-related fever.

In a study published in the *Journal of Alternative and Complementary Medicine* in 1995, use of a standardized elderberry extract shortened the duration of the flu by about three days. The placebo-controlled, double-blind study involved the residents of an Israeli kibbutz. "A significant improvement of the symptoms, including fever, was seen in 93.3% of the cases in the SAM-treated group [elder-treated group] within 2 days," the researchers reported, "whereas in the control group 91.7% of the patients showed an improvement within 6 days." About 90% of the people treated with elder were considered flu-free in two to three days, while the majority of patients in the

KEY TERMS

Antispasmodic—An agent with the ability to prevent or relieve convulsions or muscle spasms.

Diuretic—An agent that increases the production of urine.

Echinacea—A popular herbal remedy used to treat colds, the flu, and urinary tract infections.

Edema—Abnormal swelling of tissue due to fluid buildup. Edema, which typically occurs in the legs, liver, and lungs, is often a complication of heart or kidney problems.

placebo group only got well after about 6 days. The authors of the study recommended elder as a possible treatment for **influenza** A and B based on the herbal remedy's effectiveness, lack of side effects, and low cost. By way of comparison, over-the-counter synthetic drugs may offer some measure of symptomatic relief for a cold but have not been proven to actually speed recovery. Elder is also being investigated as a treatment for other viral infections such as human immunodeficiency virus (HIV) and herpes.

Throughout its long history, elder has been used to treat a variety of other diseases and medical problems. These include liver disease, kidney disorders, rheumatism, **insomnia**, toothaches, **measles**, **asthma**, **cancer**, chafing, **epilepsy**, **gout**, headaches, **neuralgia**, **psoriasis**, **syphilis**, and **laryngitis**. It has also been used topically as an herbal pad to reduce external swelling and heal wounds. Some women have used elder to increase the amount of milk produced during breastfeeding. However, sufficient scientific evidence to support these additional uses is lacking. While elder has been used as a folk remedy for treating diabetes, studies in rodents suggest that it has no effects on blood sugar regulation.

Preparations

Dosage of elder generally ranges from 10-15 g per day, divided into three equal doses. The drug, which is recommended for internal use only, is usually taken as a tea or liquid extract. Elder tea can be prepared by steeping 3-4 g (2 teaspoonfuls) of dried elder flower in 150 ml of hot (not boiling) water. The mixture should be strained after about 5 minutes. The tea works best when it is consumed at a temperature as hot as can be safely tolerated. Dosage is several cups of tea a day (do not exceed the daily maximum of 15 g of elder), taken in the afternoons and evenings. When using a standardized liquid extract of elder, follow the package directions for proper use.

Precautions

Taken in recommended dosages, elder is not known to be harmful. It should be used with caution in children, women who are pregnant or breastfeeding, and people with kidney or liver disorders because its effects in these groups has not been sufficiently studied.

Be careful not to confuse black elder with a more toxic species of the plant called dwarf elder (*Sambucus ebulus*). Dwarf elder is generally not recommended for medical purposes and may cause **vomiting** and **diarrhea** in large dosages.

Side effects

Side effects are considered rare. Mild abdominal distress or allergic reactions may occur.

Interactions

Elder is not known to interact adversely with other medications or herbal remedies. Preparations that combine elder with yarrow flower and peppermint leaf have been used without apparent harm.

Greg Annussek

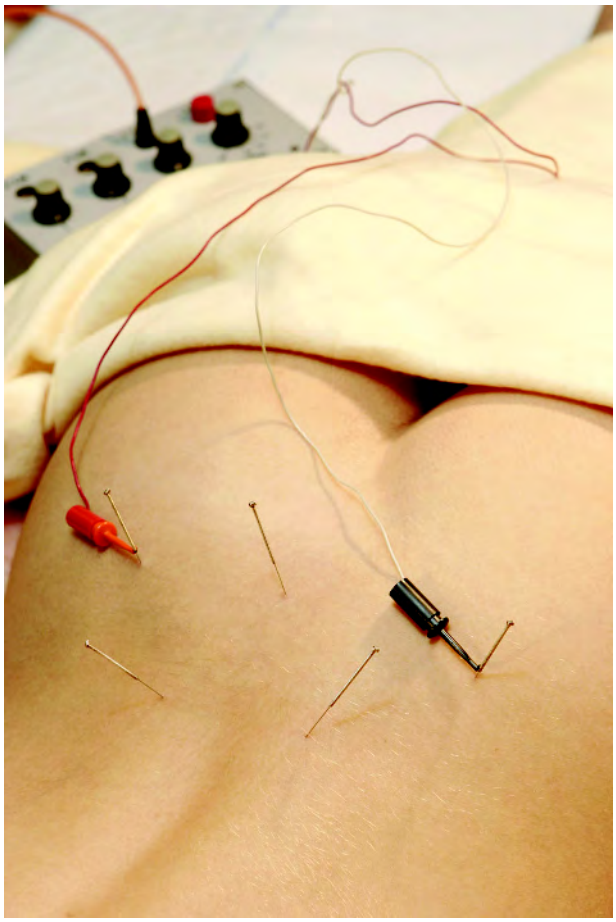
Electroacupuncture

Definition

Electroacupuncture is an **acupuncture** technique that applies small electrical currents to needles that have been inserted at specific points on the body.

Origins

Acupuncture originated thousands of years ago in China as a healing technique. Electroacupuncture was developed in 1958 in China, when acupuncturists there began experimenting with it as surgical anesthesia, or **pain** control. After several years of testing during surgery, acupuncturists began applying electroacupuncture in clinical practice for many conditions.



Electroacupuncture. *(© Peter Banos / Alamy)*

KEY TERMS

Anesthesia—Method of controlling pain during surgery.

Epilepsy—Condition characterized by sudden seizures and other symptoms.

Pacemaker—Device that is surgically implanted in patients with heart disease or disorders, that regulates the beating of the heart.

Benefits

Electroacupuncture can be used to treat the same variety of health conditions that regular acupuncture treats, and for conditions that do not respond to conventional acupuncture. It is effectively used as surgical anesthesia, as a means of reducing chronic pain and **muscle spasms**, and as a treatment for neurological (nerve) disorders.

Description

Acupuncturists begin treatment by diagnosing a patient. Diagnosis is performed with interviews, close examinations (such as of the tongue and **pulse diagnosis**), and other methods. Acupuncture strives to balance and improve the flow of *chi*, or life energy, which travels throughout the body in channels called *meridians*. According to **traditional Chinese medicine** (TCM), illness is caused when chi does not move properly in the body. Acupuncturists are trained to determine where chi is stagnated, weak, or out of balance, which indicates where and how acupuncture points on the body should be stimulated. Electroacupuncture is often recommended for cases of accumulation of chi, such as in chronic pain, and in cases where the chi is difficult to prompt or stimulate.

Patients usually lie down for acupuncture treatment. Thin, sterilized needles are used, and the surface of the skin where they will be inserted is sterilized, as well. One advantage of electroacupuncture is that the margin of error for needle placement is greater than for regular acupuncture, because the electrical current stimulates a larger area around the needle. Electroacupuncture works with two needles at a time, in order for electrical current to pass through the body from one needle to another. Small devices are used to create and regulate a pulsing electric charge, which is

REINHOLD VOLL (1909-1989)

German physician Reinhold Voll initially studied architecture in school and had no intention to become a physician. He decided to study medicine when various treatments to restore the health of his father failed. He spent much of his early career specializing in tropical diseases, sports medicine, and public health, and set up a practice in Plochingen in southern Germany. He was introduced to methods of Chinese acupuncture by a doctor who worked in the tropics and was a firm believer in the practice. By the 1950s, Voll was engaging in the ancient Chinese practice. He had an idea that modern technology might enhance acupuncture in the treatment of various chronic diseases such as allergies, chronic fatigue, migraines, and chronic liver, kidney or pancreatic diseases. His research led him to electroacupuncture (EAV), using electric currents to enhance manipulation of the traditional acupuncture points. In addition to that, he realized there were even more points, or meridians, that corresponded directly with particular organs. Voll then developed a system to measure the degree of inflammation these organs suffered.

Voll focused on certain criteria by which to treat these points. He determined that conditions were either inflammable, chronic, or subchronic. By the use of nosodes, remedies composed of bacteria or viruses, and based on the causes of those diseases and using other homeopathic agents, he was able to test for drugs before the patient ingested them. It was Voll who also discovered the relationship between teeth and the inner organs, an important key to understanding health and disease.

The Institute for ElectroAcupuncture & ElectroDiagnostics is based on Voll's original methods and is located in Munich, Germany. The website for additional information can be located at: http://www.eavnet.com.

sent to the needles by attaching small clips to their ends. The electric charge is very small, and can be adjusted by the acupuncturist or patient. Both the voltage (intensity) and the frequency of the electric charge can be adjusted for healing effects. Voltage levels should be raised slowly. Several pairs of needles may be stimulated at one time, for up to 30 or more minutes of electrical stimulation along the meridians. Another similar, though conventional, medical technique is called transcutaneous electrical nerve stimulation (TENS), which uses electrodes that are taped to the surface of the skin instead of attached to inserted needles, which may be advantageous for patients for whom needles pose risks or problems. This technique stimulates along nerve and muscle groups.

Precautions

Electroacupuncture should not be used on people who have seizures, **epilepsy**, histories of **heart disease** or strokes, or on those with heart pacemakers. Electroacupuncture should not be performed on the head, throat, or directly over the heart, and should be performed with care on spastic muscles. Another recommended precaution is that electrical current should not be sent across the midline of the body, which is the line running from the nose to the navel.

Side effects

During electroacupuncture, patients report sensations of tingling, warmth, and mild aches. Bruising and bleeding may occur, as the needles may hit small blood vessels.

Elimination diet

Definition

An elimination diet functions as a test, determining whether patients may have a sensitivity to certain foods. Elimination diets are used to detect food **allergies** and food intolerances. They are not nutritionally balanced and are intended to be used only for

diagnostic purposes. Initially, patients stop eating foods suspected of causing illness. Then, after a suitable period of time (often 10–14 days), they review their symptoms. If significant improvement has occurred, it is assumed that an allergy or intolerance to certain foods may be involved. These suspect foods are then reintroduced to the diet, one by one. When symptoms return (usually within three days), the problematic food is identified and removed from the diet.

Benefits

Elimination diets are potentially useful in identifying hard-to-detect food intolerances that proponents believe are responsible for a wide range of ailments, including **constipation**; headaches or migraine; **infections** of the ear or sinuses; frequent colds, post nasal drip, chronic nasal congestion, sore throats or chronic **cough**; **eczema**, **hives**, or **acne**; **asthma**; **pain** or stiffness in the muscles or joints; heart palpitations; **indigestion**; ulcers of the mouth, stomach, or duodenum; **Crohn's disease**; **diarrhea**; yeast infections; urticaria; **edema**; **depression** or **anxiety**; hyperactivity; weight change; and generalized **fatigue**.

Description

A true elimination diet is very rigorous and needs to be implemented under the direction of a physician often in consultation with a dietitian or nutritionist. For the elimination diet to be useful, the patient must follow the diet strictly. Cheating invalidates the results.

For two to three weeks, a person on the elimination diet eats absolutely none of the following foods (this list may be modified by the physician):

- Additives: monosodium glutamate, artificial preservatives, sweeteners, flavors, or colors
- Alcohol: beer, ale, stout, porter, malt liquors, wine, coolers, vodka, gin, rum, whiskey, brandy, liqueurs, and cordials
- Citrus fruits: oranges, calamondins, tangerines, clementines, tangelos, satsumas, owaris, lemons, limes, kumquats, limequats, and grapefruit
- Commonly eaten foods: anything consumed more than three times weekly, as well as foods that are craved or that cause a feeling of weakness
- Corn: as well as corn syrup or sweetener, corn oil, vegetable oil, popcorn, corn chips, corn tortillas
- Dairy products: milk, milk solids, cheese, butter, sour cream, yogurt, cottage cheese, whey, and ice cream
- Eggs: both yolks and whites
- Gluten: any pasta, breads, cakes, flour, or gravies containing wheat
- Honey
- Maple syrup
- Sugar: candy, soft drinks, fruit juices with added sugar or sweetener, cakes, cookies, sucrose, fructose, dextrose, or maltose

Foods that may be allowed include:

- Cereals: puffed rice or millet, oatmeal, or oat bran
- Daily multivitamin: this is especially important during extended dieting, to replace missing nutrients
- Fats and oils: soy, soy milk, soy cheese, sunflower oil, safflower oil, flaxseed oil, olive oil, and sesame oil
- Fruits and vegetables: typically, anything except corn and citrus fruits. Some practitioners suggest fruit be consumed in moderation and preferably whole as opposed to juices.
- Grain and flour products: rice cakes or crackers, rye or spelt bread (both must be 100% with no added wheat), kasha, rice, amaranth, quinoa, millet, oriental noodles, other exotic grains
- Legumes: soybeans, string beans, black beans, navy beans, kidney beans, peas, chickpeas, lentils, tofu. Canned beans should be avoided unless they are free of preservatives and sugar.
- Seeds and nuts: must not contain sugar or salt. Nut butters are allowed if they meet this requirement and are organic.
- Water: two quarts daily. Preferably bottled, as tap water contains potential allergens, including fluoride and chlorine.
- Other: white vinegar, salt, pepper, garlic, onions, ginger, herbal teas, coffee substitutes, spices or condiments (mustard, ketchup) that are free from sugar, preservatives, and citrus. These products can commonly be found at health food stores.

The individual must avoid all medicines containing aspirin (salicylates) and food colorings. After several weeks on these restricted foods, one new food is introduced in larger than normal amounts. This is the challenge food, and it is eaten for three days in a row. If no symptoms appear, the dieter continues to eat that food in normal amounts and adds another challenge food. If symptoms appear, the challenge food is stopped immediately and no new challenge food is introduced until symptoms disappear. During this time the dieter keeps a food journal, writing down everything that is eaten and any symptoms, either physical or emotional, that appear. It can take two to three months to work through all challenge foods.

Precautions

As with all therapies, anyone considering an elimination diet should consider the potential benefits against the risks. The decision, according to some, is comparable to deciding to take a prescribed medication and should be done only under the supervision of a competent medical practitioner.

Anyone suspected of having a moderate to severe food allergy should be under the care of a physician. Any food challenging must be done in a healthcare setting, as severe reactions can cause anaphylactic shock and death.

A serious risk of self-administered elimination diets is that people who self-diagnose symptoms as food intolerances using a non-medically supervised elimination diet may be ignoring symptoms of more serious and progressive diseases such as **celiac disease**, Crohn's disease, gastroesophageal reflux disease, **irritable bowel syndrome**, and other health problems that need medical treatment.

Patients need to know that following a strict elimination diet is not an easy matter. It is extremely important to read packaged-food labels carefully because many processed foods contain monosodium glutamate, sugar, and other substances that may be prohibited. It is almost impossible for elimination-diet patients to eat in restaurants, at school, or at the homes of friends. The resulting isolation must be considered as part of the decision to undertake an elimination diet. Patients should also consider whether they have sufficient time for the extra planning, shopping, and food preparation involved.

Elimination-diet patients should be vigilant to replace any nutrients missing from their restricted diet. For example, **calcium** supplements may be advisable for someone eliminating dairy products from the diet. Any prescribed medications should be continued during any diet.

Putting a very young child on an elimination diet may endanger the child's **nutrition** and normal growth. A breastfeeding mother may harm both her own health and that of her infant if she undertakes an elimination diet during lactation.

Side effects

The most significant side effects of an elimination diet are nutritional disorders resulting from a prolonged, highly restrictive diet, and the risk of a serious reaction as suspect foods are reintroduced to the diet. Some proponents also caution that patients consuming a very limited variety of foods risk becoming allergic to those very foods. For these reasons, professional supervision and substitution of missing nutrients are both essential.

KEY TERMS

Anaphylactic shock—An extreme allergic reaction characterized by swelling, constriction in the bronchi, circulatory collapse, heart failure, and even death.

Urticaria—Itchy pustules that may be caused by a hypersensitivity to food, drugs, or other substances.

Research and general acceptance

Elimination diets are widely used by medical doctors, but considerable differences of opinion exist over the range of illnesses that may be caused by food allergies or intolerances. Many physicians and researchers question the role of allergies in migraine, **rheumatoid arthritis**, **osteoarthritis**, and other conditions. Some doctors suggest that elimination diets should be used only after other diagnostic methods have been tried, including history-taking, skin tests, blind food challenges, and radioallergosorbent testing.

Training and certification

Because of the risks involved, elimination diets should be undertaken only under competent medical supervision. Some patients may wish to consult an allergy specialist.

Emphysema

Definition

Emphysema is a progressive, incurable chronic lung condition that usually develops after many years of tobacco **smoking** or exposure to air-borne pollutants. The air sacs (alveoli) at the end of the bronchial tubes are destroyed, and oxygen uptake is restricted due to the loss of elasticity of lung tissue.

Description

Emphysema frequently occurs with one or more other respiratory diseases, such as **bronchitis** and **asthma**. It is one of those diseases that are collectively referred to as chronic obstructive pulmonary disease (COPD).

Normally functioning lungs are elastic and efficiently expand and recoil as air passes freely through their passageways (bronchi) to the alveoli, where oxygen is moved into the blood and carbon dioxide is filtered out. When individuals inhale cigarette smoke or air-borne pollutants, their immune system responds by releasing substances that are meant to defend the lungs against the smoke. These substances can also attack the cells of the lungs, but the body normally inhibits such action with the release of other substances.

When individuals are exposed to air pollution or occupational pollutants over a long period of time, the lung tissue becomes damaged in such a way that it loses its elasticity. When damage has occurred to the alveoli, patients have difficulty making a complete exhalation, which causes residual volume (air trapped inside the lungs). With the passage of time, this residual volume causes the chest to permanently expand and become barrel shaped. As the disease progresses, increasingly more effort is needed to breathe.

Demographics

As reported by the American Lung Association, approximately 4.1 million Americans were diagnosed with emphysema in 2006, and 93% were aged 45 or older. This group included an estimated 3.7 million Caucasians and 193,000 African Americans affected by the condition. Men have a higher prevalence of emphysema than women; with 2.5 million men affected compared to 1.6 million women, as reported in 2006.

Every year, approximately 100,000 people die of the disease, making it the fourth largest cause of mortality in the United States (after **heart disease**, **cancer**, and **stroke**), according to the National Emphysema Foundation.

Giant bullous emphysema is a rare type of emphysema of unknown origin that affects young men, usually smokers. It is characterized by large (>1 cm in diameter) bullae in the alveoli of the upper lobes that greatly increase the risk of pneumothorax (collapsed lung). Bullae are round bubbles or air cavities that expand from beneath the pleura (thin membranes that line the lungs) and put pressure on the lungs, causing severe lung dysfunction. A giant bulla is defined as taking up one-third or more of the space in and around the affected lung. Surgical treatment is usually required to treat this type of emphysema.

Causes and symptoms

Causes

Smoking is the primary cause of emphysema. Environmental exposure and genetic factors are other contributing factors.

GENETICS. An inherited disorder called alpha 1-antitrypsin (AAT) deficiency can increase the risk of emphysema. AAT is a protein produced in the liver that is transported to the lungs to aid proper breathing function and to reduce inflammation. In people with AAT deficiency, the liver produces little or no AAT to offer these protective properties, which can lead to alveoli damage and restricted oxygen uptake.

ENVIRONMENTAL EXPOSURE. Emphysema has traditionally been a disease suffered by miners, particularly coal miners, as the fine dust that results from mining attacks the alveoli over time. Most miners develop emphysema to some degree after a lifetime in the mining pit. In fact, emphysema is sometimes referred to as miner's lung or black lung. Due to awareness of the causes of emphysema and improved working conditions for many miners, the incidence of emphysema has somewhat decreased in this population.

Any worker who is exposed to abnormal levels of dust, fumes, smoke, gases, vapors or mists over a long period of time may be at risk for emphysema. This group of workers includes sand blasters and metal grinders, as well as individuals who are exposed at work to **silica** (silicosis), asbestos (asbestososis), or **iron** filings (siderosis). In addition, dust from wood, cotton, talc, cereal grains, coffee, pesticides, drug or enzyme powders, or fiberglass may cause emphysema. People who use their lungs in their work are also susceptible (such as trumpet players and glass blowers).

People who develop emphysema as a result of their work often develop asthma prior to emphysema.

Symptoms

People with emphysema typically complain that they cannot get enough air as stale air builds up inside the lungs and the person is starved of oxygen. Coughing, **wheezing** and chronic mucus production, blueness of the lips and fingernails, and exhaustion are common symptoms.

Diagnosis

A diagnosis of emphysema is not made on the basis of symptoms alone. A detailed medical history is taken along with x rays and pathology examinations. Diagnostic tests may include:

- chest x ray
- pulmonary function tests (also called spirometry) to determine air flow in the lungs and the movement of oxygen in the blood
- pulse oximetry to measure blood oxygen saturation
- arterial blood gas test to determine the amount of oxygen and carbon dioxide in the blood
- exercise testing to determine if the oxygen level in the blood drops during exercise
- electrocardiogram to rule out heart disease as a cause of shortness of breath

Treatment

Damage to the lungs as a result of emphysema cannot be reversed, so preventative measures to limit its progression are essential. The following measures and treatments are regarded as beneficial for emphysema patients.

Herbalism

Herbs can be beneficial in relieving the symptoms of emphysema, helping the body to ward off infection, and easing the asthmatic symptoms that often accompany emphysema.

Some beneficial herbs are:

- Lobelia: This is a mild sedative, also having strong expectorant properties. It is widely used for chest complaints, including emphysema and bronchitis, and can help to shorten an asthma attack.
- Thyme: A tea made with thyme is recommended for overcoming shortness of breath. It is also a powerful antiseptic.
- Mullein: This is another traditional remedy for chest complaints. To make a tea, boil two tablespoons of the dried leaves with a glass of milk and drink the mixture.
- Echinacea: Echinacea is a powerful immune system stimulant and strengthens the body in general, warding off colds and infections.
- Lungwort: A member of the borage family, this herb is very healing for the lungs. It should be taken as an infusion.
- Black cohosh: This herb is an expectorant and astringent. It relieves coughing.
- Sage: This is one of the most useful of all herbs and is said to be good for whatever it is taken for. It is antiviral and bactericidal.
- Garlic: A very powerful anti-viral, garlic can be of real help to those trying to avoid infections and lung congestion.

Chinese herbal medicine

Qing Qi Hua Tan Wan (**Pinellia** expectorant pills) are the Chinese herbalists' treatment for chronic lung complaints, particularly bronchitis and asthma.

Juices for emphysema

Kitty Campion, a British naturopathic herbalist expert, recommends the following juices for the treatment of emphysema: equal parts of carrot juice, parsnip juice, watercress juice, and potato juice, or equal parts of orange juice and lemon juice, diluted half and half with a strong decoction of rosehip tea.

Aromatherapy

Aromatherapy involves massaging the patient with potent plant **essential oils**, which have been proven to enter the circulation through the skin. The constituents of the oils can have a powerful effect on a variety of illnesses, but since their beneficial qualities are also transported through the air, they are considered to be doubly beneficial to those who have respiratory ailments.

Aromatherapy oils for respiratory disease:

- *Canada balsam* may alleviate respiratory symptoms and is an expectorant. It is also a bactericide and recommended for those with chronic chest ailments.
- *Tolu balsam* is an excellent treatment for chest infections.
- *Frankincense* is good for infection and catarrhal discharge.

- *Niaouli* is a very strong antiseptic and beneficial for pulmonary trouble.
- *Rose damascena* is recommended for bronchial complaints, and it also lifts the spirits.
- *Tea tree oil* is one of the most potent anti-viral, anti-bacterial and anti-fungal agents known to herbal medicine, therefore, highly beneficial as a preventative measure against chest infection.

Acupuncture

This ancient Chinese system of holistic treatment works on the principal that illness is the result of blockage in the flow of life force. The practitioner aims to stimulate relevant meridians in the body and thus release trapped life force, returning bodily functions to normal. The treatment is virtually painless.

Treatment can be expected to improve blood circulation and the capacity of the body to restore itself. Research has indicated that **acupuncture** can produce changes in the electrical fields of body cells, which promote a return to the body's normal state. Consequently, few negative side effects are associated with acupuncture treatment.

Breathing techniques

Very few people actually breathe correctly, and if lung function is not up to par, the difference between breathing fully and taking shallow, ineffective breaths can make a remarkable difference to the way persons feel and their bodies functions. Oxygen shortage in the body promotes disease, and ensuring that oxygen levels are kept up can avert disaster, even with the existence of lung-impairment. Improved breathing techniques can rid the body of free radicals, neutralize environmental toxins, and destroy many harmful microbes that cannot exist in an oxygen-rich environment. Without sufficient oxygen, the body cannot fully utilize nutrients from food, and bodily functions generally become less efficient, so every effort must be made to promote proper breathing, in order to offset the effects of reduced lung function.

In cases of emphysema, it is particularly important to ensure that the out breath expels all of the previous in-breath. When exhalation is incomplete wastes produced by breathing are not expelled from the body in the normal way and residual volume, which is a common occurrence with progressive emphysema, may cause chest enlargement.

Postural positions can help manage shortness of breath by relieving strain on the upper chest. When sitting, patients can lean forward slightly, resting the elbows on the knees. When lying down, the patient can rest on his side with a pillow between his legs and his head elevated with pillows.

Homeopathy

Homeopathy is the treatment of illness according to a system of "like cures like" that stimulates the body to heal itself. While it could definitely contribute to the successful treatment of emphysema, homeopathy requires a qualified practitioner, as the patient's condition must be accurately assessed so that the correct remedy can be prescribed. Even for the same disorder, no two patients receive the same treatment.

Lifestyle

For lung dysfunction of any kind, it is vital to take steps to ensure that a person's lifestyle is not contributing to the problem. Pollution must be avoided at all costs, and steps should be taken to ensure that the living environment is free of chemical irritants, which may involve avoiding fragrances, as they can overburden damaged lungs. Some unscented products use a masking fragrance, which only increases toxicity. Common household products, such as fabric softeners, bleach, scented detergents, and furniture polish, can harm the body and the environment.

It must be noted that pesticides, fungicides, herbicides, and fertilizers are all neurotoxins (poisonous to the nervous system). Natural alternatives are obtainable for most household cleaning products. Personal care products can also cause damage, so only natural sources should be used. Chlorinated swimming pools should be avoided.

Every effort should be made to obtain food that is organically grown, in order to avoid pesticides and chemicals. Processed foods should be avoided because they often contain chemicals, dyes, and preservatives and because the food is stripped of most of its nutritional value. Notably, artificial sweeteners, particularly aspartame, break down into deadly poisons in the body.

Clothing should be all natural fibers, as permanent press and wrinkle-resistant clothes have often been treated with formaldehyde, which does not wash out. For the same reasons, synthetic fiber bed coverings should also be avoided. All plastic products should be avoided as much as possible as they all have toxic elements. Windows should be open as often as possible to increase oxygen in the atmosphere. Some houseplants should be acquired, as they give off oxygen.

It is also very important to undertake some form of gentle, regular **exercise** as this can do much to

improve symptoms. Suitable forms of exercise may be swimming, walking, and gentle rebounding. If an emphysema patient is very weak, he could sit on a mini-trampoline while a helper does the strenuous bit; very real benefits will still be obtained in this way. Strenuous activities are not suitable for anyone with lung impairment.

Naturopathy

According to the principles of naturopathy, the body has the power to heal itself. Treatment should focus on providing the system with optimum **nutrition** in order that it can carry out all repairs necessary, which involves ensuring that all food that is eaten is of the highest quality.

Naturopaths advocate dietary supplements to assist with this process, and certain dietary supplements can be very valuable in arresting the progress of emphysema. Trials have been conducted involving treating emphysema patients with **vitamin A**, which is known to play an important role in healthy body tissue. **Vitamin E** can also be helpful, and **vitamin C** should always be taken, as it is a catalyst for other nutrients. For best results, it is advised to consult a practitioner.

Allopathic treatment

Prior to any other treatment, it is essential that emphysema patients who smoke take steps to give up the habit. Otherwise, damage to the lungs will continue to go unchecked, and other measures will be very limited in their success. Apart from lifestyle changes, physicians generally recommend avoidance of infection, and antibiotics may be prescribed as a preventative measure.

A physician may also prescribe bronchodilator medicines (including beta agonists and anticholinergics) if there is any obstruction of the airways. For the same reason, anti-inflammatories, including corticosteroids, may also be prescribed. There are a variety of delivery methods for emphysema medications, including metered dose inhalers, dry powder inhalers, nebulizer breathing treatments, and powder-filled inhalation capsules.

Pulmonary rehabilitation, which typically includes chest physiotherapy, breathing exercises, and a program of physical exercise, is considered to benefit all emphysema patients, regardless of the degree of impairment. Supplemental **oxygen therapy** may be required at some stage.

Augmentation therapy is available for the treatment of alpha-1 antitrypsin deficiency. This intravenous therapy involves the delivery of AAT from healthy plasma donors, which replaces the so-called faulty AAT in the patient's blood. The dosage is adjusted based on the patient's body weight and is usually delivered once a week. As of 2008, further research was needed to evaluate the effectiveness of augmentation therapy in preventing the progression of emphysema.

In select patients, lung volume reduction surgery may be recommended. In this procedure, the damaged parts of the lung are removed, in order to allow healthy lung tissue to expand. If successful, this surgery may eliminate the need for supplemental oxygen and improve breathing function. However, the National Emphysema Therapy Trial (NETT) demonstrated that only a small number of people with COPD actually benefit from this surgery. Therefore, careful screening is required to determine patient eligibility.

Bullectomy is the surgical removal of bullae that may develop with the giant bullous emphysema. This procedure results in improved total lung capacity and overall morbidity improvements.

A final resort is lung transplant surgery. Because of the relatively large risk involved, transplant surgery is carried out in only a small minority of patients.

Promising research is being conducted to evaluate several less-invasive procedures to treat emphysema. These procedures include bronchoscopic techniques to reduce lung volume, including bypass stents; bronchial occlusive devices; and endobronchial valves, as well as biological reagents to remodel and shrink damaged lung tissue. Minimally invasive surgical techniques are also being evaluated.

Prognosis

It is generally accepted that emphysema is incurable. Physicians and alternative medicine practitioners assert that they can relieve patients greatly from symptoms and halt the progress of the disease with appropriate management, preventative measures, along with the patient's lifestyle changes.

Prevention

Individuals who feel that their work conditions are likely to be a possible cause of emphysema should take steps to protect themselves. A respirator should be worn, at least until work conditions can be improved. Improving ventilation can also help remedy working conditions.

Early diagnosis is vital to the successful management of emphysema. If preventative and therapeutic

KEY TERMS

Acupuncture—An ancient Chinese system of treatment, which involves the painless insertion of very fine needles under the skin at certain key points on the body.

Alveoli—Small, thin-walled sacs located at the end of the smallest airways in the lungs where the exchange of oxygen and carbon dioxide takes place.

Anti-inflammatory—Medication that reduces inflammation (swelling in the airway and mucus production).

Bronchial tubes—Airways in the lungs that branch from the trachea (windpipe).

Bronchioles—The smallest branches of the airways in the lungs.

Bronchodilators—Medications that help relax the muscles surrounding the breathing tubes to aid breathing.

Catalyst—An agent that helps other substances to do their work.

Free radicals—The result of oxidization in the body, these molecules are chemically unbalanced and cause a chain reaction of damage to other molecules in the body, one of the prime causes of aging symptoms and deterioration in body functions.

Inflammation—A basic response in the body to infection, irritation or injury. Inflammation is marked by redness, warmth, swelling, and pain.

Naturopathy—A medical paradigm of diagnosis and healing based on removing the obstacles to cure and using as modalities: diet, therapeutic nutrition, botanical medicine, homeopathy, physical medicine, and counseling.

Peak Expiratory Flow (PEF)—A test used to measure how fast air can be exhaled from the lungs to measure the openness of the airways.

Pulmonary function tests—Tests that measure the amount and rate of air breathed in over a period of time. PFTs also measure how well the lungs move oxygen into the blood.

Residual volume—The amount of air trapped inside the lungs as a result of incompletely exhaling.

measures are taken at the early onset of symptoms, damage can be restricted and the outlook is positive. At all times, care should be taken to eliminate sources of pollution or chemical irritants from the environment, both in the home and elsewhere. The first step in overcoming emphysema for any patient should be to remove the cause, whether it be smoking, working conditions, or polluted atmosphere.

People with emphysema have an increased risk for developing lung **infections**. To reduce the risk of infection, patients should keep the house clean and free from excess dust and bathrooms free from mold or mildew; keep breathing equipment clean and covered when not in use; and frequently wash hands. Patients should notify their doctor if they have any of these signs of infection: increased shortness of breath, difficulty breathing or wheezing; coughing up increased amounts of mucus; change in color of mucus; **fever** or **chills**; increased **fatigue** or weakness; **sore throat** or **pain** when swallowing; unusual sinus drainage or nasal congestion; headaches or pain along upper cheeks.

Numerous smoking cessation programs are available, and physicians can provide referrals to community programs. The American Lung Association also offers many resources to help people quit smoking.

Regular exercise of moderate intensity may reduce lung function decline in smokers, as shown in a 2007 study published in the *American Journal of Respiratory and Critical Care Medicine*.

Endometriosis

Definition

Endometriosis is a condition in which bits of tissue similar to the lining of the uterus (endometrium) grow in other parts of the body (and within the uterus). Like the uterine lining, this tissue builds up and sheds in response to monthly hormonal cycles. The blood discarded from these implants falls onto surrounding organs, causing swelling and inflammation. This repeated irritation leads to the development of scar tissue and adhesions.

Description

Endometriosis is estimated to affect 7% of women of childbearing age in the United States. It most commonly strikes between the ages of 25 and 40. Endometriosis can also appear in the teen years, but never before the start of **menstruation**. It is seldom seen in postmenopausal women.

Endometriosis was once called the career woman's disease because it was thought to be a product of delayed childbearing. The statistics defy such a narrow generalization; however, **pregnancy** may slow the progress of the condition. Women whose periods last longer than a week with an interval of less than 27 days between them seem to be more prone to the condition.

Endometrial implants are most often found on the pelvic organs, including the ovaries, uterus, fallopian tubes, and in the cavity behind the uterus. Occasionally, this tissue grows in such distant parts of the body as the lungs, arms, and kidneys. **Ovarian cysts** may form around endometrial tissue (endometriomas) and may range from pea to grapefruit size. Endometriosis is a progressive condition that usually advances slowly, over the course of many years. Doctors rank cases from minimal to severe based on factors such as the number and size of the endometrial implants, their appearance and location, and the extent of the scar tissue and adhesions in the vicinity of the growths.

Causes and symptoms

Although the exact cause of endometriosis is unknown, a number of theories have been put forward. Some of the more popular ones are:

- Implantation theory. This theory states that a reversal in the direction of menstrual flow sends discarded endometrial cells into the body cavity where they attach to internal organs and seed endometrial implants. There is considerable evidence to support this explanation. Reversed menstrual flow occurs in 70 to 90% of women and is thought to be more common in women with endometriosis.
- Vascular-lymphatic theory. This theory suggests that the lymph system or blood vessels (vascular system) are the vehicles for distribution of endometrial cells out of the uterus.
- Coelomic metaplasia theory. According to this hypothesis, remnants of tissue left over from prenatal development of the woman's reproductive tract transform into endometrial cells throughout the body.
- Induction theory. This explanation postulates that an unidentified substance found in the body forces cells from the lining of the body cavity to change into endometrial cells.

In addition to these theories, the following factors are thought to influence the development of endometriosis:

- Heredity. A woman's chance of developing endometriosis is seven times greater if her mother or sisters have the disease.
- Immune system function. Women with endometriosis may have lower functioning immune systems that have trouble eliminating stray endometrial cells, which would explain why a high percentage of

women experience reversed menstrual flow while relatively few develop endometriosis.

- Dioxin exposure. Some research suggests a link between exposure to dioxin (TCCD), a toxic chemical found in weed killers, and the development of endometriosis.

While many women with endometriosis experience debilitating symptoms, others have the disease without knowing it. Strangely, there does not seem to be any relation between the severity of the symptoms and the extent of the disease. The most common symptoms are:

- Menstrual pain. Pain in the lower abdomen that begins a day or two before the menstrual period starts and continues until the end is typical of endometriosis. Some women also report lower back aches and pain during urination and bowel movement, especially during their periods.
- Painful sexual intercourse. Pressure on the vagina and cervix causes severe pain for some women.
- Abnormal bleeding. Heavy menstrual periods, irregular bleeding, and spotting are common features of endometriosis.
- Infertility. There is a strong association between endometriosis and infertility, although the reasons for this connection had not been fully explained as of 2008. Some experts believe that the buildup of scar tissue and adhesions blocks the fallopian tubes and prevents the ovaries from releasing eggs. Endometriosis may also affect fertility by causing hormonal irregularities and a higher rate of early miscarriage.

Diagnosis

The first step in diagnosing endometriosis is to perform a pelvic examination to determine if implants are present. Very often there is no strong evidence of endometriosis from a physical exam. The only way to make a definitive diagnosis is with a minor surgery called a laparoscopy. A laparoscope, a slender scope with a light on the end, is inserted into the woman's abdomen through a small incision near her navel. This procedure allows the doctor to examine the internal organs. Often, a sample of tissue is taken for later examination in the laboratory. Endometriosis is sometimes discovered when a woman has abdominal surgery for another reason such as tubal ligation or hysterectomy.

Various imaging techniques such as ultrasound, computed tomography scan (CT scan), or magnetic resonance imaging (MRI) can offer additional information but are not useful in making the initial diagnosis. A blood test may also be ordered because women with endometriosis have higher levels of the blood protein CA125. Testing for this substance before and after treatment can predict a recurrence of the disease, but is not reliable as a diagnostic tool.

Treatment

Although severe endometriosis should not be self-treated, many women find they can help relieve symptoms through alternative therapies. In a survey conducted by the Endometriosis Association, 40% to 60% of the women who used alternative medicines reported relief of **pain** and other symptoms.

Diet

A **high-fiber diet**, particularly from grains and beans, may decrease cramping and inflammation. The oils in seeds, nuts, and certain fish (cod, salmon, mackerel, and sardines) may help to relieve cramping. Carrots, beets, lemons, cauliflower, brussels sprouts, cabbage, onions, **garlic**, citrus fruits, vegetables, **chicory**, radicchio, and yogurt may help to reduce symptoms. Some women have found relief when they turned to a **macrobiotic diet** (one that is very restrictive and intended to prolong life). Occasionally, an allergy **elimination diet** may be recommended.

Sugar and animal fats can increase inflammation and aggravate pain. Milk and meat may contain hormones, so these should be avoided. Vegetarian or vegan **diets** may be recommended for those with endometriosis.

Supplements

The following supplements can be used to treat endometriosis:

- vitamin B complex to help the liver break down excess estrogen
- vitamin C to reduce heavy menstrual bleeding
- calcium
- bioflavonoids to help reduce heavy menstrual bleeding
- magnesium to relieve pain and flush out toxins
- vitamin E to heal inflamed tissues
- iron for anemia resulting from heavy bleeding
- lipotropic factors (Choline, methionine, and inositol enhance liver function)
- fish oil capsules, flax oil, or any essential fatty acid to reduce cramping

Several herbal remedies for endometriosis exist. The first four in this list are the most commonly used remedies:

- Genistein (soy/isoflavone) helps the body excrete excess estrogen and possibly blocks estrogen's effect.
- Cramp bark (*Viburnum opulus*) helps ease cramping.
- Dong quai (*Angelica sinensis*) balances hormone levels and reduces inflammation.
- Black cohosh (*Cimicifuga racemosa*) helps the body excrete excess estrogen and improves the health of pelvic organs.
- Red clover (*Trifolium pratense*) balances hormone levels.
- Milk thistle (*Silybum marianum*) may improve liver function.
- Life root (*Senecio aureus*) may improve the health of pelvic organs.
- Feverfew (*Chrysanthemum parthenium*) eases pain and cramping.
- Dandelion eases pain and cramping and supports the liver.
- Yarrow (*Archillea millefolium*) eases cramping and restores hormonal balance.
- Evening primrose (*Oenothera biennis*) oil relieved endometriosis symptoms in 90% of patients in one study.
- Shepherd's purse (*Capsella bursa-pastoris*) reduces heavy menstrual bleeding and tones the uterus.
- Meadowsweet (*Filipendula ulmaria*) reduces pain.

Other treatments

Other remedies for endometriosis include **acupuncture** or **acupressure** to relieve pain, visualization, **guided imagery**, naturopathy, **homeopathy** (Lilium tigrum, **sepia**, and **belladonna**), **hydrotherapy**, **exercise**, and **meditation**.

Allopathic treatment

How endometriosis is treated depends on the woman's symptoms, her age, the extent of the disease, and her personal preferences. The condition cannot be fully eradicated without surgery. Treatment focuses on managing pain, preserving fertility, and delaying the progress of the condition.

Medication

Over-the-counter pain relievers such as aspirin, acetaminophen (Tylenol), ibuprofen (Motrin, Advil), and naproxen (Aleve, Naprosyn) are useful for mild cramping and menstrual pain. If pain is severe, a doctor may prescribe narcotic medications, although these can be addicting and are rarely used.

Hormonal therapies effectively tame endometriosis but also act as contraceptives. They include oral contraceptives, synthetic male hormones (danazol, gestrinone), progestins, and gonadotropin-releasing hormone antagonists.

Surgery

Endometrial implants and ovarian cysts can be removed with laser surgery performed through a laparoscope. For women with minimal endometriosis, this technique is usually successful in reducing pain and slowing disease progress. It may also help infertile women increase their chances of becoming pregnant.

Removing the uterus, ovaries, and fallopian tubes (a hysterectomy) is the only permanent method of eliminating endometriosis. This extreme measure deprives a woman of her ability to bear children and forces her body into **menopause**.

Expected results

Most women who have endometriosis have minimal symptoms and do well. Overall, endometriosis symptoms come back in an average of 40% of women over the five years following treatment. A 2002 review found that teenagers and young women under the age of 22 years have almost twice the chance of symptom recurrence after surgical removal of endometriosis compared with older women. Some researchers believe that younger women may have a different form of endometriosis than that found in older women.

With hormonal therapy, pain returned after five years in 37% of patients with minimal symptoms and 74% of those with severe cases. The highest success rate from conservative treatment followed complete removal of implants using laser surgery. Of these women, 80% were still pain-free five years later. Hysterectomy may be necessary should other treatments fail.

Prevention

There is no proven way to prevent endometriosis. One study, however, indicated that girls who begin participating in aerobic exercise at a young age are less likely to develop the condition.

Resources

BOOKS

Krotec, Joseph, and Sharon Perkins. *Endometriosis for Dummies*. Indianapolis, IN: For Dummies, 2006.

KEY TERMS

Adhesions—Web-like scar tissue that may develop as a result of endometriosis and bind organs to one another.

Endometrial implants—Growths of endometrial tissue that attach to organs, primarily in the pelvic cavity.

Endometrium—The tissue lining the uterus that grows and sheds each month during a woman's menstrual cycle.

Estrogen—A female hormone that promotes the growth of endometrial tissue.

Laparoscopy—Procedure used to diagnose and treat endometriosis. It is performed by inserting a slender, wand-like instrument through a small incision in the woman's abdomen.

Menopause—The end of a woman's menstrual periods when the body stops making estrogen.

Retrograde menstruation—Menstrual flow that travels into the body cavity rather than out through the vagina.

Energy medicine

Definition

Energy medicine is based upon the belief that changes in the "life force" of the body, including the electric, magnetic and electromagnetic fields, affect human health and can promote healing.

Origins

The notion of a life force or energy is shared by people around the world. Since ancient times, traditional cultures have believed that a special energy vitalizes all life. This energy is known as chi, prana, pneuma, orgone, mana, ether, odyle, élan vital, biocosmic energy and many other names.

Early Ayurvedic references to a life force, or prana, go back to the eighth century B.C. In the West, as early as the sixth century B.C., Pythagoras conceived of a life energy, or pneuma, visible in a luminous body. A century later, Hippocrates, the father of modern medicine, recognized the body's natural capacity for healing, or *Vis medicatrix naturae*. He instructed physicians to find the blocking influences both within a patient and between them and the cosmos, in order to restore the healing life force. Nature, not the doctor, is the source of healing.

In the sixteenth century, the Swiss alchemist and physician Paracelsus reported "a healing energy that radiates within and around man like a luminous sphere." He believed this energy could cause and cure disease and could work from a distance. He also thought that magnets, planets, and stars could influence this energy. There are echoes of these beliefs in some of theories and practices of contemporary energy medicine. However, the ideas of Francis Bacon and the French philosopher and mathematician René Descartes have had a much greater impact on Western medicine as a whole.

Bacon applied logical mathematical concepts to analyze humans and the world. He believed that the laws of science should be used to "master rather than become harmonious with nature." Descartes proposed that the body, which was measurable, and the mind, which was immeasurable, were firmly separate. The body could influence the mind but the mind could not influence the body. These notions promoted the search for physical causes of human illness. They also led to a denial of the mind's ability to affect physical health. As a result, mainstream science came to devalue or reject any phenomenon that cannot be measured or objectively proved.

KEY TERMS

Aura—A light or radiance that is claimed to emanate from the body and to be visible to certain persons with psychic or spiritual powers.

Bioenergetics—The study of energy transformation in living systems.

Paradigm—A pattern or model.

From the seventeenth century onward, Western medicine has focused primarily upon the physical aspects of disease. Scientists who studied forces within the body that were difficult to measure were often ignored or ridiculed. The Austrian psychiatrist Wilhelm Reich, who had been a student and colleague of Sigmund Freud, was jailed and his books publicly burned because of his theories about "orgone" energy. His views, however, have influenced the development of many body-mind approaches, particularly bioenergetics.

The 1990s brought a new emerging scientific paradigm in relation to medicine and health care. According to biophysicist Beverly Rubik, this emerging paradigm "... celebrates the creative, subtle, empowering, wise, and enduring features of life that were never acknowledged during the age of machines and mechanistic thought. Living systems are self-organizing systems that expend energy in order to maintain their coherence and integrity...Healing is ultimately self-healing, a natural response to internal dynamic shifts or external challenges." This new paradigm also conveys that "...very small or subtle stimuli applied to the body-mind can have profound effects and set a person on the road to recovery."

Benefits

In a 1990 review of more than 131 controlled scientific studies of healers from around the world, Dr. Daniel Benor found evidence of healing for a wide range of human conditions. These include changes in immune system functioning as well as improvement of skin—wound healing, blood pressure, nearsightedness, **leukemia**, **anxiety**, **asthma**, **bronchitis**, **epilepsy**, tension **headache**, neck and back **pain**, post-operative pain, self-esteem, **heart disease**, and relationships.

Patients have also reported spontaneous healing of a variety of conditions including **cancer** and paralysis. Spiritual awakenings or new attitudes and a fresh sense of meaning in life can also result from energy healing.

Description

Energy medicine is a broad term that includes touch therapies, movement therapies, spiritual healing, **meditation**, magnetic field therapy, **homeopathy**, **acupuncture**, **light therapy**, and other innovative methods of healing. What these various approaches have in common is an energetic understanding of health and healing. These therapies may affect the patient's internal energy, external energy (aura, or other energy fields surrounding the body) or both. Many of these therapies fall into several different categories at once and their benefits may not be exclusively due to changes in life force. Energetic touch therapies include, but are not limited to, **reiki**, **therapeutic touch** (although the physical body is not touched), watsu, **polarity therapy**, Ayurvedic massage, zero balancing, **reflexology**, Jin Shin Jyutsu, **lomilomi**, **breema** bodywork, **Thai massage**, **shiatsu**, amma, Chi Nei Tsang, Jin Shin Do, Shen, and **Chinese massage**, and **acupressure**. Energetic movement therapies include **qigong**, **t'ai chi** chuan, aikido, karate, and **yoga** (there are many different forms of yoga). Spiritual healing includes distance healing, laying on of hands, meditation, ceremony, ritual and other shamanic practices.

Some of the methods of energy medicine involve gentle physical touch, while others work with the energy around the body with the practitioner holding his or her hands several inches away. Some methods can be applied from a distance, others require attendance at a ceremony and may include family and friends. The movement modalities may require learning and practicing a particular movement or breath sequence. Other therapies may involve wearing magnets, being exposed to various kinds of light rays, or receiving energy stimulation with needles and heat.

The duration and cost of an energy medicine session vary greatly depending upon the method and the healer. Some methods are expensive while others are free or offered for a modest donation. These modalities are not covered by insurance unless administered by a licensed health care professional.

Preparations

The amount and type of preparation vary. While some forms of energy medicine require no specific preparations, others do. These preparations may range from wearing loose clothing for yoga and other movement therapies, to an hour-long diagnostic interview with a practitioner of **traditional Chinese medicine** prior to receiving certain types of Chinese massage. In general, people with heart problems,

CAROLINE MYSS (1953–)

Caroline Myss graduated with a B.A. in Journalism in 1974 from St. Mary of the Woods College in Terre Haute, Indiana. Working as a journalist in her native Chicago, Myss interviewed Dr. Elisabeth Kubler Ross, M.D., who was devoted to the study of death and the dying. She credits Kubler Ross with inspiring her to go on to Loyola Mundelein University, a Jesuit school in Chicago, to get an M.A. in Theology in 1979. Myss then started a small New Age publishing company, consulted with holistic doctors, and gave individuals intuitive readings. It was her pairing with Dr. C. Norman Shealy, founder of the American Holistic Medical Association, in 1984, that began to thrust her into the limelight in energy medicine. With television appearances on such high profile shows as *Oprah*, Myss is the best known intuitive on the circuit of holistic practitioners. Her belief stems from a principle that the mind and body work together to contribute to a person's well being. While the traditional medical community is skeptical of the scientific basis for her claims, her interna tional popularity continues to rise.

Her first book, *Anatomy of the Spirit*, was published in 1996, followed in the fall of 1997 with *Why People Don't Heal and How They Can*. Those, along with an audiotape series called *Energy Anatomy*, are bestsellers. By 2000, Myss discontinued private readings and devotes herself to workshops and seminars worldwide.

Myss can be contacted at her office, at 7144 N. Har lem Avenue, Chicago, IL 60631, or through her website: http://www.myss.com.

recent surgery, or back problems should consult a physician before attempting any of the movement therapies.

Precautions

Other treatments besides, or instead of, energy medicine may be needed for a particular disease or condition. In addition, persons who have experienced physical violence or abuse may have strong emotional reactions to therapies that involve physical contact; they should consult a knowledgeable counselor before undertaking these forms of treatment.

Side effects

The side effects can vary depending upon the modality. It is not unusual for people to experience some soreness or stiffness after a session of bodywork or movement therapies, particularly if they have not been accustomed to regular physical **exercise**. Some people experience headaches after light therapy. Lastly, some people find that energy therapies bring up painful emotions and memories.

Research and general acceptance

In the course of the past three decades, energy medicine has moved from being a marginal area of research to gaining a large measure of mainstream acceptance. The Human Potential movement of the 1960s and the counterculture of the early 1970s helped to stimulate popular interest in Eastern practices and belief systems, while the feminist movement of the same period led many women to explore mind/body connections and question the masculine assumptions and values of Western science and medicine. In recent years, the medical establishment has shown a new openness to research in the area of energy medicine, as was shown by the funding of the Office of Alternative Medicine at the National Institutes of Health. At present there are a number of clinical trials that have been designed to measure the effectiveness of alternatives to conventional treatment.

Despite over 300 studies during the past 40 years showing the efficacy of energy healing, however, these findings are still ignored or rejected by many scientists. Benor details many reasons for this rejection, including the fact that healers have not been able to produce results with reliability and consistency in a laboratory setting. Benor writes, "The time has come to accept that healing is the way it is. It appears to be influenced by multiple factors—so many, in fact, that it is virtually impossible to establish a repeatable experiment in which all would occur in the same combination more than once...We will have to be content with our human limitations and settle for approximate results, measured in probabilities over large numbers of trials. No apologies are needed. These are the limitations of healing."

Training and certification

There is no course of training leading to certification or licensure for energy medicine as such. Various schools of touch and **movement therapy**, as well as energy healing, offer their own forms of certification. The requirements vary according to each modality and each school. Spiritual healers may be certified through a school of energy healing, recognized within a particular religious tradition for their healing aptitude, or initiated into healing by another means. Many healers develop

their healing gifts on their own. The evidence suggests that any caring person can develop a certain amount of healing ability through meditation, **prayer**, study with other experienced healers, and practice.

Environmental therapy

Definition

Environmental therapy, also known as environmental medicine and formerly called clinical ecology, is the diagnosis and treatment of conditions caused by environmental factors.

Origins

The founder of environmental medicine was Theron G. Randolph, M.D., who was a trained specialist in internal medicine, immunology, and **allergies**. Several decades ago, Randolph became concerned with chronically ill patients who had symptoms of allergies and immune system disorders, but did not respond to conventional medical care. Randolph believed that patients were getting sick from environmental substances and pollutants that allergy specialists could not determine or did not recognize as causing illness. Conventional allergy specialists in Randolph's time believed that allergies could only be detected by measuring the response of immunoglobulin E (IgE). IgE is a particular antibody produced by the immune system when an antigen (foreign substance) triggers a reaction. Randolph believed that testing for allergies using only this technique limited the determination of immune system problems. Using other tests and techniques, he found that many substances that did not necessarily cause increased amounts of IgE could create allergic symptoms and complications in the body. Research has since shown that food allergies cause increases in immunoglobulin G (IgG) and not in IgE. Scientists now recognize that the immune system is too complex to be measured by only one test.

Randolph also found that allergic and toxic substances often produce subtle reactions in the body that may accumulate into major illnesses and problems. Many of these substances were not previously thought of as allergenic or toxic, including numerous common foods and chemicals (particularly petrochemicals and by-products of industry). Randolph determined that environmental agents could cause mental and behavioral disturbances as well as physical symptoms. Randolph and other doctors developed and used new diagnostic techniques, including intradermal (between skin layers) and sublingual (under the tongue) allergy tests, to determine exactly which environmental factors were influencing illnesses. Environmental doctors were able to heal many patients simply by removing certain foods and chemicals from their environment.

Randolph went on to dedicate his work to studying the interaction between patients and their environment. He and his colleagues called this new field of medicine clinical ecology, which was later changed to environmental medicine. The field's basic ideas are that doctors must consider both the patient and the patient's environment in treatment, and that there are cause and effect relationships between environmental factors and illness. Environmental factors include food, air, water, living arrangements, and workplace

KEY TERMS

Allergen—A foreign substance, such as mites in house dust or animal dander that, when inhaled, causes the airways to narrow and produces symptoms of asthma.

Antibody—A protein, also called immunoglobulin, produced by immune system cells to remove antigens.

Fibromyalgia—A condition of debilitating pain, among other symptoms, in the muscles and the myofascia (the thin connective tissue that surrounds muscles, bones, and organs).

Hypersensitivity—The state where even a tiny amount of allergen can cause severe allergic reactions.

Multiple chemical sensitivity—A condition characterized by severe and crippling allergic reactions to commonly used substances, particularly chemicals. Also called environmental illness.

environments. For illnesses that are caused by exposure to negative environmental factors, healing can be induced not by drugs, but by testing for and removing the environmental causes of illness and by strengthening the patient's resistance.

Environmental therapists have isolated many substances that cause illness and adverse reactions in people, including chemicals, car exhaust, tobacco smoke, pesticides, drugs, food additives, and common allergens like dust, mold, animal dander, and pollen. Many people may also have allergic and negative reactions to common foods such as dairy products, corn syrup, sugar, wheat, certain fruits and vegetables, nuts, and meat. Exposure to toxic and allergenic substances may exert a cumulative effect on the body, weakening and taxing the immune system over time so that the body becomes hypersensitive (more susceptible) to substances that were once tolerated.

In 2002, a Harvard University study demonstrated that global warming was adding to the presence of airborne allergens like ragweed pollen. Atmospheric carbon dioxide concentration is up 29% since industrial times began and is expected to double again in the next 50 to 100 years. The heavy carbon dioxide concentration helps plants grown faster and larger, producing more allergens.

Environmental medicine has become increasingly popular in the last few decades as the public has become more aware of environmental pollution. Every year, more than 700,000 different chemicals are released into the environment, and the figure has been growing by 10% or more per year. Toxic or allergenic chemicals can be found in everything from common household materials like carpet and furniture to basic items like food and water. Environmental therapists believe that new medical problems have arisen due to the immune system's inability to handle all of the new pollutants and synthetic chemicals to which it is exposed. Environmental illness is the cumulative effect of lengthy or constant exposure to these toxins. Those with environmental illness become hypersensitive to even minute quantities of common materials. Environmental hypersensitivity can cause severe disability in many people.

Environmental medicine recognizes that some new and baffling illnesses have appeared that conventional medicine either does not recognize or is unable to treat, sometimes called "twentieth century diseases." These conditions include environmental illness/multiple chemical sensitivity (EI/MCS), **chronic fatigue syndrome**, **fibromyalgia**, **Gulf War syndrome**, and **sick building syndrome**. Furthermore, diseases for which environmental causes are believed to be major factors are also increasing (like **cancer** and **asthma**), making environmental medicine increasingly important.

Benefits

Environmental medicine is helpful for patients with chronic allergies, asthma, chronic **fatigue** syndrome, EI/MCS, fibromyalgia, Gulf War syndrome, and sick building syndrome. It is helpful for those with conditions that are influenced by environmental factors, such as cancer, as well as for those who have been exposed to high levels of toxic materials due to accident or occupation. Environmental medicine is also used for people with allergic or immune system problems that conventional medicine is unable to diagnose or treat. Symptoms for patients with environmental illness include unexplained fatigue, increased allergies, hypersensitivity to common materials, intolerance to certain foods and **indigestion**, aches and pains, low-grade **fever**, headaches, **insomnia**, **depression**, sore throats, sudden weight loss or gain, lowered resistance to infection, general malaise, and disability.

Description

Environmental therapy treats patients by first identifying the environmental causes of illness. The

next step is removing environmental causes and reducing exposures to all potential toxins. Cleansing and detoxifying the body of toxic substances and supporting overall (holistic) healing and recovery are the other components of the treatment process.

The cost of treatment by a practitioner of environmental medicine can vary depending on the education of the practitioner. Costs are generally comparable to visits to trained medical specialists. Practitioners may be conventionally trained medical doctors, researchers with graduate degrees in environmental medicine, or alternative medicine practitioners such as homeopaths, **Ayurvedic medicine** practitioners, **traditional Chinese medicine** practitioners, and naturopaths. Treatment costs vary, depending on the type and number of tests required to identify problems and the subsequent healing therapies required. Many insurance policies cover costs of environmental therapy, particularly when the practitioner is a certified medical doctor. Consumers should be aware of their insurance company's policies on coverage.

Diagnosing environmental illness

Environmental therapists use extensive testing to determine the environmental factors that may be causing illness. These factors include infection, allergy, addictions, and toxic chemicals. **Infections** that often plague those with environmental illness can be caused by parasites, bacteria, viruses, and yeast. Blood, urine, stool, and hair analyses are used to measure a variety of bodily functions that may indicate problems. Environmental therapists have access to laboratories that specialize in sophisticated blood, urine, and other diagnostic tests.

In testing for environmental illness, liver function is studied closely because the liver is the principle organ in the body responsible for removing toxic compounds. Another useful blood test is a test for **zinc** deficiency, which may indicate **heavy metal poisoning**. Heavy metal poisoning can be caused by lead, mercury, arsenic, cadmium, and aluminum, all of which are present in the environment. Hair analysis is also used to test for heavy metal toxicity. Blood and urine tests can also be completed that screen for toxic chemicals such as PCBs (environmental poisons), formaldehyde (a common preservative), pesticides, and heavy metals. Immune system tests, which show levels of particular antibodies, can also indicate specific environmental factors. Hormone levels also may indicate environmental illness. Certain blood and urine tests may suggest nutritional deficiencies and proper recovery **diets** can be designed for patients.

Environmental therapists also perform extensive allergy and hypersensitivity tests. Intradermal and sublingual allergy tests are used to determine a patient's sensitivity to a variety of common substances, including formaldehyde, auto exhaust, perfume, tobacco, chlorine, jet fuel, and other chemicals.

Food allergies require additional tests because these allergies often have reactions that are delayed for several days after eating the food. The RAST (radioallergosorbent test) is a blood test that determines the level of immunoglobulins in the blood after specific foods are eaten. The cytotoxic test is a blood test that determines if certain substances affect blood cells, including foods and chemicals. The ELISA-ACT (enzyme-linked immunoserological assay activated cell test) is considered one of the most accurate tests for allergies and hypersensitivity to foods, chemicals, and other agents. Other tests for food allergies are the elimination and rotation diets, where foods are systematically evaluated to isolate those that are causing problems.

Therapies used in environmental medicine

After environmental causes of illness are identified, the next step is to reduce or eliminate the patient's exposure to them to reduce the burden on the immune system. Patients are advised to immediately remove toxic and allergic agents from the home and workplace, and to make lifestyle and dietary changes to reduce exposure and to improve general physical and mental health.

Detoxification methods are used by alternative practitioners in treating environmental illnesses. These methods try to rid the body of accumulated toxic substances and to restore efficient functioning. Detoxification methods include dietary therapies, **fasting**, **exercise**, sweating, laxatives, enemas, and other techniques that stimulate and support the body's natural detoxification mechanisms. Nutritional and herbal supplements are used in the detoxification and strengthening process. These supplements include **antioxidants** and vitamins, numerous herbs that detoxify the body and stimulate the immune system, and enzymes to improve digestion. Natural and holistic treatments are used to rebuild and strengthen the patient's overall health and resistance. Traditional healing systems such as traditional Chinese medicine, naturopathy, ayurveda, and **homeopathy** may be used as therapeutic programs for environmental illness.

Preparations

Patients can assist diagnosis and treatment by keeping detailed diaries of their activities, symptoms, and contact with environmental factors that may be affecting their health.

Side effects

If detoxification treatments are used, patients may experience side effects of fatigue, malaise, aches and pains, emotional duress, **acne**, headaches, allergies, and symptoms of colds and flu. Detoxification specialists claim that these negative side effects are part of the healing process. These reactions are sometimes called *healing crises*, which are caused by temporarily increased levels of toxins in the body due to elimination and cleansing.

Research and general acceptance

Environmental medicine is gaining more respect in the medical community and is now a field in conventional medicine. Many leading medical schools and universities offer programs or specialties in environmental medicine. Research in environmental medicine is being widely funded and conducted by mainstream organizations such as the National Institutes of Health, the Environmental Protection Agency, as well as alternative medical schools. The National Academy of Science recognizes that many illnesses are caused or influenced by environmental factors, including cancer and **multiple chemical sensitivity**. The U.S. Centers for Disease Control estimates that up to 82% of diseases may be due to environmental and lifestyle factors.

Training and certification

The American College of Occupational and Environmental Medicine is the world's largest organization for environmental medicine. Its members include certified and practicing doctors. The American Academy of Environmental Medicine certifies environmental medicine practitioners. The National Institute of Environmental Health Sciences is affiliated with the National Institutes of Health. It conducts research in environmental medicine and supports several academic programs of study in environmental medicine, including those at Harvard, Oregon State University, Vanderbilt, University of California, and MIT.

Enzyme therapy

Definition

Enzyme therapy is a plan of dietary supplements of plant and animal enzymes used to facilitate the digestive process and improve the body's ability to maintain balanced metabolism.

Origins

Enzymes are protein molecules used by the body to perform all of its chemical actions and reactions. The body manufactures several thousand enzymes. Among them are the **digestive enzymes** produced by the stomach, pancreas, small intestine, and the salivary glands of the mouth. Their energy-producing properties are responsible for not only the digestion of nutrients, but their absorption, transportation, metabolism, and elimination as well.

Enzyme therapy is based on the work of Edward Howell in the 1920s and 1930s. Howell proposed that enzymes from foods work in the stomach to pre-digest food. He advocated the consumption of large amounts of plant enzymes, theorizing that if the body had to use less of its own enzymes for digestion, it could store them for maintaining metabolic harmony. Four categories of plant enzymes are helpful in pre-digestion: protease, amylase, **lipase**, and cellulase. Cellulase is particularly helpful because the body is unable to produce it.

Animal enzymes, such as pepsin extracted from the stomach of pigs, work more effectively in the duodenum. They are typically used for the treatment of nondigestive ailments.

The seven categories of food enzymes and their activities are:

- Amylase: breaks down starches
- Cellulase: breaks down cellulose
- Lactase: breaks down lactose (milk sugar)
- Lipase: breaks down fats
- Maltase: breaks down maltose (malt sugar)
- Protease: breaks down proteins
- Sucrase: breaks down sucrose (table sugar)

Enzyme theory generated further interest as the human diet became more dependent on processed and cooked foods. Enzymes are extremely sensitive to heat, and temperatures above 118°F (48°C) destroy them. Modern processes of pasteurization, canning, and microwaving are particularly harmful to the enzymes in food.

Benefits

In traditional medicine, enzyme supplements are often prescribed for patients with disorders that affect the digestive process, such as cystic fibrosis, Gaucher's disease, diabetes, and **celiac disease**. A program of enzyme supplementation is rarely recommended for healthy patients. However, proponents of enzyme therapy believe that such a program is beneficial for everyone. They point to the ability of enzymes to purify the blood, strengthen the immune system, enhance mental capacity, cleanse the colon, and maintain proper pH balance in urine. They believe that by improving the digestive process, the body is better able to combat infection and disease.

Some evidence exists that pancreatic enzymes derived from animal sources are helpful in **cancer** treatment. The enzymes may be able to dissolve the coating on cancer cells and may make it easier for the immune system to attack the cancer cells.

A partial list of the wide variety of complaints and illnesses that can be treated by enzyme therapy includes:

- AIDS
- anemia
- alcoholism
- anxiety
- acute inflammation
- back pain
- cancer
- colds
- chronic fatigue syndrome
- colitis
- constipation
- diarrhea
- food allergies
- gastritis
- gastric duodenal ulcer
- gout
- headaches
- hepatitis
- hypoglycemia
- infections
- mucous congestion
- multiple sclerosis
- nervous disorders
- nutritional disorders
- obesity
- premenstrual syndrome (PMS)
- stress

Evidence to support enzyme therapy for treatment of these conditions tends to be sparse or lacking.

Description

Enzyme supplements are extracted from plants such as pineapple and papaya and from the organs of cows and pigs. The supplements are typically given in tablet or capsule form. Pancreatic enzymes may also be given by injection. The dosage varies with the condition being treated. For nondigestive ailments, the supplements are taken in the hour before meals so that they can be quickly absorbed into the blood. For digestive ailments, the supplements are taken immediately before meals accompanied by a large glass of fluids. Pancreatic enzymes may be accompanied by doses of **vitamin A**.

Preparations

Enzyme preparations are available in a variety of forms, including tablets, capsules, liquid formations, and topical ointments.

Precautions

People with **allergies** to beef, pork, pineapples, and papaya may have allergic reactions to enzyme supplements. Tablets are often coated to prevent them from breaking down in the stomach and usually should not be chewed or crushed. People who have difficulty swallowing pills can request enzyme supplements in capsule form. The capsules can then be opened and the contents sprinkled onto soft foods such as applesauce.

Side effects

Side effects associated with enzyme therapy include **heartburn**, **nausea** and **vomiting**, **diarrhea**, bloating, **gas**, and **acne**. According to the principles of therapy, these are temporary cleansing symptoms. Drinking eight to ten glasses of water daily and getting regular **exercise** can reduce the discomfort of these side effects. Individuals may also experience an increase in bowel movements, perhaps one or two per day. This side effect is also considered a positive effect.

Plant enzymes are safe for pregnant women, although individuals should always check with a doctor before using enzymes. Pregnant women should avoid animal enzymes. In rare cases, extremely high doses of enzymes can result in a build up of uric acid in the blood or urine and can cause a break down of proteins.

Research and general acceptance

In the United States, the FDA has classified enzymes as a food. Therefore, they can be purchased without a prescription. Insurance coverage is usually dependent upon the therapy resulting from a doctor's orders. As of 2008, the use of enzyme therapy was still controversial among traditional physicians and some alternative healers. Scientific evidence for the effectiveness of enzyme therapy was still very limited.

Training and certification

There is no specific training or certification required for practicing enzyme therapy.

KEY TERMS

Celiac disease—A chronic disease characterized by defective digestion and inadequate fat metabolism.

Cystic fibrosis—A genetic disease that causes multiple digestive, excretory, and respiratory complications. Among the effects, the pancreas fails to provide secretions needed for the digestion of food.

Duodenum—The upper part of the small intestine.

Gaucher's disease—A rare genetic disease caused by a deficiency of enzymes needed for the processing of fatty acids.

Metabolism—The system of chemical processes necessary for living cells to remain healthy.

Ephedra

Description

Ephedra, also known as Ma Huang, is banned from sale in the United States. On February 5, 2004, the United States Food and Drug Administration (FDA) issued a press release stating it prohibited the

Ephedra. *(©PlantaPhile, Germany. Reproduced by permission.)*

sale of dietary supplements containing ephedrine alkaloids (ephedra) because such supplements present an unreasonable risk of illness or injury. The rule became effective 60 days later.

Although ephedra has a long history of medicinal use, the FDA, in banning ephedra, concluded that: "Multiple studies demonstrate that dietary supplements containing ephedrine alkaloids, like other sympathomimetics, raise blood pressure and increase heart rate. These products expose users to several risks, including the consequences of a sustained increase in blood pressure (e.g., serious illnesses or injuries including **stroke** and **heart attack** that can result in death). There is also a risk of increased morbidity and mortality from worsened heart failure and pro-arrhythmic effects. Although the pro-arrhythmic effects of these products typically occur only in susceptible individuals, the long-term risks from elevated blood pressure can occur even in nonsusceptible, healthy individuals. These risks are not outweighed by the known or reasonable likely benefits of dietary supplements containing ephedrine alkaloids. These products do not provide a meaningful health benefit. The best clinical evidence for a benefit is for weight loss, but even there the evidence supports only a modest short-term weight loss insufficient to positively affect cardiovascular risk factors or health conditions associated with being overweight or obese. Other possible benefits, such as enhanced athletic performance, enhanced energy, or a feeling of alertness, lack scientific support and/or they would provide only temporary benefits that are trivial in comparison to the risks."

This prohibition on sale of ephedra was appealed, and in 2005 sales of low-dose preparations were briefly reinstated, but on August 17, 2006, the U.S. Court of Appeals for the Tenth Circuit upheld the FDA's 2004 regulation. On May 14, 2007, the United States Supreme Court declined to review the decision, and so the FDA ruling remained in effect. Laws in other nations vary: In some countries ephedra is not restricted, while in others low doses are permitted.

Ephedra is an herb used by Chinese medicine for more than 2,500 years due to its ability to remedy symptoms of **asthma** and upper respiratory **infections**. A member of the Ephedracae family of herbs (*Ephedra sinica*), ephedra is native to northern China and Inner Mongolia where it thrives in desert areas as a jointed, barkless plant with branches that bear few leaves and tiny yellow-green flowers that bloom in summer. While varieties of ephedra grow throughout the world, the United States version flourishes in the dry southwest.

Ephedra became popular to Mormon settlers in the early 1800s as a stimulant consumed in the form of tea in place of the coffee and black tea from which they abstained, giving the plant one of its many names, Mormon tea. Other folk names that have resulted over time include desert tea, desert herb, and squaw tea. The herbal drink was named whorehouse tea after it was served in brothels during the 1800s due to unproven beliefs that it cured **gonorrhea** and **syphilis**.

The medicinal herb Ma Huang is made of the dried, young branchlets of ephedra. Harvested in the autumn, ephedra is reproduced from seed or by root division and the stems are dried in the sun throughout the year for production. The herb should be stored away from light. Ephedra gains its strength primarily from the alkaloid ephedrine, pseudephedrine, and norpseudephedrine. These active ingredients produce central nervous system stimulation.

Other key components of ephedra include:

- tannin, an acidic substance found in the bark
- saponin, originating in the roots

- flavone, the chemical from which natural colors of many plants originate
- volatile oil

General use

A bitter-tasting herb that has been relied upon by the Chinese throughout centuries to heal ailments from fevers and **chills** to nasal and chest congestion, ephedra also maintains its prominence as a strong stimulant. Contrary to its reputation, Zen monks used the herb to promote calm concentration during **meditation**. However, larger amounts can make a person jittery. Before the 2004 ban, ephedra was used in the United States as an herbal medicine to treat asthma and **hay fever** and the beginnings of colds and flu. The herb was also used to raise blood pressure, cool fevers, and ease the **pain** of rheumatism.

While ephedrine was used in various decongestant and bronchodilator products in the United States beginning in the late 1920s through the 1940s, its potential for causing dangerous side effects led to the creation of a chemical substitute. Scientists created the equally effective, but safer pseudephedrine that remains the active ingredient in many over-the-counter (OTC) products such as Sudafed. Primatene Mist, an OTC that contains ephedrine, is used regularly to treat asthma.

The body responds to ephedra as one of its key ingredients, ephedrine, opens bronchial passages, activating the heart and raising blood pressure while increasing metabolism. Due to its stimulating effect on the nervous system, many weight loss and energy products contained ephedra. Ephedrine increases basal metabolic rate (BMR), causing the body to burn calories faster. Dieters used ephedra-based products because they suppress the appetite and stimulate metabolism. While these diet products proved to be effective, their results were rarely permanent, and long-term use was perceived to be quite harmful. Chinese sources only recommended its use for acute situations.

As an "energy" product, ephedra increases alertness and perception. The use of ephedra in this way dates back to bodyguards of Genghis Khan, who, legend has it, fearful of being beheaded if they fell asleep on duty, consumed tea containing ephedra to stay alert. **Caffeine** products, such as coffee, tea, chocolate, and cola drinks, enhance the effect of energy products containing ephedra. Additional medicinal uses of ephedra include the promotion of **menstruation**, the decreased desire for cigarettes, and the promotion of uterine contractions. Ma Huang is also known for its ability to increase sexual sensation.

Some controversy surrounds the extended use of ephedra. It is recommended that products containing ephedra be taken only for short periods of time. Tachyphylaxis, or becoming immune to a drug's effectiveness due to overuse, and dependence on the drug may develop when it is taken consistently over time. Both ephedrine and Ma Huang are considered doping substances. In April 1996, the FDA issued a warning on dietary supplements containing ephedra that were labeling themselves as safe substitutes for "street drugs," such as the illegal drug ecstasy. The FDA stated that these products could have "potentially dangerous effects on the nervous system and heart."

While questions surround the correct use of ephedra in the United States, the German government's Federal Institute for Drugs and Medical Devices (Commission E) certifies that ephedra herba, ephedra, and Ma Huang is an approved remedy for diseases of the respiratory tract with mild bronchospasms. Approval from Commission E, however, is not equivalent to the FDA's higher standards of drug approval.

Preparations

Before the 2004 ban in the United States, ephedra was available over the counter as a fluid extract, in tablet form, or as a dried bulk herb at Chinese pharmacies, Asian markets, and health food stores.

Chinese herbalists prepare ephedra for use by combining one part honey, four parts dried herb in combination with other herbs, and a small amount of water in a wok. The herbs are simmered over low heat until the water has evaporated and the herb begins to turn brown. Other forms of preparation include frying ephedra in vinegar or wine to improve its tonic effect on blood circulation and toasting it to an ash so that it may increase its ability to stop bleeding.

To treat **fever** and chills, Chinese herbalists recommend combining ephedra with cinnamon twig and other herbs. Coughing and **wheezing** are remedied with a mixture of ephedra and **apricot seed**, while **licorice** is added to the herb for **stomachaches**. An upper respiratory infection, or congestion, is treated with a combination of ephedra and **ginger**. The powder form, mixed with rehmannia, is also used by the Chinese to treat kidney energy (yin) deficiency.

When the United States adopted the herb for its healing properties, the variety of ephedra preparations increased. The average single dose of ephedrine for adults is 15–30 mg, with a maximum allowed daily dose of 300 mg per day. When consumed as a tea, 1 teaspoon (5 ml) of ephedra is boiled with 1 cup (250 ml) water for 15–20 minutes, with up to 2 cups (500 ml) of the tea allowed per day. This tea (also known as a decoction) is prescribed by herbalists for asthma. The tincture preparation is used in treatments to ease the

aches and joint pains caused by rheumatism. The amount of tincture recommended is 1/4 teaspoon (1.25 ml)–1 teaspoon (5 ml) in combination with other herbs, up to three times a day.

Precautions

While ephedra has an extensive history of medicinal use, the supplement has shown to be harmful to children, adolescents, older or chronically ill people, and pregnant women or women who are breastfeeding. Those with **heart disease**, high blood pressure, **prostate enlargement**, pheochromocytoma, diabetes, **glaucoma**, thyrotoxicosis, overactive thyroid gland (**hyperthyroidism**), nervousness, anorexia, **insomnia**, suicidal tendencies, stomach ulcers, or bulimia should not take ephedra. The herb should be avoided by those with **diarrhea** or abdominal bloating.

Before its ban, ephedra was an ingredient in many weight-loss aids. While it is effective for a dieter's purpose as it accelerates the metabolism, the excess stimulation can cause dangerous consequences. The herb is extremely powerful as a stimulant, with its active ingredient epinephrine mimicking the effects of adrenaline. The molecular structure of epinephrine is close to methampetamine, also known as speed, and the use of ephedra can result in a positive test for amphetamines in the urine. Regular use of ephedra has been shown to lead to dependence on the herb.

Many cases of Ma Huang toxicity were reported to the FDA and possibly serious cardiovascular effects have been associated with its use. Health Canada issued a recall for products containing more than recommended levels of ephedra in early 2002 because of serious, possibly fatal, side effects. The dose limits set by Canadian authorities were more than 8 mg of ephedrine or a label that recommended more than 8 mg per dose or 32 mg per day. It also included products recommended use exceeding seven days.

A 2002 study concluded that use of Ma Huang could be associated with serious complications, including increased risk of stroke, heart attack or even sudden death, and urged that the effects were not limited to massive doses.

Side effects

Side effects of ephedra include insomnia, **dry mouth**, nervousness, irritability, **headache**, and **dizziness**. The following side effects are considered serious: increased blood pressure, increased heart rate, and heart palpitations. If these develop, the use of ephedra should be stopped, and a physician should be consulted immediately.

KEY TERMS

Central nervous system—Consisting of the brain and spinal cord, with their nerves and end organs that control voluntary acts; includes sensory and motor nerve fibers controlling skeletal muscles.

Dietary supplement—According to the United States Food and Drug Administration (FDA), any product intended for ingestion as a supplement to the diet.

Ergot preparations—A classification of drugs made from a fungus, used primarily for the treatment of migraines.

Metabolism—The result of all physical and chemical changes that take place within an organism, for example, the human body.

Pheochromocytoma—A tumor of the sympathoadrenal system that produces hypertension resulting in excessive headaches, sweating, and palpitation, apprehension, flushing of the face, nausea, and vomiting.

Thyrotoxicosis—Toxic condition due to hyperactivity of the thyroid gland.

Drugs that may cause adverse effects if combined with ephedra include:

- methyl xanthines, such as caffeine
- beta blockers
- Dexamthasone
- Reserpine
- Amitriptyline
- urinary alklinizers, such as sodium bicarbonate
- unrinary acidifiers, for example, ammonium chloride
- monoamine oxidase inhibitors, such as heart glycosides
- secale alkaloid derivatives, such as oxytocin
- Yohimbine
- Gaunethidine, which leads to the enhancement of the sympathomimetic effect, or stimulation of the nervous system

People who are taking any of these drugs should avoid ephedra. The isolated drug ephedrine (the active ingredient of ephedra) has also been shown to cause side effects if combined with other drugs, including antidepressants that increase the overall effect of ephedrine; methyldopa, due to possible increased blood pressure; and ergot preparations that may lead to

serious blood pressure problems. Other substances that may cause alarming circumstances if combined with any form of ephedra include cocaine, **marijuana**, and caffeinated drinks. While it is known that Ma Huang taken with certain drugs and other substances may causes adverse effects, overall drug interactions with the supplement ephedra have not been thoroughly studied. It is recommended that a physician be notified before beginning the use ephedra in any form, or of any herbal supplement.

Epididymitis

Definition

Epididymitis is the inflammation or infection of the epididymis, the long coiled tube that attaches to the upper part of each testicle. The epididymis functions as a storage, transport, and maturation place for sperm before ejaculation.

Saw palmetto is one herbal remedy for epididymtis. *(David Davis / Photo Researchers, Inc.)*

Description

In adults, epididymitis is the most common cause of **pain** in the scrotum, and in adolescents, the second most common cause. The acute form is usually associated with the most severe pain and swelling. If symptoms last for more than six weeks after treatment begins, the condition is considered chronic.

Epididymitis is most common between the ages of 18 and 40, but children can get it, too. Boys who experience painful urination, have a history of urinary tract **infections**, abnormal bladder function, or abnormalities of the genitals and urinary structures are more inclined to get epididymitis. It is seldom found in adolescents who are not sexually active.

The infection is especially common among members of the military who **exercise** for extended periods without emptying their bladders.

Factors that increase the risk of developing epididymitis include:

KEY TERMS

Acute—Refers to a condition or pain that is sharp and short in course.

Chronic—A condition that has a long duration.

Testicle—One of the two male sex glands, located in the scrotum, where sperm and hormones are produced.

Urethra—Refers to the opening at the end of the penis; drains urine from the bladder.

Vas deferens—The duct that stores sperm and carries it from the testicles to the urethra.

- infection of the bladder, kidney, prostate, or urinary tract
- other recent illness
- narrowing of the urethra (the tube that drains urine from the bladder)
- use of a urethral catheter

The infection does not start in the epididymis. It is an ascending infection that most often starts in the urethra or urinary tract before spreading to the epididymis.

Causes and symptoms

Among men under age 35 who are sexually active, *Chlamydia trachomatis* or *Neisseria gonorrhoeae* are the most common causes of epididymitis.

Nonsexually transmitted epididymitis is associated with urinary tract infections and is more common in men who have undergone surgery for urinary tract problems or who have anatomical abnormalities.

Although epididymitis is often caused by and associated with some of the same organisms that cause some sexually transmitted diseases, there are other causes as well. The condition can also be attributed to pus-generating bacteria associated with infections in other parts of the body. This cause, however, is rare.

Epididymitis can be caused by injury or infection of the scrotum or by irritation from urine that has accumulated in the vas deferens (the duct through which sperm travels after leaving the epididymis).

Epididymitis is characterized by pain in the testes. The pain, which usually develops gradually over several hours or days, is followed by sudden redness and swelling of the scrotum. Generally, only one testicle is affected. The affected testicle is hard and sore, and the other testicle may feel tender. The patient has **chills**, a low-grade **fever** and usually has acute urethritis (inflammation of the urethra).

Sometimes, there is a discharge from the urethra and blood in the semen. Ejaculation can be painful.

Enlarged lymph nodes in the groin cause scrotal pain that intensifies throughout the day and may become so severe that walking normally becomes impossible.

Diagnosis

Doctors test for epididymitis through:

- Urinalysis, which will likely show an elevated white blood-cell count and the presence of bacteria.
- Urine culture, to identify the organism responsible for the infection.
- Examination of discharges from the urethra and prostate gland.
- Blood tests to measure white-cell counts, which will be elevated.
- Ultrasound, which will reveal an enlarged epididymis.

The condition may lead to an **abscess** or cause such complications as **infertility**, so it is best to consult a urologist about the condition and treatment.

Treatment

Conventional treatment involves the use of antibiotics to treat the infection and pain killers to ease the pain. With alternative therapies, the treatment involves increasing circulation to the area. This reduces inflammation, which helps the body heal.

Fasting is recommended for some people, since digestion slows down the body's healing mechanisms. A water fast is best, but if that is not possible, the patient should confine intake to fruit and vegetable juices. If food must be eaten, a light diet of fresh fruits and vegetables is recommended. Fasting eases pain. Fluids should also be increased.

In **traditional Chinese medicine**, there are formulas of herbs that need to be designed to fit the individual case. Herbs like philodendron (Huang Bai) are used for inflammation in the lower torso area. **Pulsatilla**, which helps with swelling and pain, particularly in the genitals, and podophyllum are the most effective in treating epididymitis. These plants, however, are toxic, and the herb should only be taken under the direct supervision of an experienced herbalist. **Echinacea**, **horsetail**, **saw palmetto** berries, **cranberry** extract, and chimaphilla are also effective.

Hydrotherapy may also help. Sitting in hot water increases circulation to the prostate area, alleviating discomfort and speeding recovery. Patients are advised to sit in a tub for 15 to 30 minutes once or twice a day. The water should be as hot as can be tolerated.

Homeopathy is also an option. Homeopathic physicians may prescribe remedies that are specific to the person.

Since epididymitis is caused by an infection and often involves the urinary tract, the following alternative remedies may also be helpful in treatment of the condition:

- Acupuncture, which may help ward off another infection.
- Aromatherapy. A hot sitz bath with drops of juniper berry or sandalwood may relieve symptoms of the infection.
- Chiropractic. Strengthening bladder muscles by adjusting the joints and bones in the pelvic area may keep infection at bay.

Allopathic treatment

Epididymitis is traditionally treated with antibiotic therapy. To prevent reinfection, patients must take their medication exactly as prescribed, even if the patient's symptoms disappear or if he begins to feel better. Over-the-counter anti-inflammatories may be taken to relieve pain. The over-the-counter medicines will have the same effects as herbal anti-inflammatories.

Bed rest is recommended until symptoms subside, and patients are advised to wear athletic supporters when they resume normal activities. If pain is severe, a local anesthetic like lidocaine (Xylocaine) may be injected directly into the spermatic cord. Scrotal ice packs and scrotal elevation are also recommended.

Self-care

A patient who has epididymitis should not drink beverages that contain **caffeine**. To prevent **constipation**, he should use stool softeners or eat plenty of fruit, nuts, whole grain cereals, and other foods with laxative properties.

Strenuous activity should be avoided until symptoms disappear. Sexual activity should not be resumed until a month after symptoms disappear.

If a second course of treatment does not eradicate stubborn symptoms, long-term anti-inflammatory therapy may be recommended. In rare instances, chronic symptoms require surgery.

Surgery

There are two surgical procedures used to treat epididymitis, and both of them cause sterility.

Epididymectomy involves removing the inflamed section of the epididymitis through a small incision in the scrotum.

Bilateral vasectomy prevents fluid and sperm from passing through the epididymis. This procedure is usually performed on men who have chronic epididymitis or on elderly patients undergoing prostate surgery.

Before considering surgeries that will lead to infertility, patients may want to try alternative therapies.

Expected results

Herbal preparations are very effective in treating epididymitis. Some sources say that given in medicinal doses, the herbs pulsatilla and podophyllum can treat epididymitis with the same results as conventional medicine.

Pain may begin to subside within 24 hours of treatment, but complete healing may take weeks or even months.

Prevention

Using condoms and not having sex with anyone who has a sexually transmitted disease (STD) can prevent some cases of epididymitis. Also, drinking plenty of fluids, which will increase urine flow, will help prevent urine retention, which can lead to infection.

Epilepsy

Definition

Epilepsy is a condition characterized by recurrent seizures that may include repetitive muscle jerking called convulsions. A seizure is a sudden disruption of the brain's normal electrical activity accompanied by altered consciousness and/or other neurological and behavioral manifestations.

Description

Epilepsy affects 2.7 million people in the United States. Although epilepsy is as common in adults over 60 as in children under 10, 25% of all cases develop before the age of five. One in every two cases develops before the age of 25. About 200,000 new cases of epilepsy are diagnosed each year, and a significant number of children and adults that have not been diagnosed or treated have epilepsy.

Most seizures are benign, but a seizure that lasts a long time can lead to status epilepticus, a life-threatening condition characterized by continuous seizures, sustained loss of consciousness, and respiratory distress. Nonconvulsive epilepsy can impair physical coordination, vision, and other senses. Undiagnosed seizures can lead to conditions that are more serious and more difficult to manage.

Types of seizures

Generalized epileptic seizures occur when electrical abnormalities exist throughout the brain. A partial seizure does not involve the entire brain. A partial seizure begins in an area called an epileptic focus, but it may spread to other parts of the brain and cause a generalized seizure. Some people who have epilepsy have more than one type of seizure.

Motor attacks cause parts of the body to jerk repeatedly. A motor attack usually lasts less than an hour and may last only a few minutes. Sensory seizures begin with numbness or tingling in one area. The sensation may move along one side of the body or the back before subsiding.

Visual seizures that affect the area of the brain that controls sight cause people to hallucinate. Auditory seizures affect the part of the brain that controls hearing and cause the patient to imagine hearing voices, music, and other sounds. Other types of seizures can cause confusion, upset stomach, or emotional distress.

PARTIAL SEIZURES. Simple partial seizures do not spread from the focal area from which they arise. Symptoms are determined by the part of the brain affected. The patient usually remains conscious during the seizure and can later describe it in detail.

COMPLEX PARTIAL SEIZURES. A distinctive smell, taste, or other unusual sensation (aura) may signal the start of a complex partial seizure.

Complex partial seizures start as simple partial seizures but move beyond the focal area and cause loss of consciousness. Complex partial seizures can become major motor seizures. Although individuals who are having a complex partial seizure may not seem to be unconscious, they do not know what is happening and may behave inappropriately. They do not remember the seizure but may seem confused or intoxicated for a few minutes after it ends.

Causes and symptoms

The origin of 50 to 70% of all cases of epilepsy is unknown. Epilepsy sometimes results from trauma at birth. Such causes include insufficient oxygen to the brain; head injury; heavy bleeding or incompatibility between a woman's blood and the blood of her newborn baby; and infection immediately before, after, or at the time of birth.

Other causes of epilepsy include:

- head trauma resulting from a car accident, gunshot wound, or other injury
- alcoholism
- brain abscess or inflammation of membranes covering the brain or spinal cord
- phenylketonuria (PKU), a disease that is present at birth, is often characterized by seizures and can result in mental retardation
- other inherited disorders
- infectious diseases such as measles, mumps, and diphtheria
- degenerative disease
- lead poisoning, mercury poisoning, carbon monoxide poisoning, or ingestion of some other poisonous substance
- genetic factors

Status epilepticus, a condition in which a person suffers from continuous seizures and may have trouble breathing, can be caused by the following:

- suddenly discontinuing anti-seizure medication
- hypoxic or metabolic encephalopathy (a brain disease resulting from lack of oxygen or malfunctioning of other physical or chemical processes)
- acute head injury
- infection spread from blood (for example, meningitis or encephalitis) caused by inflammation of the brain or the membranes that cover it

Diagnosis

Personal and family medical history, description of seizure activity, and physical and neurological examinations help primary care physicians, neurologists, and epileptologists diagnose this disorder. Doctors rule out conditions that cause symptoms that resemble epilepsy, including small strokes (transient ischemic attacks, or TIAs), fainting (syncope), pseudoseizures, and sleep attacks (**narcolepsy**).

Neuropsychological testing uncovers learning or memory problems. Neuroimaging provides views of brain areas involved in seizure activity.

The electroencephalogram (EEG) is the main test used to diagnose epilepsy. EEGs use electrodes placed on or within the skull to record the brain's electrical activity and pinpoint the exact location of abnormal discharges.

Individuals may be asked to remain motionless during a short-term EEG or to go about their normal activities during extended monitoring. Some patients are deprived of sleep or exposed to seizure triggers, such as rapid, deep breathing (hyperventilation) or flashing lights (photic stimulation). In some cases, people may be hospitalized for EEG monitorings that can last as long as two weeks. Video EEGs also document what individuals were doing when the seizure occurred and how the seizure changed their behavior.

Other techniques used to diagnose epilepsy include:

- Magnetic resonance imaging (MRI), which provides clear, detailed images of the brain. Functional MRI (fMRI), performed while the patient does various tasks, can measure shifts in electrical intensity and blood flow and indicate which brain region each activity affects.
- Positron emission tomography (PET) and single photon emission tomography (SPECT) monitor blood flow and chemical activity in the brain area being tested. PET and SPECT are effective in locating the brain region in which metabolic changes take place between seizures.

Treatment

Relaxation techniques

Stress increases seizure activity in 30% of people who have epilepsy. **Relaxation** techniques can provide some sense of control over the disorder, but they should never be used instead of anti-seizure medication or without the approval of the patient's doctor. **Yoga**, **meditation**, and favorite pastimes help some people relax and manage stress more successfully. **Biofeedback** can teach adults and older adolescents how to recognize an aura and what to do to stop its spread. Children under 14 usually are not able to understand and apply principles of biofeedback.

Acupuncture

Acupuncture treatments (acupuncture needles inserted for a few minutes or left in place for as long as 30 minutes) make some people feel pleasantly relaxed.

Acupressure

Acupressure can have the same pleasantly relaxed effect on children or on adults who dislike needles.

Aromatherapy

Aromatherapy involves mixing aromatic plant oils into water or other oils and massaging them into the skin or using a special burner to waft their fragrance throughout the room. Aromatherapy oils affect the body and the brain, but undiluted oils should never be applied directly to the skin. Ylang ylang, **chamomile**, or **lavender** can create a soothing mood. People who have epilepsy should not use **rosemary**, **hyssop**, citrus (such as lemon), **sage**, or sweet **fennel**, which seem to stimulate the brain.

Nutritional therapy

KETOGENIC DIET. A special high-fat, low-protein, low-carbohydrate diet sometimes is used to treat patients whose severe seizures have not responded to other treatment. Calculated according to age, height, and weight, the ketogenic diet induces mild starvation and dehydration. This procedure forces the body to create an excessive supply of ketones, natural chemicals with seizure-suppressing properties.

The goal of this controversial approach is to maintain or improve seizure control while reducing

medication. The ketogenic diet works best with children between the ages of one and 10. It is introduced over a period of several days, and most children are hospitalized during the early stages of treatment.

If a child following this diet remains seizure-free for at least six months, increased amounts of carbohydrates and protein gradually are added. If the child shows no improvement after three months, the diet gradually is discontinued. A 2003 study of the diet and its effect on growth noted that if the diet is used, clinicians should recommend adequate intake of energy foods and protein and a higher proportion of unsaturated to saturated dietary fats. The report also recommended use of vitamin and mineral supplements with the diet.

Introduced in the 1920s, the ketogenic diet had limited, short-term success in controlling seizure activity. Its use exposes patients to such potentially harmful side effects as the following:

- staphylococcal infections
- stunted or delayed growth
- low blood sugar (hypoglycemia)
- excess fat in the blood (hyperlipidemia)
- disease resulting from calcium deposits in the urinary tract (urolithiasis)
- disease of the optic nerve (optic neuropathy)

Homeopathy

Homeopathic therapy also can work for people with seizures, especially constitutional homeopathic treatment that acts at the deepest levels to address the needs of the individual person.

Allopathic treatment

The goal of epilepsy treatment is to eliminate seizures or make the symptoms less frequent and less severe. Long-term anticonvulsant drug therapy is the most common form of epilepsy treatment.

Medication

A combination of drugs may be needed to control some symptoms, but many patients who have epilepsy take one of the following medications:

- phenytoin (Dilantin)
- carbamazepine (Tegretol)
- phenobarbital (Barbita)
- primidone (Mysoline)
- valproic acid, sodium valproate (Depakene)
- clonazepam (Klonopin)
- ethosuximide (Zarontin)

Dilantin, Tegretol, Barbita, and Mysoline are used to manage or control generalized tonic-clonic and complex partial seizures. Depakene, Klonopin, and Zarontin are prescribed for patients who have absence seizures.

Neurontin, Lamictal, and Topamax are among medications approved in the United States to treat adults who have partial seizures or partial and grand mal seizures. Another medication, levetiracetam (Keppra), was approved and showed particularly good results in reducing partial seizures among elderly patients with few side effects. Having minimal side effects is important because elderly patients often have other conditions and must take other medications that might interact with seizure medications. In 2003, Keppra's manufacturer was working on a new anti-epilectic drug from the same chemical family as Keppra that was anticipated to be more potent and effective. That drug was in phase III trials as of 2008. Available medications frequently change, and the physician determines the best treatment for an individual patient. A 2003 report found that monotherapy (using just one medication rather than a combination) works better for most patients. The less complicated the treatment, the more likely the patient will comply and better manage the seizure disorder.

Even epileptic patients whose seizures are well controlled should have regular blood tests to measure levels of anti-seizure medication in their system and to check to see if the medication is causing any changes in blood or liver function. A doctor should be notified if any signs of drug toxicity appear, including uncontrolled eye movements; sluggishness, **dizziness**, or hyperactivity; inability to see clearly or speak distinctly; **nausea** or **vomiting**; or sleep problems.

Status epilepticus requires emergency treatment, usually with Valium, Ativan, Dilantin, or Barbita. An intravenous dextrose (sugar) solution is given to patients whose condition is due to low blood sugar, and a vitamin B_1 preparation is administered intravenously when status epilepticus results from chronic alcohol withdrawal. Because dextrose and **thiamine** are essentially harmless and because delay in treatment can be disastrous, these medications are given routinely, as it is typically difficult to obtain an adequate history from a patient suffering from status epilepticus.

Intractable seizures are seizures that cannot be controlled with medication or without sedation or other unacceptable side effects. Surgery may be used to eliminate or control intractable seizures.

Surgery

Surgery can be used to treat patients whose intractable seizures stem from small focal lesions that can be removed without endangering the patient, changing the patient's personality, dulling the patient's senses, or reducing the patient's ability to function.

A physical examination is conducted to verify that a patient's seizures are caused by epilepsy, and surgery is not used to treat patients with severe psychiatric disturbances or medical problems that raise risk factors to unacceptable levels.

Surgery is never recommended unless the following have occurred:

- The best available anti-seizure medications have failed to control the patient's symptoms satisfactorily.
- The origin of the patient's seizures has been precisely located.
- There is good reason to believe that surgery will significantly improve the patient's health and quality of life.

Every patient considering epilepsy surgery is carefully evaluated by one or more neurologists, neurosurgeons, neuropsychologists, and/or social workers. A psychiatrist, chaplain, or other spiritual advisor may help the patient and his family cope with the stresses that occur during and after the selection process.

TYPES OF SURGERY. Surgical techniques used to treat intractable epilepsy include:

- Lesionectomy. Removing the lesion (diseased brain tissue) and some surrounding brain tissue is very effective in controlling seizures. Lesionectomy is generally more successful than surgery performed on patients whose seizures are not caused by clearly defined lesions, but removing only part of the lesion lessens the effectiveness of the procedure.
- Temporal resections. Removing part of the temporal lobe and the part of the brain associated with feelings, memory, and emotions (the hippocampus) provides good or excellent seizure control in 75 to 80% of properly selected patients with appropriate types of temporal lobe epilepsy. Some patients experience post-operative speech and memory problems.
- Extra-temporal resection. This procedure involves removing some or all of the frontal lobe, the part of the brain directly behind the forehead. The frontal lobe helps regulate movement, planning, judgment, and personality. Special care must be taken to prevent post-operative problems with movement and speech. Extra-temporal resection is most successful in patients whose seizures are not widespread.
- Hemispherectomy. This method of removing brain tissue is restricted to patients with severe epilepsy and abnormal discharges that often extend from one side of the brain to the other. Hemispherectomies are most often performed on infants or young children who have had an extensive brain disease or disorder since birth or from a very young age.
- Corpus callosotomy. This procedure, an alternative to hemispherectomy in patients with congenital hemiplegia, removes some or all of the white matter that separates the two halves of the brain. Corpus callosotomy is performed almost exclusively on children who are frequently injured during falls caused by seizures. If removing two-thirds of the corpus callosum does not produce lasting improvement in the patient's condition, the remaining one-third is removed during another operation.
- Multiple subpial transection. This procedure is used to control the spread of seizures that originate in or affect the so-called eloquent cortex, the area of the brain responsible for complex thought and reasoning.

Other forms of treatment

VAGUS NERVE STIMULATION. Approved for adults and adolescents (over 16 years old) with intractable seizures, vagus nerve stimulation (VNS) uses a pacemaker-like device implanted under the skin in the upper left chest, to provide intermittent stimulation to the vagus nerve. Stretching from the side of the neck into the brain, the vagus nerve affects swallowing, speech, breathing, and many other functions, and VNS may prevent or shorten some seizures.

First aid for seizures

A person with epilepsy having a seizure should not be restrained, but sharp or dangerous objects should be moved out of reach. Anyone having a complex partial seizure can be warned away from danger by someone calling his/her name in a clear, calm voice.

A person with epilepsy having a grand mal seizure should be helped to lie down, and those aiding the patient should contact emergency medical personnel. Tight clothing should be loosened. A soft, flat object like a towel or the palm of a hand should be placed under the person's head. Forcing a hard object into the mouth of someone having a grand mal seizure could cause injuries or breathing problems. If the person's mouth is open, placing a folded cloth or other soft object between his or her teeth will protect the tongue. Turning the patient's head to the side will help with breathing. After a grand mal seizure has ended, the person who had the seizure should be told what has happened and reminded of where he or she is.

KEY TERMS

Acupressure—Needleless acupuncture.

Acupuncture—An ancient Chinese method of relieving pain or treating illness by piercing specific areas of the body with fine needles.

Biofeedback—A learning technique that helps individuals influence automatic body functions.

Epileptologist—A physician who specializes in the treatment of epilepsy.

Expected results

People who have epilepsy have a higher than average rate of suicide; sudden, unexplained death; and drowning and other accidental fatalities.

Benign focal epilepsy of childhood and some absence seizures may disappear in time, but remission is unlikely if seizures occur several times a day, several times in a 48-hour period, or more frequently than in the past.

Epilepsy can be partially or completely controlled if the individual takes anti-seizure medication according to directions; avoids seizure-inducing sights, sounds, and other triggers; gets enough sleep; and eats regular, balanced meals.

Individuals who have epilepsy should wear a bracelet or necklace identifying the seizure disorder and listing the medication they take.

Prevention

Eating properly, getting enough sleep, and controlling stress and fevers can help prevent seizures. A person who has epilepsy should be careful not to hyperventilate. Those who experience auras should find a safe place to lie down and stay until the seizure passes. Anticonvulsant medications should not be stopped suddenly, and if other medications are prescribed or discontinued, the doctor treating the seizures should be notified. In some conditions, such as severe head injury, brain surgery, or subarachnoid hemorrhage, anticonvulsant medications may be given to the patient to prevent seizures.

Epimedium

Description

Epimedium is a genus of 21 species and is a member of the buttercup family. *Epimedium* is a woody, pungent ornamental herb found in western and eastern Asia and the Mediterranean. Various hybrids are grown elsewhere and most often are used as groundcover, particularly in shady areas. The herb also goes by the name

Epimedium is a woody, pungent ornamental herb found in western and eastern Asia and the Mediterranean. *(© Frank Blackburn / Alamy)*

KEY TERMS

Expectorant—A preparation that loosens or liquefies thick mucus.

Impotence—Refers to a condition where the penis is unable to get erect or stay erect.

Shen Nong—A legendary emperor, he was called the "Divine Farmer" of China. Shen Nong made many discoveries concerning herbal medicine and cataloged 365 species of medicinal plants. An early herbal text, written around 400 A.D., was named after him.

Sinusitis—An infection of the sinus cavities characterized by pain in the eyes and cheeks, fever, and difficulty breathing through the nose.

Suet—Refers to the hard fat found around cattle and sheep kidneys and loins; it is used in cooking.

horny goat weed and barrenwort. The Chinese call it *Yin Yang Huo*, which means "licentious goat plant."

The plant was named epimedium because it is akin to a plant found in the ancient southwest Asian kingdom of Media, now a part of Iran. Plants used for medicinal purposes include *Epimedium sagittatum, Epimedium brevicornum, Epimedium wushanense, Epimedium koreanum,* and *Epimedium pubescens.*

General use

The use of epimedium as a medicinal herb dates back thousands of years. Shen Nong's *Canon of Medicinal Herbs,* compiled around 400 A.D., mentions its use.

The odorless, bitter herb has been used as a:

- Kidney tonic to help relieve problems of frequent urination and correct problems of lightheadedness and weakness associated with improper body fluid volumes.
- Reproductive system tonic to treat impotence and premature ejaculation.
- Rejuvenating tonic, as an aphrodisiac or to relieve fatigue.

The herb, which dilates blood vessels, has also been used to treat coronary **heart disease**, **asthma**, **bronchitis**, and sinusitis. An expectorant, it can be used to control coughing. It can also be used to lower blood pressure.

Studies have shown that epimedium raises adrenaline, noradrenaline, serotonin, and dopamine levels in animals. It is the dopamine that may be responsible for the herb's use as a reproductive tonic. The increased dopamine levels in the body set off a chain reaction that leads to a release of testosterone, the male sex hormone.

Other evidence suggests the herb increases sensitivity in nerve endings, which may explain why it is prescribed as an aphrodisiac.

Preparations

The herb is collected in summer or early autumn, then dried in the sun. Some use it unprepared, while others bake it with sheep fat.

The herb can be ingested as a tea infusion. To make the tea, 1 oz (28 g) of the cut leaves are added to a pint of hot water. The recommended dosage is one to three cups per day. The tea should be taken with food.

A powder form may be made by combining 100 kg of dried epimedium leaves with 20 kg of refined suet, then stir-frying the concoction.

Epimedium may also be combined with **lycium fruit** to make a tea concoction to stimulate the Kidneys and reproductive system. Combine one ounce of epimedium and wolfberries (lycium) with hot water and drink after the concoction has steeped for 10 to 15 minutes. Note that individuals with **allergies** to

tomatoes and other vegetables in the nightshade family may also be allergic to lycium berries.

Precautions

When buying epimedium, be sure to pick leaves with a dark color. Those that are yellow or blanched probably sat in the sun too long when drying and will not be as effective.

Also, purchase herbs from reputable companies to ensure their purity.

Side effects

Ingesting an excess amount of the herb can lead to **vomiting**, **dizziness**, thirst, and nosebleed.

Interactions

Just like other drugs, herbs can be hazardous to health both by themselves and particularly in certain combinations. For this reason, consult a knowledgeable herbal therapist before taking epimedium to find out what it can and cannot be used with. Also, be aware that herbs can interfere with prescription medication.

Escharotic treatment

Description

Escharotic treatment is the use of topical herbal preparations to treat a variety of cancerous lesions. Escharotic treatments are highly corrosive and produce a thick crust (eschar) that results in extensive scarring.

General use

Escharotic treatments have been used for hundreds of years. During the late twentieth century, these agents were used for the self-treatment of basal cell, squamous cell, and melanoma skin cancers, as well as cervical **cancer**, among others.

Many components of escharotic treatments have been identified as having antioxidant, antimitotic (inhibit cell division), and other anticarcinogenic properties. Escharotic agents may have beneficial properties when used by trained, licensed medical professionals for specific applications, including debridement of chronic leg ulcers and chemosurgical debridement of bone cancers.

Frederic Mohs developed the micrographic fixed-tissue staged excision procedure of his namesake in the 1930s. For this procedure, he used the escharotic agent **zinc** chloride (later coined "Mohs paste"). The Mohs procedure in the 2000s does not involve the use of zinc chloride because the cure rate and tissue conservation associated with this procedure are related to surgical technique and not to the use of the escharotic agent. The Mohs procedure involves the surgical removal of the visible tumor, followed by microscopic examination of the removed tissue. If cancer is seen at the margins, the suspected area plus a thin margin are removed, and this process is repeated until all of the cancer appears to have been identified and removed. This procedure is associated with a very high cure rate, reduced scarring, and minimal removal of healthy tissue.

There is very little evidence-based clinical research to support the benefits of these remedies when used for other applications, especially when they are used by consumers as self-treatment in lieu of recommended conventional therapies. There have been numerous reports of adverse effects associated with the use of these products. Several case studies have reported that tumors are not reliably treated with escharotic treatments, result in extensive scarring that is often unsightly, and have been associated with tumor recurrence within the scar tissue.

Escharotic products that contain labeling or marketing statements claiming that they treat cancers cannot legally be marketed in the United States. However, the distribution of escharotic substances grew considerably in the United States between 1998 and 2008 via unregulated Internet direct-to-consumer sales. As a result, many patients who have sought alternative remedies instead of more conventional treatments have experienced serious side effects.

The U.S. Federal Trade Commission (FTC), the U.S. Food and Drug Administration (FDA), and Health Canada (the Canadian federal health department), created a law enforcement and consumer education campaign in 1999 called Operation Cure All, in order to teach consumers how to identify health fraud and to provide information for businesses about truthful marketing practices for health products.

Research is ongoing to determine how escharotic treatments alter certain diseases or reduce the risk of diseases and how they can be used effectively while minimizing side effects. In addition, labeling terminology, including product health claims, are still being determined for escharotic agents.

Preparations

Escharotic treatments are available in salve, paste, poultice, or plaster preparations. The recommended use is to apply a liberal amount over the lesion or affected area and leave it on the skin for a long period of time, up to 24 hours.

The most caustic escharotic treatments, sometimes referred to as "black salves " include:

- bloodroot *(Sanguinaria canadendid)*
- zinc chloride
- goldenseal *(Hydrastis canadensis)*

Other herbal preparations used as escharotic treatments include:

- red clover *(Trifolium pretense)*
- combination preparations containing red clover, bloodroot, galangal, and sheep sorrel (*Rumex acetosella*, also known as sour grass)
- carbamide (urea)
- graviola leaf *(Annona muricata)*

Precautions

Escharotic agents are not recommended for self-treatment applications because of the associated risk of serious side effects, which have been well-documented. Escharotic treatments do not completely remove tumors, they may damage surrounding healthy tissue, and they may result in significant scarring with poor cosmetic outcomes.

The FDA has banned black salve products, including all products containing *Cansema*, as well as **bloodroot** paste *Sanguinaria canadensis* due to their harmful effects.

In the United States, herbal supplements are not required to be standardized. Although regulated under the 1994 Dietary Supplement Health and Education Act (DSHEA), there are no safety reviews or approved therapeutic uses for escharotic treatments by the FDA. After the product is marketed, the FDA must prove the product unsafe before it can be removed from the shelves. Fortunately, several escharotic treatments have been proven unsafe and removed from the market, although there are many harmful products still available.

Manufacturing guidelines for herbal remedies are not standardized; therefore, preparations can vary widely from one brand to another and within the same brand from one purchase to the next, making inconsistency in the concentration of ingredients a potential risk.

Many people associate the term "natural" with "safe" and that is not always the case. Anyone taking herbal products of any kind should be certain to read labels carefully and discuss the products with a physician to evaluate potential interactions with other medical conditions and/or prescription medications.

Side effects

Escharotic treatments can result in large open sores or lesions that often spread well beyond the

KEY TERMS

Antioxidant—A substance that protects against the oxidative processes that may lead to cellular damage. Antioxidants are associated with a reduced risk of cancer, cardiovascular disease, and other medical conditions.

Caustic—Corrosive; capable of destroying by chemical action.

Epithelial—Tissues that line cavities and body surfaces, such as the skin.

Mohs surgery—A type of micrographic surgery for removal of a visible tumor. Mohs surgery has a high cure rate (up to 99% for certain types of new lesions and 95% for recurrent cancers), with minimal removal of healthy surrounding tissue.

Paste—Water-based products that are thick when applied and have a tendency to dry out and build up.

Poultice—A soft mass that is usually heated, spread on a cloth, and applied to sores or other lesions.

Salve—A substance that is applied to wounds or sores.

margins of the original tumor or lesion. These agents do not completely remove tumors; they damage surrounding healthy tissue, and they result in significant scarring with poor cosmetic outcomes.

Interactions

Serious side effects have occurred with the use of bloodroot paste (*Sanguinaria canadendid*) and zinc chloride combination as part of the Mohs chemosurgery fixed-tissue technique.

Essential fatty acids

Description

Essential fatty acids (EFAs) are fats that are essential to the diet because the body cannot produce them. Essential fatty acids are extremely important nutrients for health. They are present in every healthy cell in the body and are critical for the normal growth and functioning of the cells, muscles, nerves, and organs. EFAs are also used by the body to produce a class of hormone-like substances called prostaglandins, which are key to many important processes. Deficiencies of EFAs are linked to a variety of health problems, including major ones such as **heart disease**, **cancer**, and diabetes. It has been estimated that as many as 80% of Americans may consume insufficient quantities of EFAs.

Very few health issues received as much attention during the last third of the twentieth century as the question of fat in the diet. Sixty-eight percent of deaths in the United States are related to fat consumption and diet, including heart disease (44% of deaths), cancer (22%) and diabetes (2%). There are several types of dietary fats. Saturated fat is found mainly in animal products, including meat and dairy products, avocados, and nuts. **Cholesterol** is a dietary fat that is only found in animal products. Cholesterol is also made by the body in small amounts from saturated fats. Heavy consumption of saturated fat and cholesterol has been linked to heart disease and cancer. Unsaturated fats are typically oils from vegetables and nuts and are present in some fish. These are considered the healthiest dietary fats. Essential fatty acids are unsaturated fats. EFAs are the only fats that may need to be increased in the U.S. diet.

Scientists classify essential fatty acids in two types, **omega-3 fatty acids** and **omega-6 fatty acids**, depending on their chemical composition. Technically, the omega-3 fatty acids are alpha-linolenic acid, stearidonic acid, and two others called EPA and DHA. Alpha-linolenic acid is found mainly in **flaxseed** oil, canola oil, soybeans, walnuts, hemp seeds, and dark green leafy vegetables. Stearidonic acid is found in rarer types of seeds and nuts, including black currant seeds. EPA and DHA are present in cold-water fish, including salmon, trout, sardines, mackerel, and cod. Cod liver oil is a popular nutritional supplement for omega-3 EFAs.

Omega-6 fatty acids are more common in the U.S. diet than the omega-3 EFAs. These include **linoleic acid**, which is found in safflower, olive, almond, sunflower, hemp, soybean, walnut, pumpkin, sesame, and flaxseed oils. Gamma-linolenic acid (GLA) is found in some seeds and evening primrose oil. Arachidonic acid (AA) is present in meat and animal products.

Both types of EFAs, omega-3 and omega-6 fatty acids, are necessary in a healthy diet. Deficiencies of EFAs have been brought about by changes in diet and

the modern processing of foods and oils. Many nutritionists believe that a major dietary problem is the use of hydrogenated oils, which are present in margarine and many processed foods. Hydrogenated oils are highly refined by industrial processes and contain toxic by-products and trans-fatty acids. Trans-fatty acids are fat molecules with chemically altered structures and are believed to have several detrimental effects on the body. Trans-fatty acids interfere with the absorption of healthy EFAs and may contribute to **atherosclerosis** or damage to the arteries. Deep-fried foods, which are cooked in oil that is altered by very high temperatures, also contain trans-fatty acids. Many health professionals, including those at the World Heath Organization, have protested against the use of hydrogenated oils in food and the consumption of trans-fatty acids. Health conditions linked to the consumption of trans-fatty acids and hydrogenated oils include cancer, heart disease, high cholesterol, diabetes, **obesity**, immune system disorders, decreased sperm counts, and infant development problems.

Dietary changes that have contributed to EFA deficiency or imbalances include the increased use of oils that contain few or no omega-3 EFAs; the industrial milling of flour that removes the EFA-containing germ; the increase of sugar and fried foods in the diet that may interfere with the body's absorption of EFAs; and the decreased consumption of fish.

A balance of omega-3 and omega-6 EFAs in the diet is recommended by experts. Americans typically consume higher quantities of omega-6 EFAs because these are found in meat, animal products, and common cooking oils. Research has shown that too many omega-6 EFAs in the diet can lead to the imbalanced production of prostaglandins, which may contribute to health problems. Experts recommend that omega-3 and omega-6 EFAs be present in the diet in a ratio of around one to three. Americans consume a ratio as high as one to 40. Thus, the need for greater amounts of omega-3 EFAs in the diet has increased.

Symptoms of EFA deficiency or imbalance include dry or scaly skin, excessively dry hair, cracked fingernails, **fatigue**, weakness, frequent **infections**, **allergies**, mood disorders, hyperactivity, **depression**, memory and learning problems, slow wound healing, aching joints, poor digestion, high blood pressure, obesity, and high cholesterol.

General use

EFA supplementation is recommended for more than 60 health conditions. EFAs are used therapeutically to treat and prevent cardiovascular problems, including heart disease, high cholesterol, strokes, and high blood pressure. EFAs also have anti-inflammatory effects in the body and are used in the nutritional treatment of arthritis, **asthma**, allergies, and skin conditions (e.g., **eczema**). EFAs are used as support for immune system disorders, including **AIDS**, **multiple sclerosis**, and lupus. EFAs have been thought to reduce the risk of cancer, but this assumption came under question in 2006 when an analysis of previous studies, called a meta-analysis, found mixed results. The study concluded that there is not enough evidence to suggest a significant relationship between consumption of omega-3 fatty acids and a reduced risk of cancer. Meta-analyses became fashionable topics in major medical journals in the late 1990s and 2000s, mainly because they are easy to conduct, require no new research, and are relatively inexpensive. However, many researchers point out that the findings of meta-analysis studies can be biased, depending on what criteria are used in selecting previous studies to be included in the meta-analysis. This criticism has been leveled at the 2006 study of omega-3 and cancer. In the August-September issue of *Townsend Letter: The Examiner of Alternative Medicine*, Melvyn R. Werbach wrote: "Not only are there numerous problems with the selection of studies for this meta-analysis, but the lack of consistently positive findings was not a basis for reaching such a negative conclusion." Werbach added that further research is needed to prove the positive effects of EFAs in fighting cancer as well as in establishing the correct dosages required. With the ratio of omega-3 to omega-6 fatty acids widening, Werbach suggests this imbalance may be contributing to rising cancer rates and that an increase in the dietary intake of omega-3 fatty acids should reduce the risk of cancer.

Other conditions that may improve with EFA supplementation include **acne** and other skin problems, depression, menopausal problems, nervous conditions, obesity, memory and learning disabilities, eye problems, and digestive disorders. A 2007 University of Colorado study found that a diet rich in omega-3 fatty acids might delay the onset of type 1 diabetes in children at risk for the disease. EFAs are recommended for weight loss programs, as they may assist fat metabolism in the body. In 2007, two studies reported that **diets** high in omega-3 fatty acids could be helpful in treating several psychiatric disorders. An Australian study found that children with early signs of psychosis who were given omega-3 supplements were six times less likely to develop a psychotic disorder than those who did not take a supplement. The second study, a meta-analysis done by U.S. researchers, reported that omega-3 fatty acid supplements

were effective in treating borderline personality disorder (BPD). BPD occurs primarily in women and symptoms include a lack of self-sense, chaotic relationships with other people, depression, impulsive aggression, and unstable personality traits.

Preparations

Common EFA supplements are flaxseed oil, **evening primrose oil**, **borage oil**, **black currant seed oil**, hemp seed oil, and cod liver oil. Consumers should search for supplements that contain both omega-3 and omega-6 EFAs because imbalances of EFAs may occur if either is taken in excess over long periods of time. Flaxseed oil is a recommended supplement because it contains the highest percentage of omega-3 fatty acids with some omega-6 EFAs as well. Flaxseed oil is generally the least expensive source of omega-3 EFAs as well, generally much cheaper than **fish oil** supplements. Evening primrose oil is a popular supplement as well because the GLA it contains has shown benefits in treating **premenstrual syndrome** and other conditions. However, evening primrose oil contains no omega-3 EFAs. Hemp seed oil is a well-balanced source of both EFAs.

Supplements are available from health food stores in liquid and capsule form. The recommended daily dosage is one to two tablespoons (13-26 capsules), taken with meals. EFAs can also be obtained from a diet that includes cold-water fish consumed twice per week, whole grains, dark green leafy vegetables, walnuts, pumpkin seeds, **wheat germ**, soy products, canola oil, and other foods. Whole flaxseeds are a wholesome source of EFAs as well and can be freshly ground and added to salads and other dishes. Supplements that contain the enzyme **lipase** help the body more efficiently digest the oils.

In 2007, *USA Today* named omega-3 fatty acids one of the hottest food additives of 2007 because an increasing number of food manufacturers add omega-3 fatty acids to a wide range of food products, including milk, soy milk, yogurt, flax oil, canola oil, butter-like spreads, mayonnaise, and even microwavable popcorn. The reason is that dozens of studies conducted between 2000 and 2007 in the United States, Britain, Australia, Italy, and elsewhere showed that a diet high in omega-3 fatty acids significantly reduces the risk of heart disease.

Precautions

EFA supplements are generally fragile products and must be produced, packaged, and handled properly. Consumers should search for quality EFA supplements produced by reputable manufacturers. Products that are organically grown and certified by a third party are recommended. EFA products should be produced by cold or modified expeller pressing, which means that they were produced without damaging temperatures or pressure. Products should be packaged in light-resistant containers because sunlight damages EFAs. Packages should include manufacturing and expiration dates, in order to assure freshness. Stores and consumers should keep EFA products under refrigeration because heat damages them. Taste can indicate the quality of EFA oils: those that have no flavor usually are overly refined, and those that taste bitter are old or spoiled. Because of their low temperature threshold, nearly all oils that are used as EFA supplements are not suitable for use as cooking oils.

The U.S. Food and Drug Administration (FDA) cautions pregnant and nursing women and parents of infants and toddlers about the potential dangers of exposure to mercury from fish rich in omega-3 fatty acids and from fish oil capsules. High levels of mercury can affect brain development in fetuses and young children. The FDA recommends that these groups instead opt for younger species of fish such as canned tuna or farm-raised fish and skip fish oil capsules altogether. Vegetarians can supplement their diets with foods high in alpha-linoleic acids, including certain oils, flaxseed, and walnuts.

Side effects

Side effects with most EFA supplements are rare because EFAs are nontoxic and are used by the body as energy when taken in excess. The exception is cod liver and fish oil supplements, which can cause **vitamin A** and D toxicity when taken in excess. Side effects of vitamin A and D toxicity include headaches, skin discoloration, fatigue, **nausea**, and gastrointestinal problems. Fish oil supplements that have vitamins A and D removed are available.

Interactions

To maximize the benefits of EFA supplements, several recommendations can be followed. EFA users should reduce the amount of fat, particularly saturated fat from animal products, in their diet. The American Heart Association recommends that a healthy diet contains 30% or less of its total calories from fat. For 2,000 total calories per day, 600 calories or less should be from fat, including EFA supplements. Consumers should also completely eliminate hydrogenated and partially hydrogenated oils from their diets, which includes eliminating all processed foods that contain them, such as margarine and many packaged foods. Other foods that contain

KEY TERMS

Atherosclerosis—Hardening of the arteries.

Cholesterol—A steroid fat found in food derived from animals that is also produced in the body for several important functions. Excess cholesterol intake is linked to many diseases.

Hydrogenated fat—Unsaturated fat, commonly vegetable oil, that is processed with high heat and hydrogen to make it solid at room temperature. Margarine is a common hydrogenated fat.

Trans-fatty acid—A toxic type of fat created by hydrogenating oils and by deep frying foods.

trans-fatty acids, such as deep fried foods, should also be eliminated. Recommended cooking oils are olive, safflower, canola, and sesame oils. EFA effectiveness may be increased by lowering the intake of sugar and alcohol in the diet. Nutrients that assist EFA uptake are the B-complex vitamins, **vitamin C**, **zinc**, and **magnesium**. As with any supplement, EFA effectiveness can be augmented with a nutritious, high fiber diet that emphasizes fresh and natural foods, and the intake of fish two times a week.

Essential oils

Description

Essential oils are fragrant oils present in many plants. Hundreds of plants yield essential oils that are used as perfumes, food flavorings, medicines, and as fragrant and antiseptic additives in many common products.

Essential oils have been used for thousands of years. The ancient civilizations of Mesopotamia, more than 5,000 years ago, had machines for obtaining essential oils from plants. Essential oils were the primary source of perfumes for the ancient civilizations of Egypt, India, Greece, and Rome. Essential oils have been found in 3,000-year-old tombs in the Pyramids. Early Greek physicians, including Hippocrates, mentioned aromatic plant essences and oil massages for their healing and mood-enhancing qualities. The Romans associated essential oils and their fine aromas with wealth and success. **Ayurvedic medicine**, the world's oldest healing system, has long recommended essential oil massage as a health treatment for many conditions.

In modern times, essential oils have been used in the manufacture of high quality perfumes, as additives in many common products, and in the healing practice of **aromatherapy**. Aromatherapy was begun in the 1920s by a French chemist named Réné-Maurice Gattefosse, who became convinced of the healing powers of essential oils when he used **lavender** oil to

effectively heal a severe burn on his body. Gattefosse also discovered that essential oils could be absorbed into the bloodstream when applied to the skin and had medicinal effects inside the body. Another Frenchman, Jean Valnet, used essential oils during World War II to treat soldiers' **wounds** and wrote a major book on the topic in 1964 titled *Aromatherapie*. Another European biochemist, Marguerite Maury, performed thorough studies of how essential oils influence the body and emotions and popularized essential oil massages as therapy. During the 1990s, aromatherapy was one of the fastest growing alternative health treatments.

Essential oils are produced in several ways. Distillation uses water and steam to remove the oils from dried or fresh plants, and the expression method uses machines to squeeze the oil out of plants. Other techniques may use alcohol or solvents to remove essential oils from plant materials.

Essential oils are extremely concentrated. It would take roughly thirty cups of herbal tea to equal the concentration of plant essence in one drop of essential oil. Some essential oils made from rose plants require 4,000 lbs (1,814 kg) of rose petals to make 1 lb (0.5 kg) of essential oil and are thus very expensive. Lavender is one of the easiest essential oils to produce because it takes only 100 lbs (45 kg) of plant material to produce 1 lb (0.5 kg) of essential oil. Essential oils are generally very complex chemically, containing many different substances. Some experts have theorized that essential oils are the lifeblood of a plant and contain compounds that the plant uses to fight **infections** and drive away germs and parasites. Scientific research has isolated hundreds of chemicals in essential oils and has shown many essential oils to have antibacterial, anti-fungal, and anti-parasitic properties. Some essential oils contain more than 200 identified chemical substances.

Although there are hundreds of essential oils used regularly in healing treatments and perfumes, some of the more commonly used essential oils are lavender, **chamomile**, **peppermint**, **tea tree oil**, **eucalyptus**, geranium, jasmine, rose, lemon, orange, **rosemary**, frankincense, and sandalwood.

General use

Essential oils are used in several healing systems, including aromatherapy, Ayurvedic medicine, and **massage therapy**. Essential oils are used for skin and scalp conditions, including **acne**, **athlete's foot**, **burns**, **cuts**, **dandruff**, **eczema**, insect **bites**, parasites, **sunburn**, **warts**, and wrinkles. They are recommended for muscle, joint, and circulation problems such as arthritis, high blood pressure, **cellulite**, aches and pains, and **varicose veins**. For respiratory problems and infections, various essential oils are prescribed for **allergies**, **asthma**, **earache**, sinus infections, congestion, and colds and flu. Essential oils are also used to improve digestion, promote hormonal balance, and tone the nervous system in conditions such as **anxiety**, **depression**, **sexual dysfunction**, and exhaustion.

Essential oils can be used as quick and effective mood enhancers, for increasing energy and alertness, reducing **stress**, and promoting **relaxation**. Essential oils can be used as perfumes and lotions and can be used as incense to improve the atmosphere in houses and offices.

Preparations

Essential oils work by entering the body in two ways, through the nose and through the skin. The nose is a powerful sense organ, and the sense of smell is connected directly to the limbic system of the brain, which helps control emotions, memory, and several bodily functions. Research has shown that aromas and the sense of smell influence memory recall, moods, and bodily responses such as heart rate, respiration, hormone levels, and stress reactions. Essential oils with their potent aromas can be used to enhance moods, promote relaxation, and increase energy levels.

Essential oils are also absorbed by the skin and act medicinally once they are absorbed into the body. For instance, eucalyptus oil, long used in common **cough** and cold remedies, can be rubbed on the chest to break up congestion and mucus inside the lungs. Some essential oils, such as tea tree oil, lavender, and **thyme**, have natural antiseptics in them and can be applied to cuts, burns, and sores to disinfect and promote healing.

Because essential oils are strong and concentrated, they should be diluted with *base oils* before rubbing them directly on the body. Base oils are gentle and inexpensive oils such as almond, jojoba, grapeseed, sunflower, and **sesame oil**. Mineral oil is not recommended as a base oil. Essential oils should be diluted to make up 1 to 3% of a base oil solution, which is one to three drops of essential oil per teaspoon of base oil. For larger quantities, 20 to 60 drops can be added per 100 milliliters of base oil. Only a few essential oils can be rubbed directly on the skin without dilution. These are lavender, tea tree oil, eucalyptus, and geranium, although people with sensitive skin should use these oils with care.

Allergic reactions are possible with essential oils. People with sensitive skin or allergies should perform a

simple skin test when using essential oils for the first time. To do a skin test, one drop of essential oil can be added to a teaspoon of base oil, and a small amount of this solution can be rubbed on a sensitive spot on the skin, such as the soft side of the arm or behind the ear. If no irritation occurs after 24 hours, then the essential oil is non-allergenic.

Essential oils can be used in a variety of ways. They can be added to massage oils for therapeutic massages. Essential oil solutions can be used on the skin, scalp, and hair as lotions, conditioners, and perfumes. A few drops of essential oils can be added to bath water or used in the sauna. Essential oil diffusers, lamps, and candles are available that use heat and steam to spread (diffuse) the aroma of essential oils in rooms. Essential oils can be added to hot-and-cold compresses for injuries and aches. Some essential oils, such as tea tree, **fennel**, and peppermint oil, can be combined with a mixture of water and **apple cider vinegar** and used as mouthwash. For colds and congestion in the lungs or sinuses essential oils can be inhaled by adding a few drops to a pot of boiling water, and covering the head with a towel over the pot and breathing the vapors.

Consumers should search for essential oils made by reputable manufacturers. Essential oils should be certified to be 100% pure, without chemical additives or synthetic fragrances. The highest quality oils are generally obtained from distillation and cold pressing methods.

Precautions

Essential oils should not be taken internally, by mouth, rectum, or vagina, unless under medical supervision. Essential oils should be kept away from the eyes. If an essential oil gets into the eyes, the eyes should be rinsed immediately with cold water. Essential oils should be used with care on broken or damaged skin.

Some essential oils had not been thoroughly tested as of 2008 and may be toxic. The oils to be avoided include **arnica**, bitter almond, calamus, cinnamon, clove, **mugwort**, **sage**, **wintergreen**, and **wormwood**. Pregnant women should avoid these oils as well as oils of basil, fennel, marjoram, **myrrh**, oregano, star **anise**, and tarragon. In general, those essential oils that have not been tested or for which adequate information is not available should be avoided.

Some essential oils may cause the skin to become photosensitive, or more sensitive to sunlight and more likely to become sunburned. Essential oils that are photosensitizing include bergamot, orange, lemon, lime, grapefruit, and **angelica** root. These oils should be avoided before exposure to sunlight and ultraviolet light such as in tanning salons. People with sun-related skin problems should avoid these oils.

KEY TERMS

Aromatherapy—The use of essential oil aromas as health therapies.

Ayurvedic medicine—Healing system developed in ancient India and practiced around the world in the twenty-first century.

Homeopathic remedy—Medication prescribed by a homeopathic doctor.

Individuals with health conditions should use care with essential oils. Steam inhalation of essential oils is not recommended for people with asthma. The essential oils of rosemary, fennel, and sage should be avoided by those with **epilepsy**.

Pregnant and nursing women should use caution with essential oils because their skin and bodies are more sensitive, and some oils may cause adverse reactions. Essential oils should not be used during the first three months of **pregnancy**, and after that they should only be used when heavily diluted with base oils. Women with histories of miscarriage should not use essential oils during pregnancy at all. Pregnant women should perform skin tests before using essential oils. Essential oils are not recommended for nursing mothers.

Essential oils should be used with care on children. They are not recommended for children under one year of age and should be heavily diluted with base oils when used as a skin massage or lotion for children.

Essential oils should be stored out of the reach of children. Clean glass containers are the best storage vessels and should be dark in color to keep sunlight from damaging the oil. Some essential oils can damage wood, varnish, plastic and clothing, and should be handled with care.

Side effects

Most readily available essential oils are safe if used in small doses, and side effects are generally rare. Possible side effects include **rashes**, **itching**, and irritation on the skin. Allergic reactions include watery eyes, **sneezing**, and inflammation. Some essential oils may cause **nausea**, **dizziness**, or gastrointestinal discomfort when used in excess or by those with allergic reactions. Some essential oils, particularly those derived from citrus fruit plants, can cause increased sensitivity to sunlight and increased risk of sunburn.

Interactions

Essential oils are not recommended for those taking homeopathic remedies, as essential oils are believed to interfere with their effectiveness. Essential oils are often blended together to enhance their healing effects, and mixtures can be tailored to individual preferences and conditions. Aromatherapists specialize in creating essential oil blends for individuals and health conditions.

Essiac tea

Description

Essiac tea is based on a Canadian Ojibwa Indian formula containing primarily **burdock root** (*Arctium lappa*), Turkish **rhubarb root** (*Rheum palmatum*), **sheep sorrel** (*Rumex acetosella*), and the inner bark of the **slippery elm** (*Ulmus fulva* or *Ulmus rubra*). It is used in alternative medicine mainly as a treatment for **cancer**.

The formula is said to have been first developed by an Ojibwa healer to purify the body and balance the spirit. In 1922, the formula came to the attention of Rene Caisse (essiac is Caisse spelled backwards), a nurse in Ontario, Canada, after hearing first-hand accounts of it curing cancer. She began administering the tea to cancer patients and found it to have remarkable healing abilities. She continued treating cancer patients with the tea until she died in 1978. In 1977, Caisse sold the essiac tea formula to the Resperin Corp. of Ontario, Canada.

Caisse reported that hundreds of her patients had been cured of their cancers through the use of her tea, sometimes used as intramuscular injections. Most of the patients came to her after conventional cancer treatments (surgery, chemotherapy, and radiation therapy) failed. Several alternative health care practitioners report essiac tea seems to work best in patients who have had the least amount of radiation therapy or chemotherapy.

The mainstream medical community does not embrace essiac tea. Critics contend that a certain number of cancers deemed incurable spontaneously go into remission without an adequate medical explanation as to why. Others chalk up the successes to the so-called **placebo effect**, where the belief that the treatment is working effects a cure rather than the treatment itself. The treatment is not approved by the American Medical Association or the American Cancer Society.

In 1938, a bill in the Canadian Parliament to legalize essiac tea failed by three votes. It is still not approved for marketing in the United States or Canada. However, the Canadian Health and Welfare Department permits compassionate use of essiac tea on an emergency basis.

In 1975 and again in 1982, the Memorial Sloan-Kettering Cancer Center in New York tested only the sorrel component in the tea. They boiled it, which may have neutralized any beneficial compounds in the left-over tea and administered it to mice with cancerous tumors. It determined the formula had no anticancer effects. The National Cancer Institute and Canadian Bureau of Prescription Drugs reached the same conclusion in the 1980s.

General use

Essiac tea is generally used by alternative health care practitioners to treat, and even cure, various forms of cancer and the side effects of conventional

KEY TERMS

Chemotherapy—The use of chemical agents to treat or control diseases, especially cancer.

Cholesterol—A steroid alcohol found in human cells and body fluids, implicated in the onset of heart disease.

Degenerative diseases—A group of diseases characterized by progressive degenerative changes in tissue, including arteriosclerosis, diabetes mellitus, and osteoarthritis.

Diabetes—Any of a variety of abnormal conditions characterized by excessive amounts of urine.

Diabetes mellitus—A degenerative disease characterized by inadequate production or absorption of insulin, excessive urine production, and excessive amounts of sugar in the blood and urine.

cancer therapy. It is also used to treat **AIDS**. It is used to a lesser extent to treat a variety of other medical conditions, including diabetes, skin inflammation, liver and thyroid problems, **diarrhea**, ulcers, and some other degenerative diseases. It is more commonly used in Canada than the United States. Other uses include treating **pain**, purifying the blood, healing **wounds**, lowering **cholesterol**, and increasing energy levels.

Although each of the four main ingredients in essiac tea are used to treat other conditions, only the sorrel is used separately to treat cancer. Only when the four are combined do they effect anti-cancer properties. It is not clear exactly how or why the ingredients work in combination, but it is generally believed they work synergistically to stimulate production of antibodies. Caisse herself said she believed essiac tea purified the blood and carried away damaged tissue and infection related to the cancer. She also believed the tea strengthened the immune system, allowing healthy cells to destroy cancerous cells.

Caisse also maintained that tumors not destroyed by essiac tea would be shrunk and could be surgically removed after six to eight weeks of treatment. To insure any malignant cells that remained after treatment and surgery were destroyed, Caisse recommended at least three months of additional weekly essiac treatments.

One of Caisse's patients was her mother, Friseide Caisse, who was diagnosed with liver cancer at the age of 72. Her mother's physician reportedly said she had only days to live. Rene Caisse began giving her mother daily intramuscular injections of the tea. Friseide began recovering within a few days and after a few months, with less frequent doses of essiac, her cancer was gone. She lived to be 90, finally succumbing to **heart disease**.

Preparations

The four main ingredients of essiac tea are sold separately and can be combined at home. Essiac tea is also marketed as tea bags and in bottles of the prepared formula. The basic formula for essiac tea is to combine 6.5 c of cut burdock root, 16 oz of powdered sheep sorrel (including stems, seeds, and leaves), 1 oz of powdered Turkish rhubarb root, and 4 oz of powdered slippery elm bark. Mix the ingredients thoroughly. Boil 2 gal of fresh spring water, add 8 oz of the essiac blend, cover, and boil on high heat for 10 minutes. Turn heat off and let sit for six hours. Remove cover and stir. Replace cover and let steep another six hours. Turn on heat and return the mixture to a boil. Remove from heat and strain into another pot. Wash original pot and strain mixture again into it. Then pour liquid into amber bottles, cap, and store in a dark cool location. Refrigerate after opening.

The formula is ready to use immediately. When ready, shake the bottle well to mix the sediments. Blend 4 tsp of the essiac formula with 4 tsp of warm spring water. The usual daily dosage is 2–4 oz of tea for persons weighing 100–150 lb and 2 oz for every 50 lb over 150 lb. Some alternative health practitioners recommend regular doses of essiac to strengthen the immune system and as a preventative for certain diseases, including cancer. The frequency ranges from daily to weekly.

Precautions

Essiac tea is not recommended for pregnant or lactating women. The formula should not be prepared or stored in plastic or aluminum containers. Sunlight and freezing temperatures destroys the formula's effectiveness. It is generally recommended that persons consult with their physician before treating any condition with essiac. It is important to remember that essiac is often used in combination with traditional cancer treatments, such as chemotherapy, radiation, and surgery.

Side effects

No major adverse side effect have been associated with essiac tea.

Interactions

Essiac is not known to adversely interact with other medications or nutritional supplements.

Eucalyptus

Description

The eucalyptus tree is a large, fast-growing evergreen that is native to Australia and Tasmania. The tree can grow to 375-480 ft (125-160 m). Eucalyptus belongs to the myrtle (Myrtaceae) family. There are more than 300 species of eucalyptus, and *Eucalyptus globulus* is the most well-known species. One species (*E. amygdalin*) is the tallest tree known in the world. The tree grows best in areas with an average temperature of 60°F (15°C).

Eucalyptus trees constitute over 75% of the tree population of Australia. The eucalyptus tree is also known in Australia as the blue gum tree or malee. Other names for eucalyptus include Australian **fever** tree and stringy bark tree. The name is actually derived from the Greek word "eucalyptos," which means "well covered," and refers to the cuplike membrane that covers the budding flowers of the tree.

The bluish green leaves carry the medicinal properties of the tree and grow to a length of 6-12 in (15-30 cm). While the leathery leaves are the sole food for koala bears, the leaves also contain a fragrant volatile oil that has antiseptic, expectorant, antibacterial, anti-inflammatory, deodorant, diuretic, and antispasmodic properties. Other constituents of the leaves include tannins, phenolic acids, flavonoids (eucalyptin, hyperin, hyperoside, quercitin, quercitrin, rutin), sesquiterpenes, aldehydes, and ketones.

KEY TERMS

Diuretic—A substance that promotes urination.

Expectorant—A substance that promotes the coughing up of mucous or other fluids from the lungs.

Febrifuge—A substance that reduces fevers.

Infusion—An herbal tea created by steeping herbs in hot water. Generally, leaves and flowers are used in infusions.

Eucalyptus oil is obtained through a steam distillation process that removes the oil from the fresh, mature leaves and branch tips of older trees. Approximately 25 species of eucalyptus trees in Australia are grown for their oil.

There are three grades of eucalyptus oil: medicinal, which contains the compound eucalyptol (also called cineol); industrial, in which a component of the oil is used in mining operations; and aromatic, which is used in perfumes and fragrant soap products. These oils vary greatly in character. When choosing an oil for therapeutic use, it is important to know from what species the oil was derived. Species used medicinally include *E. globulus*, which contains up to 70% eucalyptol; *E. polybractea*, which contains 85% eucalyptol; and *E. Smithii*. *E. amygdalina* and *E. dives* contain little eucalyptol and are used to separate metallic sulfides from ores in the mining industry. *E. citriodora* contains a lemon-scented oil and is an ingredient in perfumes, as is *E. odorata* and *E. Sturtiana*. Two species, *E. dives* and *E. radiata*, have oils with a strong **peppermint** odor.

The most common species grown for its medicinal oil is *E. globulus*. The eucalyptol found in this species is a chief ingredient in many over-the-counter cold and **cough** remedies, such as cough lozenges, chest rubs, and decongestants. It acts to stimulate blood flow and protects against infection and germs. The *British Pharmocopoeia* requires that commercial eucalyptus oils contain 55% eucalyptol by volume.

Origins

The Australian aborigines have used eucalyptus for hundreds of years as a remedy for fever, **wounds**, coughs, **asthma**, and joint **pain**. Australian settlers

named the eucalyptus the fever tree because of its disease-fighting properties. Baron Ferdinand von Miller, a German botanist and explorer, was responsible for making the properties of eucalyptus known to the world in the mid-1800s. Likening eucalyptus' scent to that of cajaput oil (a disinfectant), von Miller suggested that eucalyptus might also be used as a disinfectant in fever districts. Seeds of the tree were sent to Algiers, France and planted. The trees thrived and, because of the drying action of the roots, turned one of the marshiest areas of Algiers into a dry and healthy environment, thereby driving away malaria-carrying mosquitoes. Eucalyptus trees were then planted in temperate areas around the world to prevent **malaria**. As a result, eucalyptus trees are now cultivated in China, India, Portugal, Spain, Egypt, South and North Africa, Algeria, South America, and in the southern portion of the United States.

Commercial production of eucalyptus began in Victoria, Australia in 1860. The nineteenth century eclectic doctors adopted eucalyptus as a treatment for fevers, **laryngitis**, asthma, chronic **bronchitis**, **whooping cough**, **gonorrhea**, ulcers, gangrenous tissue, **edema**, and gastrointestinal disturbances. European doctors used eucalyptus oil to sterilize their surgical and medical equipment. Eucalyptus leaves were often made into cigars or cigarettes and smoked to relieve asthma and bronchial congestion.

Modern medicines around the world have included eucalyptus in their practices. Indian ayurvedics use eucalyptus to treat headaches resulting from colds. Eucalyptus is listed in the *Indian Pharmacopoeia* as an expectorant and in the *Chinese Pharmacopoeia* as a skin irritant used in nerve pain. In France, eucalyptus leaves are applied topically to relieve congestion from colds and to treat acute bronchial disease. A standardized eucalyptus tea is licensed in Germany to treat bronchitis and throat inflammations. Eucalyptus is also an ingredient in German herbal cough preparations. The German Commission E has approved the internal use of eucalyptus to treat congestion of the respiratory tract, and the external use to treat rheumatic complaints. In the United States, eucalyptus is a component of many decongestant and expectorating cough and cold remedies, such as cough drops, cough syrups, and vapor baths. Eucalyptus is often used in veterinary medicine. It is used to treat horses with flu, dogs with distemper, and to treat parasitic skin conditions.

General use

Eucalyptus is most popular for its ability to clear congestion due to colds, coughs, flu, asthma, and sinusitis. The tannins found in eucalyptus have astringent properties that reduce mucous membrane inflammation of the upper respiratory tract. Eucalyptol, the chemical component of the oil, works to loosen phlegm. Cough drops containing eucalyptus promote saliva production, which increases swallowing and lessens the coughing impulse. Earaches can also be treated with eucalyptus. When inhaled, the eucalyptus fumes open the eustachian tubes, draining fluids and relieving pressure. Eucalyptus enhances breathing, which makes it an effective remedy for asthma, bronchitis, sinusitis, whooping cough, and colds.

Eucalyptus is a component of many topical arthritis creams and analgesic ointments. When applied to the skin, eucalyptus stimulates blood flow and creates a warm feeling to the area, relieving pain in muscles and joints.

The oil extracted from the eucalyptus leaf has powerful antiseptic, deodorizing, and antibacterial properties. It is especially effective in killing several **strains** of *Staphylococcus* bacteria. A mixture of 2% eucalyptus oil evaporated in an aroma lamp has been shown to destroy 70% of the *Staphylococcus* bacteria in the affected room. When the oil is applied to **cuts**, scrapes, and other minor wounds, it inhibits **infections** and viruses. A 2002 report out of Australia made researchers around the world take note when two cases of patients with staph infections resistant to traditional antibiotic therapy responded to a mixture of eucalyptus leaf oil abstract. The Australian researchers recommended formal clinical trials to test the therapy, based on an ancient aboriginal remedy. Eucalyptus also fights plaque-forming bacteria and is used to treat **gum disease** and gingivitis.

In large doses, the oil can be a kidney irritant and can induce excretion of bodily fluids and waste products. Eucalyptus oil added to water may be gargled to relieve **sore throat** pain or used as a mouthwash to heal mouth sores or gum disorders. Consequently, eucalyptus is an ingredient in many commercial mouthwashes.

Eucalyptus' pain-relieving properties make it a good remedy for muscle tension. One study showed that a mixture of eucalyptus, peppermint, and ethanol oils successfully relieved headache-related muscle tension.

Eucalyptus may lower blood sugar levels. Placing a drop of the oil on the tongue may reduce **nausea**. The oil has also been used to kill dust mites and fleas.

Eucalyptus oil is one of the most well-known fragrances in **aromatherapy**. Two species of eucalyptus are used in aromatherapy oils: *E. globulus* and *E. citriodora.*

The essential oil of eucalyptus is used to relieve cramps, cleanse the blood, heal wounds, disinfect the air, and to treat conditions such as asthma, bronchitis, throat and sinus infections, fevers, **kidney infections**, rheumatism, bladder infections, and sore muscles.

The essential oil can be diluted and added to a massage oil to ease aching muscles. The oil can be added to hot water and inhaled to reduce nasal congestion. It can also be diffused in the room of a sick patient to disinfect the air.

Some believe that inhaling the diffused oil can enhance concentration and thought processes. Studies have shown that inhalation of the cineole compound of eucalyptus stimulates coordination and motor activities in mice. Eucalyptus oil may also uplift the spirit during times of emotional overload or general sluggishness.

Applying a diluted oil to the skin instead of inhaling it increases the rate of absorption into the blood. Often the speed with which it is absorbed is so fast, the odor can be detected on the breath within minutes.

The oil is also an effective febrifuge, and a cold compress with eucalyptus oil added to it has a cooling effect that is useful in helping to reduce a fever. The essential oil of eucalyptus is also used to treat wounds, herpes simplex virus, skin ulcers, and **acne**. Combined with water, the oil makes an effective insect repellant. Because of its skin-moistening properties, the oil is often an ingredient in **dandruff** shampoo.

Eucalyptus oil may be combined with other oils that have similar properties, such as niaouli, pine, Swiss pine, **hyssop**, and **thyme** oils. It also mixes well with lemon, verbena, balm, and **lavender** oils.

Preparations

Eucalyptus is available as a tincture, cream, ointment, essential oil, or lozenge. Many health food stores carry fresh or dried eucalyptus leaf in bulk. Eucalyptus can be ingested through the use of teas or tincture preparations, inhaled, or applied externally.

Eucalyptus infusion is ingested to treat coughs, colds, bronchitis, congestion, and throat infections. To create an infusion, 1 cup of boiling water is poured over 1-2 teaspoons of crushed eucalyptus leaves. The mixture is covered and steeped for 10 minutes and is then strained. Up to 2 cups can be drunk daily.

Inhaling eucalyptus vapors is beneficial for sinus and bronchial congestion that occurs with bronchitis, whooping cough, colds, asthma, **influenza**, and other respiratory illnesses. A drop of eucalyptus oil or two to three fresh or dried leaves are added to a pan of boiling water or to a commercial vaporizer. The pan is removed from the heat, a towel is placed over the pan and the patient's head, and the patient inhales the rising steam. Patients should close their eyes when inhaling the steam to protect them from eucalyptus' strong fumes.

For healing wounds and preventing infection, the wound is washed and then diluted eucalyptus oil or crushed eucalyptus leaves are applied to the affected area.

For relief of muscle aches or arthritis pain, several drops of the diluted oil are rubbed onto the affected area, or a few drops of diluted oil are added to bath water for a healing bath. Adding eucalyptus leaves wrapped in a cloth to running bath water is also effective.

For gum disease, a few drops of diluted oil are placed on a fingertip and massaged into the gums.

Tinctures should contain 5-10% essential oil of eucalyptus. A person can take 1 ml three times daily.

Ointments should contain 5-20% essential oil of eucalyptus. The person should use as directed for chapped hands, joint and muscle pains, and dandruff.

Precautions

Children or infants should not be treated with eucalyptus. Of special note, eucalyptus oil should not be applied to the facial areas (especially the nose or eyes) of small children or infants. Pregnant or breast-feeding women should not use eucalyptus.

People with digestive problems, stomach or intestinal inflammations, biliary duct disorders, or liver disease should not take eucalyptus.

Undiluted eucalyptus oil should never be ingested. Small amounts of undiluted oil (even in amounts as little as one teaspoon) are toxic and may cause circulatory problems, collapse, suffocation, or death. Eucalyptus oil should always be diluted in a carrier oil such as almond, grapeseed, or other vegetable oil before applying to the skin.

Side effects

Nausea, **vomiting**, or **diarrhea** may occur in rare cases. Applying eucalyptus to the skin may cause a rash in those who are sensitive or allergic to eucalyptus.

Interactions

Eucalyptus works to detoxify the body. If it is used simultaneously with other drugs, the effects of those drugs may be weakened.

Eucommia bark

Description

Eucommia bark is the gray, grooved bark of the tree *Eucommia ulmoides*, commonly called the hardy rubber tree or the gutta-percha tree. The Chinese name for eucommia bark is *Du Zhong*. This name refers to a Taoist monk who was said to be immortal, suggesting that the herb provides long life, good health, and vitality. The tree is a member of the rubber family and is native to the mountainous regions of China. It normally grows to about 50 ft (15 m) in height. Small patches of bark are harvested from trees over 10 years old in late summer and early autumn. The outer bark is peeled away and the smooth inner bark is dried. This inner bark contains pure white, elastic latex that is thought to contain the compounds that account for eucommia bark's healing properties. Older, thicker inner bark with more latex is considered more desirable for the herbalist to use than younger, thinner bark.

Although traditionally only the bark of *E. ulmoides* was used for healing, research in the later half of the 1990s in Japan indicated that the leaves also have healing properties. The green leaves are shiny, narrow, and pointed. The tree's flowers are very small and are not used in healing.

General use

Eucommia bark has been used in **traditional Chinese herbalism** for over 3,000 years. Since the tree does not grow widely outside China, this herb was not used in other cultures until the later twentieth century.

Eucommia bark is strongly associated with the kidneys and to a lesser extent with the liver. In Chinese medicine, the kidneys store *jing*. *Jing* is an essential life source and associated with whole body growth and development, as well as normal sexual and reproductive functioning. The kidney and liver *jing* also affects the bones, ligaments, and tendons.

In the Chinese system of health, *yin* aspects must be kept in balance with *yang* aspects. Ill health occurs when the energies and elements of the body are out of balance or in disharmony. Health is restored by taking herbs and treatments that restore that balance.

Eucommia bark is the primary herb used to increase *yang* functions in the body. However, it also supports *yin* functions. Eucommia bark helps to build strong bones and a flexible skeleton with strong ligaments and tendons. It is a primary herb used to heal tissues that are slow to mend after an injury or that have weakened through **stress** or age. It is given to treat lower back and leg **pain**, stiffness, arthritis, and knee problems, including continual dislocation. Eucommia bark is also believed to have diuretic properties that aid in reducing swelling. Although it can be used alone, eucommia bark is most often used in conjunction with other herbs that support its functions.

In addition to healing tissues, eucommia bark has two other major functions. In pregnant women it is given to calm the fetus, soothe the uterus, and prevent miscarriage. Eucommia bark also has the ability to lower blood pressure. This property has been investigated since 1974 and is well established. It may be related to the herb's mild diuretic action.

Other modern uses of eucommia bark include treatment of **impotence**, premature ejaculation, and as a mild anti-inflammatory. It is included in tonics that boost the immune system and generally improve wellness. However, as of the early 2000s, there was little rigorous scientific research to support these uses.

In the late 1990s Japanese researchers became interested in eucommia bark. In 2000, researchers at Nihon University in Chiba, Japan, published two studies showing that both the leaves and the bark of *Eucommia ulmoides* contained a compound that encourages the development of collagen in rats. Collagen is an important part of connective tissues such as

KEY TERMS

Collagen—A white, fibrous protein that is found in skin, bones, ligaments, tendons, cartilage, and all other connective tissue.

Decoction—The liquid made by boiling an herb, then straining out the solid material.

Diuretic—Any substance that increases the production of urine.

Yang aspects—Identifies qualities such as warmth, light, and activity.

Yin aspects—Identifies qualities that are the opposite of yang aspects, such as cold, stillness, darkness, and passiveness.

tendons and ligaments. They found that the compound was present in much greater quantities in fresh leaves and fresh bark and that much of it was destroyed during the drying process.

In modern Japan, eucommia leaves are also believed to help with weight loss by reducing the urge to eat. For this reason, beginning in the late 1990s eucommia leaves became an increasingly popular herb there. As of the early 2000s, there were no scientific studies to support this function of the herb.

Preparations

Eucommia bark is harvested and dried. Before boiling, it is sliced to expose the inside of the bark. The bark is then boiled to make a decoction. Generally this decoction is combined with other herbs and extracts to create *yang* enhancing tonics to treat kidney and liver deficiencies and impotence.

Precautions

Eucommia bark has a long history of use with no substantial reported problems.

Side effects

No side effects have been reported with the use of eucommia bark. However, the bark contains latex. People who develop **contact dermatitis** (a rash) from exposure latex appear to be able to ingest tonics containing eucommia bark without stimulating an allergic reaction. Nevertheless, individuals with latex allergy should be cautious about using this herb.

Interactions

Eucommia bark is often used in conjunction with other herbs with no reported interactions. Since eucommia bark has been used almost exclusively in Chinese medicine, there are no studies of its interactions with Western pharmaceuticals as of the early 2000s. People who are taking tonics containing eucommia bark should tell their doctors before taking traditional drugs, especially drugs that regulate blood pressure.

Eupatorium

Definition

Eupatorium is a genus of flowering plants with a somewhat uncertain taxonomic description. At times, it has included anywhere from a few dozen to a few hundred species of plants. Some herbal specialists suggest that the genus is one of the most valuable groups of plants for medical purposes of any in the plant kingdom. Some species to which health benefits are credited are:

- *E. ageratoides*, or White Snake-root
- *E. album*, or White Thoroughwort
- *E. aromaticum*, or Mata
- *E. ayapana*, or Water Hemp
- *E. cannabinum*, or Hemp Agrimony
- *E. glutinosum*

- *E. nervosum*, or Bitter-Bush
- *E. perfoliatum*, or Boneset
- *E. purpureum*, or Joe Pye Weed, or Gravelroot (also Gravel Root)
- *E. rotundifolium*
- *E. rebaudiana*, or Sweet Herb
- *E. teucrifolium*, or Wild Horehound

Eupatorium occurs naturally in temperate regions of North American, Europe, and eastern Asia. Most species are herbaceous plants or shrubs ranging in height from 2 to 10 feet. Flower color, leaf structure, and other physical properties differ somewhat from species to species within the genus.

Medical uses

The two most widely used members of the Eupatorium genus are *E. perfoliatum* and *E. purpureum*. *E. perfoliatum*, or **Boneset** has been widely used by Native Americans for centuries for a variety of uses, and it continues to be popular among herbalists today. The herb is recommended as a digestive tract stimulant, and as a diuretic, laxative, and diaphoretic (an agent that increases perspiration). It is also used as an antipyretic (for the reduction of **fever**) and for the treatment of **gout** and **influenza**. Because of its modest anti-inflammatory properties, it is sometimes used to treat arthritis. All parts of the *E. purpureum* plant are used for medical purposes, although the roots are thought to have the strongest effects. The plant is named after an American Indian who reputedly used it to cure typhus among his neighbors. The dried plant is said to be an effective treatment for kidney and urinary problems, while a tea made from those parts is used as a diaphoretic and antipyretic and for the treatment of rheumatism and **edema**. A less familiar member of the genus in North America is *E. ayapana*, a native of South America, where people have traditionally used the herb to treat a wide variety of disorders including stomach and liver disorders. It has also been used as an antiseptic and vulnerary (wound healing) agent and for the treatment of coughs and tumors.

Side effects

Both Boneset and Joe Pye weed are toxic to humans and other animals in large doses. Pregnant women and individuals with liver problems are advised not to take any form of Eupatorium internally. In general, care must be observed in using either herbal medicine. Some possible side effects include the following:

- nausea
- diarrhea
- vomiting
- rash or itchy or swollen skin
- chest pain
- tightness in the throat or chest
- difficulty in breathing
- muscular weakness or tremors
- constipation

KEY TERMS

Antidiuretic—An agent that reduces fever.

Diaphoretic—A substance that increases the rate of perspiration.

Diuretic—A substance that increase urination.

Interactions

No interactions between Eupatorium preparations and other drugs or foods have as yet been reported. The lack of such information should not be taken to mean that interactions are not possible, however, and individuals should report to their physicians or healers of other medications or herbal supplements they may be taking.

David Edward Newton, Ed.D.

Euphrasea officinalis see **Eyebright**

Euphrasia

Definition

Euphrasia is a genus of about 450 herbaceous flowering plants. The common name for the genus is **eyebright**, (*Euphrasia officinalisa*) name that comes from the most common traditional medical use for the plant: the treatment of eye disorders.

Description

The name *euphrasia* is derived from one of the three graces in Greek mythology, Euphrosyne, whose name means "gladness." In spite of this classical reference, the plant's medicinal uses were apparently not mentioned until about the fourteenth century, when it was recommended for the cure of all manner of eye diseases. Some early writers (as well as some modern observers) claim healing powers for euphrasia that extend beyond eye problems to include a cure for colds, headaches, and other head problems and an aid to improved memory.

The physical characteristic of euphrasia plants vary depending on soil and other growing conditions. In less desirable conditions, it is a very small plant, sometimes no more than 1 in (2.5 cm) in height. In better environments, it may grow to 8 in (20.3 cm) or more. It has deeply–cut leaves and flowers set on terminal spikes that may be white, bluish–white, violet, or purple in color, often with distinct purple veins. The lower (and sometimes upper) lip contains a yellow patch that apparently acts as a guide for bees, which relish the plant's nectar. The plant occurs in many parts of the world, ranging from mountain tops to near–desert conditions.

Uses

Herbalists, naturopaths, and homeopaths recommend the use of euphrasia for nearly every manner of eye disorder, including irritated eyes, **conjunctivitis**, inflammation of the eyes and eyelids, watery eyes, injuries to the eyes, impaired eyesight, and eye problems related to other diseases and disorders, such as colds, the flu, and **allergies**. They often suggest using the herb in a variety of other head–related problems, such as **headache**, nasal problems, sore throats, and discharge from the eyes, nose, or mouth. In 2008, Natural Standard, an international agency that collects data on complementary and alternative therapies, noted that "[l]ittle data exists regarding the safety and toxicity of eyebright," that there was little clinical evidence on the efficacy of eyebright in treating pink eye, and that there had been essentially no research on the use of eyebright for the treatment of other eye problems or other conditions for which it is recommended.

Natural Standard did take note of the fact that euphrasia contains significant amounts of iridoid glycosides, which have been found to have significant antibacterial action and hepatoprotective (liver–protecting) properties. No research has yet suggested medicinal uses of euphrasia based on these properties.

Preparations

Euphrasia is usually commercially available as a tincture in which the leaves, flowers, and stems of the plant are collected, cut up, and dried and **essential oils** removed in alcoholic solution. The herb can also be prepared as an extract by combining two cups of water with one tablespoon of dried plant parts and boiled for ten minutes. Euphrasia, as a water extract, is also often used as a topical application to the eyes and surrounding areas.

Side effects

Scientific research on the safety and efficacy of euphratis is limited. For this reason, the German Commission E, which has studied the medicinal value of more than 300 herbal medications, has recommended that consumers not use euphratis. The herb is available for sale and use in the United States, however. Almost nothing is known about possible toxic effects of euphratis, although a number of side effects have been documented, including:

- headache
- stuffy nose
- vision problems
- stuffy nose
- muscle weakness
- confusion
- restlessness
- sneezing

KEY TERMS

Allopathy—A method of treating disease by using substances that are opposite to the symptoms presented by a patient.

Conjunctivitis—Inflammation of the conjunctiva, the mucous membrane surrounding the eye. Also known as pinkeye.

Ophthalmic—Relating to the eye.

Tincture—A preparation made by mixing an herb with an alcohol water solution.

Because of uncertainties about its safety, euphrasia is generally not recommended during **pregnancy** and breastfeeding. In 2008, the website Drugs.com recommended that "[t]he range of adverse effects [of eyebright] is considered to outweigh the dubious benefits."

Interactions

No interactions between euphratis and prescription or non–prescription medications have been reported. However, some providers warn against using the herb with allopathic ophthalmic products since the combination of drug and herb might tend to "overwhelm" the body's optical system.

Evening primrose oil

Description

Evening primrose (*Oenothera biennis*) is a tall, hardy, native biennial of the Onagraceae family. Its Latin name is derived from the Greek word *oinos* for wine and *thera* for hunt and reflects the folk belief that the herb could minimize the ill effect of over-indulgence in wine following a hunt.

The plant thrives in dry, sunny meadows, and is abundant in many parts of the world. The leaves of the first-year plant form a bright-green, basal rosette. In the second year, the coarse, erect stalk reaches up to 4 ft (1.2 m) high with hairy, alternate, lanceolate leaves with a distinctive mid rib. Leaves grow from 3–6 in (7.6–15.2 cm) long. The blossoms are pale yellow with a slight lemon scent and a cup-like shape. They grow in clusters along the flower stalk, and bloom from June to September, opening at dusk to attract pollinating insects and night-flying moths. These phosphorescent blossoms inspired a common name for the herb, evening star. The seeds grow within an oblong, hairy capsule. The root is large and fleshy.

General use

The medicinal components of evening primrose are found in the seed-extracted oil, which contains **essential fatty acids** including gamma **linoleic acid** (GLA). GLA is often deficient in the Western diet and is needed to encourage the production of prostraglandins. Low levels of essential fatty acids may increase the symptoms of **premenstrual syndrome** (PMS), diabetes, etc. Evening primrose oil has been used to treat PMS and menopausal symptoms, **asthma**, and has been shown to reduce high blood **cholesterol** levels.

Evening primrose flower. *(© Photo Researchers, Inc. Reproduced by permission.)*

KEY TERMS

Antioxidant—Any of several substances that have been shown to counteract the damaging effects of oxidation in human and animal tissue. Evening primrose oil is rich in antioxidants.

Biennial—A plant that requires two years to complete the cycle from seed to maturity and death.

Catechin—A yellow, slightly bitter antioxidant found in evening primrose oil. Catechin appears to slow tumor growth and to protect against heart disease.

Mucilage—A gelatin-like plant substance found in leaves and stems. Any substance that resembles mucilage in having a thick or sticky texture is said to be mucilaginous.

Research conducted in Great Britain has indicated that evening primrose oil can also be medicinally useful in the treatment of nerve disorders, such as **multiple sclerosis** and **rheumatoid arthritis**. The essential oil does appear to be of some benefit in cases of alcohol poisoning and in alleviating hangovers, and to ease symptoms of alcohol withdrawal. The oil can also help relieve dry eyes, brittle nails, and **acne** when combined with **zinc**. When taken as a supplement, evening primrose has helped to promote weight loss.

Traditionally, Native Americans valued evening primrose as a treatment for **bruises** and **cuts**. The Flambeau Ojibwe tribe soaked the whole plant in warm water to make a poultice for healing bruises and to overcome skin problems. The mucilaginous juice in the stem and leaf can be applied externally to soothe skin irritations, or may be eaten to relieve digestive discomfort and for its stimulating effect on the liver and spleen. The astringent properties of the plant are helpful to soothe inflamed tissue. The plant has sedative properties and has been used to decrease hyperactivity in children.

The entire plant is edible. The root from the first-year growth is a nutritious pot herb. Boiled roots taste somewhat like parsnips.

Evening primrose oil is valued for its antioxidant properties. **Antioxidants** are substances that counteract the damaging effects of oxidation in living tissue. A team of Canadian researchers has recently identified the specific antioxidant compounds in evening primrose oil; one of them, a yellow substance known as catechin, appears to inhibit the growth of cancerous tumors and to lower the risk of **heart disease**.

Preparations

Evening primrose oil is prepared commercially and widely available in health food stores. The extract should be stored in a cool, dry place in order to avoid spoilage. Capsules are also available. Correct dosage should be decided in consultation with a practitioner.

An ointment can be prepared by mixing one part of the diced plant with four parts of heated petroleum jelly. Stored in a tightly closed container and refrigerated, the preparation will maintain its effectiveness. Apply as needed to soothe the skin.

Precautions

Use by persons with **epilepsy** is discouraged because evening primrose oil appears to lower the effectiveness of medications used to treat epilepsy. Physicians should be consulted before using evening primrose oil on children.

Side effects

There have been some reports of **headache**, **nausea**, loose stools, and skin rash after using evening primrose preparations.

***Evodia rutaecarpa* blooming.** *(©blickwinkel / Alamy)*

Evodia fruit

Description

Evodia fruit is the small, reddish fruit of the plant *Evodia rutaecarpa*. This plant is native to northern China and Korea, although it is cultivated as an ornamental landscaping plant in many other places in the world.

E. rutaecarpa is a deciduous tree that grows to a height of about 30 ft (10 m) along the sunny edges of woodlands and in suburban settings as an ornamental. It has long, dark green, shiny leaves and blooms with many small clusters of white flowers in the summer. The fruit, which is the part of the plant used in healing, is reddish when it appears in August and darkens to black by November. The fruit is harvested for medicinal purposes when it is not yet ripe and reddish brown in color. It is then either used fresh or dried. Evodia fruit is also known by its Chinese name *wu zhu yu* and is called *gosyuyu* in Japan.

General use

Evodia fruit has been used since at least the first century A.D. in **traditional Chinese medicine** (TCM). It is characterized as having a warm nature and an acrid, bitter, slightly toxic taste, although the fruit is quite fragrant.

Taken internally, evodia fruit is used to treat symptoms of abdominal distress. These include **nausea**, **vomiting**, and **diarrhea**. It is said to be especially effective in treating morning diarrhea. Evodia is used to stimulate the appetite and to treat abdominal symptoms associated with lack of interest in food.

Evodia is also used as a painkiller. It is a remedy for headaches, especially headaches associated with nausea and vomiting. Traditional Chinese herbalists use it to treat **pain** in the upper abdomen and pain associated with abdominal hernias. According to Chinese herbalism, the warm nature of the evodia fruit counteracts cold conditions in the stomach.

There are several other reported uses of evodia fruit. The root bark taken internally is considered useful for expelling parasitic tapeworms and pinworms. The fruit is also believed to have contraceptive properties. Various healers report that the fruit has anti-inflammatory, anti-tumor, anti-viral, astringent, and diuretic properties. Although evodia fruit has been used for thousands of years in China, its use only in modern times increased in Japan.

Scientific research

Scientists, primarily from Japan and China, have undertaken laboratory studies of evodia fruit to determine which traditional uses are supported by modern medical findings.

Researchers at AGI Dermatics in Freeport, New York, studied the effect of evodia extract on skin inflammation. The researchers concluded that compounds found in evodia had powerful anti-inflammatory activity when used on human skin.

That finding was consistent with previous studies by Japanese researchers. They found that compounds extracted from dried evodia fruit had anti-inflammatory and pain-reducing properties in dogs. Reduction of pain was believed to occur because the compounds interfere with pain receptors.

Furthermore, Chinese researchers in Taiwan consistently reported that extracts of evodia fruit interferes with blood clotting. It was anticipated that this finding could be of significance in treating **stroke**.

In addition, Japanese researchers discovered that in test-tube studies extracts of evodia fruit strongly inhibit the growth of one specific bacteria (*Helicobacter pylori*, a bacteria usually treated in mainstream medicine with antibiotics). Unlike conventional antibiotics, the extract did not alter the growth patterns of any other intestinal bacteria. This finding supported the traditional use of evodia fruit in digestive disorders.

Preparations

Evodia fruit can be used fresh, or it can be dried and ground into a powder for medicinal use. Powdered evodia fruit is sometimes mixed with vinegar to make a paste that is applied externally to the navel to relieve **indigestion**. A similar paste is applied to the soles of the feet to treat high blood pressure or directly to sores in the mouth.

Powdered evodia fruit is also taken internally. The usual daily dosage is 1.5 g to 5 g. The herb may be boiled in water and consumed.

Evodia fruit is often mixed with other herbs, such as **ginger**, **pinellia** root, or **coptis**, in formulas to control vomiting. In addition, evodia fruit is used in the TCM formulas ilex and evodia to treat symptoms of cold and flu, including **fever**, **chills**, swollen glands, and sore throat.

KEY TERMS

Deciduous—A tree or bush that sheds its leaves seasonally.

Diuretic—Any substance that increases the production of urine.

Yin—Opposite of yang and having qualities such as cold, stillness, darkness, and passiveness.

Precautions

Evodia fruit is considered by herbalists to be slightly toxic. It should be taken under the supervision of a practitioner or healthcare provider. Pregnant women should not use evodia fruit. Women who desire to conceive a child should keep in mind that evodia fruit is thought to have anti-fertility properties.

Furthermore, the United States Food and Drug Administration does not regulate herbal supplements such as evodia fruit, which means that the remedies have not proven to be safe or effective. The safety of evodia fruit has not been established for use by children, pregnant women, and nursing mothers. In addition, ingredients are not standardized to comply with federal regulations.

Side effects

Herbalists consider evodia fruit mildly toxic, so long-term use is discouraged.

Interactions

As of 2008, there were no known interactions associated with evodia fruit. Evodia fruit is often used in conjunction with other herbs and there were no reported interactions. Since evodia fruit has been used almost exclusively in Chinese medicine, there were no studies of its interactions with Western pharmaceuticals as of 2008.

Exercise

Definition

Exercise is any activity requiring physical exertion done for the sake of health. Activities range from walking and **yoga** to lifting weights and **martial arts**.

Origins

Regular exercise as a way of promoting health can be traced back at least 5,000 years to India, where yoga originated. In China, exercises involving martial arts, such as **t'ai chi**, **qigong**, and kung fu, developed possibly 2,500 years ago. The ancient Greeks also had exercise programs 2,500 years ago, which led to the first Olympic games in 776 B.C. Other exercise routines have been in use throughout Asia for hundreds of years.

Only within the last 100 years have the scientific and medical communities documented the benefits that even light but regular exercise has on physical and mental health.

The earliest forms of exercise stressed activities that involved stretching and light muscle resistance. Next came martial arts that promoted self-defense. In nearly all forms of Asian exercise routines, some type of **meditation** was a major component because the ancients believed physical and mental health went together. The ancient Greek and Roman civilizations advocated vigorous physical activity since exercise was associated with military training. The Greeks also believed that a healthy body would promote a healthy mind.

KEY TERMS

Aerobic—Any cardiovascular exercise that increases heart rate and breathing, such as jogging, bicycling, and swimming.

Cardiovascular—Relating to the heart and blood vessels.

Kung fu—Another name for qigong; today it more commonly means a Chinese martial arts practice.

Osteoporosis—A bone disease that causes a loss in bone density; occurs most often in postmenopausal women.

Qigong—A Chinese exercise system (similar to t'ai chi) where people learn how to control the flow and distribution of qi (life energy); thought to improve health and harmony of mind and body.

T'ai chi—A slow, relaxed, stylized form of exercise developed by the Chinese; can be called an "inner" martial art.

Taoism—A philosophy of life based on the writings of Chinese philosopher Lao-tse who lived about 500 B.C.

Yin and yang—A Taoist concept that the universe is split into two separate but complementary aspects. Balance is sought between the passive force of yin (female) and the active force of yang (male). The idea of balance between yin and yang is important in traditional Chinese medicine and is the object of various healing arts.

"Physical culture" was popular in the nineteenth and early twentieth centuries. Medical journals showed exercise machines in the 1800s in Europe and North America. Although weight training became popular with a small number of people in the 1940s, it was not until the 1960s that regular exercise programs began to flourish throughout the United States. Gymnasiums, once used mainly by male weight lifters and boxers as training facilities, now are common throughout the United States. Today's gyms and health clubs offer a wide range of exercise activities for men and women that can fit every lifestyle, age group, and exertion level.

Benefits

The medical community recognizes that regular exercise, along with a proper diet, is one of the two most important factors in maintaining good physical and mental health, and in preventing and managing

many diseases. Most certified physical trainers advocate at least 20 minutes of exercise at least three times a week. But for people who have a sedentary lifestyle, even walking for 10 minutes a day has health benefits. One study of 13,000 people followed for more than eight years showed that people who walk 30 minutes a day have a significantly reduced risk of premature death than people who did not exercise regularly.

Walking and other cardiovascular exercises can reduce the risk of **heart disease**, some cancers, **hypertension** (high blood pressure), arthritis, **osteoporosis**, **stroke**, and **depression**. A study by the Centers for Disease Control and Prevention (CDC) reported in 2001 that running just once a month could help keep bones strong. In addition to physical benefits, a 2001 study showed that exercising just 10 minutes a day can improve mental outlook.

A study released in 2003 reported that exercise combined with **behavioral therapy** may even help manage the symptoms experienced by Gulf War veterans. Specifically, exercise helped improve symptoms related to **fatigue**, distress, cognitive problems and mental health functioning. In the same year, the American Heart Association released a statement saying that exercise was beneficial even for patients awaiting heart transplants. Another study showed that women who participated in strenuous physical activity over a number of years could reduce their risk of **breast cancer**. Finally, research showed that men and women age 40 to 50 who exercised moderately for 60 to 90 minutes a day were less likely to catch a cold than those who sat around.

Description

Exercise comes in many forms, but there are three basic types: resistance, aerobics, and stretching. Yoga and martial arts are basically muscle stretching routines, walking and running are primarily aerobic, and weight lifting is mainly resistance. Exercises such as swimming are considered crossover activities since they build muscle and provide a good aerobic, or cardiovascular, workout. Certified physical trainers usually advocate a combination program that involves stretching, aerobics, and at least some resistance activity for 30-60 minutes a day three times a week.

Stretching and meditative exercises

The most common types of alternative health exercises are the ancient disciplines of yoga and the martial arts (such as t'ai chi and qigong).

YOGA. The ancient East Indian discipline of yoga is probably the most widely practiced exercise advocated by alternative health practitioners. This may be because there is a heavy emphasis on mental conditioning as well as physical exertion. Yoga is the practice of incorporating mind, body, and spirit through a series of physical postures, breathing exercises, and meditation. It improves muscle flexibility, strength, and tone while calming the mind and spirit. Most contemporary **stress** reduction techniques are based on yoga principles.

There are a variety of yoga styles, each with its own unique focus. In the United States, **hatha yoga** is the most practiced. The pace is slow and involves a lot of stretching and breathing exercises. Much like the Chinese philosophy of yin and yang, hatha yoga strives to balance the opposite forces of ha (sun) and tha (moon). Astanga, or power yoga, involves more intense yoga postures done in rapid succession. Its vigorous workout is especially good in developing muscle strength. Iyengar yoga promotes body alignment while kripalu yoga develops mind, body, and spirit awareness. Pranayama yoga is a series of breathing exercises designed to increase vitality and energy.

Yoga helps strengthen the heart and slow respiration. Studies have shown it is beneficial in treating a variety of conditions, including heart disease, hypertension, arthritis, depression, fatigue, chronic **pain**, and carpal-tunnel syndrome. A 2001 study at the Cleveland Clinic Foundation in Ohio looked at yoga's effect on people with lower back pain and pain due to conditions like **carpal tunnel syndrome** and arthritis. After a four-week period, investigators noted that yoga helped lessen pain, improve participants' moods and decreased pain medication requirements.

There are four main groups of yoga postures, also called asanas: standing, seated, reclining prone, and reclining supine. Other groups include forward bends, back bends, side bends, twists, inverted, and balancing. Within each group there are dozens of different yoga poses at beginning and advanced levels.

MARTIAL ARTS. While the words "martial arts" may be associated with conflict, they usually are graceful exercise movements that keep the body and mind strong and healthy. They can be performed by young and old. Martial arts range from simple stretching and meditative exercises to complicated and demanding exercises requiring more physical activity and mental concentration.

Probably the most popular among alternative health participants is t'ai chi, derived from the Chinese philosophy of Taoism and based on the concept of yin and yang. T'ai chi has a self-defense aspect based on

counteracting an opponent's attack and then counter-attacking, all in the same movement. As an exercise to maintain health, t'ai chi strengthens muscles and joints. It requires deep breathing techniques that increase blood circulation, benefiting the heart, lungs, and other organs. New research states that t'ai chi may improve physical functioning, like bending and lifting, in older age.

Another martial art growing in popularity in the United States is qigong (pronounced chee kung), although it has several forms that are more Taoist and Buddhist than martial. Qigong is a gentle exercise program that can increase vitality, enhance the immune system, and relieve stress when performed regularly. In China, there are hospitals that use qigong to treat terminal illnesses, particularly **cancer**.

Cardiovascular and aerobic

Aerobic, also called cardiovascular, exercises use a variety of muscle groups continuously and rhythmically, increasing heart rate and breathing. Specific aerobic activities include walking, jogging, running, bicycling, swimming, tennis, and cross-country skiing. Another popular form is aerobic dance exercise. Routines should last 10-60 minutes and be performed at least three times a week. Aerobic exercise is especially beneficial for losing weight and building endurance.

Aerobic exercises can be done outside a formal setting, with little or no equipment. However, since boredom is a frequent cause for stopping exercise, it often is beneficial to participate in exercise classes or join a gym or health club. Exercising with a group often helps with motivation. Also, health clubs usually offer a variety of stationary aerobic equipment, such as bikes, treadmills, stair climbers, and rowing machines.

Resistance

Resistance exercises generally are accomplished by lifting weights such as barbells and dumbbells, or by using a variety of resistance machines. They can also be done using only the body as resistance, such as doing push-ups, pull-ups, and sit-ups. Resistance exercise is particularly good for building muscles. For patients with kidney disease, weight lifting offers added benefit. Chronic kidney disease can lead to muscle wasting, which is compounded by low-protein **diets** that may be described for these patients. A 2001 study demonstrated that resistance training can improve muscle mass in kidney disease patients.

Unlike aerobics, which can be done daily, weight-lifting exercises require a period for the muscles to rest and rebuild. A total-body workout should be done every other day, or two to three times a week. A more advanced workout would exercise the lower body muscles one day and upper body muscles the next. It is also important to do 5-10 minutes each of warm-up and cool-down exercises, which will help increase flexibility and decrease soreness and fatigue.

Preparations

No advance preparations are required for exercising. However, a trainer can test a person's strength level and outline an appropriate program. Proper shoes are essential, especially for running. Any exercise should start with a warm-up of 5-10 minutes. Anyone considering a regular exercise program should consult first with a doctor, and possibly a sports podiatrist, to avoid strain and injury. Persons with serious health problems, such as heart disease, diabetes, **AIDS**, **asthma**, and arthritis should only begin an exercise regimen with their doctor's approval.

Precautions

In most people, the main exercise precaution is to avoid strain and overexertion. Exercise does not need to be strenuous to be beneficial. People with certain chronic health problems should take special precautions. Diabetics should closely monitor their blood sugar levels before and after exercising. Heart disease patients should never exercise to the point of chest pain. Exercise can induce asthma. It is essential for people with asthma to get their doctor's permission before starting an exercise program. It also is important for people to be shown the proper form in any activity to avoid strain and possible injury, especially when using exercise equipment. People also should know what parts of the body might be stressed by a particular exercise. They can then use supplemental exercises or stretches to add balance to the exercise program.

Side effects

The primary adverse effects of exercising can be sore muscles and stiff joints a day or two after beginning an exercise routine. These pains may last for several days. Other minor problems can include headaches, **dizziness**, fatigue, and **nausea**, usually indicating the exercise routine is too strenuous. A person can agitate old injuries or create new ones by improperly using equipment or wearing inadequately cushioned shoes.

Research and general acceptance

There almost is universal acceptance by allopathic and homeopathic health practitioners that exercise can be beneficial to overall good health. Thousands of studies during the past several decades link regular exercise to reduced risks for heart disease, stroke, diabetes, **obesity**, depression, hypertension, and osteoporosis. For example, a 1998 study by Harvard University of more than 11,000 people showed that people who exercise for an hour a day cut their risk of stroke in half over people who do not exercise regularly.

Training and certification

No special training or certification is required for exercising. People who want help in developing an exercise program should consult a certified physical trainer.

Eyebright

Description

Eyebright (*Euphrasia officinalis*) is an annual plant that grows wild in meadows, grassy areas, heaths, and pastures of Britain, northern and western Asia, North America, and Europe. It belongs to the Scrophulariaceae plant family, which also includes the **foxglove** plant.

Eyebright grows to a height of 4-8 in (10-20 cm) and has small white or purple flowers with red spots. These petals resemble bloodshot eyes, suggesting the plant's name and its eye-clearing action. Downy hairs cover the stems, which produce toothed leaves.

Eyebright is a semiparasitic plant. This means that it is nourished by the roots of other plants. Generally, it does not grow well if transplanted from the wild. The plant is harvested during the late summer or fall when the flowers are in bloom. The whole plant is cut off just above the root and then dried.

Eyebright contains vitamins A, C, D, and B complex; **iron**; silicon; and traces of **iodine**, **copper**, and **zinc**. Other components of eyebright include tannins, iridoid glycosides, the flavonoids rutin and **quercetin**,

KEY TERMS

Annual—A plant that grows every year.

Blepharitis—A condition where the eyelids become red, irritated, and scaly. The eyes are painful, red, and inflamed.

Conjunctivitis—An inflammation of the mucous membranes that cover the outer eyeball and line the eyelids. The eye appears red or pink and is itchy or sore.

Infusion—An herbal tea created by steeping herbs in hot water. Generally, leaves and flowers are used in infusions.

Tincture—The concentrated solution of an herbal extract made with alcohol.

essential fatty acids, glycoside aucuboside, caffeic and ferulic acids, sterols, **choline**, and a volatile oil.

History

The Latin name *Euphrasia* is derived from the Greek word "Euphrosyne," meaning gladness. Euphrosyne was the name of one of three Graces known for her joy and happiness. The ancient Greeks used eyebright to treat eye **infections**, thereby creating happiness.

Eyebright has been used as a folk medicine to treat eye inflammations and infections, coughs, and poor memory since the Middle Ages. The poet Milton mentions eyebright in his book *Paradise Lost*, in which the archangel Michael gives eyebright to Adam to cure an eye infection. In 1485, eyebright was listed in a German book on medicinal herbs. Many sixteenth century herbalists championed eyebright as a treatment for various eye diseases. During the time of Queen Elizabeth, an eyebright ale was popular. Dried eyebright was often combined with tobacco and smoked to provide relief for bronchial colds.

General use

Modern herbalists still prescribe eyebright as a popular remedy for eye irritations and disorders, such as **conjunctivitis** and blepharitis. Icelanders use the juice from the pressed plant to treat most eye afflictions. Scottish people make an infusion in milk for inflamed or weak eyes. Eyebright is used to treat poor vision, eye strain, eye infections, sensitivity to light, and eye ulcers. Eyebright's antiseptic properties are highly regarded in soothing and cooling eyes that itch, burn, weep, and are red.

Eyebright is beneficial in the treatment of coughs, colds, **allergies**, sinusitis, **hay fever**, earaches, headaches, **jaundice**, throat and bronchial congestion, hoarseness, flu, and sinus inflammation. The flavonoids in eyebright act as anti-inflammatory agents that can help relieve inflamed mucous membranes of the eyes, sinuses, and upper respiratory tract. Eyebright's astringent properties also help reduce inflammation and mucous drainage, making the plant a popular remedy for many allergy, cold, and sinus symptoms.

Preparations

The stems, leaves, and flowers of the plant are collected and dried for medicinal use. Eyebright is often combined with **goldenseal** to treat eye afflictions. Eyebright may also be combined with **goldenrod**, **elder** flower, and/or goldenseal to provide relief from congestion.

In **homeopathy**, *Euphrasia officinalis* is a remedy used to treat colds accompanied by a nonirritating, watery nasal discharge and frequent burning tears. Conjunctivitis with symptoms of red eyes and lips, and acrid, watery tears may also be treated with this remedy. *Euphrasia officinalis* is also used as a remedy for **measles** and allergies.

Eyebright is available in bulk form for teas or compresses, and in capsule and tincture forms. Capsules and tinctures should be used as directed on the commercial package.

To make a tea, 1 cup of boiling water is poured over 2-3 teaspoons of dried eyebright and steeped for 5-10 minutes. One cup should be drunk three times daily to maintain eyesight, relieve nasal congestion, and soothe coughs. This infusion can also be used as an eye bath to treat inflamed or painful eyes. The mixture is cooled, and then the eyes are bathed with the warm liquid three to four times daily.

To make a compress, 1-2 tablespoons of dried eyebright are simmered in 1 pint (0.4 l) of water for 10 minutes. The mixture is cooled and then strained. A clean cloth is dipped in the mixture, wrung out, and then placed over the eyes for 15 minutes several times daily. Caution should be used when applying compresses. An unsterilized, homemade compress of eyebright may contain bacteria that could lead to an eye infection.

Precautions

A qualified herbalist should be consulted before administering eyebright to children. Although herbalists

maintain the benefits of eyebright, there are no known scientific studies or research to validate these claims.

Side effects

If a tincture solution of eyebright is placed on the eyes, tearing, **itching**, reddening, and swelling of the eyelids may develop because of the alcohol in the tincture. Eyebright may also cause a skin rash or **nausea**.

Interactions

There are no known interactions.

Facial massage

Definition

Facial massage is a very popular Western beauty treatment to slow down the **aging** process and achieve younger-looking and healthier skin. It is also used to relieve **stress**, **migraine headache**, **premenstrual syndrome** (PMS) and sinus congestion. It may involve a whole massage session, a portion of a whole-body massage or a part of a facial treatment. Facial massage can be done by a professional massage therapist, an esthetician, or a cosmetologist. Simple massage can also be done at home. Massage of the face is usually done with the hands; however, mechanical massaging devices are also used in beauty salons or spas. A small amount of oil or lotion is often applied to facilitate movement over the delicate facial areas.

In Eastern therapies, facial massage is part of a full-body treatment in which pressure points on the face and neck are stimulated in order to release blockages in the flow of qi, or vital energy. Lotions or oils are not used on the face in **acupressure**, **shiatsu**, or **yoga** techniques of facial massage.

Origins

Massage has been used for **pain** relief, healing and cosmetic improvement by people of all cultures since ancient times. The first written record of **massage therapy** is a Chinese medical text dating from the third century B.C. The ancient Greeks, Persians, Japanese and Indians also recorded the use of massage treatment in great detail in their early medical literature.

The Western version of facial massage as a cosmetic treatment is a relatively recent twentieth-century innovation. It has become especially popular in Europe. Many of the best-known European practitioners have set up shop in the United States and taught others. This form of facial massage has generally been regarded as belonging more to estheticians and makeup artists than to massage therapists.

Benefits

Western-style facial massage may offer the following potential benefits:

- improvement of facial skin and muscle tone.
- relaxation of facial and eye muscles
- relief from tension headaches and facial pain
- alleviation of stress and anxiety
- overall physical and mental relaxation

Facial massage as part of Eastern therapies may offer the following potential benefits:

- stimulation of meridian points on the face
- relief from eyestrain
- correction of liver and gall bladder imbalances
- relief of neck tension
- alleviation of nervous disorders
- relief of premenstrual water retention

Description

Western-style facial massage

In Western massage, a facial massage as part of a full-body treatment is different from a full facial treatment, which includes masks, steaming, and similar techniques. A regular massage simply includes massage of the face, usually at the beginning or the end of the massage session.

For a Western facial massage, a gentle effleurage (gliding) movement is most often used. To perform the facial massage, the strokes must be gentle as well as stimulating, in order not to stretch the skin. Pressure strokes should move upward to give the muscles of the

Massage therapist performing a facial massage. *(Custom Medical Stock Photo. Reproduced by permission.)*

face a lift rather than dragging them down. A typical facial massage includes the following steps:

- Before the massage, wash hands with soap and clean water. If the person to be massaged wears contact lens, ask her or him to remove them.
- Position: The most comfortable position has the client lying down on a massage table or sitting in a chair. Facial massage can be done, however, on any flat surface like a clean floor.
- Using a small amount of cleanser, gently wash the client's face. Wet cotton pads or facial sponges or wedges can be used to apply the cleanser. Then remove the cleanser, using fresh damp cotton pads.
- Apply the massage cream or lotion and begin massaging the face and neck areas in small symmetrical circles. The strokes should move up the neck and along the contour of the face. Do not leave out any facial muscles.

KEY TERMS

Massage—A rubbing or kneading with hands or other parts of the body to stimulate circulation, make joints more supple and relieve stress or tension.

- Next, gently glide the back of the hands across the forehead with light pressure. Placing the thumbs side by side on the center of the forehead with the hands cradling the face, draw the thumbs outward towards the temples and make a gentle sweeping movement around the temple. Repeat the movement several times to relieve tension in the temples.
- Apply pressure in the hollow areas under the eyebrows by placing the hands along the sides of the face; use the thumb to press gently under the ridge one spot at a time. Move the pressure point from the inner to the outer edge of the brows and repeat the thumb pressure. This technique can help relieve tension headache.
- Position the thumbs alongside the nose bridge with hands cupping the face. Firmly slide the thumbs downward to the nostrils and outwards along the contour of the cheeks applying pressure along the way. Gently release the pressure when the thumbs reach the hairline. Then pull both hands up alongside the face towards the top of the head and away from the face. Repeat this motion two more times.
- Position fingertips in the cheek muscles and gently make circling movements counter-clockwise for a few times moving along the cheek muscles. This motion alleviates tension in the cheek area.
- Gently stroke the ears with the index fingers and thumbs while moving along the rims of the ears. This technique is very relaxing and enjoyable.
- Position the fingers just behind the neck while pressing with a thumb pad on a spot in the jaw area and circling this spot before moving to the next one. Holding the chin with the fingers, stroke the chin with the thumbs using circular motions downward. Finish the jaw massage with gentle strokes alongside the chin. This movement releases tension in the mouth and jaw.
- Make circular motions on the scalp and comb the fingers through the hair to release tension from the face and the head and to stimulate the scalp.
- Finally, remove the massage cream or lotion with fresh and damp cotton pads. Most facials end with a special lotion applied to the face.

Facial massage in Eastern therapies

In shiatsu, acupressure, and similar Eastern therapies, pressure is applied to points on the face in order to stimulate or unblock the flow of vital energy in specific meridians. The pressure points located on the face, along with the conditions that they are used to treat, are as follows:

- Stomach 1, under the center of the eye along the nasal bone: Tension and eyestrain.
- Stomach 3, about 4 cm below Stomach 1 at the level of the base of the nose: Sinus and nasal congestion.
- Stomach 4, at the corners of the mouth: General stress and tension.
- Stomach 6, about 2 cm in front of the base of the ear lobe: Toothache.
- Conception vessel (end), between the lower lip and chin: Tension in the face and mouth.
- Bladder 1, at the inside corner of the eye: Headache and eyestrain.
- Gall bladder 1, a hollow about 2 cm from the outside corner of the eye: Headaches.
- Gall bladder 2, the hollow directly above and in front of the ear lobe: Ringing in the ears, swollen eyes, and dizziness.

Some yoga techniques include self-treatment for eye problems or tension by pressing the palms or knuckles against the pressure points surrounding the eyes.

Preparations

Western-style facial massage may require the following items:

- Towel to drape over the shoulders of the person to be massaged.
- Mild cleansing lotion to cleanse the face before massage.
- Moistened cotton pads, cotton-tipped swabs and facial tissues to remove cosmetics, cleansers and massage cream.
- Facial lotion or cream to facilitate the massage.

Facial massage as part of Eastern therapies does not require any specific preparation.

Precautions

Facial massage should not be done if any of the following conditions are present:

- Wearing contact lenses. The client should remove contact lenses before the procedure.
- Open sores, boils or cuts on the face.
- Inflamed or bruised skin.
- Recent scar tissue.
- Acne, psoriasis or eczema. Facial massage can worsen these conditions.

Side effects

Facial massage may irritate and worsen such skin conditions as **acne**, **psoriasis** or **eczema**.

Research and general acceptance

Western-style facial massage is a popular cosmetic procedure for many women and some men to improve the way the skin looks and feels. There is also evidence that massage can reduce stress, **headache** and facial pain.

Training and certification

Training requirements for cosmetologists and estheticians vary from state to state, ranging from a hair-care license to passing a required licensing examination. In addition to the techniques of facial massage, these beauticians may also be knowledgeable regarding clinical cosmetology and skin care.

Facial massage can also be performed by massage therapists as part of a full-body massage. Certified therapists are graduates of accredited massage programs who have passed the national certification examination in therapeutic massage. They are also required to participate in continuing education programs to keep their skills current.

Practitioners of shiatsu, acupressure, and similar Eastern therapies may be certified or licensed by institutions in the United States and abroad that offer instruction in these forms of treatment.

Farsightedness *see* **Hyperopia**

Fasting

Definition

Fasting is voluntarily not eating food for varying lengths of time. Fasting is used as a medical therapy for many conditions. It is also a spiritual practice in many religions.

Origins

Used for thousands of years, fasting is one of the oldest therapies in medicine. Many of the great doctors of ancient times and many of the oldest healing systems have recommended it as an integral method of healing and prevention. Hippocrates, the father of Western medicine, believed fasting enabled the body to heal itself. Paracelsus, another great healer in the Western tradition, wrote 500 years ago that "fasting is the greatest remedy, the physician within." **Ayurvedic medicine**, the world's oldest healing system, has long advocated fasting as a major treatment.

Fasting has also been used in nearly every religion in the world, including Christianity, Judaism, Buddhism, and Islam. Many of history's great spiritual leaders fasted for mental and spiritual clarity, including Jesus, Buddha, and Mohammed. In one of the famous political acts of the last century, the Indian leader Mahatma Gandhi fasted for 21 days to promote peace.

Fasting has been used in Europe as a medical treatment for years. Many spas and treatment centers, particularly those in Germany, Sweden, and Russia, use medically supervised fasting. Fasting has gained popularity in American alternative medicine over the past several decades, and many doctors feel it is beneficial. Fasting is a central therapy in **detoxification**, a healing method founded on the principle that the build up of toxic substances in the body is responsible for many illnesses and conditions.

Benefits

Fasting can be used for nearly every chronic condition, including **allergies**, **anxiety**, arthritis, **asthma**, **depression**, diabetes, headaches, **heart disease**, high **cholesterol**, low blood sugar, digestive disorders, mental illness, and **obesity**. Fasting is an effective and safe weight loss method. It is frequently prescribed as a detoxification treatment for those with conditions that may be influenced by environmental factors, such as **cancer** and **multiple chemical sensitivity**. Fasting has been used successfully to help treat people who have been exposed to high levels of toxic materials due to accident or occupation. Fasting is thought to be beneficial as a preventative measure to increase overall health, vitality, and resistance to disease. Fasting is also used as a method of mental and spiritual rejuvenation.

Description

The principle of fasting is simple. When the intake of food is temporarily stopped, many systems of the body are given a break from the hard work of digestion. The extra energy gives the body the chance to heal and restore itself, and burning stored calories gets rid of toxic substances stored in the body.

The digestive tract is the part of the body most exposed to environmental threats, including bacteria, viruses, parasites, and toxins. It requires the most immune system support. When food is broken down in the intestines, it travels through the blood to the liver, the largest organ of the body's natural detoxification system. The liver breaks down and removes the toxic by-products produced by digestion, including natural ones and the chemicals now present in the food supply. During fasting, the liver and immune system are essentially freed to detoxify and heal other parts of the body.

Many healers claim that fasting is a particularly useful therapy for Americans and for the modern lifestyle, subjected to heavy **diets**, overeating, and constant exposure to food additives and chemicals. Some alternative practitioners have gone so far as to estimate that the average American is carrying 5-10 pounds of toxic substances in their bodies, for which fasting is the quickest and most effective means of removal.

Physiology of fasting

Through evolution, the body became very efficient at storing energy and handling situations when no food was available. For many centuries, fasting was probably a normal occurrence for most people, and

EVARTS LOOMIS (1910–2003)

Evarts G. Loomis is known as the father of holistic medicine. A homeopathic physician of international renown, he was an advocate of holistic treatment of dis ease, natural foods, exercise and meditation. Loomis was licensed to practice traditional medicine in 1946, but began early in his career to diverge from a quiet or dull practice. He served as a dog sled doctor with the Grenfell Mission in Newfoundland, Canada, worked in Algeria, as well as with the Friends Ambulance Unit in China before he founded Meadowlark, the first holistic retreat in North America. Loomis was a pioneer in the holistic health movement in the United States. He was also a proponent of regulated, monitored 24 36 hour fasts, touting the ben efits of both the water fast and the all juice fast.

He and his partner, Fay Loomis, operated Health and Growth Associates, from their home in Hemet, California. Loomis also utilized Dream Work and Kinesiology (the study of human movement) in his health and personal growth counseling.

the body adapted to it. It is estimated that even very thin people can survive for 40 days or more without food. The body has a special mechanism that is initiated when no food is eaten. Fasting is not starvation, but rather the body's burning of stored energy. Starvation occurs when the body no longer has any stored energy and begins using essential tissues such as organs for an energy source. Therapeutic fasts are stopped long before this happens.

Many physiological changes occur in the body during fasting. During the first day or so, the body uses its glycogen reserves, the sugars that are the basic energy supply. After these are depleted, the body begins using fat. However, the brain, which has high fuel requirements, still needs glucose (sugars converted from glycogen). To obtain glucose for the brain, the body begins to break down muscle tissue during the second day of the fast. Thus, during fasting some muscle loss will occur. To fuel the brain, the body would need to burn over a pound of muscle a day, but the body has developed another way to create energy that saves important muscle mass. This protein-sparing process is called ketosis, which occurs during the third day of a fast for men and the second day for women. In this highly efficient state, the liver begins converting stored fat and other nonessential tissues into ketones, which can be used by the brain, muscles, and heart as energy. It is at this point in the fast that sensations of hunger generally go away, and many people experience normal or even increased energy levels. Hormone levels and certain functions become more stable in this state as well. The goal of most fasts is to allow the body to reach the ketosis state in order to burn excess fat and unneeded or damaged tissue. Thus, fasts longer than three days are generally recommended as therapy.

Weight loss occurs most rapidly during the first few days of a fast, up to 2 lbs (1kg) per day. In following days, the figure drops to around 0.5 pound per day. An average weight loss of a pound a day for an entire fast can be expected. Studies show that cutting back just once a month can jump-start healthier eating and help rid one's body of a lifetime of extra calories.

Performing a fast

Fasts can be performed for varying lengths of time, depending on the person and his or her health requirements. For chronic conditions, therapists recommend from two to four weeks to get the most benefits. Seven-day fasts are also commonly performed. A popular fasting program for prevention and general health is a three-day fast taken four times per year, at the change of each season. These can be easily performed over long weekends. Preventative fasts of one day per week are used by many people as well.

Juice fasts are also used by many people, although these are not technically fasts. Juice fasts are less intensive than water fasts because the body does not reach the ketosis stage. The advantage of juice fasts is that fruit and vegetable drinks can supply extra energy and nutrients. People can fit a few days of juice fasting into their normal schedules without significant drops in energy. Juice fasts are also said to have cleansing and detoxifying effects. The disadvantage of juice fasts is that the body never gets to the ketosis stage, so these fasters are thought to lack the deep detoxification and healing effects of the water fast.

Medical supervision is recommended for any fast over three days. Most alternative medicine practitioners, such as homeopaths, naturopathic doctors, and ayurvedic doctors, can supervise and monitor patients during fasts. Those performing extended fasts and those with health conditions may require blood, urine, and other tests during fasting. There are many alternative health

KEY TERMS

Ayurvedic medicine—A traditional healing system developed in India.

Toxin—A substance that has poisonous effects on the body.

clinics that perform medically supervised fasts as well. Some conventional medical doctors may also supervise patients during fasts. Costs and insurance coverage vary, depending on the doctor, clinic, and requirements of the patient.

Preparations

Fasts must be entered and exited with care. To enter a fast, the diet should be gradually lightened over a few days. First, heavy foods such as meats and dairy products should be eliminated for a day or two. Grains, nuts, and beans should then be reduced for several days. The day before a fast, only easily digested foods like fruits, light salads, and soups should be eaten. During the fast, only pure water and occasional herbal teas should be drunk. If you **exercise**, keep your workouts during fasting light and relatively brief, stopping immediately if you feel dizzy, lightheaded or short of breath.

Fasts should be ended as gradually as they are entered, going from lighter to heavier foods progressively. The diet after a fast should emphasize fresh, wholesome foods. Fasters should particularly take care not to overeat when they complete a fast.

Precautions

Fasting is not appropriate for everyone and, in some cases, could be harmful. Any person undertaking a first fast longer than three days should seek medical supervision. Those with health conditions should always have medical support during fasting. Plenty of water should be taken by fasters since dehydration can occur. Saunas and sweating therapies are sometimes recommended to assist detoxification, but should be used sparingly. Those fasting should significantly slow down their lifestyles. Taking time off of work is helpful, or at least reducing the work load. Fasters should also get plenty of rest. Exercise should be kept light, such as walking and gentle stretching.

Side effects

Those fasting may experience side effects of **fatigue**, malaise, aches and pains, emotional duress, **acne**, headaches, allergies, swelling, **vomiting**, bad breath, and symptoms of colds and flu. These reactions are sometimes called *healing crises*, which are caused by temporarily increased levels of toxins in the body due to elimination and cleansing. Lower energy levels should be expected during a fast.

Research and general acceptance

The physiology of fasting has been widely studied and documented by medical science. Beneficial effects such as lowered cholesterol and improved general functioning have been shown. Fasting as a treatment for illness and disease has been studied less, although some studies around the world have shown beneficial results. A 1984 study showed that workers in Taiwan who had severe **chemical poisoning** had dramatic improvement after a ten-day fast. In Russia and Japan, studies have demonstrated fasting to be an effective treatment for mental illness. Fasting was featured on the cover of the *New England Journal of Medicine*, although mainstream medicine has generally ignored fasting and detoxification treatments as valid medical procedures.

The majority of research that exists on fasting is testimonial, consisting of individual personal accounts of healing without statistics or controlled scientific experiments. In the alternative medical community, fasting is an essential and widely accepted treatment for many illnesses and chronic conditions.

Training and certification

The International Association of Professional Natural Hygienists (IAPNH) is an organization of healthcare professionals who specialize in therapeutic fasting. It certifies doctors who have completed approved residencies in therapeutic fasting, including conventional medical doctors, naturopaths, and osteopathic doctors.

Dried damiara is one of several herbal remedies used to counteract fatigue. *(Geoff Kidd / Photo Researchers, Inc.)*

Fatigue

Definition

Fatigue is physical and/or mental exhaustion that can be triggered by **stress**, medication, overwork, mental and physical illness, or disease.

Description

Everyone experiences fatigue occasionally. It is the body's way of signaling its need for rest and sleep. But when fatigue becomes a persistent feeling of tiredness or exhaustion that goes beyond normal sleepiness, it is usually a sign that something more serious is amiss.

Physically, fatigue is characterized by a profound lack of energy, feelings of muscle weakness, and slowed movements or central nervous system reactions. Fatigue can also trigger serious mental exhaustion. Persistent fatigue can cause a lack of mental clarity (or feeling of mental "fuzziness"), difficulty concentrating, and in some cases, **memory loss**.

Causes and symptoms

Fatigue may be the result of one or more environmental causes such as inadequate rest, improper diet, work and home stressors, or poor physical conditioning. It also can be one symptom of a chronic medical condition or disease process in the body. **Heart disease**, low blood pressure, diabetes, end-stage renal disease, iron-deficiency **anemia**, **insomnia**, **narcolepsy**, **sleep apnea**, chronic obstructive pulmonary disease (COPD), **cancer** or cancer treatment, and untreated **parasitic infections** are a few of the diseases and disorders that can cause long-term, ongoing fatigue symptoms. Acute illnesses such as viral and bacterial **infections** can also trigger temporary feelings of exhaustion. In addition, mental disorders such as **depression** can cause fatigue.

Many common medications, including antihistamines, antibiotics, and blood pressure drugs, may cause drowsiness as a side effect. Individuals already experiencing fatigue who are prescribed one of these medications may wish to check with their healthcare provider about alternative treatments.

Extreme fatigue that persists unabated for at least six months, is not the result of a diagnosed disease or illness, and is characterized by flu-like symptoms such as swollen lymph nodes, **sore throat**, and muscle weakness and/or **pain** may indicate a diagnosis of **chronic fatigue syndrome** (CFS). CFS, also called chronic fatigue immune deficiency syndrome, is a debilitating illness that causes overwhelming exhaustion and a number of neurological and immunological symptoms. Between 1.5 and 2 million Americans are estimated to have this disorder, which is found worldwide. CFS is definitely associated with immune system response and likely caused by a virus or bacteria, although no single cause has yet been identified.

Diagnosis

Patients know when they are fatigued, but because fatigue is a symptom of a number of different disorders, diseases, and lifestyle choices, diagnosing the cause may be difficult. A thorough examination and patient history by a qualified healthcare provider is the first step in determining the cause of the fatigue. A physician can order blood, urine, and other tests to rule out physical conditions and diseases that feature fatigue as a symptom and can also determine if prescription drugs, poor dietary habits, work environment, or other external stressors could be triggering the exhaustion. Several diagnostic tests may also be required to rule out common physical causes of exhaustion, such as blood tests to check for iron-deficiency anemia.

Diagnosis of chronic fatigue syndrome is significantly more difficult. Because there is no specific biological marker or conclusive blood test to check for the disorder, healthcare providers must rely on the patient's condition

and the severity of symptoms to make a diagnosis. In many cases, individuals with chronic fatigue syndrome go through a battery of invasive diagnostic tests and several years of consultation with medical professionals before receiving a correct diagnosis.

Treatment

The treatment of fatigue depends on its direct cause, but there are several commonly prescribed treatments for non-specific fatigue, including dietary and lifestyle changes, the use of **essential oils** and herbal therapies, deep breathing exercises, **traditional Chinese medicine**, and **color therapy**.

Dietary changes

Inadequate or inappropriate nutritional intake can cause fatigue symptoms. To maintain an adequate energy supply and promote overall physical wellbeing, individuals should eat a balanced diet and observe the following nutritional guidelines:

- Drink plenty of water. Individuals should try to drink a minimum of eight glasses of water a day. Dehydration can reduce blood volume, which leads to feelings of fatigue.
- Eat iron-rich foods (i.e., liver, raisins, spinach, apricots). Iron enables the blood to transport oxygen throughout the tissues, organs, and muscles, and diminished oxygenation of the blood can result in fatigue. Adequate iron is especially important for women of reproductive age, as blood, and the iron it contains, are lost with every menstrual cycle.
- Avoid high-fat meals and snacks. High-fat foods take longer to digest, reducing blood flow to the brain, heart, and rest of the body while blood flow is increased to the stomach.
- Eat unrefined carbohydrates and proteins together for sustained energy.
- Balance proteins. Limiting protein to 15 to 20 grams per meal and two snacks of 15 grams is recommended; however, not getting enough protein adds to fatigue. Pregnant or breastfeeding women should eat more protein.
- Get the recommended dietary allowance of B complex vitamins (specifically, pantothenic acid, folic acid, thiamine, and vitamin B_{12}). Deficiencies in these vitamins can trigger fatigue.
- Get the recommended daily allowance of selenium, riboflavin, and niacin. These are all essential nutritional elements in metabolizing food energy.
- Get the recommended daily allowance of calcium and vitamin D supplementation, which can lessen fatigue symptoms in persons with hypocalcaemia-caused fatigue and also help strengthen bones and prevent osteoporosis.
- Control portion size. Individuals should only eat when they are hungry and stop when they are full. An overstuffed stomach can cause short-term fatigue, and individuals who are overweight are much more likely to regularly experience fatigue symptoms.

Lifestyle changes

Lifestyle factors such as a high-stress job, erratic work hours (e.g., as flight attendants experience), lack of social or family support, or erratic sleep patterns can all cause prolonged fatigue. If stress is contributing to fatigue, **relaxation** therapies and techniques are available to help alleviate tension, including massage, **yoga**, **aromatherapy**, **hydrotherapy**, progressive relaxation exercises, **meditation**, and **guided imagery**. Some may also benefit from individual or family counseling or **psychotherapy** sessions to work through stress-related fatigue that is a result of family or social issues.

Maintaining healthy sleep patterns is critical to getting proper rest. Having a set bedtime helps to keep sleep on schedule. A calm and restful sleeping environment is also important to healthy sleep. Above all, the bedroom should be quiet and comfortable, away from loud noises and with adequate window treatments to keep sunlight and streetlights out. Removing distractions from the bedroom such as televisions and telephones can also be helpful. People who experience insomnia may find herbal or pharmaceutical treatment can help get them back into good sleep patterns.

Essential oils

Aromatherapists, hydrotherapists, and other holistic healthcare providers may recommend the use of essential oils of **rosemary** (*Rosmarinus officinalis*), **eucalyptus** blue gum (*Eucalyptus globulus*), **peppermint**, (*Mentha x piperata*), or scots pine oil (*Pinus sylvestris*) to stimulate the nervous system and reduce fatigue. These oils can be added to bathwater or massage oil as a topical application. Citrus oils such as lemon, orange, grapefruit, and lime have a similar effect and can be added to a steam bath or vaporizer for inhalation.

Herbal remedies

Herbal remedies that act as circulatory stimulants can offset the symptoms of fatigue in some individuals. An herbalist may recommend an infusion of **ginger** (*Zingiber officinale*) root or treatment with **cayenne** (*Capsicum annuum*), balmony (*Chelone glabra*), **damiana**

(*Turnera diffusa*), ginseng (*Panax ginseng*), or rosemary (*Rosmarinus officinalis*) to treat ongoing fatigue.

An infusion is prepared by mixing the herb with boiling water, steeping it for several minutes, and then removing the herb from the infusion before drinking. A strainer, tea ball, or infuser can be used to immerse loose herbs in the boiling water before steeping and separating them. A second method of infusion is to mix the loose herbal preparation with cold water first, bringing the mixture to a boil in a pan or teapot and then separating the tea from the infusion with a strainer before drinking.

Caffeine-containing central nervous system stimulants such as tea (*Camellia senensis*) and cola (*Cola nitida*) can provide temporary relief of fatigue symptoms. However, long-term use of **caffeine** can cause restlessness, irritability, and other unwanted side effects, and in some cases, it may actually work to increase fatigue after the stimulating effects of the caffeine wear off. To avoid these problems, caffeine intake should be limited to 300 mg or less a day (the equivalent of 4–8 cups of brewed, hot tea).

Traditional Chinese medicine

Chinese medicine regards fatigue as a blockage or misalignment of *qi*, or energy flow, inside the human body. The practitioner of Chinese medicine chooses **acupuncture** and/or herbal therapy to rebalance the entire system. The Chinese formula Minot Bupleurum soup (Xiao Chia Hu Tang) has been used for nearly 2,000 years for the type of chronic fatigue that follows **influenza**. In this condition, the person has low-grade **fever**, **nausea**, and fatigue. Other formulas are helpful in other cases. Acupuncture involves the placement of a series of thin needles into the skin at targeted locations on the body known as acupoints in order to harmonize the energy flow within the human body.

Deep breathing exercises

Individuals under stress often experience fast, shallow breathing. This type of breathing, known as chest breathing, can lead to shortness of breath, increased muscle tension, inadequate oxygenation of blood, and fatigue. Breathing exercises can both improve respiratory function and relieve stress and fatigue.

Deep breathing exercises are best performed while lying flat on the back on a hard surface, usually the floor. The knees are bent, and the body (particularly the mouth, nose, and face) is relaxed. One hand should be placed on the chest and one on the abdomen to monitor breathing technique. With proper breathing techniques, the abdomen will rise further than the chest. The individual takes a series of long, deep breaths through the nose, attempting to raise the abdomen instead of the chest. Air is exhaled through the relaxed mouth. Deep breathing can be continued for up to 20 minutes. After the **exercise** is complete, the individual checks again for body tension and relaxation. Once deep breathing techniques have been mastered, an individual can use deep breathing at any time or place as a quick method of relieving tension and preventing fatigue.

Color therapy

Color therapy, also known as chromatherapy, is based on the premise that certain colors are infused with healing energies. The therapy uses the seven colors of the rainbow to promote balance and healing in the mind and body. Red promotes energy, empowerment, and stimulation. Physically, it is thought to improve circulation and stimulate red blood cell production. Red is associated with the seventh chakra, located at the root, or base, of the spine. In yoga, the chakras are specific spiritual energy centers of the body.

Therapeutic color can be administered in a number of ways. Practitioners of Ayurvedic, or traditional Indian medicine, wrap their patients in colored cloth chosen for its therapeutic hue. Individuals experiencing fatigue would be wrapped in reds and oranges chosen for their uplifting and energizing properties. Patients may also be bathed in light from a color-filtered light source to enhance the healing effects of the treatment.

Individuals may also be treated with color-infused water, which is achieved by placing translucent red colored paper or colored plastic wrap over and around a glass of water and placing the glass in direct sunlight so the water can soak up the healing properties and vibrations of the color. Environmental color sources may also be used to promote feelings of stimulation and energy. Red wall and window treatments, furniture, clothing, and even food may be recommended for their energizing healing properties.

Color therapy can be used in conjunction with both hydrotherapy and aromatherapy to heighten the therapeutic effect. Spas and holistic healthcare providers may recommend red color baths or soaks, which combine the benefits of a warm or hot water soak with energizing essential oils and the fatigue-fighting effects of bright red hues used in color therapy.

KEY TERMS

Aromatherapy—Therapeutic use of plant-derived, aromatic essential oils to promote physical and psychological wellbeing.

Guided imagery—Use of relaxation and mental visualization to improve mood and/or physical wellbeing.

Hydrotherapy—Use of water (hot, cold, steam, or ice) to relieve discomfort and promote physical wellbeing.

Allopathic treatment

Conventional medicine recommends the dietary and lifestyle changes outlined as a first line of defense against fatigue. Individuals who experience occasional fatigue symptoms may benefit from short-term use of caffeine-containing central nervous stimulants such as energy drinks, which make people more alert and improve coordination. However, these should be prescribed with caution, as overuse of the drug can lead to **sleep disorders** that result in increased fatigue.

Another reason to avoid extended use of caffeine is its associated withdrawal symptoms. People who use large amounts of caffeine over long periods build up a tolerance to it. When that happens, they have to use more and more caffeine to get the same effects. Heavy caffeine use can lead to dependence. If an individual stops using caffeine abruptly, withdrawal symptoms may occur, including **headache**, fatigue, drowsiness, yawning, irritability, restlessness, **vomiting**, or runny nose. These symptoms can go on for as long as a week.

Expected results

Fatigue related to a chronic disease or condition may last indefinitely, but it can be alleviated to a degree through some of the treatment options outlined above. Exhaustion that can be linked to environmental stressors is usually easily alleviated when those stressors are dealt with properly.

There is no known cure for chronic fatigue syndrome, but steps can be taken to lessen symptoms and improve quality of life for these individuals while researchers continue to seek a cure.

Prevention

Many of the treatments mentioned are also recommended to prevent the onset of fatigue. Getting adequate rest and maintaining a consistent bedtime schedule are the most effective ways to combat fatigue. A balanced diet and moderate exercise program are also important to maintaining a consistent energy level.

Feldenkrais

Definition

The Feldenkrais method is an educational system that allows the body to move and function more efficiently and comfortably. Its goal is to re-educate the nervous system and improve motor ability. The system can accomplish much more, relieving pressure on joints and weak points, and allowing the body to heal repetitive strain injuries. Continued use of the method can relieve **pain** and lead to higher standards of achievement in sports, the **martial arts**, dancing and other physical disciplines.

Pupils are taught to become aware of their movements and to become aware of how they use their

MOSHE FELDENKRAIS (1904–1984)

Moshe Feldenkrais was born on the border between Russia and Poland. When he was only 13, he traveled to Palestine on foot. The journey took a year, and once there, young Feldenkrais worked as a laborer and cartographer, also tutoring others in mathematics. Moving to France in 1933, he graduated in mechanical and electrical engineering from the Ecole des Travaux Publiques de Paris.

Feldendrais became the first person to open a Judo center in Paris after meeting with Jigaro Kano. He was also one of the first Europeans to become a black belt in Judo, in 1936.

Obtaining his Ph.D. at the Sorbonne, he went on to assist Nobel Prize laureate, Frédéric Joliot Curie at the Curie Institute. During World War II in England, he worked on the new sonar anti submarine research.

Prompted by a recurring leg injury, he applied his knowledge of the martial arts and his training as an engineer to devise a method of re integrating the body. The concept was that more efficient movement would allow for the treatment of pain or disability, and the better functioning of the body as a whole. Later on, he would begin to teach what he had learned to others in Tel Aviv.

In addition to many books about judo, including *Higher Judo*, he wrote six books on his method.

bodies, thus discovering possible areas of **stress** and strain. The goal of Feldenkrais is to take the individual from merely functioning, to functioning well, free of pain and restriction of movement. Feldenkrais himself stated that his goal was, "To make the impossible possible, the possible easy, and the easy, elegant."

Origins

Moshe Feldenkrais (1904–1984) was a Russian-born Israeli physicist and engineer who was also an active soccer player and judo master. He devised his system in response to his own recurring knee injury, which had restricted his movement and caused him great pain over a long period of time. Feldenkrais believed that repeated muscle patterns cause the parts of the brain controlling those muscles to stay in a fixed pattern as well. He thought that the more the muscles are used, the more parts of the brain can be activated. He devised a method of re-educating the neuromuscular system and re-evaluating movement to increase efficiency and reduce stress, using his knowledge of mechanics and engineering, and applying some of his martial arts training.

Benefits

This method of re-educating the nervous system can be beneficial to a wide range of people, including athletes, children, the elderly, martial artists, those who are handicapped, people with special needs, and people with degenerative diseases. It has also proved popular with artists, particularly musicians, a number of whom have used Feldenkrais to improve their performance.

The Feldenkrais Guild of North America (FGNA) states that over half of the those who turn to Feldenkrais practitioners are seeking relief from pain. Many people who have pain from an injury compensate by changing their movements to limit pain. Often these changed movements remain after the pain from the original injury is gone, and new pain may occur. Feldenkrais helps students become aware of the changed movements and allows them to learn new movements that relieve their pain. Apart from the obvious physical benefits of more efficient movement and freedom from pain and restriction, Feldenkrais practitioners assert that there are other positive benefits for overall physical and mental health. Feldenkrais can result in increased awareness, flexibility, and coordination, and better **relaxation**. Feldenkrais practitioners have also noted other benefits in their students, including improvements in awareness, flexibility, coordination, breathing, digestion, sleep, mood, mental alertness, energy, and range of motion, as well as reduced stress and **hypertension**, and fewer headaches and backaches.

Musicians and athletes can improve their performance in many ways when they learn to use their bodies more efficiently. Feldenkrais can also help injured athletes regain lost potential and free them from pain and restriction of movement.

There are numerous accounts of the remarkable results obtained when Feldenkrais is taught to handicapped children so that they can learn to function despite their limitations. Handicapped people can learn to make full use of whatever potential they have, and to have more confidence in their abilities. Practitioners who specialize in teaching Feldenkrais to those who have handicaps have in many cases allowed the patient to discover ways of performing tasks which were previously thought to be impossible for them.

The elderly, whose movements are often restricted by pain and stiffness, can learn to overcome these

KEY TERMS

Neuromuscular—The body system of nerves and muscles as they function together.

Repetitive strain injury—Injury resulting from a repeated movement such as typing or throwing a ball.

obstacles with Feldenkrais instruction. In some instances even severe cases of arthritis have been conquered. Theoretically, Feldenkrais can make possible renewed levels of energy and freedom from restriction.

Description

Feldenkrais is described a being a dual system, with two components: "Awareness Through Movement" and "Functional Integration." The system aims to re-educate the body so that habitual movements that cause strain or pain can be relearned to improve efficiency and eliminate dangerous or painful action.

Feldenkrais helps to translate intention into action. In practice, an individual can learn to achieve his or her highest potential, while at the same time learning to avoid and eliminate stresses, **strains**, and the possibility of injury.

Functional integration

During this session, the patient wears comfortable clothing, and may sit, stand, walk, or lie on a low padded table. The practitioner helps the pupil by guiding him or her through a number of movements. The practitioner may use touch to communicate with the student, but touch is not used to correct any movements. The purpose of this session is to increase a student's awareness of his or her own movement and become open to different possibilities for movement. The instruction can be focused on a particular activity that the student does every day, or that causes him or her pain. The student can learn to alter habitual movements and re-educate the neuromuscular system. This type of session is particularly useful for those who have limitations originating from misuse, stress, illness, or accident. It can also help athletes and musicians perform to the best of their ability by increasing their possibilities for movement. It offers students the potential for improving their physical and mental performance in addition to heightening the sense of well-being.

Awareness through movement

Feldenkrais's martial arts background can be clearly identified in many of the aspects of Awareness Through Movement (ATM). During group sessions, pupils are taught to become acutely aware of all their movements and to imagine them, so that they can improve the efficiency of their actions in their minds, and put them into practice. Pupils are encouraged to be disciplined about practicing their exercises, to achieve maximum benefit.

Awareness through movement is described as an exploratory, nonjudgmental process through which pupils are encouraged to observe and learn about themselves and their movements. The range of this therapy is wide, and there are thousands of different lessons designed to help specific areas.

Preparations

No preparation is necessary for the practice of Feldenkrais, and all are encouraged to seek help from this system. No condition is considered a preclusion to the benefits of Feldenkrais.

Precautions

As with any therapy or treatment, care should be taken to choose a qualified practitioner. Feldenkrais practitioners stress that the body must not be forced to do anything, and if any movement is painful, or even uncomfortable, it should be discontinued immediately and the patient should seek professional help.

Side effects

No known side effects are associated with the practice of Feldenkrais.

Research and general acceptance

Since Feldenkrais began to teach his method, it has gradually gained acceptance as an education system. Published research using the method can be found in U.S. and foreign publications.

Training and certification

Guild-accredited Feldenkrais training courses leading to certification for the practice or teaching of the method are available throughout the United States and in other countries. Guild-certified Feldenkrais practitioners undergo a four-year training course (800 hours) that includes studying numerous movements and becoming aware of the smallest details in movement. After two years of formal training, practitioners may become authorized. The FGNA can be contacted to find a certified Feldenkrais practitioner.

Patricia Skinner

Feng shui

Definition

Feng shui, pronounced "foong swee" (Cantonese) or "fong shway" (Mandarin) is the Chinese art of arranging buildings, objects, and space in the environment in order to achieve energy harmony and balance. The English translation of Feng shui is "the way of Wind (feng) and Water (shui)" or "the natural forces of the universe."

Origins

Feng shui, derived from the Chinese concept of yin and yang, has been practiced for thousands of years. Evidence of the existence of this practice can be found in the alignment and organization of graves in the Yangshao villages from 6000 B.C. In fact, there is compelling evidence that suggests that feng shui was not strictly an Asian entity. In prehistoric Europe, the practice of arranging objects and structures to be in harmony with the universe was a relatively common practice.

A popular theory regarding the origins of feng shui suggests that the practice stemmed from ancient shaman who understood the vital importance of strategically placing a village. Areas that possessed mild winds would generate plentiful harvests while harsh winds would stunt crop growth or destroy the harvest altogether. In addition, the placement of a village in close proximity to flowing water and fresh springs would stimulate growth and ensure health, while stagnant water would foster disease and disharmony within the community. As the centuries passed, these shaman correlated their thoughts on wind and water with the teachings of Daoism, thus creating the practice of feng shui.

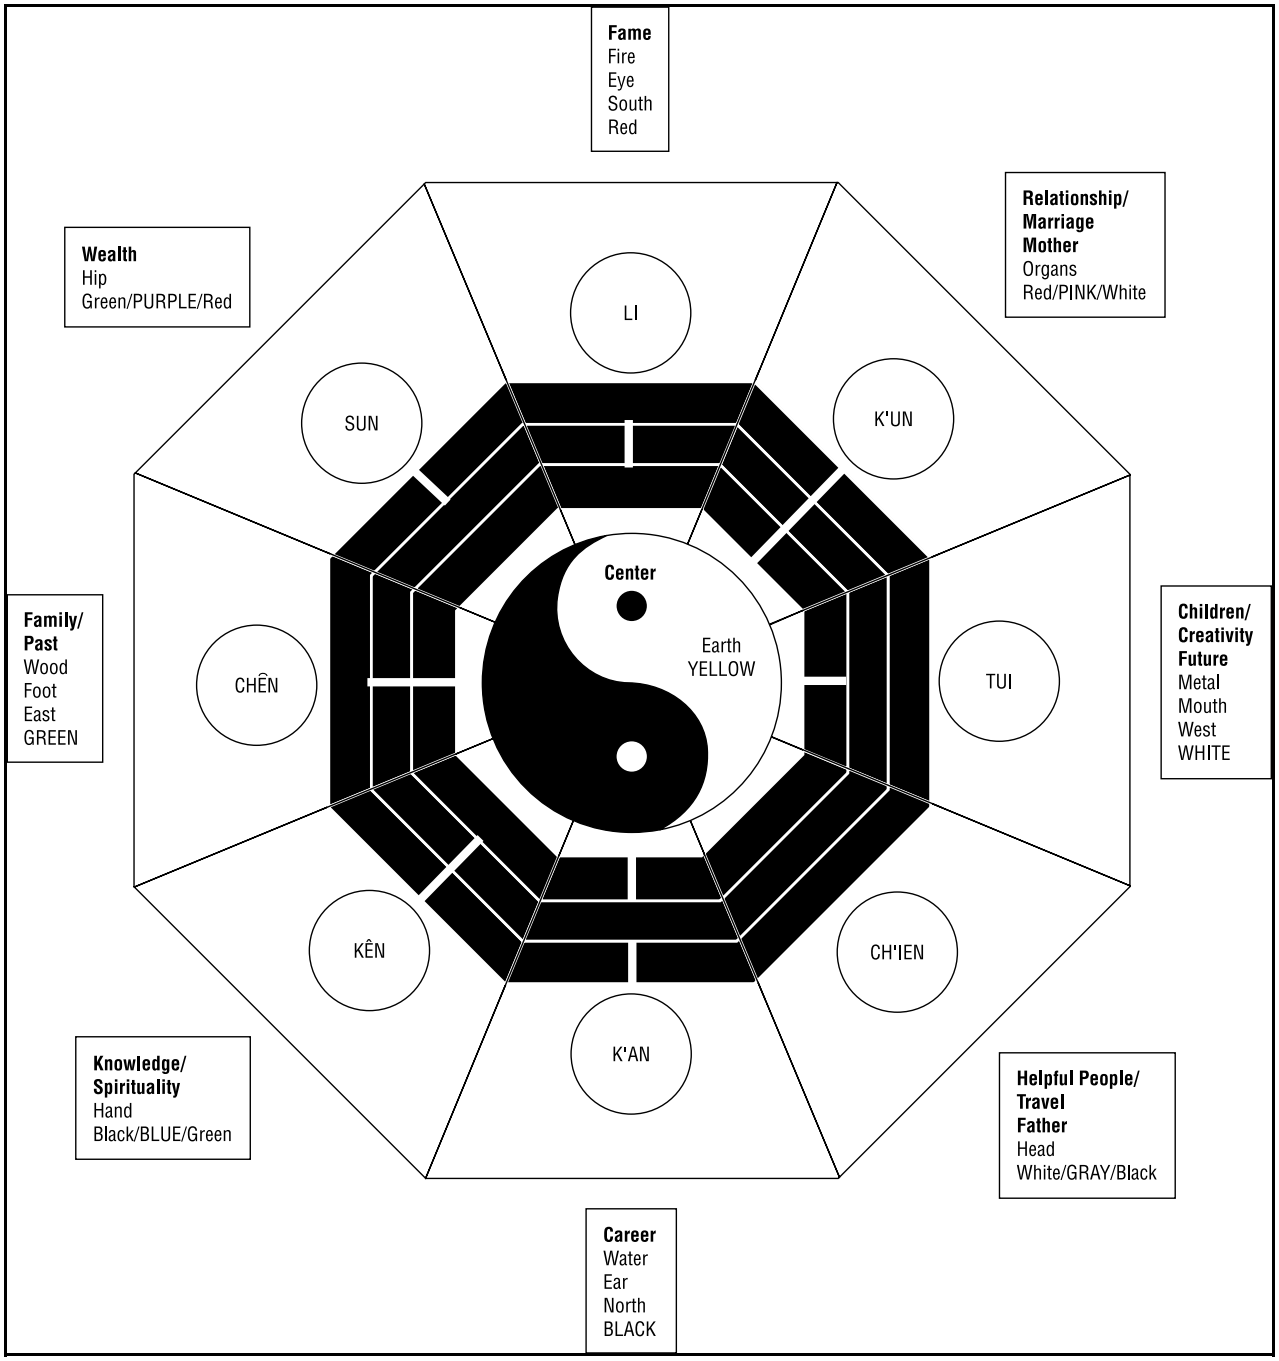
Benefits

As a design philosophy, "good" feng shui is believed to promote health, prosperity, creativity, positive social relationships, self-confidence, contemplation, and respect for others.

Description

An ancient Daoist Chinese theory of design and placement, feng shui grew from observations that an individual's surroundings elicit positive and negative effects. According to Daoism, everything that exists contains qi (chi), the energy or life force. This qi possesses two properties, yin (receptive) and yang (active)—they are opposites and cannot exist without the other. Within the qi, eight constituents compose the universe (the Lake, the Mountain, Fire, Water, Heaven, Thunder, Wind, and Earth). Each trigram, or combination of three yin/yang elements, represents a particular quality and pattern of energy. In turn, the proper arrangement of these energetic qualities would affect not only the qi of the environment, but that of the individual within the environment as well. With feng shui, the goal is to bring both into harmony so as to foster prosperity, health, and well-being with the Wind (feng) dispersing the qi throughout the universe and Water (shui).

The ba gua, or "Sequence of the Later Heaven," is the arrangement of the energy trigrams so that they exist in harmony and balance. Each trigram has a balancing partner that contributes to universal harmony. For example, Earth is balanced by the Mountain, Fire is balanced by the Water, Wind is balanced by Heaven, and Thunder is balanced by Lake. The ba gau is laid in a circular pattern with Fire at the top, followed by Earth, the Lake, Heaven, Water, the Mountain, Thunder, and



(Illustration by GGS Information Services, Inc. Cengage Learning, Gale)

Wind (clockwise). The Taiji (or yin-yang symbol) is located in the center of the trigrams, and represents the unifying force of the universe.

Practitioners of feng shui use the ba gua to determine the energy flow throughout the home and in other living spaces. By corresponding the trigram pattern to the different parts of a room, a practitioner determines if the room is in harmony with the universe. For example, when analyzing a home office or workspace of a writer or artist, a feng shui specialist would pay particular attention to the portion of the room that corresponds to the Lake of the ba gua, because the Lake represents creative energy. If there is clutter or disorganization in the section of the room that corresponds to

KEY TERMS

Daoism—Also called Taoism, Dao means "the way." Daoism is a holistic spiritual philosophy of the universe that is based on the idea that all elements in the universe are interactive and interdependent with each other and that the universe and natural world are in a constant state of change, or flux.

the Lake, or if the room is partitioned so that the Lake section is actually occupied by a bookcase or closet, then the environment would be considered to stifle creativity. A feng shui specialist might recommend moving the office to a more hospitable room in the house, or reconstructing the storage space to free up the creative energy in the Lake section of the room. Good health is said to be located in the Wind trigram of the ba gua, so maintaining this space and using it effectively is critical to practitioners of feng shui.

There are many other design tenets of feng shui, but some of the most commonly used and basic concepts include:

- Energy, or qi, enters and exits rooms through doorways. Doors facing each other encourage qi to move too quickly through and out of the room. Doors on adjoining walls encourage a circular movement of qi that is considered relaxing and "good" feng shui.
- Arranging chairs, beds, chaises, sofas, or other seating with their backs to the door and/or windows is not recommended in feng shui. It is considered "bad" feng shui to leave the back exposed to possible attack through the door.
- Homes located at the end of a cul-de-sac, across from a church or other spiritual center, at the end of a bridge, or near a freeway are not desirable to feng shui practitioners because these locations all have either too fast or not enough energy flow.
- When choosing a home site to build on, the ideal location according to feng shui principles is a rectangular plot of land, on a hill, with open space in front of the home.
- The front door of a home should be in proportion to the size of the house. Too large or too small of an entrance will not facilitate proper qi flow through the home.
- Mirrors used in the home should not face chairs or beds.
- Windows should face only pleasing, natural views when at all possible. If a view is dreary, the feng shui of the room can be improved by using window treatments inside and/or window box plantings outside.

Precautions

Individuals should observe basic building code and fire safety rules when redesigning a home according to feng shui principles.

Feng shui adjustments to living space should not be relied upon as a sole source of treatment for individuals with health problems. Although feng shui principles can be employed as an adjunct, or complementary, treatment, proper diagnosis and treatment from a qualified healthcare professional is necessary in treating any chronic or acute physical disorder.

Research and general acceptance

Feng shui has been practiced throughout Asia for thousands of years, and has recently grown in popularity in the United States as a tool for home design. Although considered part of **traditional Chinese medicine** in Asia, it is not largely regarded as a healthcare tool in the United States, preventative or otherwise.

Training and certification

Certification and/or licensing is not required to practice feng shui in the United States. However, there are some national organizations that offer training and certification programs.

Fennel

Description

Fennel (*Foeniculum vulgare*), also known as *F. officinale*, is a member of the Umbelliferae (Apiaceae) or carrot family, along with dill (*Anethum graveolens*),

caraway (*Carum carvi*), and **anise** (*Pimpinella anisum*). Fennel has a thick, spindle-shaped taproot that produces a pithy, smooth or finely-fluted round stem that may reach to 6 ft (1.8 m) in height. The finely divided leaves, with numerous thread-like segments, grow from a sheath surrounding the stalk at the base of the leaf stem. The delicate, blue-green filiform leaf segments have a pungent scent, somewhat similar to **licorice**, and an anise-like flavor. This characteristic is due to the presence of the phytochemical anethol, also a primary constituent of anise oil. Fennel's tiny yellow flowers form in large, compound umbells. The blossoms are frequently visited by bees, wasps, and other insects, and fennel leaf is a favorite food of the swallowtail-butterfly.

This perennial native of the Mediterranean is called marathon in Greece, a name derived from the word *maraino*, meaning to grow thin. Fennel was recommended as an herb for weight reduction, "to make people more lean that are too fat," according to the seventeenth century herbalist and astrologer Nicholas Culpeper. He considered fennel to be an herb of Mercury, under the sign of Virgo. In Chinese and Hindu cultures fennel was ingested to speed the elimination of poisons from the system, particularly after snakebite and scorpion **stings**. As one of the ancient Saxon people's nine sacred herbs, fennel was credited with the power to cure what were then believed to be the nine causes of disease. Fennel was also valued as a magic herb. In the Middle Ages it was draped over doorways on Midsummer's Eve to protect the household from evil spirits. As an added measure of protection, the tiny seeds were stuffed into keyholes to keep ghosts from entering the room.

Fennel was introduced to North America by Spanish missionaries for cultivation in their medicinal gardens. Fennel escaped cultivation from the mission gardens, and is now known in California as wild anise. English settlers brought the herb with them to the New England colonies where it became part of their kitchen gardens. In Puritan folk medicine fennel was taken as a digestive aid. The herb is still found growing on the sites of these early English settlements. This attractive, aromatic and sun-loving herb thrives on roadsides, embankments, sea cliffs, and in dry, stony fields.

There are several different species and varieties of fennel that may be annual, biennial, or perennial. *F. vulgare var. dulce*, known as sweet fennel, or *finocchio*, is cultivated for the fleshy basal stalks. The stalks may be eaten fresh, like celery, or boiled and baked as a vegetable. This delicacy is known in Italy as *carosella*. Fennel has naturalized in most temperate areas of the world, and is extensively cultivated for medicinal, ornamental, and culinary uses.

General use

The seeds, leaves, and roots of fennel are safe and edible. The essential oil, extracted from the seeds, is toxic even in small amounts. Fennel has been widely used in culinary and medicinal preparations for centuries. The herb acts as a carminative, and was traditionally employed as a digestive aid and remedy for flatulence. An infusion or decoction of the dried seeds is anti-spasmodic and will ease stomach pains and speed up the digestion of fatty foods. Fennel is a proven remedy for **colic** in infants, and is safe when administered as a mild infusion of the leaf and seed. It is also used for coughs and colds. Fennel exerts a calming influence on the bronchial tissues. The seeds contain large amounts of the phytochemical alpha-pinene, which acts as an expectorant and helps to loosen phlegm in the lungs. An eyewash, prepared from a decoction of the crushed seeds, is said to improve eyesight and reduce irritation and eyestrain. Fennel has a long history of use as a galactagogue. The seed, when boiled in barley water, acts to increase the flow of breast milk in nursing mothers. A poultice of the herb may be helpful to relieve swelling of the breasts during lactation. A leaf and seed tea has been used to expel hookworm and kill intestinal bacteria. Fennel has also been used to promote appetite. The entire herb is used in culinary dishes, and the fleshy sheaths surrounding the base of the leaf stems are a staple in Italian cuisine. The foliage, known as fennel weed, is used to flavor eggs, fish, stews, and vegetables. The root is sometimes grated fresh and added to salads. The licorice-flavored seeds are traditionally served after meals in India to cleanse the breath. The flowers produce a yellow tint and the leaves a light brown hue as a natural dye for wool fabrics.

Fennel seed contains volatile oil, most of which is identified as trans-anethole, with a much smaller amount identified as fenchone. Other components of the essential oil include limonene, camphene, and alpha-pinene.

Preparations

Harvest fennel leaf from time to time throughout the growing season. Use the fresh leaf when possible as the herb may lose much of the flavor when dried. The leaves may also be frozen for later use. Harvest the seeds in autumn. Seeds are fully ripe just as the color fades and the seed-bearing umbells turn from yellow-green to a light brown. Cut the brown umbell from the stalk and place it in a paper bag to dry in a warm room. Shake the dried seeds from the umbell and store them in tightly sealed, clearly labeled, dark-glass containers.

Harvest the root late in the fall at the same time the stems are harvested as a vegetable. The root is generally less medicinally potent than the seeds.

Seed infusion: Crush 1 tsp–1 tbsp of the dried seed, add to 1 cup of unchlorinated water, fresh milk, or barley water, in a non-metallic pot. Bring to a boil; then steep, covered, for about 10 minutes. A standard dosage of the tea is two to three cups per day.

Root decoction: Add one ounce of the clean, thinly-sliced dry root, or 2 oz of thinly-sliced fresh root, to 1 pt of unchlorinated water in a non-metallic pot. Bring to a boil and simmer for about 10 minutes. Strain and cover. A decoction may be refrigerated for up to two days and retain its healing qualities.

Tincture: Combine half a cup of dried fennel seeds with 1 pt of brandy or vodka in a glass container. Seal the container with an airtight lid. Leave to macerate in a darkened place for two weeks. Shake daily. Strain the mixture through a cheesecloth or muslin bag and pour into a dark bottle for storage up to two years. Dosage is 2–4 ml of the tincture two times a day.

Precautions

Pregnant women should not use the herb, seeds, tincture, or essential oil of fennel in medicinal remedies. Small amounts used as a culinary spice are considered safe. In large doses fennel acts as a uterine stimulant. The essential oil of fennel is toxic in doses as small as 5 ml, and may cause skin irritation, **vomiting**, seizure, and respiratory problems. The volatile oil should not be ingested. The herb and seed oil may cause **contact dermatitis** in sensitive individuals.

Interactions

None reported.

Fenugreek

Description

Fenugreek is an herb native to southeastern Europe, northern Africa, and western Asia, but is widely cultivated in other parts of the world. Its botanical name is *Trigonella foenum-graecum*; its English name comes from two Latin words meaning Greek hay. Fenugreek is an annual plant that grows 2–3 ft (0.6–0.9 m) tall, with a strong odor and small pale yellow flowers. The seed of the fenugreek plant contains many active compounds with pharmaceutical applications. The seeds are collected in the autumn. The chemical components of fenugreek seed include **iron**, **vitamin A**, vitamin B_1, **vitamin C**, phosphates, flavonoids, saponins, trigonelline, and other alkaloids. The seed is also high in fiber and protein.

General use

Quite apart from its therapeutic value, fenugreek is used as a seasoning and flavoring agent in foods, particularly in Egypt, India, and the Middle East. The maple smell and flavor of fenugreek have led to its use as a spice in foods, beverages, confections, tobacco, and imitation maple syrup. In some countries, the seeds are eaten raw or boiled, or the greens are enjoyed as a fresh salad. Extracts of fenugreek are used in some cosmetic products as well.

In addition to its use in flavoring foods, the antifungal and antibacterial properties of fenugreek are now being applied to food preservation. In June 2002, a high school student from Maryland was awarded a Lemelson-MIT Invention Apprenticeship for her invention of a food packaging paper made from fenugreek seeds.

Fenugreek *Trigonella foenum graecum* plant in pod. *(© Holt Studios International Ltd. / Alamy)*

KEY TERMS

Anticoagulant—Any substance that inhibits clotting action.

Antioxidants—Enzymes that bind with free radicals to neutralize their harmful effects on living tissue.

Corticosteroid—A class of hormones generally produced by the adrenal cortex, and often used to lower inflammation.

Galactogogue—A substance that stimulates the production of breast milk in nursing mothers.

Mucilage—A gummy, gelatinous substance that coats fenugreek seeds and helps them absorb water.

Peristalsis—Sweeping, rhythmic contractions of the intestine that move the intestinal contents through the digestive tract.

Topical—Applied to the skin or external surface of the body.

Trigonelline—An alkaloid compound found in fenugreek.

The best-documented medical use of fenugreek is to control blood sugar in both insulin-dependent (type 1) and noninsulin-dependent (type 2) diabetics. Some studies also show that serum **cholesterol** levels in diabetics, and perhaps in others, are reduced by fenugreek. Doses as low as 15 mg per day may produce beneficial effects on fasting blood sugar, elevation of blood sugar after a meal, and overall glycemic control. The use of fenugreek is likely to alter the diabetic patient's need for insulin or other medications used to control blood sugar. This treatment should be supervised by a health care provider familiar with the use of herbal therapies for diabetes. The recommended doses of fenugreek can vary rather widely.

The seeds of fenugreek can also act as a bulk laxative as a result of their fiber and mucilage content. These portions of the seed swell up from being in contact with water, filling the bowel and stimulating peristaltic activity. For laxative purposes, 0.5–1 tsp of freshly powdered herb per cup of water, followed by an additional 8 oz water, can be taken one to three times daily. Patients should begin with the lowest effective dose of fenugreek; they should also avoid taking oral medications or vitamins at the same time as the herb.

Capsules of fenugreek seed are sometimes recommended as a galactogogue, or agent to increase milk production in the lactating mother. This use of the herb should be undertaken cautiously, since the evidence of safety for the nursing infant is only anecdotal. Some commercial teas promoted for the purpose of increasing lactation use fenugreek as an ingredient, but herbal concentration in teas can vary widely and are generally somewhat low.

There is some evidence that internal use of fenugreek seed can decrease some stone-forming substances in the kidney, particularly **calcium** oxalate. Patients who are prone to this type of kidney stone may wish to consult a health care provider about the advisability and dose of fenugreek seed for this use.

Fenugreek may encourage a flagging appetite, and is sometimes given during convalescence from illnesses to improve food intake, weight gain, and speed of recuperation.

Cancer researchers are also studying fenugreek for its potential effectiveness as a cancer chemopreventive. It is thought that fenugreek may help to prevent cancer by raising the levels of vitamin C, **vitamin E**, and other **antioxidants** in the bloodstream.

Historically, fenugreek has been used as a topical treatment for abscesses, **boils**, **burns**, **eczema**, **gout**, and ulceration of the skin as it has an anti-inflammatory effect. It is also reputedly useful for a number of digestive complaints, including **gastritis** and gastric ulcers. A study published in 2002 found that both an

aqueous solution and a gel fraction derived from fenugreek have anti-ulcer effects comparable to those of omeprazole, a standard medication given to reduce gastric secretions. The researchers found that the fenugreek solution protected the gastric mucosa from injury as well as reducing the secretion of gastric acid.

Fenugreek reportedly can be helpful in the induction of **childbirth**, as it is known to stimulate uterine contractions. For this reason it should not be taken during **pregnancy**. As a gargle, fenugreek may relieve sore throats and coughing. Arthritis, **bronchitis**, fevers, and male reproductive conditions are other traditional but unsubstantiated indications for this herb.

Preparations

Fenugreek may be purchased as bulk seeds, capsules, tinctures, or in teas. Due to the strong, bitter taste, capsules are used most often. The dose is variable, depending on the form of the herb that is used. The seeds may also be soaked to make a tea. For topical use, powdered fenugreek seed is mixed with water to form a paste. Herbal supplements should be stored in a cool, dry place, away from direct light and out of the reach of children.

Precautions

Fenugreek may, when taken in larger amounts than are used to season foods, cause contractions of the uterus. For this reason, women who are pregnant should avoid therapeutic doses. Frequent topical use of fenugreek preparations may cause skin irritation and sensitization. Symptoms of allergic reaction include swelling, numbness, and **wheezing**. This herb should not be used by anyone with sensitivity to fenugreek. Large doses (over 100 g per day) may cause intestinal symptoms, including **diarrhea**, **nausea**, and **gas**. Blood sugar can also drop to abnormally low levels. Fenugreek is generally recognized as safe, but its safety is not well-documented for use in small children, lactating women, or persons with liver or kidney disease.

Side effects

Depending on the dose used, fenugreek may cause a maple syrup odor in the patient's sweat and urine.

Interactions

Fenugreek can enhance anticoagulant activity, and should not be used with other herbs or medications (heparin, warfarin, ticlopidine) that have this effect due to increased risk of bleeding. It can lower blood sugar to a marked degree; blood sugar levels should be monitored closely, particularly in people who are taking insulin, glipizide, or other hypoglycemic agents. Medications that are being taken to control diabetes may need to have dosages adjusted, which should be done under medical supervision. In theory, since fenugreek is high in mucilage, it can alter the absorption of any oral medication. Corticosteroid and other hormone treatments may be less effective. Monoamine oxidase inhibitors (MAOIs) may have increased activity when used in conjunction with fenugreek.

Ferrum phosphoricum

Description

Ferrum phosphoricum, abbreviated as *Ferrum phos.*, is a homeopathic remedy compound made from **iron** and **phosphorus**. Its name is Latin for iron phosphate. The homeopathic formula of iron phosphate is derived from mixing iron sulfate, phosphate, and **sodium** acetate.

General use

Based on the homeopathic "law of similars," which states that any substance that can cause certain symptoms when given to healthy people can cure sick people with similar symptoms, *Ferrum phos.* is the remedy of choice for patients in the early stages of **fever** or other inflammatory conditions. It may also be given to patients experiencing low energy or **anemia**. Of the 2,000–3,000 homeopathic remedies that are available, *Ferrum phos.* is one that often appears on "short lists" of those recommended for a home medicine chest.

It is important to note that homeopaths do not prescribe a given remedy on the basis of a few physical symptoms. They try to match the remedy to the totality of the patient's symptoms, including emotional characteristics and personality traits. Thus a classically trained homeopath would not give *Ferrum phos.* automatically to every patient who walked into the office complaining of fever or a viral illness. A contemporary American practitioner of **homeopathy** recommends giving *Ferrum phos.* when the person does not have clear and distinct symptoms that would point to another remedy. The profile of the *Ferrum phos.* person is that he or she has a lower fever and is more alert than one who needs **belladonna** but less upset and fearful than one who needs **aconite**. Where a patient with the belladonna profile may have a face that is flushed all over with fever, the *Ferrum phos.* patient has clearly defined pink or red patches on the cheeks. The *Ferrum phos.* patient is not focused solely on his or her discomfort and may have conversations with others as if he or she were not ill.

Other characteristics of *Ferrum phos.* patients include a tendency to tire easily. They are nervous, sensitive people, disturbed by anxiety-provoking dreams. They may be restless sleepers, even though their illnesses are often brought on by overexertion. In addition, *Ferrum phos.* patients often bleed easily; they are more prone to **nosebleeds** or minor bleeding from the gums at the onset of an illness. If they **cough** up mucus, it is likely to be streaked with blood.

The homeopathic definition of "symptom" is broader than the standard medical understanding. To a homeopath, symptoms represent the body's attempts to deal with an internal or external ailment. They are guides to choosing the correct remedy rather than problems to be suppressed. A homeopathic practitioner who is asking a patient about symptoms will inquire about the circumstances (e.g., light or dark, heat or cold, rest or activity, etc.) that make the patient feel better or worse. These factors are called modalities in homeopathy. In terms of modalities, gentle motion and applications of cold make *Ferrum phos.* patients feel better, while cold air, nighttime, standing up, and heavy exertion make them feel worse.

A homeopathic practitioner might prescribe *Ferrum phos.* for any of the following conditions:

- tickling coughs accompanied by chest pain
- laryngitis
- red and swollen tonsils
- fevers that start slowly
- ear infections that have not yet produced pus
- incontinence, involuntary urination with coughing, bedwetting
- rheumatic joints
- menstrual periods that begin with headaches
- anemia
- fatigue
- nosebleeds
- sore throats, especially in singers
- vomiting
- diarrhea
- heart palpitations

Preparations

Ferrum phos. is available in the United States in both liquid and tablet form. It can be purchased from homeopathic pharmacies or over the internet. Common potencies of *Ferrum phos.* are 30C and 6X. The

KEY TERMS

Antidote—Any substance that slows or stops the effects of a homeopathic remedy. Coffee and camphor are considered to be particularly powerful antidotes.

Law of similars—A principle of homeopathic treatment according to which substances that cause specific symptoms in healthy people are given to sick people with similar symptoms.

Modality—A factor or circumstance that makes a patient's symptoms better or worse. Modalities include such factors as time of day, room temperature, the patient's level of activity, sleep patterns, etc.

Potency—The number of times that a homeopathic remedy has been diluted and succussed (shaken). In centesimal potencies, one part of the medicinal substance has been diluted with 99 parts of water or alcohol; in decimal potencies, the ratio is 1:9.

Succussion—A part of the process of making homeopathic remedies, in which the medicinal substance is diluted in distilled water and then shaken vigorously.

Symptom—In homeopathy, a positive sign of the body's self-defense and self-healing that assists the practitioner to choose the correct remedy. Symptoms include the patient's emotional state and psychological characteristics as well as physical symptoms in the narrow sense.

abbreviation 30C stands for a centesimal potency. This indicates that a process of dilution, along with vigorous shaking (succussion) of the remedy, has been repeated 30 times to achieve the desired potency. The abbreviation 6X indicates a decimal potency, and means that this decimal dilution has been repeated six times. In homeopathic practice, the strength of the remedy is in inverse proportion to the amount of chemical or plant extract in the alcohol or water; thus a 30C preparation of *Ferrum phos.* is considered a much higher potency than a 6X preparation. People using homeopathic remedies at home are generally encouraged to use the lower potencies such as 6X or 12X.

Precautions

The precautions recommended by homeopaths reflect concerns about proper administration of the remedies rather than specifying categories of patients who should not receive a given remedy. The quantity of a homeopathic remedy, for example, is less critical than the frequency of dosing. Homeopathy follows the principle of minimal dosing, which means in practice that the patient is not given a second dose of a remedy (or a dose of a different remedy) until the first has completed its action. Minimal dosing is based on the homeopathic belief that remedies work by stimulating or "jump-starting" the body's own natural defenses against illness rather than by killing germs. In general, however, the more severe the patient's acute symptoms, the more often he or she would be given the remedy. A *Ferrum phos.* patient with a bad cold might be given a dose of the remedy every three to six hours, while one with a milder illness might be given only one or two doses a day.

Precautions regarding homeopathic remedies also include avoiding contamination of the medicine. The patient should not touch the medicine; it should be dispensed into a cup and tipped directly into the patient's mouth. Homeopathic remedies are not taken with water but allowed to dissolve in the mouth. Patients are asked not to eat or drink for about twenty minutes before and after each dose.

Side effects

Homeopathic remedies rarely have side effects in the usual sense of the phrase because they are so dilute. On the other hand, a homeopathic remedy may sometimes appear to be making a patient's symptoms temporarily worse as part of the healing process. This temporary aggravation of the symptoms would be regarded by homeopaths as an indication that the remedy is effectively stimulating the patient's body to heal itself.

Interactions

Homeopathic practitioners are not as a rule concerned with drug interactions, in part because homeopathic remedies are so dilute that there is little of the original substance to interact with a prescription given by an allopathic physician. In addition, the homeopathic "single medicine" principle, according to which a patient is given only one homeopathic remedy at a time for a given illness, also minimizes potential interactions among different remedies. For example, a *Ferrum phos.* patient would not be given a different cold or cough remedy unless the homeopath determined that the patient's symptoms were changing and required a remedy with a different symptom profile. There is an ongoing debate among homeopathic practitioners about the legitimacy of combination remedies. Many homeopathic pharmacies sell preparations that

are low-potency combinations of the most commonly used remedies for use at home. Conservative homeopaths maintain that the possibility of interactions among the different ingredients makes it difficult to evaluate the effectiveness of these combinations.

Homeopaths are, however, concerned about the effect of other substances on homeopathic preparations. They believe that remedies can lose potency through interaction with heat, light, or other substances. Guidelines for proper storage of homeopathic remedies include keeping them away from strong sunlight and high temperatures, keeping them in their original containers, and not storing them near perfumes, bleach, or other strong-smelling substances. In addition, patients under the care of a homeopath are instructed to avoid coffee or products containing camphor (lip balms, chest rubs, etc.) during a period of homeopathic treatment and for two days after the last dose. Homeopaths believe that these substances counteract or "antidote" the effects of homeopathic remedies.

Rebecca Frey

Fever

Definition

A fever is a rise in body temperature to greater than 100°F (37.8°C).

Description

A healthy person's body temperature fluctuates between 97°F (36.1°C) and 100°F (37.8°C), with the average being 98.6°F (37°C). The body maintains stability within this range by balancing the heat produced by the metabolism with the heat lost to the environment. The "thermostat" that controls this process is located in the hypothalamus, a small structure located deep within the brain. The nervous system constantly relays information about the body's temperature to the thermostat. In turn, the thermostat activates different physical responses designed to cool or warm the body, depending on the circumstances. These responses include:

- Decreasing or increasing the flow of blood from the body's core, where it is warmed, to the surface, where it is cooled.
- Slowing down or speeding up the rate at which the body turns food into energy (metabolic rate).
- Inducing shivering, which generates heat through muscle contraction.
- Inducing sweating, which cools the body through evaporation.

A fever occurs when the body's thermostat resets at a higher temperature, which primarily happens in response to an infection. To reach the higher temperature, the body moves blood to the warmer interior, increases the metabolic rate, and induces shivering. The **chills** that often accompany a fever are caused by the movement of blood to the body's core, which leaves the surface and extremities cold. Once the body reaches the higher temperature, the shivering and chills stop. When the infection has been overcome or drugs such as aspirin or acetaminophen (Tylenol) have been taken, the thermostat resets to normal. When this happens, the body's cooling mechanisms switch on. The blood moves to the surface and sweating occurs.

Fever is an important component of the immune response, though its role is not completely understood. Physicians believe that an elevated body temperature has several effects. Certain chemicals in the immune system react with the fever-inducing agent and trigger the resetting of the thermostat. These immune system chemicals also increase the production of cells that fight off the invading bacteria or viruses. Higher temperatures also inhibit the growth of some bacteria and speed up the chemical reactions that help the body's cells repair themselves. Changes in blood circulation may cause the heart rate to increase, which speeds the arrival of white blood cells to the sites of infection.

KEY TERMS

Antipyretic—A drug that lowers fever, like aspirin or acetaminophen.

Autoimmune disease—Condition in which a person's immune system attacks the body's own cells, causing tissue destruction.

Epstein-Barr virus—A common herpes virus that is responsible for causing infectious mononucleosis. This virus is problematic in people who have a compromised immune system.

Febrile seizure—Convulsions brought on by fever.

Malignant hyperthermia—A rare, inherited condition in which a person develops a very high fever when given certain anesthetics or muscle relaxants in preparation for surgery.

Meningitis—A potentially fatal inflammation of the thin membrane covering the brain and spinal cord.

Metabolism—The chemical process by which the body turns food into energy, which can be given off as heat.

Pyrogen—A chemical circulating in the blood that causes a rise in body temperature.

Reye's syndrome—A disorder principally affecting the liver and brain, marked by the rapid development of life-threatening neurological symptoms.

Causes and symptoms

Fevers are primarily caused by viral or bacterial **infections**, such as **pneumonia** or **influenza**. However, other conditions can induce a fever, including these:

- allergic reactions
- autoimmune diseases
- trauma, such as breaking a bone
- cancer
- excessive exposure to the sun
- intense exercise
- hormonal imbalances
- certain drugs
- damage to the hypothalamus

When an infection occurs, fever-inducing agents called pyrogens are released, either by the body's immune system or by the invading cells themselves. These pyrogens trigger the resetting of the thermostat. In other circumstances, an uncontrolled release of pyrogens may occur when the immune system overreacts due to an allergic reaction or becomes damaged due to an autoimmune disease. A **stroke** or tumor can damage the hypothalamus, causing the body's thermostat to malfunction. Excessive exposure to the sun or intense **exercise** in hot weather can result in heat stroke, a condition in which the body's cooling mechanisms fail. Malignant **hyperthermia** is a rare, inherited condition in which a person develops a very high fever when given certain anesthetics or muscle relaxants in preparation for surgery.

A recent study showed that most parents have misconceptions about fever and view it as a disease rather than a symptom. How long a fever lasts and how high it may go depend on several factors, including its cause and the patient's age and overall health. Most fevers caused by infections are acute, appearing suddenly and then dissipating as the immune system defeats the infectious agent. An infectious fever may also rise and fall throughout the day, reaching its peak in the late afternoon or early evening. A low-grade fever that lasts for several weeks is associated with autoimmune diseases such as lupus or with some cancers, particularly **leukemia** and lymphoma.

Diagnosis

A fever is usually diagnosed using a thermometer. A variety of different thermometers are available, including traditional oral and rectal thermometers made of glass and mercury, and more sophisticated electronic ones that can be inserted in the ear. For adults and older children, temperature readings are usually taken orally. Younger children who cannot or will not hold a thermometer in their mouths can have their temperature taken by placing an oral thermometer under their armpit. Infants generally have their temperature taken rectally using a rectal thermometer.

As important as registering a patient's temperature is determining the underlying cause of the fever. The physician can make a diagnosis by checking for accompanying symptoms and by reviewing the patient's medical history, any recent trips he or she has taken, what he or she may have ingested, or any illnesses he or she has been exposed to. Blood tests hold additional clues. Antibodies in the blood point to the presence of an infectious agent, which can be verified by growing the organism in a culture. Blood tests can also provide the doctor with white blood cell counts. Ultrasound tests, magnetic resonance imaging (MRI) tests, or computed tomography (CT) scans may be ordered if the doctor cannot readily determine the cause of a fever.

Treatment

Often, doctors must remind patients, especially parents, not to "overtreat" low fevers but to remember that they are symptoms of an underlying disease or condition. Alternative therapies for treatment of fever focus not only on reducing fever but also on boosting the immune function to help the body fight infections more effectively. They include nutritional therapy, herbal therapy and **traditional Chinese medicine**.

Nutritional therapy

Naturopaths often recommend that patients take high doses of **vitamin C** to ward off diseases and prevent fever. In addition to vitamin C, other **antioxidants** such as **vitamin A** and **zinc** also boost the immune function. Naturopaths may also suggest reducing sugar intake (even fruit juices) because sugar depresses the immune system. To replace fluid that is lost during fever, patients are advised to drink vegetable juices and eat soups.

Herbal therapy

Western herbalists use tea preparations containing herbs such as bupleurum root or **boneset** to reduce fever. Mild herbs such as **peppermint**, elderflower, or **yarrow** can provide comfort to the child who has a mild fever. Others believe in sweating a fever out, literally. They often recommend that patients take hot baths to induce sweating. This helps induce or increase fever, which is believed to help the body get rid of infections.

Chinese medicine (TCM) offers many herbs and formulas for fevers. There are many distinct kinds of fevers, also called heat syndromes. For example, an excess-heat syndrome is characterized by a high fever, great thirst, and lots of sweating. Deficiency heat syndrome is characterized by a low-grade fever with afternoon fevers or night sweats. For excess heat, herbs that are dispersing and cold in nature are used. For chronic and low-grade fevers, herbs that tonify the yin (cooling aspect) are used as well as herbs that get rid of heat. There are even herbs such as bupleurum root (called *Chai Hu* in TCM) that are used for intermittent fevers or conditions alternating between fever and chills. Alternating fevers and chills occur in **malaria**, conditions connected to **AIDS**, **chronic fatigue syndrome**, and Epstein-Barr virus. The individual pattern should be diagnosed by a trained practitioner.

Aromatherapy

Patients can reduce feverish symptoms by inhaling **essential oils** of camphor, **eucalyptus**, lemon, and **hyssop**. These oils can also be mixed with an unscented body lotion or a vegetable oil for **aromatherapy** massage.

Homeopathy

Homeopathic doctors may prescribe herbal remedies based on the patient's overall personality profile as well as specific symptoms.

Allopathic treatment

Physicians agree that the most effective treatment for a fever is to address its underlying cause. Also, because a fever helps the immune system fight infection, some clinicians suggest that it be allowed to run its course. Drugs to lower fever (antipyretics) can be given if a patient (particularly a child) is uncomfortable. These include aspirin, acetaminophen (Tylenol), and ibuprofen (Advil). Aspirin should not be given to a child or adolescent with a fever since this drug has been linked to an increased risk of Reye's syndrome. Sponging a child or infant with tepid (lukewarm) water can also help reduce mild fevers.

A fever requires emergency treatment under the following circumstances:

- Newborn (three months or younger) with a fever above 100.5°F (38°C).
- Infant or child with a fever above 103°F (39.4°C). A very high fever in a small child can trigger seizures (febrile seizures) and therefore should be treated immediately.
- Fever accompanied by severe headache, neck stiffness, mental confusion, or severe swelling of the throat. A fever accompanied by these symptoms can indicate the presence of a serious infection, such as meningitis, and should be brought to the immediate attention of a physician.

Expected results

Most fevers caused by infection end as soon as the immune system rids the body of the pathogen. Most fevers do not produce any lasting effects. The prognosis for fevers associated with more chronic conditions, such as autoimmune disease, depends upon the overall outcome of the disorder.

Feverfew

Description

Feverfew (*Chrysanthemum parthenium* or *Tanacetum parthenium*) is named for one of the herb's traditional medicinal uses as a febrifuge, from the Latin *febrifugia*, indicating its fever-reducing action. This European native of the Compositae (Asteraceae) or aster family has naturalized throughout North and South America, escaping from cultivation. It can be found along roadsides and along the borders of wooded areas. Other common names include featherfew, febrifuge plant, featherfoil, mid-summer daisy, and wild **chamomile**.

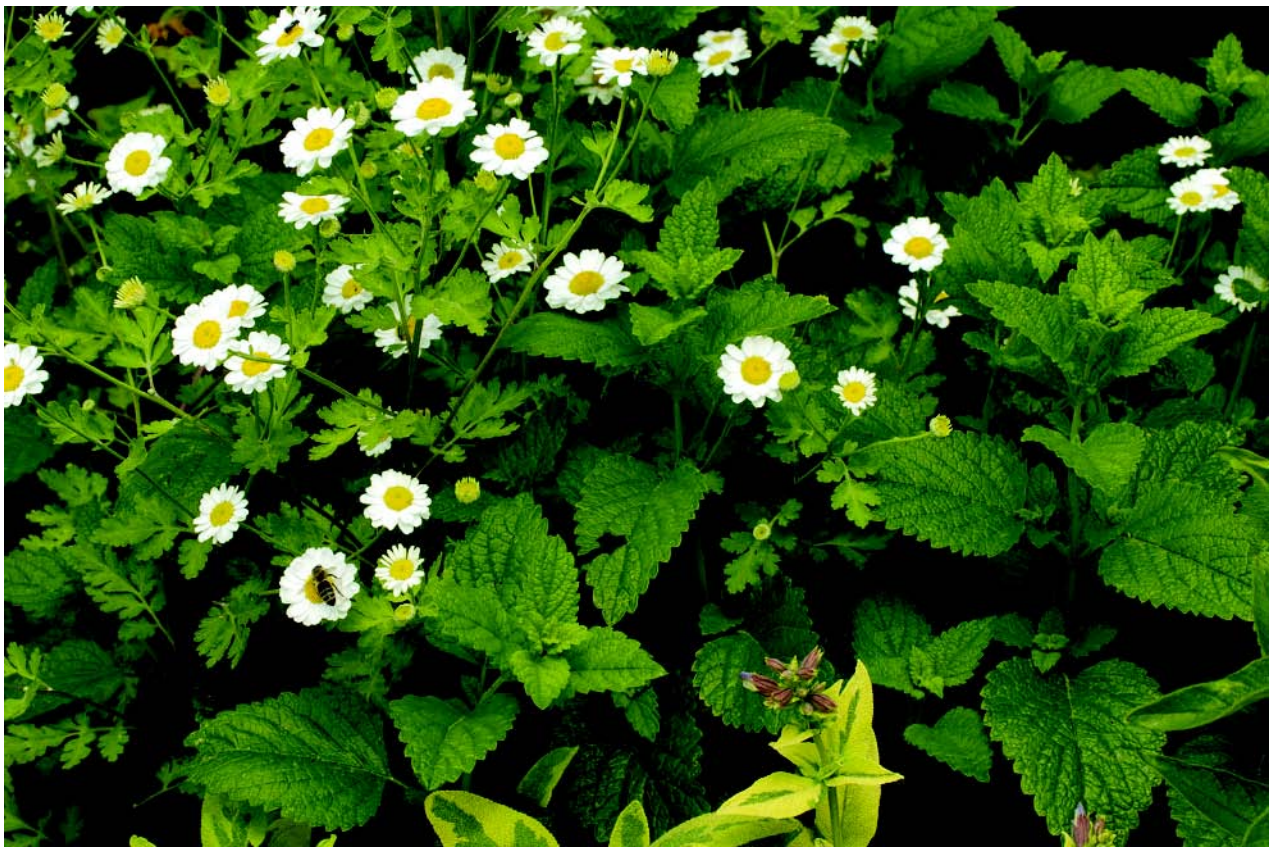
Feverfew is a bushy and herbaceous perennial that grows from a branched and tapering root to produce erect, round and slightly grooved stems. The feathery, aromatic, and bitter-tasting leaves are arranged alternately along the length of the many-branched stem. They are a yellow-green, stalked, and bipinnate with deeply cut, toothed segments in an oval shape. Flowers bloom in mid to late-summer in flat-topped clusters at the end of stems that may reach to a height of 3 ft (1 m). Smaller than daisies and without the protruding central disk of chamomile, feverfew blossoms have yellow centers consisting of tightly bunched tubular florets surrounded by creamy white rays. Bees seem to avoid feverfew, deterred by its pungent aroma. The plant self-seeds freely and thrives in full sun or partial shade in most soil.

General use

Feverfew leaves and flowers are used medicinally. Among its many uses, the herb has become a popular and proven herbal remedy for the treatment of migraine headaches. This important use of the plant was recorded as far back as 1633 by the British herbalist John Gerard. With frequent use, over time, feverfew can reduce the frequency, severity, and duration of migraine headaches and allay **nausea** and **vomiting**. It is most effective when used as a preventative. It acts to inhibit serotonin and histamine, substances that dilate blood vessels, and it helps to prevent the spasms in blood vessels that trigger migraine headaches. This much-researched herb has been shown to inhibit production of leukotines and other inflammatory substances. It is an effective remedy for relieving the **pain** and inflammation of arthritis and alleviating **hay fever**, **asthma**, and other allergy symptoms.

Other traditional uses of feverfew dating back to ancient Greece and Rome include its use as an emmenagogue (an infusion taken in cases of sluggish **menstruation** to relieve congestion and promote periodic flow). The herb has also been used after **childbirth** to help expel the placenta.

Feverfew was valued in past centuries for its believed protection against the plague and the bite of mad dogs. In the seventeenth century the herbalist John Parkinson recommended feverfew as a remedy to speed recovery from opium overdose. It has also been used in treating alcoholic delirium tremens and to expel intestinal **worms**. The seventeenth-century English physician Nicholas Culpeper recommended an external application of the fresh herb to treat ague, as the disease **malaria** was once called. Feverfew is a bitter digestive and liver tonic. A hot infusion may reduce **fever** and congestion from colds. The infusion, taken cold, has tonic properties. Feverfew may relieve mild **depression**, promote restful sleep, and ease the nerve pain of **sciatica** and **shingles**. Externally the strong infusion is an antiseptic skin wash for treatment of insect **stings** and **bites**. The wash may also be used as an insect repellent. Feverfew leaves and stems, gathered fresh, may be used as a dye plant, with a chrome mordant, to produce a light green-yellow color in natural fibers such as wool. Feverfew flowers have a purgative action if ingested, and if the blossom heads are carried into areas where bees are located, the insects will fly away.



Feverfew. *(© Arco Images / Alamy)*

The active compounds in feverfew include sesquiterpene lactones, predominantly parthenolide. Other phytochemicals include pyrethrin, volatile oils, tannins, bitter resin, and flavonoids.

Most of the benefits claimed for feverfew had not been confirmed scientifically as of 2008. In 2008, the National Center for Complementary and Alternative Medicine of the U.S. National Institutes of Health reported that most claims were either unsubstantiated or supported by limited evidence. It concluded that "There is not enough evidence available to assess whether feverfew is beneficial for [most] uses."

Preparations

Feverfew should be harvested just as the plant comes into flower and before the blossoms are fully open. Leaves are removed from the stalks and dried on paper-lined trays in a light, airy room, away from direct sunlight. The dried herb should be stored in clearly labeled, tightly sealed, dark glass containers.

Feverfew leaf in capsule form, at a 250 mg daily dose, is recommended for medicinal use. It may take four to six weeks before the herb provides noticeable relief. Studies of some commercially prepared capsules revealed that many did not contain a sufficient quantity of the active ingredient to be medicinally effective. Feverfew may be more medicinally potent when gathered fresh. Three to four fresh leaves, taken daily over a period of time are medicinally effective. A certified practitioner can help determine the most effective and safest levels for individual cases.

Fresh feverfew leaf can be added to honey or to a simple sugar syrup. The honey acts as a preservative and masks the bitter taste of the herb.

To make an infusion, one takes two to three teaspoons of chopped, fresh feverfew leaves and place them in a warmed container. One cup of fresh, nonchlorinated boiled water is added to the herbs and the mixture is covered. The tea is infused for about 15 minutes, then strained. A stronger infusion, using double the amount of leaf and steeping twice as long, is useful as a skin wash for repelling insects or soothing inflammations and **wounds**. The strong infusion has also been used as a mouthwash following tooth extraction. The prepared tea can be stored for about two

days in the refrigerator in an airtight container. The dosage is three cups at different times during the day.

To make a tincture, one combines four ounces of finely cut fresh or powdered dry herb with one pint of brandy, gin, or vodka, in a glass container. The alcohol should be enough to cover the plant parts. Place the mixture away from light for about two weeks, shaking several times each day. Strain and store in a tightly capped, dark glass bottle. A standard dose is 30 drops of the tincture three times a day.

Precautions

Since herbal preparations are not regulated by the U.S. Food and Drug Administration (FDA), consumers in the United States should check the labels of commercial products carefully for dosage instructions and the part(s) of the plant used for or contained in the product. A 2002 study of commercial feverfew preparations found wide variations in the recommended dosages and parthenolide contents of the products that were tested. The researchers found that "intake of parthenolide would range from 0.06 to 9.7 mg/day, a 160-fold variation." Any adverse effects from feverfew preparations or any other herbal products sold as dietary supplements should be reported to the FDA Center for Food Safety and Applied **Nutrition**.

Feverfew should not be used by pregnant or lactating women. Children under two years of age should not be given feverfew. Chewing the fresh leaves may irritate the mucous membranes in the mouth causing mouth ulcers in some persons. Traditionally, the fresh herb was enclosed between slices of bread to minimize the irritation and mask the bitter taste of the fresh leaves. Persons on prescribed blood-thinning drugs should not ingest feverfew as it might interfere with the rate of blood clotting.

Side effects

Feverfew is a safe herb of proven medicinal value. No side effects are reported when taken in designated therapeutic doses. Some cases of **contact dermatitis** and airborne **dermatitis**, however, have been reported by researchers in Denmark and the United States.

Interactions

According to the *PDR For Herbal Medicines*, feverfew may interact with anti-thrombotic medications, including aspirin and warfarin. The tannins in feverfew have been reported to interfere with **iron** absorption in persons who take supplemental iron.

KEY TERMS

Antispasmodic—A substance that relieves spasms in blood vessels or cramping in muscles. Feverfew has antispasmodic properties.

Delirium tremens—A potentially fatal withdrawal syndrome in persons who have become physically dependent on alcohol or other drugs, characterized by shaking, sweating, hallucinations, nausea, and agitation.

Emmenagogue—A substance or medication given to bring on a menstrual period.

Flavonoids—Plant pigments that have a variety of effects on human physiology.

Histamine—A substance released from cells that causes some of the symptoms of an allergic reaction.

Nonsteroidal anti-inflammatory drugs (NSAIDs)—A term used for a group of pain-relieving medications that also reduce inflammation when used over a period of time. NSAIDs are often given to patients with osteoarthritis.

Parthenolide—A sesquiterpene lactone isolated from feverfew that is thought to be responsible for most of its medical effectiveness.

Volatile oil—A concentrated oil that has been distilled from a plant; "volatile" means that the oil evaporates at room temperature.

Taking NSAIDs together with feverfew will decrease the beneficial effects of the herb.

Fibrocystic breast disease

Definition

Fibrocystic breast disease is a general term that refers to a variety of symptoms and diagnoses, including breast lumpiness, tenderness, and a wide range of vaguely-defined benign breast conditions. The term is also used diagnostically to describe the appearance of breast tissues viewed under the microscope, on x-ray film, or on ultrasound equipment.

Description

There is no such thing as a typical or normal female breast. Breasts come in all shapes and sizes, with varying textures from smooth to extremely lumpy. The tissues of the female breast change in response to hormone levels, normal **aging**, nursing (lactation), weight shifts, and injury. To further complicate matters, the breast has several types of tissue, each of which may respond differently to changes in body chemistry.

Fibrocystic breast disease is clearly not a single, specific disease process. Variations or changes in the way the breast feels or looks on an x ray may cause the condition to be called "fibrocystic change." Other names have been used to refer to this imprecise and ill-defined term: mammary dysplasia, mastopathy, chronic cystic mastitis, indurative mastopathy, mastalgia, lumpy breasts, or physiologic nodularity.

KEY TERMS

Selenium—A mineral supplement with antioxidant properties that may be useful for reducing breast pain and tenderness associated with fibrocystic breast disease. The recommended daily allowance of selenium is 70 mcg for men and 55 mcg for women.

Estimates vary, but 40–90% of all women have some evidence of fibrocystic condition, change, or disease. It is most common among women ages 30–50, but may be seen at other ages.

Causes and symptoms

Fibrocystic condition refers to technical findings. This discussion will focus on symptoms a woman experiences, which may fall under the general category of the fibrocystic condition.

The breast is not a soft, smooth, pulpy organ. It is actually a type of sweat gland. Milk, the breasts' version of sweat, is secreted when the breast receives appropriate hormonal and environmental stimulation.

The normal breast contains milk glands, with their accompanying ducts, or pipelines, for transporting the milk. These complex structures may not only alter in size, but can increase or decrease in number as needed. Fibrous connective tissue, fatty tissue, nerves, blood and lymph vessels, and lymph nodes, with their different shapes and textures, lie among the ever-changing milk glands. This explains why a woman's breasts may not feel uniform in texture, and why "lumpiness" may wax and wane.

Fibrocystic condition is the tenderness, enlargement, and/or changing lumpiness that many women encounter just before or during their menstrual periods. At this time, female hormones are preparing the breasts for **pregnancy**, by stimulating the milk-producing cells and storing fluid. Each breast may contain as much as three to six teaspoons of excess liquid. Swelling, with increased sensitivity or **pain**, may result. If pregnancy does not occur, the body reabsorbs the fluid, and the engorgement and discomfort are relieved.

These symptoms range from mildly annoying in some women to extremely painful in others. The severity of the sensations may vary from month to month in the same woman. Although sometimes distressing, this experience is the body's normal response to routine hormonal changes.

This cycle of breast sensitivity, pain, and/or enlargement can also result from medications. Some hormone replacement therapies used for post-menopausal women can produce these effects. Other medications, primarily, but not exclusively, those with hormones, may also provoke these symptoms.

Breast pain unrelated to hormone shifts is called "noncyclic" pain. This area-specific pain is also called "trigger-zone breast pain," and it may be continuous, or may be felt intermittently. Trauma, such as a blow to the area, or a breast biopsy performed several years before, or sensitivity to certain medications may also underlie this type of pain. Fibrocystic condition may be cited as the cause of otherwise unexplained breast pain.

Lumps, apart from those clearly associated with hormone cycles, may also be placed under the heading of fibrocystic condition. These lumps stand out from enlarged general breast tissue. The obvious concern with such lumps is **cancer**, although noncancerous lumps also occur. Two noncancerous types are fibroadenomas and cysts.

Fibroadenomas are tumors that form in the tissues outside the milk ducts. The cause of fibroadenomas is unknown. They generally feel smooth and firm, with a somewhat rubber-like texture. Typically a fibroadenoma is not attached to surrounding tissue, and will move slightly when touched. They are most commonly found in adolescents and women in their early 20s but can arise at any age.

Cysts are fluid-filled sacs in the breast. They probably develop as ducts become clogged with old cells in the process of normal emptying and filling. Cysts usually feel soft and round or oval. However, a cyst deep within the breast may feel hard, as it pushes up against firmer breast tissue. A woman with a cyst may experience pain, especially if it increases in size before her menstrual cycle, as many do. Women age 30–50 are most likely to develop cysts.

Sometimes one area of breast tissue persistently feels thicker or more prominent than the rest of the breast. This may be caused by hardened scar tissue and/or dead fat tissue from surgery or trauma. Often the cause of such tissue is unknown.

A number of other breast problems that are benign or noncancerous may be placed under the heading of fibrocystic condition. These include disorders that may lead to breast inflammation (mastitis), infection, nipple discharge, dilated milk ducts, milk-filled cyst, wart-like growth in the duct, and excess growth of fibrous tissue around the glands.

Diagnosis

Breast cancer is the concern in most cases of an abnormal breast symptom. A newly discovered breast lump should be brought to the attention of a family physician or an obstetrician-gynecologist. A physical examination of the area is usually performed. Depending on the findings, the patient may be referred for tests.

The most common tests are mammography and breast ultrasound. A cyst may be definitively diagnosed by ultrasound. To relieve the discomfort, the patient may choose to have the cyst suctioned, or drained. If there is any question as to the fluid diagnosis, the fluid is sent for analysis.

If a lump cannot be proven benign by mammography and ultrasound, a breast biopsy may be considered. Tissue is removed through a needle to obtain a sample of the lump. The sample is examined under the microscope by a pathologist, and a detailed diagnosis regarding the type of benign lesion or cancer is established.

A ductogram evaluates nipple discharge. A very fine tube is threaded into the duct, dye is injected, and the area is looked at for diagnosis. Other breast conditions such as inflammation or infection are usually recognized on the basis of suspicious history, such as breastfeeding and characteristic symptoms such as pain, redness, and swelling. A positive response to appropriate therapies will support the diagnosis.

Treatment

Warm soaks, heating pads, or ice packs may provide comfort. A well-fitted support bra worn day and night can minimize physical movement and do much to relieve breast discomfort. Breast massage may promote removal of excess fluid from tissues and alleviate symptoms. Massaging the breast with **castor oil**, straight or infused with herbs or diluted **essential oils**, can help reduce and dissipate fibroadenomas as well as keep women in touch with changes in their breasts.

Many women have reported relief of symptoms when **caffeine** was reduced or eliminated from their **diets**. Decreasing salt intake before and during the period when breasts are most sensitive may also ease swelling and discomfort. Vitamins A, B complex, and E and **selenium** supplements have been reported to be helpful. Because fat promotes estrogen production, and estrogen is thought to be linked to breast tenderness, low-fat diets and elimination of dairy products also seem to decrease soreness for some women. Restricting salt intake may also help reduce fluid retention and lessen breast pain. It may take several months to realize the effects of these various treatments.

Evening primrose oil (*Oenothera biennis*), flax oil, and fish oils have been reported to be effective in relieving cyclic breast pain for some women. In addition, a focus on liver cleansing is important to assist the body in conjugation and elimination of excess estrogens. The herb chaste tree (*Vitex angus-castus*) can be used to help relieve symptoms of **premenstrual syndrome** (PMS), including breast tenderness.

A Chinese herbalist may recommend Herba cum Radice Asari with Radix Angelicae Sinensis and Flos Carthami Tinctorii for painful breast lumps, or Rhizoma Cyperi Rotundi with Radix Bupleuri and Fructus Trichosanthis for breast masses that swell around the time of **menstruation**.

Allopathic treatment

A lump that has been proven benign can be left in the breast. Some women may choose to have a lump such as a fibroadenoma surgically removed, especially if it is large. **Infections** are treated with warm compresses and antibiotics. Lactating women are encouraged to continue breastfeeding, as it promotes drainage and healing. A serious infection may progress to form an **abscess**, which may need surgical drainage.

Once a specific disorder within the broad category of fibrocystic condition is identified, treatment can be prescribed. Symptoms of cyclical breast sensitivity and engorgement may be treated with diet, medication, and/or physical modifications.

Over-the-counter analgesics (pain relievers) such as acetaminophen (Tylenol) or ibuprofen (Advil) may be recommended. In some cases, treatment with hormones or hormone blockers may prove successful. Birth control pills may be prescribed.

Expected results

Most benign breast conditions carry no increased risk for the development of breast cancer. However, a small percentage of biopsies will uncover overgrowth of tissue in a particular pattern in some women that indicates a 15–20% risk of developing breast cancer over the next 20 years. Strict attention to early detection measures, such as annual mammograms, is especially important for these women.

Prevention

No way has yet been proven to prevent the various manifestations of fibrocystic condition from occurring. Some alternative practitioners believe that elimination of foods high in methylxanthines (primarily coffee and chocolate) can decrease or reverse fibrocystic breast changes.

Fibroids *see* **Uterine fibroids**

Fibromyalgia

Definition

Fibromyalgia is characterized by muscle **pain**, **fatigue**, and multiple tender points on the body. Many individuals with fibromyalgia describe the symptoms as similar to the aches and pains of a severe case of the flu. Fibrositis, fibromyalgia, and fibromyositis are names given to a set of symptoms believed to be caused by the same general problem.

Description

Fibromyalgia is more common than previously thought. According to the American College of Rheumatology, as many as 2–4% of the U.S. population may be affected by the disorder. Fibromyalgia is more prevalent in adults than children, with more women affected than men, particularly women of childbearing age.

Causes and symptoms

The exact cause of fibromyalgia is not known. Sometimes it occurs in several members of a family, suggesting that it may be an inherited disorder. Researchers have investigated a number of possible causes, including genetic causes, **sleep disorders**, specific injuries, **infections**, problems with muscle metabolism, problems with the neurons that transmit information about pain, and nervous system abnormalities. It is often difficult for research to determine if a specific problem, such as sleep disturbances, results from fibromyalgia or are a possible cause of the

condition. It is likely that a number of factors must occur in combination to cause fibromyalgia.

Pain is the major symptom with aches, tenderness, and stiffness of multiple muscles, joints, and soft tissues. The pain may move from one part of the body to another. It is most common in the neck, shoulders, chest, arms, legs, hips, and back. Although the pain is present most of the time and may last for years, the severity of the pain may fluctuate.

Symptoms of fatigue may result from the individual's chronic pain coupled with **anxiety** about the problem and how to find relief. The inflammatory process also produces chemicals that are known to cause fatigue. Other common symptoms are tension headaches, difficulty swallowing, recurrent abdominal pain, **diarrhea**, and numbness or tingling of the extremities. **Stress**, anxiety, **depression**, or lack of sleep can increase symptoms. Intensity of symptoms is variable, ranging from gradual improvement to episodes of recurrent symptoms.

Diagnosis

Diagnosis is difficult and frequently missed because symptoms of fibromyalgia are vague and generalized. Coexisting nerve and muscle disorders such as **rheumatoid arthritis**, spinal arthritis, or **Lyme disease** may further complicate the diagnostic process. As of 2008, there were no tests available to specifically diagnose fibromyalgia. The diagnosis is usually made after ruling out other medical conditions with similar symptoms such as lupus and **hypothyroidism**.

Because of the emotional distress experienced by people with this condition and the influence of stress on the symptoms themselves, fibromyalgia has often been labeled a psychological problem. Although the debate about fibromyalgia continues, research on possible causes of the condition and public awareness campaigns have helped promote fibromyalgia's validity as a physiological problem.

The American College of Rheumatology has developed standards for fibromyalgia that healthcare practitioners can use to diagnose this condition. According to these standards, individuals can be diagnosed with fibromyalgia if they have widespread pain in combination with tenderness in at least 11 of the 18 sites known as trigger points. Trigger point sites include the base of the neck, along the backbone, in front of the hip and elbow, and at the rear of the knee and shoulder.

Treatment

As of 2008, there was no known cure for fibromyalgia. Therefore, the goal of treatment is successful symptom management. Treatment usually requires a combination of therapies, including medication, **exercise**, and lifestyle adjustments. On June 21, 2007, the U.S. Food and Drug Administration (FDA) approved the first drug to treat fibromyalgia. Although previously many doctors had prescribed a variety of medications intended to help reduce the symptoms of fibromyalgia, Lycria (pregabalin) was the first drug approved specifically for the treatment of fibromyalgia. Made by Pfizer, Lycria was already used to treat pain associated with nerve damage caused by diabetes, pain following **shingles**, and partial seizures. A study of 1,800 patients showed that Lycria was also effective in treating the pain associated with fibromyalgia in many people. Lycria was not found to be effective in everyone with fibromyalgia, however, and it can have side effects, including sleepiness, **dizziness**, weight gain, swelling of the feet and hands, blurred vision, and **dry mouth**.

In addition to treatment with medication there are many other ways of managing the symptoms of fibromyalgia. Adequate rest is essential, as is a healthy diet. The diet should include a large variety of fruits and vegetables, which provide the body with trace elements and minerals that are necessary for healthy muscles. Avoidance of stimulating foods or drinks (such as coffee) and medications such as decongestants prior to bedtime is advised. Individuals should have a clear understanding of their role in the recovery process because it determines the successful management of this condition.

Other treatments found to be helpful include heat and occasionally cold compress applications. A regular stretching program is often useful. Aerobic activities focusing on increasing the heart rate are the preferred forms of exercise over most other forms of exertion. Exercise programs need to include good warm-up and cool-down sessions, with special attention given to avoiding exercises causing joint pain. **Hydrotherapy** exercises (exercises in a pool or tub) may be useful in providing a low impact exercise environment while soothing muscle and joint pain.

Massage therapy can be helpful, especially when a family member is instructed on specific massage techniques to manage episodes of increased symptoms. Short sessions are most helpful as repetitious movement can aggravate the condition. Specific attention to mental health, including psychological treatment, may also be important, since depression may precede or accompany fibromyalgia. **Relaxation** exercises, **yoga**, **aromatherapy**, **guided imagery**, and other relaxation therapies can be useful in easing stress and promoting overall well-being. A Mayo Clinic study

KEY TERMS

Connective tissue—Tissue that supports and binds other body tissue and parts.

Lyme disease—An acute recurrent inflammatory disease involving one or a few joints, believed to be transmitted by a tick-borne virus. The condition was originally described in the community of Lyme, Connecticut, but has also been reported in other parts of the United States and other countries. Knees and other large joints are most commonly involved with local inflammation and swelling.

Rheumatology—The study of disorders characterized by inflammation, degeneration of connective tissue, and related structures of the body. These disorders are sometimes collectively referred to as rheumatism.

released in 2006 found that **acupuncture** can be helpful in relieving the symptoms of fibromyalgia.

Herbalists and aromatherapists may recommend tub soaks or compresses with **lavender** (*Lavandula angustifolia*), **chamomile** (*Chamaemelum nobilis*), or **juniper** (*Juniperus communis*) to soothe muscle and joint pain.

Allopathic treatment

People with fibromyalgia often need a rheumatology consultation (a meeting with a doctor who specializes in disorders of the joints, muscles, and soft tissue) to decide the cause of various rheumatic symptoms, to be educated about fibromyalgia and its treatment, and to exclude other rheumatic diseases. A treatment program must be individualized to meet the patient's needs. The rheumatologist, as the team leader, enlists and coordinates the expertise of other health professionals in the care of the patient.

Expected results

Fibromyalgia is a chronic health problem. The symptoms sometimes improve and at other times worsen, but they often continue for months to years.

Prevention

There is no known or specific prevention for fibromyalgia. However, similar to many other medical conditions, remaining as healthy as possible with a good diet, safe exercise, and adequate rest is the best prevention.

Fish oil

Description

Fish oils are derived from such cold-water fish as salmon, cod, tuna, or mackerel. They have recently acquired a new visibility as dietary supplements because they are high in **omega-3 fatty acids**. Omega-3 fatty acids, together with the **omega-6 fatty acids**, are important components of a healthful diet. The body cannot manufacture them, therefore, they must be obtained from grains, fruits, vegetable oils, and other foods. In addition, people should consume a balanced ratio of omega-6 and omega-3 fatty acids. Some researchers believe that these two types of fatty acids should be consumed in a 1:1 ratio, while others maintain that people should obtain several times more omega-3 than omega-6 fatty acids from their diet. In either case, the fact that fish oils are high in omega-3 fatty acids may help people to maintain a good balance between the two types of fatty acids.

Fish oil capsules. *(Pulse Picture Library/CMP Images/ Phototake. Reproduced by permission.)*

The most important types of omega-3 fatty acids found in fish oils are eicosapentanoic acid (EPA) and docosahexaenoic acid (DHA). The body needs EPA to produce prostaglandins, which are hormone-like substances that help to protect the heart and the cell membranes. DHA is required for the normal development of the brain, the eyes, and the reproductive system.

General use

In general, fish oils are recommended as dietary supplements to lower the levels of triglycerides in the blood, counteract inflammation in various parts of the body, and thin the blood.

Heart disease and stroke

The omega-3 fatty acids in fish oils increase the concentrations of good **cholesterol** (high density lipoproteins, HDL) in the blood while decreasing the concentrations of bad cholesterol (triglycerides). They also lower the total cholesterol level. Furthermore, these omega-3 oils protect the heart by preventing the formation of **blood clots** and fatty deposits (plaque) on the arterial walls. In people with coronary **heart disease**, fish oils may help to reduce the risk of blood clots in the brain or in the lungs; **pain** associated with **angina**; and the risk of cardiac arrythmias.

The benefits of omega-3 fatty acids have been shown in clinical studies. Investigation of the possible benefits of fish oils began when researchers discovered that Eskimos rarely have heart attacks or **rheumatoid arthritis** (RA) even though their diet is high in fat from fish, seals, and whales. Because these sources of fat have a high omega-3 fatty acid content, it was assumed that the type of fatty acid that they contained helped to protect the Eskimos from the usual consequences of high-fat **diets**. Later studies confirmed that diets high in omega-3 fatty acids decrease the risk of heart attacks, strokes, and abnormal heart rhythms. In one study of 20,551 doctors, those who ate at least one fish meal per week cut their risk of heart attacks in half compared to those who ate fish once a month or less. In the five-year Lyon study, men who followed a **Mediterranean diet** with emphasis on omega-3-rich oils, fish, fruits, and vegetables had their **heart attack** rates reduced by 70% compared to subjects in the control group. One question, however, is whether fish oil used by itself as a dietary supplement is as effective as a diet high in fish, since the two are not the same. One open trial of 11,324 people who were followed for three to five years found that fish oil did reduce the risk of death from heart attack. This study, however, was not a double-blind study, and its results cannot be taken as conclusive.

High blood pressure

Fish oils may help to control high blood pressure. Several studies have shown that taking fish oil can lower blood pressure. On the other hand, a 1997 study involving 2,000 subjects found no significant effect.

Rheumatoid arthritis

Fish oil may be useful in managing the symptoms of early rheumatoid arthritis (RA). A significant reduction in joint tenderness, morning stiffness, and **fatigue**, coupled with an increase in grip strength, has been observed in patients taking fish oil capsules. Fish oil appears to reduce the symptoms of RA without side effects, and to increase the effectiveness of standard medications for it. Fish oil does not appear to slow the progress of RA.

Asthma

It has been claimed that fish oils reduce inflammation of the airways and may prevent **asthma** attacks. According to one author, allergic disorders such as asthma may be triggered by too much omega-6 and too little omega-3 fats in the diet. Two studies undertaken in 1994 and 1996 respectively found no benefits from using fish oil in the management of asthma.

Psoriasis and autoimmune disorders

Several small studies indicate that fish oil may be helpful in treating **psoriasis**, which is an inflammatory disorder of the skin; in lupus; and in Raynaud's

phenomenon, an autoimmune disorder in which the patient's hands and feet are abnormally sensitive to cold and emotional **stress**. With respect to the Raynaud's patients, small double-blind studies showed that very high doses of fish oil reduce their responses to cold. It appears that doses as high as 12 g of fish oil daily are necessary to provide this effect. With respect to lupus, a small study of 30 subjects found that 14 out of 17 patients given daily doses of 20 g of EPA derived from fish oil had significant improvement. Subjects given a placebo either showed no improvement or got worse.

Osteoporosis

When taken together with **calcium**, **essential fatty acids** may help to protect women from **osteoporosis**. One 18-month study of 65 postmenopausal women found that those who were given a combination of omega-6 fatty acids (GLA) and omega-3 fatty acids from fish oil together with calcium had higher bone density and fewer **fractures** than those who were given the calcium and a placebo.

Gynecological problems

Fish oil supplements may be helpful in alleviating the symptoms of **premenstrual syndrome** (PMS) and painful periods. A number of different substances that are high in fatty acids, including **flaxseed** oil and GLA as well as fish oil, have been recommended for painful menstrual periods. One four-month study of adolescents suggests that fish oil is useful in treating this condition. Forty-two young women were divided into two groups; half received a daily dose of 6 g of fish oil for two months, followed by two months of placebo. The other half received the placebo and fish oil in reverse order. The results indicated that the subjects had significantly less menstrual pain while taking the fish oil.

Bipolar disorder and depression

Fish oil does appear to offer considerable benefits to people with **bipolar disorder**. A four-month double-blind study of 30 subjects indicated that fish oil improves emotional stability and helps to prevent relapses. Of the 14 persons who took fish oil, 11 stayed well or improved, while only six out of 16 subjects given placebos stayed well. A 2001 report looked at the effects of fish oil on mood and **depression**. Two large studies showed a strong connection between rates of depression and bipolar disorder in countries with high amounts of fish in diets. Although researchers cannot say that fish oil is the only reason for the difference, evidence continues to mount that omega-3 and omega-6 fatty acids may work as mood stabilizers.

Other conditions

Fish oil has been touted as a useful treatment for diabetic neuropathy, **allergies**, migraine headaches, **Crohn's disease**, **gout**, and ulcerative **colitis**, but there has been little systematic research involving these applications. In addition, health food manufacturers list **hair loss**, memory problems, muscle strain, failing eyesight, liver complaints, rickets, and dental problems as ailments that can be treated with fish oil. No clinical studies have been cited in support of these claims.

Early studies in laboratories indicate that fish oils might prolong life in people with automimmune disorders like diabetes. Early results show that a diet high in fish oils helped improve immune system function in these patients.

Preparations

There is no minimum daily requirement of fish oil as such, but a healthy diet should supply at least 5 g of essential fatty acids every day. Typical doses of fish oil are 3–9 g daily, although some participants in research studies have taken much higher doses. If fish oil is taken as a dietary supplement, it should be taken in large enough doses to supply about 1.8 g of EPA and 0.9 g of DHA on a daily basis. Fish oil capsules are available in health food stores as over-the-counter items; prices range from $7 for 180 capsules of Norwegian cod liver oil to $14 for 180 capsules of salmon oil. Capsules of tuna oil and halibut liver oil are also available from several commercial suppliers.

Precautions

Fish oil can easily become rancid. The capsules can be stored in the refrigerator to slow the rate of oxidation. Another option is to purchase capsules that have added **vitamin E**.

The type of fish oil may make a difference. Although cod liver oil is the easiest form to obtain, it can cause a buildup of **vitamin A** and **vitamin D** in the body because these two vitamins are fat-soluble. Pregnant women should not take more than 2,500 IU of vitamin A per day because higher amounts can cause birth defects. Other adults should not consume more than 5,000 IU of vitamin A per day. Vitamin D can produce toxicity when taken at levels above 1,000 IU daily for long periods of time. Persons who obtain their fish oil from cod liver oil should check the label to see how much vitamin A and vitamin D it contains.

KEY TERMS

Essential fatty acid (EFA)—A fatty acid that the body cannot make but must obtain from the diet. EFAs include omega-6 fatty acids found in primrose and safflower oils, and omega-3 fatty acids oils found in fatty fish and flaxseed, canola, soybean, and walnuts.

Prostaglandins—Hormone-like substances that the body produces from essential fatty acids. Prostaglandins control the contraction of smooth muscle, body temperature, and many other processes.

Raynaud's disease—A vascular disorder in which the patient's fingers ache and tingle after exposure to cold or emotional stress, with characteristic color changes from white to blue to red. Raynaud's phenomenon may be seen in scleroderma and systemic lupus erythematosus.

It may be prudent to take salmon oil, mackerel oil, or oil from other coldwater fish.

Women who are pregnant or breastfeeding should talk to their physicians before taking fish oil supplements or any other medications.

Because fish oil can thin the blood, it should not be taken together with aspirin and other nonsteroidal anti-inflammatory drugs (NSAIDs, or over-the-counter pain killers), Coumadin (warfarin), or other anti-clotting medications. Fish oil does not seem to cause problems with bleeding when it is taken by itself, however.

Side effects

Fish oil generally appears to be safe when taken as a dietary supplement. The most common side effects are mild **indigestion** or a fishy taste in the mouth.

Interactions

Fish oil supplements may interact with nonsteroidal anti-inflammatory drugs (NSAIDs), warfarin, or other anti-clotting medications to cause excessive bleeding.

5-Hydroxytryptophan *see* **5-HTP**

5-HTP

Description

5-HTP is the acronym for 5-hydroxytryptophan, also called 5-hydroxy-L-tryptophan. 5-HTP is found primarily in the brain. This compound is made from tryptophan, a natural amino acid found in foods. Tryptophan is an essential amino acid, which means that it cannot be made by the body; it must be obtained from food, particularly proteins. In the liver and brain, 5-HTP is converted to an important monoamine neurotransmitter called serotonin. Neurotransmitters are chemical messengers that transmit signals between neurons (nerve cells).

Taking 5-HTP increases the body's supply of the compound, which leads to higher serotonin levels in the brain. Serotonin, also called 5-hydroxytryptamine or 5-HT, plays an important role in controlling behavior and moods. It influences many normal brain activities and also regulates the activity of other neurotransmitters. Having adequate levels of serotonin instills a feeling of **relaxation**, calm, and mild euphoria (extreme happiness). Low levels of serotonin, serotonin deficiency syndrome, leads to **depression**, **anxiety**, irritability, **insomnia**, and many other problems.

Conditions associated with low levels of serotonin include:

- anxiety
- attention deficit hyperactivity disorder (ADHD)
- bulimia
- depression
- epilepsy
- fibromyalgia

- headaches
- hyperactivity
- insomnia
- obesity
- obsessive compulsive disorder (OCD)
- panic attacks
- premenstrual syndrome (PMS)
- schizophrenia
- seasonal affective disorder (SAD)

5-HTP has other effects on the body. It is an antioxidant that protects the body from damage by substances called free radicals (unstable, toxic molecules). In this role, 5-HTP may help slow the **aging** process and protect the body from illness. Because serotonin is used to make **melatonin**, taking 5-HTP may help achieve some of the same benefits as melatonin, such as treating **jet lag**, depression, and insomnia. There is some evidence that 5-HTP can replenish the supply of the pain-relieving molecules called endorphins. Studies have shown that low levels of endorphins are associated with **chronic fatigue syndrome**, **fibromyalgia**, **stress**, and depression. In addition, 5-HTP affects other neurotransmitters, including norepinephrine and dopamine.

General use

In studies, 5-HTP has been proven effective in the treatment of carbohydrate cravings and binge eating, chronic headaches, depression, fibromyalgia, insomnia, anxiety, and panic disorders.

Much of the clinical research with 5-HTP focused on the treatment of depression. In 15 separate studies, 5-HTP was tested on a total of 511 patients with different kinds of depression. Over half (56%) of these patients had significant improvement in depression while taking 5-HTP. The compound was found to be as effective as the selective serotonin reuptake inhibitor (SSRI) fluvoxamine and the tricyclic antidepressants, chloripramine and imipramine. Many of these studies used relatively high doses ranging from 50–3,250 mg daily.

Three clinical studies found that 5-HTP can significantly improve the **pain**, anxiety, morning stiffness, and **fatigue** associated with fibromyalgia. The doses ranged from 300–400 mg daily. In one study, 5-HTP treatment was as effective as a tricyclic antidepressant (amitriptyline) and monamine oxidase inhibitors (MAOI; pargilyne or phenelzine).

Three clinical studies found that 5-HTP use led to decreased intake of food and subsequent weight loss in obese patients. The dose used in one study was 900 mg daily, which initially caused **nausea** in 80% of the patients.

A few clinical trials have found that 5-HTP can effectively prevent chronic headaches, including **migraine headache** and tension **headache**. In addition, 5-HTP compared favorably with propranolol and methysergide, drugs commonly used to prevent migraines.

In treating insomnia, 5-HTP is effective because it increases the length of rapid eye movement (REM) sleep, which improves sleep quality.

The symptoms of anxiety may be significantly reduced by 5-HTP. In studies, it instilled a sense of relief in patients with panic disorders.

Other conditions that may be treated with 5-HTP, but for which no studies exist, include chronic fatigue syndrome, **premenstrual syndrome**, **Parkinson's disease**, and seizure disorders (such as **epilepsy**).

Although 5-HTP may be a useful alternative to conventional antidepressant drugs, one study indicated that it may be of no value for patients who have failed to respond to traditional drugs. In this study, patients who failed to respond to tricyclic antidepressants were treated with either 5-HTP or a monoamine oxidase inhibitor (MAOI). Half of the patients improved with the MAOI treatment, while none showed any benefit from 5-HTP treatment.

Some uncertainty remained about the efficacy of 5-HTP. In reviewing the evidence about the use of 5-HTP in 2008, the Internet source SupplementWatch.com concluded that "The overall scientific evidence for the effectiveness of 5-HTP is not very strong."

Preparations

The 5-HTP preparation available commercially is isolated from the seed of an African plant called *Griffonia simplicifolia*. It is available as an enteric coated tablet, which does not break down until it reaches the intestine.

The recommended starting dose for headaches, weight loss, depression, and fibromyalgia is 50 mg three times daily. It can be taken with food. However, for weight loss it should be taken 20 minutes before eating. If it is not effective after two weeks, the dose may be increased to 100 mg three times daily, but only with the recommendation of a physician. Insomnia is treated with 25 mg (which may be increased to 100 mg after a few days) taken 30–45 minutes before bedtime.

Precautions

The Mayo Clinic detected, and the U. S. Federal Drug Administration (FDA) confirmed, the presence of a contaminant (peak X) in 5-HTP produced by six different manufacturers. This contaminant is similar

KEY TERMS

Eosinophilia myalgia syndrome (EMS)—A chronic, painful disease of the immune system that causes joint pain, fatigue, shortness of breath, and swelling of the arms and legs. EMS can be fatal.

Monoamine oxidase inhibitor (MAOI)—An antidepressant drug that prevents the breakdown of monoamine neurotransmitters (such as serotonin) in the gaps between nerve cells. Nardil and Parnate are common MAOI brands.

Neurotransmitter—A chemical messenger that transmits signals between nerve cells.

Selective serotonin reuptake inhibitor (SSRI)—A family of antidepressant drugs that block the reabsorption of serotonin by nerve cells. Prozac, Zoloft, and Paxil are common brand names for these drugs.

Serotonin syndrome—A syndrome characterized by agitation, confusion, delirium, and perspiration, which is caused by high levels of serotonin in the brain.

Tricyclic antidepressant (TCA)—A group of antidepressant drugs that all have three rings in their chemical structure. Their mechanism of action is not fully understood, but they appear to extend the duration of action of some neurohormones, including serotonin and norepinephrine. They have also been used to treat some forms of chronic pain. Common brand names are Aventyl, Elavil, Surmontil, and Vivactil.

to one found in L-tryptophan, which in 1989 caused the potentially fatal eosinophilia myalgia syndrome (EMS) in some persons. The L-tryptophan supplements were subsequently banned by the FDA. There have been 10 reports of EMS associated with 5-HTP use. The 5-HTP contaminant was not at levels high enough to cause illness. However, taking excessive doses of 5-HTP may lead to toxic levels of peak X.

Long-term studies on the safety of 5-HTP use had not been conducted as of 2008. To be safe, 5-HTP should be considered a short-term remedy.

Pregnant women should not take 5-HTP because there are no clinical studies on the compound's use among this population.

Side effects

Side effects associated with 5-HTP are rare but may include headaches, mild **stomachaches**, nausea, nasal congestion, and **constipation**. There are anecdotal reports that taking high doses of 5-HTP causes nightmares or vivid dreams. Side effects may be minimized by starting with a low dose of 5-HTP and taking it with food.

Interactions

It is theorized that the effectiveness of 5-HTP may be enhanced by taking vitamin B_6 and niacinamide. The action of 5-HTP may be enhanced by extracts of **ginger**, **passionflower** (*Passiflora incarnata*), **St. John's wort**, and *Ginkgo biloba*.

Dopa-decarboxylase inhibitors, such as carbidopa or benserazide block the enzyme that is responsible for the destruction of dopamine. A study by the Massachusetts College of Pharmacy and Health Sciences demonstrated that 5-HTP reaches the brain without the use of a dopa-decarboxylase inhibitor and will produce the benefits of stress reduction and reduced food intake even when used alone.

There is a chance of developing serotonin syndrome when taking 5-HTP with an antidepressant drug. Serotonin syndrome was seen in patients taking high doses (greater than 1,200 mg daily) of L-tryptophan and MAOIs. Combining 5-HTP with a MAOI or selective serotonin reuptake inhibitor antidepressant should be done with caution, under the supervision of a physician.

Flatulence *see* **Gas**
Flavonoids *see* **Bioflavonoids**

Flaxseed

Description

Flaxseed (also called linseed) comes from the flax plant (*Linum usitatissimum*), which belongs to the Linaceae plant family. The flax plant is a small, single-stemmed annual that grows to about 2 ft (0.6 m) tall and has grayish green leaves and sky blue flowers. Flax has been cultivated for thousands of years. Linen made from flax has been found in the tombs of Egyptian pharaohs and is referred to in the Bible and in Homer's *Odyssey*. The Roman naturalist Pliny wrote about the laxative and therapeutic powers of flax in the first century A.D., and many authorities believe it has been used as a folk remedy since ancient times. Flax is believed to be native to Egypt, but its origins are questionable since it has been used widely around the world. It is cultivated in many places, including Europe, South America, Asia, and parts of the United States. Only the seeds (flaxseed) and oil of the flax plant (flaxseed oil) are used medicinally. Linseed oil is the term usually used for the oil found in polishes, varnishes, and paints.

Flaxseed oil is derived from the flax plant's crushed seeds, which resemble common sesame seeds but are darker. The amber oil is very rich in a type of fat called alpha-linolenic acid (ALA), an omega-3 fatty acid that is good for the heart and found in certain plants. High amounts of **omega-3 fatty acids** are found in fish and smaller amounts are found in green leafy vegetables, soy-derived foods, and nuts. Many doctors consider these acids important for cardiovascular health. Studies suggest that they can lower triglyceride levels and reduce blood pressure. Omega-3 fatty acids may also decrease the risk of heart attacks and strokes by preventing the formation of dangerous **blood clots**. In high dosages, the fatty acids may help to alleviate arthritis, though flaxseed products have not yet been shown to be effective for this purpose. The National Center for Complimentary and Alternative Medicine (NCCAM) funded a study on the effects of flaxseed on high **cholesterol** levels and in the prevention of **heart disease** and **osteoporosis**.

In addition to omega-3 fatty acids, flaxseed products also contain potentially therapeutic chemicals called lignans. Flaxseed contains from 100 to 800 times more lignans than any other plant. Lignans are believed to have antioxidant properties and may also act as phytoestrogens, very weak forms of estrogen found in fruits, vegetables, whole grains, and beans. Unlike human estrogen, phytoestrogens have dual properties: They can mimic the effects of the hormone in some parts of the body while blocking its effects in others. Many herbalists believe that phytoestrogens can be useful in the prevention or treatment of a variety of diseases, including **cancer**, cardiovascular disease, and osteoporosis. The estrogen-blocking effects of phytoestrogens may be particularly effective at combating certain cancers that depend on hormones, such as cancers of the breast or uterus. Women who consume large amounts of lignans appear to have lower rates of **breast cancer**. The fact that heart disease and certain cancers occur less frequently in Asian countries is sometimes attributed to a diet rich in plant foods containing phytoestrogens.

General use

While not approved by the United States Food and Drug Administration (FDA), flaxseed products are reputed to have a number of beneficial effects. Flaxseed is sometimes referred to as a nutraceutical, a term that includes any food or food ingredient thought to confer health benefits, including preventing and treating disease. In the late twentieth century and early 2000s, the omega-3 fatty acids derived from flaxseed and other sources became an important food additive. Omega-3 is included in cereals, eggs (derived from hens on a flaxseed-enhanced diet), orange juice, and even in pet foods. Since 2006, as many as 250 food products have added the fatty acid Omega-3 as a nutritional boost. Several studies, some conducted in people, suggest that flaxseed products (or agents contained in them) may help to keep the heart and cardiovascular system healthy. Flaxseed products may lower cholesterol levels, help control blood pressure, and may reduce the buildup of plaque in arteries. Test tube and rat studies suggest that chemicals in flaxseed may help to prevent or shrink cancerous tumors. Due to its estrogen-like effects, some women use flaxseed oil to ease breast tenderness, alleviate symptoms of **premenstrual syndrome** (PMS), and help control menopausal symptoms. Flaxseed oil has also been recommended to treat skin conditions, inflammation, and arthritis. It is usually taken internally for all the purposes mentioned above. The oil may be used externally to help the healing of scalds and **burns**.

Additionally, flaxseed has been shown to be beneficial for people suffering from digestive disorders. It is recommended as an "effective herbal agent" for treating **irritable bowel syndrome** (IBS).

Clinical studies

The link between flaxseed and heart disease has been examined in a number of published studies. One of these studies published in the journal *Atherosclerosis*

in 1997, observed the effects of adding flaxseed to the diet of rabbits with **atherosclerosis**. Researchers found that flaxseed reduced the development of plaque build-up by almost 50%. The authors concluded that flaxseed may help to prevent heart attacks and strokes related to high cholesterol levels. However, a 2002 clinical trial on postmenopausal women concluded that the evidence remained "indeterminate," as to the effectiveness of dietary flaxseed for chloresteral reduction.

A study at the University of Toronto, reported in Clinical Cancer Research in 2005, concluded that dietary flaxseed has the potential to reduce tumor growth in patients with breast cancer. The clinical trial consisted of a randomized, double-bind, placebo controlled study on a small group of postmenopausal patients with newly diagnosed breast cancer. Participants ingested either a 25 g flaxseed-containing muffin or a (placebo) muffin, without the flaxseed. Researchers reported that the results of the clinical trial agreeed with previous clinical and preclinical studies showing antitumor effects of flaxseed in **prostate cancer** patients and in laboratory animal studies with carcinogen-treated rats.

Though early animal research and small clinical trials with people suggest that flaxseed has the potential as a dietary cancer fighter and a useful nutritional aid in preventing the spread of cancer, a review of 38 studies conducted between 1966 and 2005, reported in 2006 in the *Journal of the American Medical Association* suggests that omega-3s (found in abundance in flaxseed and in many kinds of fish) "have no significant effect" on cancers of the breast, colon, lung and prostate, according to Dr. Catherine MacLean, lead author of the study and a researcher at the Rand Corp.

While the cancer-inhibiting effects of flaxseed in people may be in doubt, some practitioners of alternative medicine continue to recommend the herb as a healthy dietary choice.

The American Institute for Cancer Research reported in 2006 on a study at the University of Pennsylvania examining the role of flaxseed in preventing oxidative lung tissue damage, a side effect of irradiation used in treating **lung cancer**. Early in the first year of a two-year study with mice, flaxseed-treated mice showed a "major increase in survival rates and decrease in lung tissue oxidative damage after radiation," according to the principal investigator in the study.

The therapeutic effects of flaxseed are not limited to people, according to some authorities. Flaxseed is sometimes used as a purgative in horses and sheep. In addition, flaxseed is included in a rapidly expanding list of nutraceutical products for dogs, cats, and other domestic pets. In 2006, the U.S. Department of Agriculture approved Canadian "Omega-3 pork" for sale in U.S. supermarkets. Canadian Omega-3 pork is derived from enhancing the animal feed with flaxseed.

Preparations

Flaxseed products are commercially available as whole or ground seeds, gelatin capsules, and oil. Some herbalists recommend adding the ground or whole seeds to the diet to get the maximum benefit from the herb. Nutritionists advise that the healthy fiber, protein, and lignans of flaxseed are only found in the milled seed and defatted ground flax, though some manufacturers of flaxseed oil return particulate matter containing lignans to the oil. Whole seeds can be stored in a cool, dry place for up to one year. Crushed seeds should be used immediately or frozen for future use. No standard guidelines have been established on how much of these forms should be consumed. Research subjects have been given as much as 1/4 cup of ground flaxseed per day, but a Canadian **nutrition** expert suggests that 1–2 tablespoons per day is enough for most adults.

Several nutraceutical companies have marketed a flaxseed ingredient. The flaxseed ingredient is a fine-milled flour with 5% lignan content, intended for addition to commercial baked goods, snack foods, cereals, dry pet foods, and similar products.

Capsules can be taken according to package directions. Some herbalists believe that the capsules available are highly processed, contain fewer beneficial properties, and may be an expensive alternative to flaxseed oil.

The optimum daily dosage of flaxseed oil has not been established. Usually, 1 tablespoon daily of the oil can be taken for general health. As a remedy, 1–3 tablespoons may be taken daily based on the person's weight and health needs. Some people consume the oil as an ingredient in salad dressing. The oil is often combined with limewater when used to treat burns and scalds.

Precautions

Flaxseed products are not known to be harmful when taken in recommended dosages, though it is important to remember that the long-term effects of taking flax-derived remedies (in any amount) have not been studied as of 2008. Due to lack of sufficient medical study, flaxseed products should be used with caution in children, women who are pregnant or breastfeeding, and people with liver or kidney disease.

Because flaxseed oil tends to become rancid relatively quickly, it should be kept in the refrigerator.

KEY TERMS

Antioxidant—An agent that helps to protect cells from damage caused by free radicals, the destructive fragments of oxygen produced as a byproduct during normal metabolic processes.

Atherosclerosis—Narrowing and hardening of the arteries due to plaque buildup.

Nonsteroidal anti-inflammatory drugs (NSAIDs)—A group of pain-relieving medications that also reduce inflammation when used over a period of time. NSAIDs are often given to patients with osteoarthritis.

Nutraceutical—Any food or food ingredient that is thought to provide health benefits, including the prevention and treatment of disease. Flaxseed is considered a nutraceutical.

Osteoporosis—An age-related disease in which bones become fragile and prone to debilitating fractures.

Purgative—A substance that encourages bowel movements.

Triglyceride—The total amount of fat in the blood. Triglyceride should not be confused with cholesterol, which is technically classified as a steroid and not as a fat.

While the oil may be added to cooked food, it should not be used during cooking because heat can destroy the effectiveness of the oil.

Persons who are adding ground flaxseed to their diet for its fiber content are advised to start off with small amounts and increase them gradually and to drink plenty of water. Otherwise the high fiber content of flaxseed can produce intestinal cramping and **diarrhea**.

Consumers should read the labels of all flaxseed products to insure that the product is for medicinal or nutritional purposes.

Side effects

When taken in recommended dosages, flaxseed products are not associated with any significant side effects.

Interactions

Consumers should consult their healthcare professional for information on flaxseed products and interactions with medications and other remedies. More specifically, the omega-3 fatty acids in flaxseed may increase the blood-thinning effects of such medications as aspirin or warfarin. Flaxseed may help a group of medications known as statins (lovastatin, simvastatin, etc.), which are given to lower blood cholesterol, to work more effectively.

Flaxseed may help to reduce the toxic side effects (kidney damage and high blood pressure) of cyclosporine, which is a drug given to organ transplant patients to prevent rejection of the new organ.

Flaxseed appears to reduce the risk of ulcers from high doses of NSAIDs.

In general, flaxseed oil should not be taken at the same time of day as prescription medications or other dietary supplements, as it will slow down the body's absorption of them.

Flower remedies

Definition

Flower remedies are specially prepared flower essences, containing the healing energy of plants. They are prescribed according to a patient's emotional disposition, as ascertained by the therapist, doctor, or patients themselves.

Origins

Perhaps the most famous and widely used system is the Bach flower remedies. This system originated in the 1920s when British physician and bacteriologist, Dr. Edward Bach (1886–1936), noticed that patients with physical complaints often seemed to be suffering from **anxiety** or some kind of negative emotion. He concluded that assessing a patient's emotional disposition and prescribing an appropriate flower essence could treat the physical illness. Bach was a qualified medical doctor, but he also practiced **homeopathy**.

As a result of his own serious illness in 1917, Bach began a search for a new and simple system of medicine that would treat the whole person. In 1930, he gave up his flourishing practice on Harley Street at the Royal London Homeopathic Hospital and moved to the countryside to devote his life to this research. It is known that at this point, he ceased to dispense the mixture of homeopathy and allopathic medicine that he had been using. Instead, he began investigating the healing properties of plant essences and discovered that he possessed an "intuition" for judging the properties of each flower. Accordingly, he developed the system of treatment that bears his name, and is also the foundation for all other flower-remedy systems.

The Bach Flower Remedies were ostensibly the only system of significance from the 1920s until in the 1970s, when there was a renewed interest in the subject by doctors working in the field of natural medicine. Perhaps the most notable was Dr. Richard Katz, who was seeking new methods of dealing with modern **stress** and the resulting ailments. He focused on the concept of a psychic, psychological effect and chose to pursue this line of research.

In 1979, Katz founded the Flower Essence Society in California, (FES). This society pledged to further the research and development of Bach's principles. FES hosts a database of over 100 flower essences from more than 50 countries. FES is now an international organization of health practitioners, researchers, students, and others concerned with flower essence therapy.

The Society has connections with an estimated 50,000 active practitioners from around the world, who use flower essence therapy as part of their treatment. FES encourages the study of the plants themselves to determine the characteristics of flower essences. They are compiling an extensive database of case studies and practitioner reports of the use of essences therapeutically, allowing verification and development of the original definitions. They are also engaged in the scientific study of flower essence therapy.

FES says they have developed the theories of Paracelsus and Goethe who researched the "signatures" and "gestures" of botanical specimens, on the premise that the human body and soul are a reflection of the system of nature. FES plant research interprets the therapeutic properties of flower essences according to these insights.

In this regard, they have devised 12 "windows of perception" for monitoring the attributes of plants. Each of these windows reveals an aspect of the plant's qualities, although they maintain that what they are seeking is a "whole which is greater than the sum of its parts." The 12 windows are not considered independent classifications, but more of a blended tapestry of views of the qualities that each plant possesses.

The first window is concerned with the "form" of a plant—its shape classification. The second focuses on its "gesture" or spatial relationship. The third window is a plant's botanical classification; the Flower Essence Society maintains that considering a plant's botanical family is essential to obtaining an overview of its properties as a flower essence. The fourth window concerns the time orientation of a particular specimen regarding the daily and seasonal cycles. Why do some flowers bloom at different times of the day, while others, such as the evening primrose, respond to the moon? The fifth window observes a plant's relationship to its environment. Where a plant chooses to grow, and where it cannot survive, reveals much about its qualities. The sixth window observes a plant's relationship to the Four Elements and the Four Ethers, as FES maintains that plants exist in one of the elemental or etheric forces in addition to their physical life. "Elements" refers to those developed by the Greeks, as opposed to the modern concept of "molecular building blocks." It seems that commonly, two elements predominate in a plant, indicating a polarity of qualities, while two can be said to be recessive. The seventh window relates to a plant's relationship with the other kingdoms of nature: mineral, animal and human, while the eighth relates to the color and color variations of a plant. Katz explains

Bach flower remedies

Name	Remedy For
Agrimony	Upset by arguments, nonconfrontational, conceals worry and pain
Aspen	Fear of the unknown, anxiety, prone to nightmares, and apprehension
Beech	Critical, intolerant, and negative
Centaury	Submissive and weak-willed
Cerato	Self doubting and overly dependent
Cherry plum	Emotional thoughts and desperation
Chestnut bud	Repeats mistakes and has no hindsight
Chicory	Selfish, controlling, attention-seeking and possessive
Clematis	Absorbed, impractical, and indifferent
Crab apple	Shame and self-loathing, cleansing remedy
Elm	Overwhelmed by responsibility and feelings of inadequacy
Gentian	Negative, doubt, and depression
Gorse	Pessimism, hopelessness, and despair
Heather	Self-centered and self-absorbed
Holly	Jealousy, hatred, suspicion, and envy
Honeysuckle	Homesick, living in the past, and nostalgic
Hornbeam	Procrastination, fatigue, and mental exhaustion
Impatiens	Impatience, irritability, and impulsivity
Larch	No confidence, inferiority complex, and despondency
Mimulus	Timid, shy, and fear of the known
Mustard	Sadness and depression of unknown origin
Oak	Obstinate, inflexible, and overachieving
Olive	Exhaustion (following mental or physical effort)
Pine	Guilt and self blame
Red chestnut	Fear and anxiety for loved ones
Rock rose	Nightmares, hysteria, terror, and panic
Rock water	Obsessive, repression, perfectionism, and self denial
Scleranthus	Indecision, low mental clarity, and confusion
Star-of-Bethlehem	Grief and distress, shock
Sweet chestnut	Despair and hopelessness
Vervain	Overbearing and fanatical
Vine	Arrogant, ruthless, and inflexible
Walnut	Difficulty accepting change
Water violet	Pride and aloofness
White chestnut	Worry, preoccupation, and unwanted thoughts
Wild oat	Dissatisfaction and uncertainty over one's directing in life
Wild rose	Apathy and resignation, drifting
Willow	Self pity and bitterness

(Illustration by Corey Light. Cengage Learning, Gale)

KEY TERMS

Aura—Emanation of light from living things (plants and animals) that can be recorded by Kirlian photography.

Essence—The constituent of a plant that determines its characteristics.

Potentization—The process of transferring the healing energy of a plant into spring water.

Window—A perspective adopted to assess the property of a given plant.

how the language of color tells us so much about the "soul qualities" of a plant. The ninth window concerns all other sensory perceptions of a plant, such as fragrance, texture, and taste. The tenth window involves assessing the chemical substances and properties; the eleventh studies medicinal and herbal uses, as by studying the physical healing properties of plants, their more subtle effects on the soul can be understood. Finally, the twelfth window involves the study of the lore, mythology, folk wisdom, and spiritual and ritual qualities associated with a particular plant. Katz relates how in the past, human beings were more in touch with the natural world, and the remnants of this unconscious plant wisdom live on in the form of folklore, mythology, and so on.

Benefits

Flower remedies are more homeopathic than herbal in the way they work, effecting energy levels rather than chemical balances. They have been described as "liquid energy." The theory is that they encapsulate the flowers' healing energy, and are said to deal with and overcome negative emotions, and so relieve blockages in the flow of human energy that can cause illness.

Description

Because flower remedies operate on approximately the same principles as homeopathy, practitioners quite often prescribe the two therapies in conjunction with each other. They can also be used concurrently with allopathic medicine.

The system consists of 38 remedies, each for a different disposition. The basic theory is that if the remedy for the correct disposition is chosen, the physical illness resulting from the present emotional state can then be cured. There is a **rescue remedy** made up of five of the essences—cherry plum, clematis, impatiens, rock star, and star of Bethlehem—that is recommended for the treatment of any kind of physical or emotional shock. Therapists recommended that rescue remedy be kept on hand to help with all emergencies.

The 38 Bach Remedies are:

- agrimony: puts on a cheerful front, hides true feelings, and worries or problems
- aspen: feelings of apprehension, dark foreboding, and premonitions
- beech: critical, intolerant, picky
- centaury: easily comes under the influence of others, weak-willed
- cerato: unsure, no confidence in own judgement, intuition, and seeks approval from others
- cherry plum: phobic, fear of being out of control, and tension
- chestnut bud: repeats mistakes, does not learn from experience
- chicory: self-centered, possessive, clingy, demanding, self pity
- clematis: absent minded, dreamy, apathetic, and lack of connection with reality
- crab apple: a "cleanser" for prudishness, self–disgust, feeling unclean
- elm: a sense of being temporarily overwhelmed in people who are usually capable and in control
- gentian: discouraged, doubting, despondent
- gorse: feelings of pessimism, accepting defeat
- heather: need for company, talks about self, and concentrates on own problems
- holly: jealousy, envy, suspicion, anger, and hatred
- honeysuckle: reluctance to enter the present and let the past go
- hornbeam: reluctant to face a new day, weary, can't cope (mental fatigue)
- impatiens: impatience, always in a hurry, and resentful of constraints
- larch: feelings of inadequacy and apprehension, lack of confidence and will to succeed
- mimulus: fearful of specific things, shy, and timid
- mustard: beset by "dark cloud" and gloom for no apparent reason
- oak: courageous, persevering, naturally strong but temporarily overcome by difficulties
- olive: for physical and mental renewal, to overcome exhaustion from problems of long–standing
- pine: for self–reproach, always apologizing, assuming guilt
- red chestnut: constant worry and concern for others

EDWARD BACH (1886–1936)

Edward Bach was a graduate of University College Hospital (M.B., B.S., M.R.C.S.) in England. He left his flourishing Harley Street practice in favor of homeopathy, seeking a more natural system of healing than allopathic medicine. He concluded that healing should be as simple and natural as the development of plants, which were nourished and given healing properties by earth, air, water, and sun.

Bach believed that he could sense the individual healing properties of flowers by placing his hands over the petals. His remedies were prepared by floating summer flowers in a bowl of clear stream water exposed to sunlight for three hours.

He developed 38 remedies, one for each of the negative states of mind suffered by human beings, which he classified under seven group headings: fear, uncertainty, insufficient interest in present circumstances, loneliness, over sensitivity to influences and ideas, despondency or despair, and overcare for the welfare of others. The Bach remedies can be prescribed for plants, animals, and other living creatures as well as human beings.

- rock rose: panic, intense alarm, dread, horror
- rock water: rigid–minded, self–denial, restriction
- scleranthus: indecision, uncertainty, fluctuating moods
- star of Bethlehem: consoling, following shock or grief or serious news
- sweet chestnut: desolation, despair, bleak outlook
- vervain: insistent, fanatical, over–enthusiastic
- vine: dominating, overbearing, autocratic, tyrannical
- walnut: protects during a period of adjustment or vulnerability
- water violet: proud, aloof, reserved, enjoys being alone
- white chestnut: preoccupation with worry, unwanted thoughts
- wild oat: drifting, lack of direction in life
- wild rose: apathy, resignation, no point in life
- willow bitter: resentful, dissatisfied, feeling life is unfair

Originally, Bach collected the dew from chosen flowers by hand to provide his patients with the required remedy. This became impractical when his treatment became so popular that production could not keep up with demand. He then set about finding a way to manufacture the remedies, and found that floating the freshly picked petals on the surface of spring water in a glass bowl and leaving them in strong sunlight for three hours produced the desired effect. Therapists explain that the water is "potentized" by the essence of the flowers. The potentized water can then be bottled and sold. For more woody specimens, the procedure is to boil them in a sterilized pan of water for 30 minutes. These two methods produce "mother tinctures" and the same two methods devised by Bach are still used today. Flower essences do not contain any artificial chemical substances, except for alcohol preservative.

Bach remedies cost around $10 each, and there is no set time limit for treatment. It may take days, weeks, or in some cases months. Flower essences cost around $6 each, and there is also no set time for the length of treatment, or the amount of essences that may be taken. These treatments are not generally covered by medical insurance.

Precautions

Bach remedies and flower essences are not difficult to understand, and are considered suitable for self administration. The only difficulty may be in finding the correct remedy, as it can sometimes be tricky to pinpoint an individual's emotional disposition. They are even safe for babies, children, and animals. An important aspect of treatment with flower remedies, is that if you feel instinctively that you need a particular remedy, you are encouraged to act on that instinct. However, it is advisable not to continue a particular remedy once it is no longer needed, and to try a different one if progress is not being made.

The remedies are administered from a stoppered bottle and need to be diluted. Individuals sensitive to alcohol can apply the concentrate directly to temples, wrists, behind the ears, or underarms. When kept in a cool dark place, they should last indefinitely. However, a diluted remedy should not be kept longer than three weeks. Two drops of each diluted remedy should be taken four times a day, including first thing in the morning and last thing at night. If the rescue remedy is being used, four drops should be used instead. Most therapists recommend that they be taken in spring water, but the remedy can be taken directly from the bottle, if care is taken that the

dropper does not touch the tongue, as this would introduce bacteria that would spoil the remedy.

It is not recommended that more than six or seven Bach remedies be used at any one time. Instead, it is preferable to divide a larger amount up into two lots to ensure the optimum effectiveness of the remedies. No combination, or amount of combinations of the remedies can cause any harm, rather they become less effective.

Unlike FES, the Bach Centre does not encourage research to "prove" that the remedies work, preferring that people find out for themselves. They strive to keep the use of the Bach remedies as simple as possible, and to this end they do not keep case records. Bach warned before he died that others would try to change his work and make it more complicated. He was determined to keep it simple so that anyone could use it, and that is why he limited the system to only 38 remedies. The Centre points out that many who have used Bach's research as a starting point have added other remedies to the list, even some that Bach himself rejected.

Side effects

Flower remedies or essences are generally regarded as being totally safe, and there are no known side effects apart from the rare appearance of a slight rash, which is not a reason to discontinue treatment, says the Bach Centre.

Research and general acceptance

Bach flower remedies and flower essences have not yet officially won the support of allopathic medicine, despite the fact that more and more medical doctors are referring patients for such treatments on the strength of personal conviction. However, it is difficult to discount the scores of testimonials. Some practitioners refer skeptics to the research that has been done regarding the "auras" of living things. Theoretically, the stronger the aura, the more alive an organism is. Flower essences have very strong auras.

Among mainstream medical practitioners, psychiatrists and family practitioners appear to be more willing to study flower essences than physicians in other specialties. One pilot study at Penn State Hershey Medical Center found that the **Bach flower essences** were effective in reducing the symptoms of **attention-deficit hyperactivity disorder** (ADHD) in children as measured by two standard assessment instruments for ADHD.

Another area of medicine in which acceptance of Bach flower essences is growing is small-animal veterinary practice. Two full-length books on the use of flower essences for behavioral problems in animals were published in 1999, and some schools of veterinary medicine now include flower essences as part of elective courses in holistic or complementary veterinary treatments.

Training and certification

The official Bach International Education Program training courses are all recognized by the Dr. Edward Bach Foundation, and taught by accredited Bach trainers. These qualifications are not recognized by the medical authorities.

Bach therapy may be self-administered, but for those who would prefer the advice of a practitioner, look for a registered Bach practitioner, or a homeopath or herbalist who also deals with the Bach flower remedies.

Fo ti

Description

Fo ti is the American name for the herb *Polygonum multiflorum*. *Polygonum* is a member of the Polygonaceae family of plants and is a perennial flowering vine that reaches heights of 3–6 ft (0.97–1.8 m). It is native to southwestern China, Japan and Taiwan, but can be cultivated in many regions, including parts of North America.

In Chinese herbalism, fo ti (sometimes spelled fo-ti) is called *he shou wu* or *ho shou wu*. Other names are fleeceflower and Chinese cornbind. In Japan, the herb goes by the name *kashuu*. Fo ti is one of the most popular herbs in Oriental medicine. It is used as an overall health tonic, as a tincture to increase longevity, and as a remedy for various health conditions.

Chinese herbalists most frequently use the root of the plant for medicinal purposes, but occasionally draw on the stems for different applications. The root has a sweet and slightly bitter taste. Chinese herbalists claim it has slightly warming effects in the body, and works by increasing levels of blood and vital essence. These are two of three essential substances in the body, according to Chinese medicine. Chinese herbalists also maintain that fo ti strengthens the liver and kidneys. They use fo ti root in conjunction with other herbs in many medicinal tonics.

Research has shown that fo ti has antitumor and antibacterial properties. It also lowers blood pressure (hypotensive effects) and increases circulation (vasodilatory effects), providing an overall protective effect on the cardiovascular system. In addition, it has antioxidant and anti-free radical properties, which may associated with its connection to reported benefits to patients with **atherosclerosis**. A 2005 study in rabbits confirmed that it is "a powerful agent against atherosclerosis." In addition, a 2003 study showed that it contained significant estrogen activity, similar to that found in soy and **red clover**, and therefore may have applications as an alternative-medicine treatment for **menopause** symptoms. A 2005 study confirmed the high estrogen-content of fo ti.

Fo ti contains emodin and rhein, two laxative agents that have shown promising anti-cancer activity as well. Fo ti also contains **lecithin**, a B vitamin that aids in fat metabolism and lowers **cholesterol**. Researchers have isolated a flavonoid in fo ti called catachin, which is also found in **green tea**. Catachin inhibits tumor cells and has antioxidant effects, which may be the source of the anti-aging properties for which the herb is known in China. Researchers who conducted an animal study in 2003 reported improvements in both memory and learning among mice, and suggested that **antioxidants** in fo ti might be the reason for the improvements.

General use

Herbalists use fo ti for many conditions. They recommend it as an overall health strengthener, and to prevent premature **aging** and graying hair. Practitioners of Chinese medicine recommend it to increase sperm quality in men and fertility in women. They also advise its use for diseases associated with weakness in the liver and kidneys. These illnesses are characterized by blurred vision, **dizziness**, weakness in the knees and lower back, intermittent fevers, dull complexion, swollen lymph glands, and sores and **boils** on the skin. **Traditional Chinese medicine** has also used fo ti for non-acute **malaria**, for lowering cholesterol, and for nervous disorders. As fo ti has both laxative and tonic effects, herbalists suggest it for **constipation** in the elderly. They also use it to treat vaginal discharges, and fo ti's slightly sedative effect has led to its application as a treatment for **insomnia**.

Practitioners of Chinese medicine use the vine part of *Polygonum*, which is called *ye jiao teng*, to treat insomnia as well as irritability, and numb or **itching** sensations in the limbs.

Preparations

Fo ti is available for purchase as whole or sliced roots, in tablets, and as a tincture. Consumers can find it in health food stores, as well as in Chinese herb stores and markets. The reader should note that the Chinese do not recognize fo ti as the herb's proper name; in Chinese markets it is known as *he shou wu* or as *Polygonum*.

Consumers will typically find fo ti root available in slices. The older and larger the root, the higher quality and more expensive it is. In addition, herbalists

KEY TERMS

Catachin—A flavonoid found in fo ti that has antioxidant and tumor-inhibiting qualities.

Flavonoids—Pigments found in plants that protect plants against environmental stress. In humans, they appear to have anti-aging effects.

Tonic—Any substance that strengthens and tones the entire system.

Sedative—A substance or medication that calms and lowers bodily activity.

consider dark roots a higher grade than roots that have white streaks in them. An herbalist may recommend eating the root or preparing it as a tea or tincture. The preparation for making tea involves boiling the root for 30 minutes or more to extract all the active ingredients. For one serving of the root or tea, herbalists recommend 5–15 g. The preparation for a tincture entails soaking chopped roots in alcohol for one month or longer, and individuals typically take 30 drops of the tincture daily. Tinctures are also available for purchase in varying concentrations, which causes associated variations in the daily dosages.

For sedative purposes, individuals generally take fo ti vine with the evening meal or before bedtime. Herbalists recommend taking fo ti continuously for up to one month, but then waiting one month before using it again.

Fo ti has uses in many herbal tonics. For longevity and overall health, Chinese herbalists recommend combining it with Asian ginseng. As a tonic for non-acute malaria or for recovery from a long illness, they suggest combining fo ti with Asian ginseng, **dong quai** and **tangerine peel**. For sore knees and lower back problems, herbalists combine fo ti with **cuscuta**, psorolea fruit, and **lycium fruit**. As part of a program of **cancer** treatment, they advise combining fo ti with other tonic and immune-enhancing herbs, including **Korean ginseng**, **astragalus**, milletia, and codonopsis. Experienced herbalists can assist consumers with special preparations and applications.

Precautions

Fo ti is generally a safe herb, but practitioners of Chinese medicine do not recommend it for patients with **diarrhea** or heavy phlegm in the respiratory tract.

Side effects

Reported side effects with fo ti are generally rare. They include diarrhea, abdominal **pain**, **nausea**, numbness in the extremities, flushing of the face, and skin **rashes**. Three case reports of acute **hepatitis** arising in patients following their use of an herbal product called Shou-wu-pian, which is derived from fo ti. In two of the three cases, medical professionals were not able to determine whether the fo ti or a product contaminant contributed to the hepatitis. In the third case, however, medical professionals found no contaminants and attributed the hepatitis to fo ti.

Interactions

Some herbalists advise patients to reduce their intake of onions, **garlic**, and chives while taking fo ti for extended periods.

Folate *see* **Folic acid**

Folic acid

Description

Folic acid is a water-soluble vitamin belonging to the B-complex group of vitamins. These vitamins help the body break down complex carbohydrates into simple sugars that can be readily used for energy. Excess B vitamins are excreted from the body rather than stored for later use. This is why sufficient daily intake of folic acid is necessary.

Folic acid is also known as folate or folacin. It is one of the nutrients most often found to be deficient in the Western diet, and there is evidence that deficiency

Recommended dietary allowance of folate (folic acid)

Age	mcg/day
Children 0-6 mos.	65 (AI)
Children 7-12 mos.	89
Children 1-3 yrs.	150
Children 4-8 yrs.	200
Children 9-13 yrs.	300
Children 14-18 yrs.	400
Adult ≥ 19 yrs.	400
Pregnant women	600
Breastfeeding women	500

Foods that contain folate	mcg
Cereal, 100% fortified, 3/4 cup	400
Beans, pinto, cooked, 1/2 cup	147
Turnip greens, cooked, 1/2 cup	135
Asparagus, cooked, 1/2 cup	132
Spinach, cooked, 1/2 cup	131
Beans, navy, cooked, 1/2 cup	127
Beans, great northern, cooked, 1/2 cup	90
Broccoli, steamed, 1/2 cup	85
Beets, boiled, 1/2 cup	68
Rice, long-grain white, enriched, cooked, 1/2 cup	65
Corn, yellow, cooked, 1/2 cup	37
Tomato juice, canned, 6 oz.	35
Bread, white, enriched, 1 slice	25
Bread, whole wheat, enriched, 1 slice	25
Raspberries, 1/2 cup	16

AI = Adequate Intake
mcg = microgram

(Illustration by GGS Information Services. Cengage Learning, Gale)

is a problem worldwide. Folic acid is found in leafy green vegetables, beans, peas and lentils, liver, beets, brussels sprouts, poultry, nutritional yeast, tuna, **wheat germ**, mushrooms, oranges, asparagus, broccoli, spinach, bananas, strawberries, and cantaloupes. In 1998, the U.S. Food and Drug Administration (FDA) required food manufacturers to add folic acid to enriched bread and grain products to boost intake and to help prevent neural tube defects (NTD) in the fetus during **pregnancy**.

General use

Folic acid works together with **vitamin B_{12}** and **vitamin C** to metabolize protein. It is important for the formation of red and white blood cells. Folic acid is necessary for the proper differentiation and growth of cells and for fetal development. It is also used to form the nucleic acid of DNA and RNA. It increases the appetite, stimulates the production of stomach acid for digestion, and aids in maintaining a healthy liver. A folic acid deficiency may lead to megaloblastic **anemia**, in which there is decreased production of red blood cells and the cells that are produced are abnormally large. This condition reduces the amounts of oxygen and nutrients that are able to reach the tissues. Symptoms may include **fatigue**, reduced secretion of digestive acids, confusion, and forgetfulness. During pregnancy, a folic acid deficiency may lead to preeclampsia, premature birth, and increased bleeding after birth.

People who are at high risk for strokes and **heart disease** may benefit from folic acid supplements. An elevated blood level of the amino acid homocysteine has been identified as a risk factor for some of these diseases. High levels of homocysteine have also been found to contribute to problems with **osteoporosis**. Folic acid, together with vitamins B_6 and B_{12}, aids in the breakdown of homocysteine, and may help reverse the problems associated with elevated levels of homocysteine.

Pregnant women have an increased need for folic acid, both for themselves and their unborn child. Folic acid is necessary for the proper growth and development of the fetus. Adequate intake of folic acid is vital for the prevention of several types of birth defects, particularly neural tube defects (NTDs). The neural tube of the embryo develops into the brain, spinal cord, spinal column, and the skull. If this tube forms incompletely during the first few months of pregnancy, a serious—and often fatal—defect such as spina bifida or anencephaly, may occur. Folic acid, taken from one year to one month before conception through the first four months of pregnancy, can reduce the risk of NTDs by 50 to 70%. It also helps prevent cleft lip and palate.

Research shows that folic acid can be used to successfully treat **cervical dysplasia**, a condition that is diagnosed by a Pap smear, and consists of abnormal cells in the cervix. This condition is considered to be a possible precursor to cervical **cancer**. Daily consumption of 1,000 micrograms (mcg) of folic acid for three or more months has resulted in improved cervical cells upon repeat Pap smears.

Studies suggest that long-term use of folic acid supplements may also help prevent lung and colon cancers. However, a study involving over 1,000 individuals, conducted at universities and research centers in the United States, Canada, and Norway, found that folic acid given in a dose of 1 mg per day does not lower the risk of colorectal adenoma. Scientists concluded that additional research in this area is needed.

Alcohol is believed to interfere with the absorption of such important nutrients as folic acid. Researchers have found that alcoholics who have low folic acid levels face a greatly increased chance of developing colon cancer.

Supplements are taken to correct a folic acid deficiency. Since the functioning of the B vitamins is interrelated, it is generally recommended that the appropriate dose of B-complex vitamins be taken in place of single B vitamin supplements. The Recommended Dietary Allowance (RDA) for folate is 400 mcg per day for adults, 600 mcg per day for pregnant women, and 500 mcg daily for nursing women. Medicinal dosages of up to 1,000 to 2,000 mcg per day may be prescribed.

In January 2000, the Chile Ministry of Health required wheat flour (primarily used in bread) to be fortified with folic acid. A study performed at the University of Chile several years after the law was put into effect found that the folate status of Chilean women of childbearing age was improved.

Precautions

Folic acid is not stable. It is easily destroyed by exposure to light, air, water, and cooking. Therefore, the supplement should be stored inside a dark container in a cold, dry place, such as a refrigerator. Many medications interfere with the body's absorption and ability to use folic acid. These medications include sulfa drugs, sleeping pills, estrogen, anti-convulsants, birth control pills, antacids, quinine, and some antibiotics.

The anemia caused by folic acid deficiency is identical to that caused by lack of vitamin B_{12}. Using large amounts of folic acid (e.g., over 5,000 mcg per day) can mask a vitamin B_{12} deficiency, since the anemia will improve but the other effects of vitamin B_{12} deficiency will continue. This condition can lead to irreversible nerve damage. People with megaloblastic anemia should be treated under medical supervision, since regular testing may be required.

Side effects

Folic acid is generally considered safe at levels of 5,000 mcg or less. Side effects are uncommon. However, large doses may cause **nausea**, decreased appetite, bloating, **gas**, decreased ability to concentrate, and **insomnia**. Large doses may also decrease the effects of phenytoin (Dilantin), a seizure medication.

Interactions

As with all B-complex vitamins, it is best to take folic acid with the other B vitamins. Vitamin C is important to the absorption and functioning of folic acid in the body.

KEY TERMS

Homocysteine—An amino acid involved in the breakdown and absorption of protein in the body.

Preeclampsia—A serious disorder of late pregnancy, in which the blood pressure rises, there is a large amount of retained fluids, and the kidneys become less effective and excrete proteins directly into the urine.

Raynaud's disease—A symptom of various underlying conditions affecting blood circulation in the fingers and toes and causing them to be sensitive to cold.

Recommended Daily Allowance (RDA)—Guidelines for the amounts of vitamins and minerals necessary for proper health and nutrition. The RDA was established by the National Academy of Sciences in 1989.

Water-soluble vitamins—Vitamins that are not stored in the body and are easily excreted. These vitamins must be consumed regularly as foods or supplements to maintain health.

Food poisoning

Definition

Food poisoning is a general term for health problems arising from eating food contaminated by viruses, chemicals, or bacterial toxins. Types of food

Seafood with evidence of chemicals and toxins

Fish	Chemicals/Toxins
Bass	Dioxin, chlordane, DDT, PCBs, mercury
Catfish	Chlordane, DDT, dioxin, PCBs, etc.
Caviar	Chlordane, DDT, PCBs
Cod	DDT, PCBs
Maine Lobster	Dioxin, PCBs
Shark	DDT, PCBs, mercury
Striped Bass	PCBs, chlordane, DDT, mercury, etc.
Sturgeon	Chlordane, DDT, dieldrin, mercury, etc.
Swordfish	Mercury, DDT, PCBs
Tilefish	Mercury
Whitefish	Dioxin

(Illustration by Corey Light. Cengage Learning, Gale)

poisoning include bacterial food poisoning, shellfish poisoning, and mushroom poisoning. The medical term for food poisoning is **gastroenteritis**.

Description

The Centers for Disease Control and Prevention (CDC) estimates that there are up to 33 million cases of food poisoning in the United States each year. Many cases are mild, and they pass so rapidly that they are never diagnosed. Occasionally, a severe outbreak creates a newsworthy public health hazard, but these instances are rare. Anyone can get food poisoning, but the very young, the very old, and those with compromised immune systems have the most severe and life-threatening cases.

Causes and symptoms

General indications of food poisoning include **diarrhea**, stomach **pain** or cramps, gurgling sounds in the stomach, **fever**, **nausea**, and **vomiting**. Dehydration is a common complication, since fluids and electrolytes are lost through vomiting and diarrhea. Dehydration is more likely to happen in the very young, the elderly, and people who are taking diuretics.

Bacterial sources of food poisoning

Bacteria are major causes of food poisoning. Symptoms of bacterial food poisoning occur because foodborne bacteria release enterotoxins, or poisons, as a byproduct of their growth in the body. These toxins often diminish the absorptive ability of the intestines and cause the secretion of water and electrolytes that leads to dehydration. The severity of symptoms depends on the type of bacteria, the amount of bacteria and food consumed, and the individual's health and sensitivity to the bacteria's toxin.

SALMONELLA. Symptoms of poisoning begin 12–72 hours after eating food contaminated with *Salmonella*. Classic food poisoning symptoms, including fever, occur for about two to five days. *Salmonella* is usually transmitted through the consumption of food contaminated by human or other animal feces. This contamination is mostly due to lack of hand washing by food handlers.

***ESCHERICHIA COLI* (*E. COLI*).** Symptoms of food poisoning from *E. coli* O157:H7 and similar **strains** of *E. coli* are slower to appear than those caused by some of the other foodborne bacteria. One to three days after eating contaminated food, the victim begins to have severe abdominal cramps and watery diarrhea that usually becomes bloody. The diarrhea may consist mostly of blood and very little stool, so the condition is sometimes called hemorrhagic **colitis**. There is little or no fever, the bloody diarrhea lasts from one to eight days, and the condition usually resolves by itself. Food contamination from *E. coli* O157:H7 has mostly been found in raw or undercooked ground beef. Raw milk has also been a source of food poisoning by *E. coli*.

CAMPYLOBACTER JEJUNI. *C. jejuni* **infections** are most often caused by contaminated chicken, but unchlorinated water and raw milk may also be sources of infection. Classic symptoms of food poisoning, including fever and diarrhea, begin two to five days after consuming food or water contaminated with *C. jejuni*. The diarrhea may be watery and may contain blood. Symptoms last from seven to 10 days, and relapses occur in about one quarter of the people who are infected.

Common pathogens causing food poisoning

Pathogen	Onset of Symptoms	Common Host(s)
Campylobacter	2 - 5 days	Poultry, unpasteurized milk, and contaminated water.
E. coli 0157:H7	1 - 8 days	Undercooked, contaminated ground beef. Can also be found in unpasteurized milk or apple cider, alfalfa sprouts, and contaminated water.
Listeria	9 - 48 hours	Found in a variety of raw foods, such as uncooked meats and vegetables, and in processed foods that become contaminated after processing, such as hot dogs, luncheon meats, and milks and cheeses.
Salmonella	1 - 3 days	Poultry, eggs, meat, milk, inadequately cooked foods.
Shigella	24 - 48 hours	This bacteria is transmitted through direct contact with an infected person or from food or water that become contaminated by an infected person.
Vibrio vulnificus	1 - 7 days	Contaminated seafood, raw or undercooked oysters, mussels, clams, and whole scallops, and contaminated water.

SOURCE: Food and Safety Inspection Service, U.S. Department of Agriculture

(Illustration by Corey Light. Cengage Learning, Gale)

***STAPHYLOCOCCUS AUREUS* (STAPH).** *Staph* is spread primarily by food handlers with *Staph* infections on their skin. However, contaminated equipment and food preparation surfaces may also be at fault. Almost any food can be contaminated, but salad dressings, milk products, cream pastries, and food kept at room temperature, rather than hot or cold, are likely candidates. Classic symptoms of food poisoning appear rapidly, usually two to eight hours after the contaminated food is eaten. Such symptoms usually last only three to six hours and rarely more than two days. Most cases are mild and the victim recovers without any assistance.

SHIGELLA. Symptoms of food poisoning by *Shigella* appear 36–72 hours after eating contaminated food. These symptoms are slightly different from those associated with most foodborne bacteria. In addition to the familiar symptoms of food poisoning, up to 40% of children with severe infections show neurological symptoms. These include seizures, confusion, **headache**, lethargy, and a stiff, sore neck. The disease runs its course in two to three days.

CLOSTRIDIUM BOTULINUM. *C. botulinum* (commonly known as botulism) is the deadliest of the bacterial foodborne illnesses. Sources for adult botulism are often improperly canned or preserved food. Symptoms of adult botulism appear about 18 to 36 hours after the contaminated food is eaten, although there are documented times of onset ranging from four hours to eight days. Unlike other foodborne illnesses, there is no vomiting and diarrhea associated with botulism. Initially, a person with botulism feels weakness, **dizziness**, and double vision. Symptoms progress to difficulty with speaking and swallowing. The toxins from *C. botulinum* are neurotoxins—they poison the nervous system, causing paralysis. If the disease proceeds unchecked, paralysis will move throughout the body. Eventually, without medical intervention, the respiratory muscles will become paralyzed and the victim will suffocate.

With infant botulism, the spores of *C. botulinum* lodge in the infant's intestinal tract. Honey, especially when consumed by infants younger than 12 months, is sometimes the source of these spores. Onset of the symptoms is gradual. The infant initially has **constipation**, followed by poor feeding, lethargy, weakness, drooling, and a distinctive wailing cry. Eventually the

Types of food poisoning

Type	Cause
Traveler's diarrhea	Usually caused by otoxigenic *ESCHERICHIA COLI*, *(E.coli)* bacteria found in contaminated food and water.
Salmonella	Caused by bacteria in contaminated poultry, eggs, meat, and dairy products. Although it can be fatal, most cases are mild.
Botulism	Caused by anaerobic bacteria that is found in home canned products and honey.
Viral	Caused most often by contaminated raw seafood.
Chemical	Caused by pesticides.

(Illustration by Corey Light. Cengage Learning, Gale)

baby loses the ability to control its head muscles. Paralysis then progresses to the rest of the body.

Fish-associated food poisoning

Ciguatera fish poisoning is caused by toxins accumulated in the tissues of certain tropical fish, including groupers, barracudas, snappers, and mackerel. Signs of poisoning occur about six hours after eating the fish. Around the mouth, there may be numbness and tingling, which may spread to other places including the hands and feet. There is often muscle pain and weakness, headache, dizziness, joint pain, sensitivity to temperature, heart arrhythmias, dramatic changes in heart rate, and reduced blood pressure. Reef fish contaminated with ciguatoxin are being exported all over the world, occurrence of ciguatera is becoming more likely in colder climates.

Pufferfish, or *fugu*, is a traditional gourmet dish served mostly in Japan. The skin and other organs of the pufferfish contain a strong poison called tetradotoxin. The first stage of tetradotoxin poisoning is indicated by numbness of the lips and tongue, which may occur 20–180 minutes after eating the fish. This is followed by tingling and numbness of the face, hands, and feet. Classic symptoms of food poisoning are accompanied by other neurological symptoms such as light-headedness, headache, and unsteady gait. The second stage of tetradotoxin poisoning brings on a progressive paralysis. Breathing, talking, and other movement becomes difficult. Cyanosis (bluish or purplish skin discoloration), low blood pressure, and arrhythmias may occur. Convulsions and mental impairment may happen right before death, or the person may be completely lucid, though unmoving. Death usually occurs four to six hours after ingestion of the fish if there is no proper intervention; that time, however, has been known to be as little as 20 minutes.

Shellfish poisoning is caused by toxins made by certain algae eaten by shellfish. The toxins are then accumulated in the bodies of the shellfish. Cockles, mussels, clams, oysters, and scallops are most often affected. Sometimes the toxin-producing algae multiply to such an extent that they cause the waters they live in to take on the reddish color of their bodies. This phenomenon is known as a red tide. Warnings are often given against eating shellfish from such areas. Symptoms of food poisoning show up within a half an hour to two hours of eating the shellfish, depending on the amount and type eaten. There may be burning and tingling in the face and mouth, numbness, drowsiness, muscular pain, dizziness, diarrhea, stomachache, confusion, nausea, vomiting, odd temperature sensations, difficulty breathing, and possibly coma. The symptoms may last from a few hours to a few days.

KEY TERMS

Arrhythmia—A disrupted heartbeat pattern.

Disulfiram-like poison—Disulfiram is a chemical compound that causes a severe physiological reaction to alcohol. This poison behaves like disulfiram.

Electrolytes—Salts and minerals in the body that are important because they control body fluid balance and support all major body reactions.

Nasogastric intubation—Insertion of a tube through the nose and mouth for delivery of food and oxygen.

Neurotoxin—A poison that acts on the central nervous system.

Peristalsis—Waves of contractions, such as through the intestines, forcing the contents onward.

Histamine poisoning can occur from eating fish whose body tissues have begun to produce high levels of histamine. Mackerel, tuna, and mahi mahi are most often the sources. After consumption of the fish, immediate facial flushing and **hives** may occur, as well as classic symptoms of food poisoning becoming evident a few minutes later. Symptoms usually last less than 24 hours.

Mushroom poisoning

Mushroom poisoning is classified by the effects of the poisons. Protoplasmic poisons result in cell destruction, often in the liver, which progresses to complete organ failure. Neurotoxins cause neurological symptoms such as sweating, convulsions, hallucinations, excitement, **depression**, coma, and colon spasms. Gastrointestinal (GI) irritants rapidly bring on the classic symptoms of food poisoning and then resolve just as quickly. Disulfiram-like poisons are generally nontoxic, except when alcohol is consumed within 72 hours of eating them. In these cases, the poisons cause headache, nausea, vomiting, flushing, and cardiac disturbances for two to three hours.

Other possible sources

Other possible sources of food poisoning include ingestion of green or sprouting raw potatoes, ingestion of fava beans by susceptible persons, and ergot poisoning from ingestion of contaminated grain. Chemical contaminant food poisoning may result from the ingestion of unwashed produce sprayed with arsenic, lead, or insecticides. Food served or stored in lead-glazed pottery cadmium-lined containers may also lead to food poisoning.

Diagnosis

An important aspect of diagnosing food poisoning is the clinical interview. A history of the illness should be thoroughly traced to include ingestion of food, recent travel, and contact with those showing similar symptoms of illness. Because it may take 30 minutes to three days for symptoms to develop, it is not necessarily the most recent food eaten that is the cause of the symptoms. Diagnosis is confirmed with a stool culture. Other laboratory tests may be used to examine vomitus, blood, or the contaminated food. A blood chemistry panel may be performed to determine the extent of any tissue damage or electrolyte imbalances. Many cases of food poisoning go undiagnosed, and treatment focuses on the short-lived GI symptoms.

Botulism is usually diagnosed from its distinctive neurological symptoms, since rapid treatment is essential to save the patient's life. Electromyography, a test analyzing the electrical activity of muscles, may later be done to further confirm diagnosis. The test shows abnormal muscle activity in most cases of botulism.

Treatment

People with food poisoning should reduce all sugar and normal food for eight to 24 hours, and increase fluids to avoid dehydration. Charcoal tablets, *Lactobacillus acidophilus*, *Lactobacillus bulgaricus*, and citrus seed extract are all recommended. For mild cases of food poisoning, the homeopathic remedies *Arsenicum album, Veratrum album, Podophyllum,* or ***Nux vomica*** are recommended. The remedy should be given in 12C potency every three to four hours until symptoms subside. If a ready-made electrolyte replacement is not available, a homemade one can be made by dissolving exactly 1 tsp (5 ml) of salt and 4 tsp (20 ml) of sugar in 1 qt (1 l) of water.

Cinnamon (*Cinnamonum zeylanicum)*, cloves (*Syzigium aromaticum)*, oregano (*Origanum vulgare*), and **sage** (*Salvia officinalis*) are food herbs that are also strong inhibitors of bacteria. Liberal amounts can be added to foods, especially when traveling. **Grapefruit seed extract** has a natural antibiotic effect and may be of help. Large amounts of **garlic**, in food and in supplement form, are also recommended for the same reason.

Allopathic treatment

In serious cases of food poisoning, medications may be given to stop abdominal cramping and vomiting. Medications are not usually given for the diarrhea, since stopping it might keep toxins in the body longer and prolong the illness. Severe bacterial food poisonings are sometimes treated with antibiotics, but their use is controversial. Washing out the stomach contents to remove the toxic substances may be required. This procedure is called gastric lavage, familiarly known as having the stomach pumped. Neurotoxins often interfere with the breathing process. If the ability to breathe is affected, patients may have to be put on a mechanical ventilator to assist their breathing and are fed intravenously until the paralysis passes.

People who show any signs of botulism poisoning must receive immediate emergency medical care. Both infants and adults suffering from food poisoning by *C. botulinum* require hospitalization, often in the intensive care unit. A botulism antitoxin is given to adults, if it can be administered within 72 hours after

symptoms are first observed. If given later, it provides no benefit. Nasogastric intubation is recommended for the feeding of infants with active botulism. As well as supplying **nutrition**, it will stimulate peristalsis, helping in the elimination of *C. botulinum*.

Treatment of food poisoning that is usually not an emergency situation may include drugs such as **ipecac** syrup to induce vomiting or laxatives to empty the intestines. Intravenous fluids containing salts and dextrose may be given to correct dehydration and electrolyte imbalances. Pain medications are given for severe stomach pain. Atropine is given for muscarine-type mushroom poisoning. If illness comes on after eating unidentified mushrooms, vomiting should be induced immediately, and the vomitus saved for laboratory testing. Intravenous mannitol is sometimes used to treat severe ciguatera poisoning. Antihistamines may be effective in reducing the symptoms of histamine fish poisoning. In 2001, Japanese scientists made a synthetic version of ciguatoxin, an important step in developing an antibody to help diagnose ciguatera.

In mild cases of food poisoning, dietary modifications are often the only treatment necessary. During periods of active vomiting and diarrhea, people with food poisoning should avoid solid food for eight to 24 hours, and should increase fluids. Clear liquids should be consumed in small quantities. Once active symptoms stop, a diet of bland, easily digested foods such as broth, eggs, rice and other cooked grains, and toast is recommended for two to three days. Milk products, spicy food, alcohol, sweets, raw vegetables, and fresh fruit should be avoided.

Expected results

Many cases of food poisoning clear up on their own within a week without medical assistance. There are usually few complications once possible dehydration has been addressed. **Fatigue** may continue for a few days after active symptoms stop, however. In the more severe types of poisoning, especially those involving neurotoxins, the respiratory muscles may become paralyzed. In such cases, death will result from asphyxiation unless there is medical intervention. Deaths due to food poisoning are rare and tend to occur in the very young, the very old, and in people whose immune systems are already weakened.

C. botulinum, is likely to cause serious illness or fatalities, even when ingested in very small quantities. Children affected by food poisoning from *E. coli* often need to be hospitalized. In some cases, *E. coli* toxins may be absorbed into the bloodstream where they destroy red blood cells and platelets, which are important in blood clotting. About 5% of patients, regardless of age, develop hemolytic uremia syndrome, which results in kidney failure.

Prevention

Eighty-four percent of adults surveyed in 2001 were unaware that feces on beef and poultry was the main carrier of *Salmonella, Campylobacter*, and *E. coli*. Other than informing the public, food poisoning prevention efforts include:

- hot foods should be kept hot, and cold foods should be kept cold
- meat should be cooked to the recommended internal temperature; eggs should be cooked until no longer runny
- leftovers should be refrigerated promptly and food should never be left to stand at room temperature
- contact of utensils and surfaces with the juices of raw meats should be avoided
- fruits and vegetables should be washed before using
- unpasteurized dairy products and fruit juices should be avoided
- bulging or leaking canned foods or any food that smells spoiled should be discarded
- hands should be washed with soap before food preparation and after using the bathroom
- food preparation surfaces should be sanitized regularly
- infants under 12 months should not be fed honey, which may contain spores of *C. botulinum*
- proper canning and adequate heating of home-canned food before serving are essential (boiling for three minutes is recommended)

Taking *Lactobacillus acidophilus* or *L. bulgaricus* may help prevent food poisoning, especially when traveling. Populating the intestines with these bacteria will make it less likely that harmful bacteria are able to gain a foothold.

Fractures

Definition

A fracture is a crack or break in a bone. It results from the application of excessive force through injuries, such as a fall or a hard blow.

Description

Up to the age of 50, more men suffer from fractures than women because of occupational hazards. However, after the age of 50, more women suffer fractures than men because of the osteoperosis. Simple, or closed, fractures are not obvious on the surface because the skin remains intact. Compound, or open, fractures break through the skin, exposing bone. They are generally more serious than closed fractures. When bones are broken, there may be an accompanying soft tissue injury or an infection either in the surrounding tissue or the bone itself. If an artery is damaged, there can be a significant loss of blood. Single and multiple fractures refer to the number of breaks in the same bone. Fractures are termed complete if the break is completely through the bone, and described as incomplete, or greenstick, if the fracture occurs partly across a bone shaft. This latter type of fracture is often the result of bending or crushing on the bone. A **stress** fracture is usually a small break in the bone due to repeated or prolonged force.

Causes and symptoms

Fractures usually result from an injury to a bone that causes the bone tissue or cartilage to be disrupted or broken. Bones weakened by disease or misuse are more likely to break. In some women who have gone through **menopause**, the bones fracture easily due to osteoperosis. This is because the body produces less estrogen at that time of life, and estrogen is a major regulator of bone density through its effects on **calcium** in the body. Moderate **exercise** and weight training is helpful in building and maintaining strong bones; so, the bones of an inactive person may also tend to fracture easier than those who are moderately active. However, individuals with a very high activity level have a greater risk of fractures. This group includes children and athletes participating in contact sports. Because bones start to thin out with the **aging** process, the elderly are also at a high risk of sustaining a fracture. Diseases that may lead to an increased risk of fractures include Paget's disease, rickets, osteogenesis imperfecta, **osteoporosis**, tumors, deficiencies of vitamins A or D, and **stroke** induced paralysis.

Fractures usually begin with intense **pain** and swelling at the site of injury. Obvious deformities, such as a crooked or otherwise misshapen limb, point to a possible fracture. Pain that prevents the use of a limb may also indicate a break. In severe fractures, there may be a loss of pulses below the fracture site and a resultant numbness, tingling, or paralysis in the feet, hands, fingers, or toes below the site. An open fracture is often accompanied by bleeding or bruising. If a leg is fractured, there will usually be difficulty bearing weight on it. If there is **dizziness**, sweating, disorientation, or thirst, the onset of shock may be indicated.

Diagnosis

Diagnosis begins immediately with the individual's own observation of symptoms. A thorough medical history and physical exam completed by a physician often provides enough information to determine if further testing is necessary. An x ray of the injured area is most commonly used to determine the presence of a bone fracture. However, it is important to note that not all fractures are apparent on an initial x ray. Rib fractures are often difficult to diagnose and may require several views at different angles. If the fracture is open and occurs in conjunction with soft tissue injury, further laboratory studies may have to be done.

In the event of stress fractures, a tuning fork can provide a simple, inexpensive test. The tuning fork is a metal instrument with a stem and two prongs that vibrate when struck. If a patient has increased pain when the tuning fork is placed on the bone, such as the lower leg bone or shinbone, the likelihood of a stress fracture is high. Bone scans also are helpful in detecting stress fractures or other difficult-to-detect fractures.

Treatment

Prevention is the most effective way to avoid fractures. Wearing protective gear, such as a helmet, or

KEY TERMS

Bone scan—A diagnostic procedure in which radioactive tracer is injected and images are taken of specific areas or the entire skeleton.

Osteoporosis—Literally meaning "porous bones," this condition occurs when bones lose an excessive amount of their protein and mineral content, particularly calcium. Over time, bone mass and strength are reduced leading to the increased risk of fractures.

Paget's disease—A common disease of the bone of unknown cause usually affecting middle-aged and elderly people, characterized by excessive bone destruction and unorganized bone repair.

Rickets—A condition caused by the deficiency of vitamin D, calcium, and usually phosphorus, seen primarily in infancy and childhood, and characterized by abnormal bone formation.

using protective equipment, such as safety gear, while playing sports may greatly reduce the risk of a fracture.

A daily multivitamin and mineral supplement (for instance, containing calcium, **magnesium**, **boron**, strontium) is recommended to help build and maintain a healthy, resilient skeleton. These, together with an adequate protein intake, will also help rebuild the bone and surrounding tissue. Some physical therapists use electro-stimulation over a fractured site to promote and expedite healing. Chinese traditional medicine seeks to reconnect the qi through the meridian lines along the line of a fracture. **Homeopathy** can enhance the body's healing process. A particularly useful homeopathic remedy for soft tissue is *Arnica* 12c, taken every 10 minutes for the first two hours after injury, and then once every eight hours for two to three days. *Symphytum officinalis* is also a good remedy to help heal the fractured bone.

Calming herbs are often useful for relief of pain and tension. Cups of **chamomile** (*Matricaria recutitca*), **catnip** (*Nepeta cataria*), or **lemon balm** (*Melissa officinalis*) tea can be given freely for a calming effect. Fifteen drops of **skullcap** (*Scutellaria lateriflora*), **St. John's wort** (*Hypericum perforatum*), or **valerian** (*Valeriana officinalis*) tincture can be given every half hour as needed. A tea to encourage the bone tissue to knit and heal can be made by mixing together one ounce each of **comfrey** leaves (*Symphytum officinale*), nettles (*Urtica dioica*), and oatstraw (*Avena sativa*), plus half an ounce each of **horsetail**, skullcap, and **marsh mallow** root (*Althaea officinalis*). One quarter ounce each of **fennel** seeds (*Foeniculum officinalis*) and **peppermint** leaves (*Mentha piperita*) should also be added. A strong tea should be made of one ounce of the mixture in one quart of boiling water, which should steep for at least a half hour. The dosage is two cups taken daily. Frequent soaks or compresses with comfrey root in the water is recommended if there is no broken skin. *Arnica montana*, *Calendula officinalis*, St. John's wort, or comfrey salves or ointments can improve healing when applied externally, as well.

After initial treatments, the application of contrast **hydrotherapy** to a hand or foot below the area of the fracture can be used to assist healing by enhancing circulation. Contrast hydrotherapy uses an alternating series of hot and cold water applications. Either compresses or basins of water may be used. First, hot compress is applied for three minutes. It is followed by cold water for 30 seconds. These applications are repeated three times each, ending with the cold water.

Allopathic treatment

Broken bones need to be treated as soon as possible by a physician. Temporary measures include applying ice packs to injured areas, and the use of aspirin or nonsteroidal anti-inflammatories (NSAIDS) to reduce pain and swelling. Initial first aid for a fracture may include splinting, control of blood loss, and monitoring of vital signs, such as breathing and circulation. Medical treatment will depend on the location of the fracture, its type and severity, and the individual's age and general health status. If an open fracture is accompanied by serious soft tissue injury, it may be necessary to control bleeding and the shock that can accompany it.

Immobilization of the fracture site can be done internally or externally. The primary goal of immobilization is to maintain the realignment of the bone long enough for healing to start and progress. Immobilization by external fixation uses splints, casts, or braces; this may be the primary and only procedure for fracture treatment. Splinting to immobilize a fracture can be done with or without traction. In emergency situations, splinting is a useful form of fracture management, if medical care is not immediately available. It should be done without causing additional pain and without moving the bone segments. In a clinical environment, plaster of Paris casts are used for immobilization. Braces are useful as they often allow movement above and below the fracture site.

Open reduction is surgery that is usually performed by an orthopedist. It allows the surgeon to

examine and correct soft tissue damage while the bones are being repositioned into their normal alignment. Internal fixation devices, such as metal screws, plates, and pins, hold the bones in place as they heal. Fragments are often held together with metal rods. The physician may or may not elect to remove these devices when healing is complete. Open reduction is most often used for open, severe, or comminuted fractures. Fractures with little or no displacement of the bones do not usually require such surgery.

Closed reduction refers to realigning the bones without using surgery. It is accomplished by manually adjusting the bones or using traction, and often requires the use of an anesthetic. Traction is a form of closed reduction that works by applying a steady force to the bones, pulling on them with weights until the proper alignment is achieved. The traction device can also be used to immobilize the affected area while the bone heals. Since traction restricts movement, this treatment means that the patient will be confined to bed rest for an extended period of time.

In external fixation, pins or screws are attached to the bone directly above and below the site of the fracture. They are then connected to a device of metal bars fixed over the skin. These act as a frame, keeping the bones aligned so they can heal properly. With any type of treatment for a fracture, muscle and joint strength and flexibility should be maintained through proper exercises done as the bone tissue heals.

Healing time for fractures varies from person to person, with the elderly generally needing more time to heal completely. Recovery is complete when there is no bone motion at the fracture site, and x rays indicate complete healing.

Expected results

Fractures can normally be cured with proper first aid and after care. Proper realignment of the bones is much more difficult if the break has occurred more than six hours in the past. If broken bones are not properly treated, deformities may occur as the bones heal, and strength and flexibility may be affected.

Prevention

Adequate calcium intake, as well as intakes of other minerals like magnesium, boron, strontium, and others, is necessary for strong bones and can help decrease the risk of fractures. Foods rich in calcium should be eaten. These include fish, dairy products, sardines, broccoli, enriched soymilk, seaweed, tahini, and other sesame seed foods, nuts, molasses, and dark leafy green vegetables. Calcium supplements may be also be useful; however, those with bone meal or oyster shell have been found to often contain toxic heavy metals. Adequate stores of **vitamin D** are needed to help use calcium, therefore, some time should be spent in the sun, as this will activate vitamin D and help decrease fractures. Safety measures to avoid accidents that may bring on fractures include wearing seat belts and protective sports gear, when appropriate. Estrogen replacement combined with exercise and weight training for women past the age of 50 has been shown to help prevent osteoporosis and the fractures that may result from this condition.

Patience Paradox

French green clay

Description

French green clay is a substance that is used for external cosmetic treatments as well as some internal applications by practitioners of alternative medicine. It was used in ancient Egypt, Greece, and Rome to treat a variety of skin problems and digestive disorders.

From the standpoint of mineralogy, French green clay belongs to a subcategory of clay minerals known as illite clays, the other two major groups being kaolinite and smectite clays. Clay minerals in general are important because they make up about 40% of such common rocks as shale, and they are the main components of soil. Illite clays are usually formed by weathering or by changes produced in aluminum-rich minerals by heat and acidic ground water. They often occur intermixed with kaolinite clays—which are typically used in the ceramics industry. Illite clays have been used successfully by environmental managers to

Mixing French green clay with water. The clay's green color comes from a combination of iron oxides and decomposed plant matter, mostly kelp seaweed and other algae. *(BSIP/Phototake, Reproduced by permission.)*

remove such heavy metals as lead, cadmium, and **chromium** from industrial wastewater.

French green clay takes its name from the fact that rock quarries located in southern France enjoyed a virtual monopoly on its production until similar deposits of illite clays were identified in China, Montana, and Wyoming. The clay's green color comes from a combination of **iron** oxides and decomposed plant matter, mostly **kelp** seaweed and other algae. Grey-green clays are considered less valuable than those with a brighter color. The other components of French green clay include a mineral known as montmorillonite, as well as **dolomite**, **magnesium**, **calcium**, **potassium**, **manganese**, **phosphorus**, **zinc**, aluminum, silicon, **copper**, **selenium**, and cobalt.

French green clay is prepared for the commercial market by a process of sun-drying and crushing. After the clay has been mined, it is spread in the sun to remove excess water. It is then ground by large hydraulic crushers and micronized, or finely pulverized. The last stage in the process is a final period of sun-drying to remove the last traces of water. French green clay is available in a dry powdered form for a variety of uses as well as in premixed soaps, scrubs, facial powders, and masks for cosmetic purposes. Prices for an eight-ounce jar of powdered clay range between $4.50 and $11.00 in health food stores. Soaps made with French green clay are priced at about $4.50 a bar.

General use

External

French green clay is most commonly used in the United States and Canada for cosmetic purposes, as distinct from medicinal treatments. It is regarded as a useful treatment for stimulating the skin and removing impurities from the epidermis (outermost layer of skin cells). The clay works by adsorbing impurities from the skin cells, by causing dead cells to slough off, and by stimulating the flow of blood to the epidermis. As the clay dries on the skin, it causes the pores to tighten and the skin to feel firm.

Other external uses for French green clay include poultices to treat arthritis, sore muscles, and **sprains**;

KEY TERMS

Adsorption—A process in which an extremely thin layer of one substance (liquid, gas, or solid) forms on the surface of another substance. French green clay works as a cosmetic treatment by adsorbing toxic substances from the skin.

Epidermis—The outermost layer of skin cells.

Illite—A family of hydrous potassium aluminosilicate clays, characterized by a three-layer structure and a gray, light green, or yellow-brown color. The name is derived from Illinois, where these clays were first classified in 1937. French green clay belongs to this group of clays.

Poultice—A soft cloth filled with a warm moist mass of grains, herbs, or other medications applied to sores or injured parts of the body.

ready-to-use pastes for application to **cuts**, **bruises**, insect **bites**, **stings**, and minor **burns**; and mineral baths for **stress** relief. Some practitioners maintain that the plant matter in French green clay has anti-inflammatory as well as antiseptic or bactericidal properties. It is interesting that a group of Italian researchers reported in 2002 that French green clay powder is as effective as salicylic sugar powder in preventing infection of the umbilical stump in newborns. The clay powder was found to be superior to powders containing **colloidal silver**, antibiotics, or fuchsine.

Internal

Internal uses of French green clay are more popular in Europe than in North America, although some American alternative healers recommend drinking or gargling with solutions of French green clay to cleanse the digestive tract, treat **nausea** or other gastric disorders, ease menstrual cramps, or relieve sore throats. It is claimed that French green clay absorbs toxins from the stomach and intestines as well as neutralizing radioactivity in the body. A French naturopath states that the copper in the clay fights **infections**, the cobalt helps to prevent **anemia**, the selenium aids liver function and slows down the **aging** process, and the other minerals restore the body's overall equilibrium.

Preparations

External

Facial masks: Commercial prepackaged clay masks are generally spread on the face directly from the jar or tube, care being taken to avoid the eye area. After the clay dries—usually about 10–15 minutes—the mask is washed off with warm running water. To make a facial mask from powdered clay, combine 1/2 to 1 tbsp of the powder with 1–2 tbsp of water and apply to the skin; rinse with warm water after 10 minutes. Some users add a few drops of **aloe** vera gel to the clay mixture. A recipe for a facial mask for oily skin consists of mixing 1 tbsp of powdered clay with five drops of **jojoba oil**.

A recipe for a "gourmet spa facial mask" calls for mixing 1/4-cup of French green clay powder with 1/4-cup water. After the clay and water have been well blended, 2 tbsp of honey and 1/4-cup of mashed banana or avocado are added to the mixture. The mask is applied to the face, allowed to remain for 10 minutes, and rinsed off with warm water.

Deodorizing foot treatment: A half-cup of powdered French green clay is mixed with 1/2-cup of water and 2–3 drops of tea tree essential oil. The mixture is applied to the feet, covered loosely with plastic wrap, and rinsed off after 15 minutes with cool water. The feet may then be rubbed with a moisturizing cream.

Poultice: One poultice recipe calls for mixing several tablespoons of powdered clay with enough water to form a thick paste and allowing it to stand in a glass bowl for two hours. The paste is then applied in a layer about 1/4-in thick to a piece of gauze. The poultice is applied to the injured area with the gauze uppermost and held in place with adhesive tape. It can be left in place as long as two hours, but the clay should not be allowed to dry. Up to six drops of essential oil of **lavender**, Roman **chamomile**, **ginger**, or **rosemary** may be added if desired. Poultices should not be reused but discarded after use.

Mineral bath: A half-cup of powdered French green clay can be added to a tub of warm water to soothe sunburned or irritated skin, or relieve arthritis or muscle pains.

Internal

To cleanse the digestive system, mix 1 tsp of powdered clay in an 8–10-oz glass of mineral water and allow to stand overnight. The mixture may be taken the next morning either as the clear liquid that has risen to the top or after stirring to recombine the clay and water. It is to be taken every morning for 21 days. The treatment should not be repeated until a week after the last dose. The clay mixture can also be used to relieve menstrual cramps; it is taken each morning during the first three weeks of the woman's cycle. After the flow begins, a warm clay poultice can be applied to the abdomen in the morning and evening.

A recipe for a **sore throat** gargle consists of 1–2 tsp of clay added to a glass of salt water with 1–2 drops of essential oil of rosemary or lavender. The gargle can be used several times a day until the symptoms are relieved.

A European regimen for treating **hemorrhoids** consists of drinking three glasses of powdered clay in water each day for three weeks, alternating with three weeks without the mixture over a total period of three months. The clay-and-mineral water mixture can also be combined with tinctures of Indian vine and **witch hazel**. In addition, poultices made with green clay can be applied to the affected areas in the morning, followed by a cold bath. The poultices may also be applied at night.

Precautions

Alternative healers state that French green clay should never be mixed with metal spoons or stored in metal containers; the only materials that should be used in preparation or storage are wooden spoons or glass stirrers, and either glass or ceramic containers. It is thought that the clay loses its beneficial qualities through contact with metal. This belief has some scientific basis in the fact that illite clays have been found to be highly effective in removing heavy metals in the wastewater produced by various industries.

External

As a rule, French green clay masks should be used only once a week because the clay tends to dry the skin. In addition, cosmetics containing French green clay are not recommended for naturally dry or sensitive skins, as the mineral content of the clay is an irritant. Soaps made with French green clay should be used only for oily skin.

Internal

French green clay may cause **constipation** when taken internally. Some practitioners recommend drinking only the water without the clay at the bottom of the glass in the morning for this reason.

Side effects

French green clay may cause skin **rashes** or patches of dry flaky skin when used on the face. It may cause constipation when taken internally. No side effects from mineral baths or poultices have been reported.

A group of American toxicologists reported in 2003 that illite clays as a group appear to be safe for short-term internal use in humans as well as external cosmetic applications. There have, however, been isolated reports of lung damage caused in workers exposed to particles of montmorillonite—one of the major components of French green clay—in spray paints and primers.

Interactions

No interactions with prescription drugs or herbal remedies have been reported for French green clay as of 2008. However, because of the adsorptive qualities of French green clay, it may interfere with absorption of medications.

Fritillaria

Description

Fritillaria is the processed bulb of *Fritillaria cirrhosa*, a flowering plant in the Liliaceae family. A perennial temperate herb, it grows in mountain slope and sub-alpine meadows, usually on open, stony, and moist hillsides. In the West, fritillaria is most commonly regarded as an ornamental garden plant. By contrast, it is traditionally valued as an herbal remedy in Nepal and China, where it grows in the Gansu, Qinghai, Sichuan, Xizang, and Yunnan provinces. Two related species, *F. thunbergii* and *F. hupehensis*, are also used medicinally, and in some regions, *F. unibracteata, F. przewalski,* and *F. delavayi* are used as botanical substitutes.

In **traditional Chinese medicine**, fritillaria is called *chuan bei mu,* which translates as "Shell mother from Sichuan." English common names include fritillary, tendrilled fritillary bulb, and Sichuan fritillary bulb. Its pharmaceutical name, used to distinguish it as a medicine, is Bulbus Fritillariae Cirrhosae, and it is one of more than 500 plants recognized as official drugs in traditional Chinese medicine.

General use

Practitioners of Chinese medicine believe that fritillaria affects the heart and lung meridians, or energy pathways in the body, and use it primarily to treat various lung conditions, including **asthma**, **bronchitis**, **tuberculosis**, and coughs of any type. In the traditional Chinese medical system, the white color of fritillaria is thought to indicate its usefulness for treating ailments of the lungs, which are associated with the color white. In the categories of Chinese herbal medicine, fritillaria is classified as being bitter, sweet, and mildly cold.

Fritillaria is used for many types of **cough**, particularly chronic cough, cough associated with difficult expectoration, and cough with blood-streaked sputum. Chinese practitioners prescribe it to moisten dry mucous membranes, resolve phlegm, and control coughing. It is thought to be most effective for coughs accompanied by reduced appetite and a stifling sensation in the chest and upper abdomen, symptoms that indicate suppressed qi, or vital energy.

Fritillaria's secondary use is as a lymphatic decongestant to reduce swellings, nodules, fibrocystic breasts, goiter, and swollen lymph glands. In China, it also is used for thyroid and **lung cancer**.

Research on *F. cirrhosa* and its botanical relatives has generally been conducted in China and has focused on pharmacological investigation. These studies show that *F. cirrhosa* and other related species contain compounds that have antitussive and expectorant activity because they inhibit contraction of bronchial smooth muscle and decrease secretion of mucus. Compounds responsible for this activity, as defined in Western chemistry, include several bioactive isosteroidal alkaloids (verticine, verticinone, isoverticine, imperialine, hupehenine, ebeiedine, ebeienine, and ebeiedinone) and two nucleosides (thymidine and adenosine). The discovery of a new diterpenoid ester in fritillaria was reported in 2002.

Animal research has also demonstrated central-nervous-system inhibition, including a prolonged decrease in blood pressure, stimulation of the heart muscle, and dysfunction of breathing. In addition, a study conducted by scientists in Korea in 2007 tested *F. cirrhosa* in a model of asthma in mice. They found that it inhibits airway inflammation by several methods including the suppression of certain types of proteins/peptides called Th2 cytokines, an antibody known as immunoglobulin E (IgE), and the production of histamine.

Preparations

Fritillaria is not generally available in American health food stores, but processed forms are available at Chinese pharmacies and Asian groceries. Consumers can purchase fritillaria-containing Chinese patent medicines in pill, capsule, powder, and syrup form over the Internet. As medicine, fritillaria comes in four categories, based on shape and the location in which it was grown: *song-pei, lu-pei, ching-pei,* and *ming-pei*. Because the raw bulb is toxic, all medicinal forms are processed. Good-quality processed powder is white and has a fine consistency. Small, white, lobed bulbs that have been boiled or steamed and dried also may be available.

The standard dose ranges from 3–12 g daily as a decoction (strong tea) or 1–1.5 g as powder. Pills in equivalent doses are also available, and the herb also may be applied externally as either a powder or cream.

Practitioners of Chinese medicine commonly combine fritillaria in patent formulas along with other Chinese herbs such as ma huang (*Ephedra sinica*) and ballanflower (*Platycodon grandiflorum*). It is also found in many cough medicine formulas in liquid form. The following are the major herbs with which

KEY TERMS

Alkaloids—A diverse group of nitrogen-containing substances that typically taste bitter. Most alkaloids are toxic, although a minority of them are medicinally beneficial.

Cold—In Chinese pathology, the term defines a condition that has insufficient warmth, either objective (hypothermia) or subjective (feeling cold).

Decoction—A strong tea brewed for twenty to thirty minutes; generally used for woodier herbs.

Meridians—Energetic pathways inside the body through which qi flows.

Nucleosides—Any of various compounds consisting of a sugar and a purine or pyrimidine base, especially a compound obtained by hydrolysis of a nucleic acid.

Patent formulas—Chinese herbal formulas that were patented centuries ago and are believed to be proven over centuries of use and study.

Qi—The Chinese medical term for physiological energy or more generally for the life force.

Sputum—Matter coughed up from the respiratory tract, including saliva, mucus, or phlegm.

it is combined and the symptoms for which the combinations are prescribed:

- bitter apricot kernel (*Prunus armeniaca; xing ren*) for cough and wheezing with copious sputum
- loquat leaf (*Eriobotrya japonica; pi pa ye*), dwarf lilyturf root (*Ophiopogon japonicus; mai men dong*) and Solomon's seal root (*Polygonatum odoratum; yu zhu*) for chronic cough with fatigue, irritability, and lack of appetite
- thin-leaf milkwort root (*Polygala tenuifolia; yuan zhi*), hoelen fungus (*Poria cocos; fu ling*), and snakegourd fruit (*Trichosanthes* spp.; *gua lou*) for painful obstruction of the chest with palpitations and insomnia
- Zhejiang fritillary bulb (*F. thunbergii; zhe bei mu*) for scrofula (a form of tuberculosis affecting the lymph nodes) and abscess

Precautions

The unprocessed bulb of fritillaria is toxic, and commercial sources are generally processed. Pregnant women should not use fritillaria unless under the advice of a practitioner trained in the use of the herb. Fritillaria should never be given to children. It is also contraindicated for patients with digestive weakness.

Australian authorities recommend that products containing *F. cirrhosa* include the following label caution: "Warning: Do not exceed the stated dose." Canadian regulations list *F. thunbergii*, a close relative of *F. cirrhosa*, as unacceptable for inclusion in nonmedicinal oral products.

A general precaution to observe when using any Chinese patent medicine is to purchase only well-known brands recommended by a practitioner of traditional Chinese medicine. Cases have been reported of incorrect labeling, contamination with heavy metals, and substitution of Western pharmaceuticals for the Chinese ingredients. Any of these occurrences can present a serious health hazard.

Side effects

Side effects from fritillaria extracts used in Chinese patent medicines are rare, but this is partly because fritillaria is usually a minor ingredient in these formulae, often only 10% of the formula by weight. Even in medicines that list fritillaria as a major ingredient, it is never more than 28% of the compound. Tests of fritillaria extract in human subjects reported no side effects when the extract was taken by mouth. On the other hand, high-dosage intravenous injections of alkaloids isolated from fritillaria produced pupil dilation, **tremor**, slowing of the heart rate, and lowered blood pressure in human subjects.

Interactions

No interactions with standard pharmaceuticals have been described in the literature, but the absence of reported interactions may again be due to the fact that fritillaria extract is not the sole ingredient in any Chinese medicine, and in fact, is often a minor ingredient.

Tradition dictates that fritillaria not be combined with **aconite** root (*wu tou*) or *qin jiao (Gentiana macrophylla)*.

Frostbite and frostnip

Definition

Frostbite is localized tissue injury that occurs because of exposure to freezing or near freezing temperatures. Frostnip is a milder cold injury that does not cause tissue loss.

Description

In North America, frostbite is largely confined to Alaska, Canada, and the northern states. In recent years, there has been a substantial decline in the number of cases. This is probably for several reasons, including better winter clothing and footwear and greater public understanding of how to avoid cold-weather dangers. At the same time, the nature of the at-risk population has changed. Rising numbers of homeless people have made frostbite an urban as well as a rural public health concern. The growing popularity of outdoor winter activities has also expanded the at-risk population.

Frostbite on hand. *(Southern Illinois University / Photo Researchers, Inc.)*

Causes and symptoms

Frostbite

Skin exposed to temperatures a little below the freezing mark can take hours to freeze, but very cold skin can freeze in minutes or seconds. Air temperature, wind speed, and moisture all affect how cold the skin becomes. A strong wind can lower skin temperature considerably by dispersing the thin protective layer of warm air that surrounds our bodies. Wet clothing readily draws heat away from the skin. The evaporation of moisture on the skin also produces cooling. For these reasons, wet skin or clothing on a windy day can lead to frostbite even if the air temperature is above the freezing mark.

The extent of permanent injury, however, is determined more by the length of time the skin is frozen than by how cold the skin and the underlying tissues become. Thus, homeless people and others whose self-preservation instincts may be clouded by alcohol or psychiatric illness face a greater risk of frostbite-related amputation. They are more likely to stay out in the cold when prudence dictates seeking shelter or medical attention. Alcohol also affects blood circulation in the extremities in a way that can increase the severity of injury, as does **smoking**. A review of 125 Saskatchewan frostbite cases found a tie to alcohol in 46% and to psychiatric illness in 17%. Driving in poor weather can also be dangerous: vehicular failure was a predisposing factor in 15% of the Saskatchewan cases.

Frostbite is classified by degree of injury (first, second, third, or fourth), or simply divided into two types, superficial (corresponding to first- or second-degree

KEY TERMS

Amputation—Surgical removal of an extremity.
Edema—Excess tissue fluid.

injury) and deep (corresponding to third- or fourth-degree injury). Most frostbite injuries affect the feet or hands. The remaining 10% of cases typically involve the ears, nose, cheeks, or penis. Once frostbite sets in, the affected part begins to feel cold and, usually, numb; this is followed by a feeling of clumsiness. The skin turns white or yellowish. Many patients experience severe **pain** in the affected part during rewarming treatment and an intense throbbing pain that arises two or three days later and can last days or weeks. As the skin begins to thaw during treatment, **edema** often occurs, causing swelling in the area. In second- and higher-degree frostbite, **blisters** appear. Third-degree cases produce deep, blood-filled blisters and, during the second week, a hard black eschar (scab). Fourth-degree frostbite penetrates below the skin to the muscles, tendons, nerves, and bones. In severe cases of frostbite, the dead tissue can mummify and drop off. Affected areas are also more prone to infection.

Frostnip

Like frostbite, frostnip is associated with ice crystal formation in the tissues, but no tissue destruction occurs and the crystals dissolve as soon as the skin is warmed. Frostnip affects areas such as the earlobes, cheeks, nose, fingers, and toes. The skin turns pale and numb or tingly until warming begins.

Diagnosis

Frostbite diagnosis relies on a physical examination and may also include conventional radiography (x rays), angiography (x-ray examination of the blood vessels using an injected dye to provide contrast), **thermography** (use of a heat-sensitive device for measuring blood flow), and other techniques for predicting the course of injury and identifying tissue that requires surgical removal. During the initial treatment period, however, severity is difficult to judge. Diagnostic tests only become useful 3-5 days after rewarming, once the blood vessels have stabilized.

Treatment

Mechanical treatment

Frostnipped fingers are helped by blowing warm air on them or holding them under one's armpits. Other frostnipped areas can be covered with warm hands. The injured areas should never be rubbed.

By contrast, emergency medical help should always be sought whenever frostbite is suspected. While waiting for help to arrive, one should, if possible, remove wet or tight clothing and put on dry, loose clothing or wraps. A splint and padding are used to protect the injured area. Rubbing the area with snow or anything else is dangerous. The key to prehospital treatment is to avoid partial thawing and refreezing, which releases more mediators of inflammation and makes the injury substantially worse. For this reason, the affected part must be kept away from heat sources such as campfires and car heaters. Experts advise rewarming in the field only when emergency help will take more than two hours to arrive and refreezing can be prevented.

Because the outcome of a frostbite injury cannot be predicted at first, all hospital treatment follows the same route. Treatment begins by rewarming the affected part for 15-30 minutes in water at a temperature of 104-108°F (40-42.2°C). This rapid rewarming halts ice crystal formation and dilates narrowed blood vessels. **Aloe** vera (which acts against inflammatory mediators) is applied to the affected part, which is then splinted, elevated, and wrapped in a dressing. Milky blisters are debrided (cleaned by removing foreign material), and hemorrhagic (blood-filled) blisters are simply covered with aloe vera.

Hydrotherapy

Alternative practitioners suggest several kinds of treatment to speed recovery from frostbite after leaving the hospital. Bathing the affected part in warm water or using contrast **hydrotherapy** can enhance circulation. Contrast hydrotherapy involves a series of hot and cold water applications. A hot compress (as hot as the patient can stand) is applied to the affected area for three minutes followed by an ice-cold compress for 30 seconds. These applications are repeated three times each, ending with the cold compress. For patients who have been hospitalized with frostbite, hydrotherapy should only be performed after checking with a physician to ensure it is done correctly and does not aggravate the condition.

Homeopathy

Homeopathic *Hypericum* (*Hypericum perforatum*) is recommended when nerve endings are affected (especially in the fingers and toes) and *Arnica* (*Arnica montana*) is prescribed for shock and if there is accompanying blunt trauma to the frostbitten area.

Nutritional supplements

Cayenne pepper (*Capsicum frutescens*) can enhance circulation and relieve pain. Drinking hot **ginger** (*Zingiber officinale*) tea also aids circulation.

Other complementary therapies

Other possible approaches include **acupuncture** to avoid permanent nerve damage and **oxygen therapy**.

Allopathic treatment

In addition to the necessary rewarming and debridement, a **tetanus** shot and antibiotics may be used to prevent infection. The patient is given ibuprofen to combat inflammation. Narcotics are needed in most cases to reduce the excruciating pain that occurs as sensation returns during rewarming. Except when injury is minimal, treatment generally requires a hospital stay of several days, during which hydrotherapy and physical therapy are used to restore the affected part to health. Experts recommend a cautious approach to tissue removal, and advise that 22-45 days must pass before a decision on amputation can safely be made.

Expected results

The rapid rewarming approach to frostbite treatment, pioneered in the 1980s, has proved to be much more effective than older methods in preventing tissue loss and amputation. The extreme, throbbing pain that many frostbite patients endure for days or weeks after rewarming is not the only prolonged symptom of frostbite. During the first weeks or months, people often experience tingling, a burning sensation, or a sensation resembling shocks from an electric current. Other possible consequences of frostbite include changes of skin color, nail deformation or loss, joint stiffness and pain, hyperhidrosis (excessive sweating), and heightened sensitivity to cold. For everyone, a degree of sensory loss lasting at least four years—and sometimes a lifetime—is inevitable.

Prevention

With the appropriate knowledge and precautions, frostbite can be prevented even in the coldest and most challenging environments. Appropriate clothing and footwear are essential. To prevent heat loss and keep the blood circulating properly, clothing should be worn loosely and in layers. Covering the hands, feet, and head is also crucial for preventing heat loss. Outer garments need to be wind and water resistant, and wet clothing and footwear must be replaced as quickly as possible. Alcohol and drugs should be avoided because of their harmful effects on judgment and reasoning. Experts also warn against alcohol use and smoking in the cold because of the circulatory changes they produce. Paying close attention to the weather report before venturing outdoors and avoiding unnecessary risks such as driving in isolated areas during a blizzard are also important.

Fructooligosaccharides

Description

Fructooligosaccharides (FOS) are a type of non-digestible oligosaccharide, a short-chain polysaccharide (sugar molecule or type of carbohydrate).

FOS are found naturally in various fruits, vegetables, and grains, including bananas, tomatoes, onions, asparagus, leeks, **garlic**, edible burdock, wheat, rye and barley. FOS are also found in concentrated amounts in **chicory** root and artichokes, particularly the tuber of the Jerusalem **artichoke**. The majority of FOS products are commercially made from sucrose as

a starting carbohydrate material, and use a food-grade fungal enzyme called fructosyltransferase to make the FOS from sucrose. Most of the commercially derived FOS products come from chicory root (*Cichorium intybus)*, which contains significant quantities of inulin, a fiber in many fruits and vegetables.

Both FOS and inulin are recognized as natural food ingredients (not additives) in most European countries and have been labeled generally regarded as safe by the U.S. Federal Drug Administration (FDA). FOS are also considered functional foods, defined by the International Food Information Council as dietary components that provide a health benefit beyond basic **nutrition**. FOS are categorized as prebiotics, non-digestible food ingredients that escape digestion by passing through the stomach into the intestines, where they ferment and selectively stimulate the growth and/or activity of certain colonic bacteria. When FOS are consumed, they aid digestion by encouraging the growth of healthy intestinal microflora (**probiotics** or beneficial bacteria known as bifidobacteria or bifidus), such as *bifidobacteria* and *lactobacilli*. FOS are completely fermented in the colon by certain components of the microflora, so they are not excreted in feces.

Increasing beneficial bacteria in the digestive tract promotes gastrointestinal health, enhancing the digestion and absorption of nutrients and boosting the immune system by reducing the activity of potentially harmful or cancer-promoting bacterial enzymes, such as *E. coli,* clostridia, and coliforms. FOS aid in the synthesis of vitamins B_2 (**riboflavin**), B_3 (**niacin**), B_6 (pyridoxine), **folic acid**, and **biotin** by boosting the bacteria's ability to synthesize these key vitamins. FOS also stimulate the production of lactate and short-chain fatty acids, especially butyrate.

In 2008 research was ongoing to determine the function of prebiotics on the metabolism of ingested and existing microflora in the colon. Studies were also underway to determine how prebiotics affect certain physiological functions such as bowel function, and how they alter certain diseases or reduce the risk of diseases. In addition, labeling terminology, including product health claims, were still being determined for products containing FOS by the FDA under the Nutrition Labeling and Health Education Act of 1995.

General use

FOS have two general uses, as artificial sweeteners and as prebiotics. Because FOS are non-digestible, they provide almost no calories and are used in many foods as artificial sweeteners. They have about half the sweetness of sugar and provide bulk and flavor to certain dairy products, baked goods, and beverages.

Case reports from both animal and human studies have shown a wide variety of health benefits associated with FOS supplementation, including reduced risk of **diarrhea**, **osteoporosis**, **bladder cancer**, and colon **cancer**; improved management for inflammatory bowel diseases, including **Crohn's disease**; lowered total **cholesterol** and LDL cholesterol levels; as well as treatment for lactose intolerance, bacterial vaginosis, vaginal candidiasis (**yeast infection**), **allergies**, and diarrhea associated with antibiotic use. As more data from human trials continue to be published about the beneficial effects of FOS supplementation, scientific evidence will be available to support health risk reduction claims.

Several studies indicate FOS are especially beneficial to infants, reducing the incidence of diarrhea and the risk of infection, including upper respiratory tract **infections**. One study showed a decreased incidence of clinical **eczema** in infants. A November 2007 double-blind, placebo-controlled study published in the *Journal of Nutrition* demonstrated the immune-protective properties of long-chain FOS supplementation in formula-fed infants during the first six months of life. The health benefits of FOS supplementation in this study were comparable to human milk oligosaccharides, indicating the potential for preventing infections and reducing allergies. More research was needed to determine the role of prebiotic supplementation of infant formula for the prevention of allergies and food hypersensitivities.

FOS supplementation also appears to benefit older adults. Results from a December 2007 study published in the *Nutrition Journal* showed that dietary FOS significantly increased fecal bifidobacteria (beneficial bacteria) in adults aged 69 and older, which in turn stimulated the immune system and intestinal immunoglobulin A in the small intestine and colon.

Preparations

Commercial FOS products are available as bulk powder or in capsule form. Preparations may be composed of single FOS components or mixtures of FOS and other oligosaccharides. FOS-containing products include inulin-type fructans, inulin, and oligofructose.

The appropriate doses and mixtures of FOS and oligosaccharides to yield maximum positive health benefits were unknown as of 2008, but studies had shown that a well-tolerated, optimal dosage is 10 g of FOS supplement per day to yield gastrointestinal benefits. A dosage of less than 3 g per day did not appear to increase beneficial colonic bacteria.

KEY TERMS

Inulin—A carbohydrate belonging to a class of compounds known as fructans. Inulin fiber is resistant to digestion in the upper gastrointestional tract, so it reaches the large intestine essentially intact.

Microflora—Beneficial bacteria in the intestines. Microflora reinforce the barrier function of the intestinal mucosa to help prevent the attachment of pathogenic microorganisms and the entry of allergens.

Oligosaccharide—A carbohydrate consisting of three to six units of simple sugars (monosaccharides). A large number of oligosaccharides have been prepared by partially breaking down more complex carbohydrates (polysaccharides).

Polysaccharide—A complex carbohydrate that characterizes most forms of carbohydrates.

Prebiotics—Non-digestible food ingredients that pass through the stomach into the intestines, where they selectively stimulate the growth and/or activity of healthy colonic bacteria.

Probiotics—Live microorganisms or bacteria that, when administered in adequate amounts, confer a health benefit on the host.

Precautions

FOS dietary supplements are generally safe when taken according to proper dosing guidelines. FOS supplementation may not be appropriate for people who have severely weakened immune systems due to disease or cancer treatments, as they can develop serious infections, including bacterial blood infections. People who have recently had bowel surgery, have intestinal damage, or have **inflammatory bowel disease** should not take FOS supplements without first consulting their physician. There is a rare risk of heart valve infections, particularly in people who have artificial heart valves, so patients with heart valve disease should consult their doctor before taking FOS supplements.

Studies have been conducted in pregnant women and infants, and no adverse effects related to fetal development during **pregnancy** or to breastfed infants have been reported.

Side effects

Severe, adverse or toxic effects of FOS supplementation have not been published in the research as of 2008. Ingesting products containing FOS may result in mild gastrointestinal discomfort, including excess **gas**, abdominal cramps, and bloating, which typically subside within two weeks after initiating therapy. Symptoms are dependant on the dosage and appear to be more prevalent with higher doses. To minimize side effects, practitioners recommend starting with a low dose of FOS and increasing it gradually until the desired maximum dose is achieved. People who are sensitive to lactose may develop abdominal discomfort from dairy products containing FOS.

Interactions

Limited research has shown that alcohol interferes with the action of FOS, so practitioners recommend that alcohol be avoided while taking FOS supplements. Some studies have shown that antibiotics damage bifidobacteria, so FOS should be taken two to three hours after antibiotic doses. Other drug interactions have not been determined, as most supplements, including FOS, have not been thoroughly tested for interactions with other herbs, supplements, drugs, or food.

Fungal infections

Definition

Fungi are types of parasitic plants that include molds, mildew, and yeast. A fungal infection is an inflammatory condition in which fungi multiply and invade the skin, the digestive tract, the genitals, and other body tissues, particularly the lungs and liver. Fungal **infections** of the skin are often called ringworm or tinea.

Description

Microscopic fungi, which are called dermatophytes, often live exclusively on such dead body tissues as hair, the outer layer of the skin, and the nails. The fungus grows best in moist, damp, dark places with poor ventilation and on skin that is irritated, weakened, or continuously moist. Superficial fungal infections include tinea capitis, an infection of the neck and scalp; tinea barbae, also called barber's itch, along the beard area in adult males; tinea corporis on parts of the body, such as the arms, shoulders, or face; tinea cruris, or **jock itch**, involving the groin; tinea pedis, or **athlete's foot**; tinea versicolor; and tinea unguium, or infection of the nails. The term tinea gladiatorum is sometimes used to describe ringworm infections in athletes. Tinea gladiatorum is most common in swimmers, wrestlers, and athletes involved in other contact sports. Fungal infections of the skin and nails are very common in children, but they can affect all age groups.

Systemic fungal infections occur when spores are touched or inhaled, or there is an overgrowth of fungi in or on the body. Such infections are most often a serious problem in individuals with suppressed immune systems. Candidiasis is a rather common fungal infection. When it occurs in the mouth, it is called thrush. Less often, it occurs in the mucous membranes of other parts of the digestive system, or in the vagina, heart valves, urinary tract, eyes, or blood. Other systemic fungal infections include aspergillosis, which mostly affects the lungs and may also spread to the brain and kidneys; blastomycosis, a lung infection that may spread through the bloodstream; coccidioidomycosis, also known as San Joaquin or valley **fever**; mucormycosis, which can develop into a serious life-threatening infection; and histoplasmosis.

Causes and symptoms

Fungi are widespread in the environment, so it is not unusual that a certain amount of fungi and their spores end up being inhaled into the lungs or landing on the skin. Under conditions of moisture, warmth, irritation, or injury, these fungi grow rapidly and may cause illness. Superficial fungal infections may be due to an overgrowth of fungi already present, or the infection may be the result of contact with an infected person or with contaminated surfaces, bed sheets, towels, or clothing. Fungal infections can be spread from one part of the body to another by scratching or touching. Additionally, tinea unguium infections have been linked to the use of methyl methacrylate, a glue used for attaching acrylic fingernails.

Fungal spores are often present in soil and are likely to be inhaled when the soil is dug up or otherwise disturbed. Systemic fungal infections are commonly contracted in this way. In addition, fungi that normally inhabit the intestines, such as *Candida albicans*, may multiply, causing an infection due to an overgrowth of the fungi.

Tinea infections usually cause itchy, red, scaly, ring-shaped patches on the skin that spread easily. Hairs in the area of infection often fall out or break off, and the skin may crack. The skin may also develop a secondary bacterial infection. In tinea unguium, the nails discolor, crack, and thicken. Tinea versicolor may cause pigment changes in the skin that persist for up to a year.

Systemic fungal infections develop slowly. Symptoms often may be nonexistent, or there may be only the feeling of having a cold or the flu. Coughing, a fever, chest **pain**, **chills**, weight loss, and difficulty with breathing may become evident. Additional symptoms depend on the type and site of the infection.

Fungal infections are more common and more severe in people taking antibiotics, corticosteroids, immunosuppressant drugs, and contraceptives. Such is also the case in people with endocrine disorders, immune diseases, and other conditions such as **obesity**, **AIDS**, **tuberculosis**, major **burns**, **leukemia**, and **diabetes mellitus**. Fungal infections often occur due to the use of antibiotic drugs for other conditions because antibiotics kill off the bacteria that normally keep fungi at bay.

Diagnosis

Fungal infections of the skin, hair, and nails often can be diagnosed based on the characteristic

appearance of affected areas. A **potassium** hydroxide (KOH) prep is a simple laboratory test to confirm the diagnosis. The test uses tissue samples treated with a 20% potassium hydroxide solution to detect fungi. Examining the skin with a Wood's ultraviolet lamp is another easy and convenient method to determine the presence of a fungus. Culture and sensitivity testing can be used if a more definitive diagnosis is required. Systemic fungal infections may be initially diagnosed from blood tests. Confirmation is determined by cultures made from sputum, blood, urine, bone marrow, or infected tissue samples.

Treatment

Among the herbs that slow down or halt the growth of fungus are **goldenseal** (*Hydrastis canadensis*), **myrrh** (*Commiphora molmol*), **garlic** (*Allium sativa*), **pau d'arco** (*Tabeebuia impestiginosa*), **turmeric** (*Curcuma longa*), oregano (*Origanum vulgare*), cinnamon (*Cinnamonum zeylanicum*), jewelweed, **sage** (*Salvia officinalis*), *Impatiens aurea*, **yellow dock** (*Rumex crispus*), the lichen known as old man's beard (*Usnea barbata*), **black walnut** husks and bark (*Juglans nigra*), **licorice** (*Glycyrrhiza glabra*), and *Calendula officinalis*. These herbs can be applied to external fungus as infusions, salves, powders, or vinegars. Many of them can also be taken internally as capsules or tinctures. Antifungal herbs can be quite strong and care should be taken that a given remedy is suitable for internal use.

When an infusion is used, the affected area should be washed or soaked in the herbal water for at least 15 minutes twice daily. Store-bought or homemade tea bags can be soaked in water or vinegar for about 10 minutes and then used as a poultice for the same effect. Herbal vinegars make excellent remedies for fungus, as vinegar is in itself antifungal. Special vinegars with such antifungal ingredients as oregano and garlic are often readily available at grocery stores. The vinegar can be applied a few times daily with cotton or compresses. In addition, a bentonite clay dusting powder can be useful for drying out the environment of moist skin in which fungus thrives. It works best when mixed with powdered antifungal herbs such as myrrh or goldenseal. Dusting powder is especially helpful for athlete's foot.

Many herbs high in **essential oils** also have antifungal action, particularly tea tree (*Melaleuca alternifolia*), oregano, **lavender** (*Lavandula officinalis*), *Eucalyptus* spp., rose geranium (*Pelargonium graveolens*), **peppermint** (*Mentha piperita*), **chamomile** (*Matricaria recutita*), and myrrh. Peppermint oil is especially helpful in relieving the **itching** associated with many fungal infections. The simplest way to use **aromatherapy** to fight fungal infections is to add several drops of any single essential oil or combination of oils to bathwater. Essential oil can also be added to mixtures for soaking or compresses. Tea tree is the herb most frequently recommended for the treatment of superficial fungal infections. As with all essential oils, the full-strength oil should be diluted in a carrier. A dilution of **tea tree oil** can be made by adding the essential oil to a carrier oil. This mixture can be applied directly to the site of a skin infection.

A healthy diet should be maintained. Foods that are high in yeast, such as beer and wine, breads, and baked goods should be avoided. Fermented foods and sugary foods, including honey and fruit juices, should also be avoided until symptoms have cleared. Antifungal culinary herbs such as garlic, turmeric, oregano, sage, and cinnamon should be used liberally in foods. Yogurt containing live cultures can be incorporated into the diet to supply needed gut bacteria and help reduce digestive infections such as candidiasis and thrush. *Lactobacillus acidophilus* and *Lactobacillus bulgaricus* can also be taken directly as supplements.

Supplements that can be taken for fungal infections include vitamins A, B complex, C, and E. Caprylic acid, an extract of the coconut plant, is also recommended as an antifungal, as well as **grapefruit seed extract**. **Essential fatty acids**, contained in **evening primrose oil**, fish liver oil, or **flaxseed** oil, can help reduce the inflammation of systemic or superficial fungal infections. A dose of one of these oils is recommended as a daily supplement.

Allopathic treatment

Superficial fungal infections are usually treated with such antifungal creams or sprays as tolnaftate (Aftate or Tinactin), clotrimazole, miconazole nitrate (Micatin products), econazole, ketoconazole, ciclopirox, naftifine, itraconazole, terbinafine hydrochloride, fluconazole, or Whitfield's tincture made of salicylic acid and benzoic acid. If the infection is resistant, a doctor may prescribe an oral antifungal drug such as ketoconazole or griseofulvin. Drugs used for systemic infections include amphotericin B, which is highly toxic and is used for severe or life-threatening infections; the azoles, particularly fluconazole and itraconazole, which have been found to be the least toxic of these medications; and flucytosine alone or in combination with other antifungal medications. Fungal infections that become inflamed may be treated with a combination antifungal/steroid medication. Certain infections may require surgery.

KEY TERMS

Azole—Any member of a group of chemical compounds with five-membered rings containing one or more nitrogen atoms. Several azoles are used as antifungal medications.

Bentonite clay—A green clay of aluminum silicate containing magnesium and trace minerals. The clay can draw out agents of infection.

Dermatophyte—A type of fungus that is parasitic on skin and causes a skin disease.

Tinea—Any of several fungal infections of the skin, especially ringworm.

Expected results

Infections usually respond to treatment within several weeks. However, many fungal infections are resistant to treatment, and it may take an extended time and repeated treatments to effect a cure. Infections may spread, and secondary bacterial infections may develop. Medications for fungal infections are often strong, and their use may cause such undesirable side effects as **headache**, **dizziness**, **nausea**, **vomiting**, or abdominal pain. Fungal infections are usually not serious in otherwise healthy individuals. However, a systemic fungal infection may be severe and life-threatening for those with compromised immune systems.

Prevention

Good personal hygiene should be maintained. In the case of superficial infections, the skin should be kept clean and dry, and care should be taken to avoid contact with other parts of the body. If someone in the household has a superficial fungal infection, bed sheets, towels, floors, shower stalls, and other contact surfaces should be washed with hot water and disinfected after use.

Gallstones

Definition

Gallstones are solid crystal deposits that form in the gallbladder, a pear-shaped organ that stores bile until it is needed to help digest fatty foods. These crystals can migrate to other parts of the digestive tract, causing severe **pain** and life-threatening complications. Gallstones vary in size and chemical structure. They may be as tiny as a grain of sand, or as large as a golf ball.

Description

Gallstones usually develop in adults between the ages of 20 and 50. The risk of developing gallstones increases with age. Young women are up to six times more likely to develop gallstones than men in the same age group. In patients over 50, however, the condition affects men and women with equal frequency. Native Americans develop gallstones more often than any other segment of the population, and Mexican Americans have the second highest incidence of this disease. Gallstones tend to be passed down genetically in families.

Eighty percent of gallstones are composed of **cholesterol**. They are formed when the liver produces more cholesterol than the digestive juices can liquefy. The remaining 20% of gallstones are composed of **calcium** and an orange-yellow waste product called bilirubin, which gives urine its characteristic color and sometimes causes **jaundice**.

People who have gallstones may remain without symptoms for an extended period, especially if the stones remain in the gallbladder. In most cases, medical treatment is only deemed necessary if the individual is experiencing symptoms. When symptoms do appear, it is usually because the stones have left the gallbladder and are stuck somewhere else within the biliary system, blocking the flow of bile. If gallstones remain stuck in the biliary system, there can be damage to the liver, pancreas, or the gallbladder itself.

Gallstones bring on several disorders including:

- Cholelithiasis: Gallstones within the gallbladder itself. Pain is caused by the contractions of the gallbladder around the stone.
- Choledocholithiasis: The presence of gallstones within the common bile duct, which is the passage that empties into the small intestine. Once discovered, common duct stones need to be removed in order to avoid further problems.
- Cholecystitis: A disorder marked by inflammation of the gallbladder. It is usually caused by the passage of a stone from the gallbladder into the cystic duct, which connects the gallbladder to the common bile duct. Cholecystitis causes painful enlargement of the gallbladder and is responsible for 10–25% of all gallbladder surgery.

Causes and symptoms

Gallstones are caused by an alteration in the chemical composition of bile, which is a fluid that helps the body break down and absorb fats. It is widely held that a diet high in fats and processed foods, and low in fiber and whole foods, is a strong contributor to gallstone formation. High levels of estrogen, insulin, or cholesterol can increase a person's risk of developing gallstones. If left untreated, the risk of developing **anemia** is also increased.

Gallbladder attacks usually follow a meal of rich foods, typically high in fat. The attacks often occur in the middle of the night, sometimes waking the patient with such intense pain that the episode ends in a visit to the emergency room. Pain often occurs on the right side of the body. The pain of a gallbladder attack begins in the abdomen and may radiate to the chest, back, or the area between the shoulders. Other symptoms of gallstones include inability to digest fats, low **fever**, **chills**

KEY TERMS

Bile—A bitter, greenish liquid secreted by the liver that aids in the digestion and absorption of fats.

Cholecystectomy—Surgical removal of the gallbladder.

Common bile duct—The passage through which bile travels from the cystic duct to the small intestine.

Lithotripsy—A nonsurgical technique for removing gallstones by breaking them apart with high-frequency sound waves.

and sweating, **nausea** and **vomiting**, **indigestion**, **gas**, belching, and clay-colored bowel movements.

Pregnancy or the use of birth control pills slow down gallbladder activity and increase the risk of gallstones, as do diabetes, **pancreatitis**, and **celiac disease**. This is due to an individual's higher levels of cholesterol, insulin, or estrogen from oral contraceptives. Other factors that may encourage gallstone formation are:

- infection
- anemia
- obesity
- intestinal disorders
- coronary artery disease
- multiple pregnancies
- a high-fat, low-fiber diet
- smoking
- heavy drinking
- rapid weight loss

Diagnosis

When gallstones are suspected, blood tests for liver enzyme levels are often given. The levels are usually elevated when the stone cannot pass through the cystic duct or bile duct. Test results, taken together with symptom history and a physical exam, are simple and relatively inexpensive for diagnosing the presence of gallstones. However, ultrasound is the method of choice for a definite diagnosis. It has a high degree of accuracy, except in diagnosing cholecystitis (a stone in the cystic duct). Cholescintigraphy is an alternative method of diagnosis, in which radioactive dye is injected and photographed as it passes through the biliary system.

Treatment

An allergic reaction to certain foods may contribute to gallbladder attacks. These foods should be identified and removed from the diet, or at least seriously limited. Foods that might possibly bring on allergic reactions include eggs, pork, onions, chicken, milk, coffee, citrus, corn, nuts, and beans.

Other dietary changes may help relieve the symptoms of gallstones. Generally, a vegetarian diet is protective against the formation of gallstones. Recurrent attacks can be diminished by maintaining a healthy weight and a healthy diet.

Choleretic herbs encourage the liver to secrete bile. They help maintain the appropriate chemical composition of bile so that it does not form stones. These herbs include:

- A tincture of dandelion (*Taraxacum officinale*), 2–6 ml once daily.
- Milk thistle seeds (*Sylibum marianum*), a dose equivalent to 70–210 mg of silymarin.
- Artichoke leaves (*Cynara scolymus*), 150 mg three times per day.
- Turmeric (*Curcuma longa*), used as a spice; 150 mg three times per day.

Use of the above herbs cause some possible reactions, such as gas, **diarrhea**, nausea, and indigestion.

Other therapeutic approaches that have been found to be helpful in treating gallstones include **homeopathy**, traditional Chinese herbal medicine, and **acupuncture**. Knowledgeable practitioners should be consulted.

Allopathic treatment

Watchful waiting

One-third of all patients with gallstones never experience a second attack. For this reason, many doctors advise an attitude of "wait and see" after the first episode. Changing the diet or following a sensible weight loss plan may be the only treatments required. A person having only occasional mild gallstone attacks may be able to manage them by using nonprescription forms of acetaminophen, such as Tylenol or Anacin. A doctor should be notified if pain intensifies or lasts for more than three hours; if the fever rises above 101°F (38.3°C); or if the skin or whites of the eyes have a yellowish cast.

Surgery

Surgical removal of the gallbladder, called cholecystectomy, is the most common conventional treatment for recurrent or worsening gallstone attacks. However,

surgery is unecessary in most cases where the gallstones remain without symptoms. Laparoscopic cholecystectomy is the technique most widely used. It has mostly replaced traditional open surgery because of a shorter recovery time, decreased pain, and reduced scarring. However, the open surgery procedure is still used in about 5% of cases because of various complications.

Nonsurgical therapy

If surgery is considered inappropriate, gallstones can be dissolved in 30–40% of patients by taking bile acids in tablet form. Dissolution of gallstones by this method may take many months or years depending on the size. Unfortunately, recurrence of stones is common after cessation of the medication.

Lithotripsy uses high-frequency sound waves directed through the skin to break up the stones. The process can be combined with the use of bile acid tablets. Lithotripsy requires special equipment and is not always readily available.

Direct cholangiography can be used to remove gallstones by contact dissolution. The procedure is used to insert a catheter to inject medication into the gallbladder. Stones are often dissolved within a few hours by this method.

Expected results

Forty percent of all patients with gallstones have "silent gallstones" that do not require treatment. If symptoms develop, then medical intervention may become necessary. Gallstone problems requiring treatment may also develop **infections** that require antibiotics. In rare instances, severe inflammation can cause the gallbladder to burst, causing a potentially fatal situation. The gallbladder is not an organ that is required to retain health. It can be successfully removed, with no recurrence of stones. Fat digestion, however, becomes more difficult after surgery, since the gallbladder is no longer there to store and release bile as needed.

Prevention

It is easier, in general, to prevent gallstones than to reverse the process. The best way to prevent gallstones is to minimize risk factors. Since gallstones seem to develop more often in people who are obese, eating a balanced diet, exercising, and losing weight may help keep gallstones from forming. In addition, a diet high in dietary fiber and low in fats, especially saturated fats, is recommended. Processed foods should be replaced by complex carbohydrates, such as whole grains.

Increased intake of fluids will dilute the bile and inhibit gallstone formation. Six to eight glasses of water should be consumed daily, along with plenty of herbal teas and diluted juices.

Recent studies indicate that consumption of about two tablespoons of olive oil per day, which can be mixed with food, helps reduce cholesterol levels in the bloodstream and the gallbladder. Large amounts of olive oil, taken as a so-called liver flush, should be avoided. This method can **stress** the gallbladder and lead to an emergency situation.

Patience Paradox

Gamma-linoleic acid

Description

Gamma-linoleic acid (GLA) is an omega-6 polyunsaturated fatty acid made in the body from linolenic acid, an essential fatty acid (EFA). GLA is the product

of the body's first biochemical step in the transformation of a major essential fatty acid, linolenic acid (LA), into important prostaglandins. Prostaglandins are essential to the proper functioning of each cell. Every cell's structure in the human body depends on fatty acids formed from GLA.

The amount of GLA found in the seed oils of evening primrose (*Oenothera biennis L.*) is 10%, borage (*Borago officinalis L.*) 17%, and black currant (*Ribes nigrum L.*) 23%.

General use

Evening primrose oil (EPO), very high in GLA, has been used for decades to treat medical conditions. Native American women chewed evening primrose seeds to relieve menstrual problems. Evening primrose was also used by Native Americans and early American settlers from Europe to treat coughs and stomach problems. In the 1800s, the leaves of the plant were used to treat several skin conditions.

EPO was imported to Europe during the 1600s and 1700s, and used to treat **gout**, **rheumatoid arthritis**, headaches, and skin conditions.

In animal studies GLA has been shown to reduce certain inflammations and reduce joint tissue injury. Human studies showed similar findings in its anti-inflammatory effects.

GLA has also been used as a treatment option for a number of conditions, including **alcoholism**, **asthma**, attention deficit/hyperactivity disorder (ADHD), high **cholesterol**, diabetic neuropathy, certain cancers, **eczema** (a skin inflammation), **hypertension** (high blood pressure), **premenstrual syndrome** (PMS), rheumatoid arthritis, and scleroderma (a skin disease).

There is also research data that indicates GLA in combination with other measures may help in treating people with Sjögren's syndrome—a chronic inflammatory disease of the immune system that effects mostly older women.

Other animal studies suggest GLA may enhance **calcium** absorption, helping to reduce calcium loss and osteporosis. **Osteoporosis** is a disease occurring primarily in women after **menopause** in which the bones become very porous, break easily, and heal slowly. It may lead to curvature of the spine after vertebrae collapse.

EPO supplements taken during **pregnancy** may reduce the need for cesarean delivery as studies suggest that EPO may facilitate vaginal delivery when used as a "cervical priming agent."

Among the conditions GLA is most often used for are:

- Rheumatoid arthritis. GLA has been studied for many years for its possible effects in treating arthritis and other inflammatory conditions. GLA has been shown to be most promising in treating people with this crippling condition, due to its anti-inflammatory properties. At least three studies have shown GLA reduces inflammation and joint tissue injury, thereby reducing the pain associated with this condition. In one study, GLA reduced the incidence of tender joints by 36%, and swollen joints by 28%.
- ADHD. Studies suggest that GLA may be helpful (combined with other therapies) for helping to alleviate ADHD symptoms in children.
- Diabetes. Some studies show that GLA can help improve nerve function and help reduce peripheral neuropathy, which causes numbness, tingling, pain, or burning in the feet, legs, and toes and hands, in diabetics. Recent studies have confirmed evening primrose oil as beneficial in the treatment of distal diabetic polyneuropathy, a condition involving multiple nerves.
- High cholesterol. Research indicates that high doses of GLA may improve blood lipid levels in people with high cholesterol. Studies with laboratory animals in 1997 demonstrated the cholesterol-lowering effects of EPO. In one study, rabbits whose diet was supplemented with 15% EPO showed a total cholesterol reduction of 25%. In a 13-week study with rats, EPO dietary supplements of 10–20%, produced lower levels of liver cholesterol than in rats on the same diet, but supplemented with palm oil, soybean oil, sunflower oil, or high-oleic safflower oil.
- Skin conditions. A number of studies have been done regarding GLA and eczema with contradicting results. Several studies showed GLA relieved the symptoms such as itching, redness, and scaling of the skin, to varying degrees. It has also been shown to be helpful in reducing the symptoms of scleroderma and skin inflammations, such as dermatitis.
- Cancer. In vitro or test tube studies have shown GLA has potential to suppress tumor growth and metastasis, the spreading of cancer from the original site to other parts of the body. In one small study, combining vitamin C with the GLA supplement doubled the survival time for 11 patients with liver cancer. GLA has also shown promising results as a cancer therapy when combined with the anticancer drugs tamoxifen and paclitaxol. Research into its effects on cancer are in the earliest stages and GLA cannot

KEY TERMS

Attention deficit/hyperactivity disorder (ADHD)—A condition, occurring mainly in children, characterized by hyperactivity, inability to concentrate, and impulsive or inappropriate behavior.

Corticosteroids—Drugs used to treat inflammation.

Dermatitis—Inflammation of the skin resulting in redness, swelling, itching, or blistering.

Eczema—An inflammation of the skin characterized by redness, itching, and scaly or crusty patches.

Eicosapeniaenoic acid—A type of acid derived from gamma-linoleic acid.

Essential fatty acids—A group of necessary fats that the human body cannot produce on its own and must be obtained through diet.

Femur—The main bone in the human thigh and the strongest bone in the body.

Gout—A painful disease, mainly of the toes and feet, that causes swollen joints.

Hypertension—High blood pressure, which if untreated, can lead to heart disease and stroke.

Lipids—A group of organic compounds consisting of fats, oils, and related substances that, along with proteins and carbohydrates, are the structural components of living cells.

Lumbar vertebrae—Five bones in the lower spine.

Metastasis—The spreading of cancer from the original site to other parts of the body.

Nonsteroidal anti-inflammatory drugs (NSAIDS)—A class of drugs used to treat inflammation and pain.

Omega-6 fatty acids—A group of essential fatty acids that the humans body cannot produce on its own and must be obtained through diet.

Osteoporosis—A disease occurring most commonly in women after menopause in which the bones become very porous, break easily, and heal slowly. It may lead to curvature of the spine after vertebrae collapse.

Paclitaxol—A drug used to treat some forms of cancer.

Peripheral neuropathy—A nerve disease associated with diabetes that causes numbness, tingling, pain, or burning in the feet, legs, and toes.

Polyunsaturated—A group of fats that are less likely to be converted into cholesterol in the body than other fats.

Premenstrual syndrome (PMS)—A group of symptoms, including nervous tension, irritability, tender breasts, and headache, experienced by some women in the days before menstruation caused by changes in hormone levels.

Prostaglandin—An unsaturated fatty acid in humans that helps to control smooth muscle contraction, blood pressure, inflammation, and body temperature.

Rheumatoid arthritis—Inflammation of joints that causes stiffness and damage to joints.

Scleroderma—A skin disease.

Sjögren's syndrome—A chronic inflammatory disease that effects mostly older women, causing dry eyes and mouth.

Tamoxifen—A drug used to treat cancer.

Triglycerides—A chemical compound in many of the fats and oils of animal and vegetable tissues and, like cholesterol, can have an adverse effect on human health in excessive amounts.

Vasodilatation—A widening of the blood vessels.

be said to prevent or cure any type of cancer. However, it has been reported recently that GLA supplementation may restore normal prostaglandin E series metabolism and thus act to inhibit carcinogenesis.

- Hypertension. Several studies suggest GLA may help reduce blood pressure in some people with hypertension and thereby decrease the risk of heart attacks. Results of these studies are not considered conclusive.
- PMS. Studies show GLA is remarkably helpful in treating some PMS symptoms. One study showed that of the women who took the drug Efamol, which contains 9% GLA, 61% experienced complete relief from symptoms while 23% had partial relief. These symptoms included breast tenderness, depression, irritability, swelling, and bloating.

GLA, in combination with eicosapentaenoic acid (EPA), in the form of borage seed and fish oils, significantly reduced the need for breathing support in patients with the lung condition acute respiratory distress syndrome. It cut the average number of days a patient is in a hospital's intensive care unit from 17.5 to 12.8, according to a study published in the August 1999 issue of *Critical Care Medicine*.

Preparations

Gammalinoleic acid is found naturally in fish, animal organs such as liver, and certain plant seed oils. The major sources of GLA are **borage oil** (18–27% GLA), black currant oil (15–20% GLA), and evening primrose oil (7–14% GLA). GLA is not available as a pure extract, but only as an ingredient in combination formulas.

Dosage varies by condition it is used to treat:

- skin conditions: 360–750 mg daily
- PMS: 240–320 mg daily
- rheumatoid arthritis: 750 mg–2.8 g daily for six to 12 months
- diabetic neuropathy: 480 mg daily
- high blood pressure: 1.3 g daily
- high cholesterol: Up to 2 g daily

The United States Food and Drug Administration (FDA) has not established recommended daily allowances (RDA) for GLA.

Patients should consult with a heathcare professional regarding the proper dosage.

Several forms of GLA supplements are available, including a concentrated form. It is also available as evening primrose oil, borage oil, and **black currant seed oil**. It is also available in multi-nutrient formulas that often contain any combination of **fish oil**, flax seed oil, **omega-6 fatty acids**, and **essential fatty acids**. The usual amount of GLA in these is from 200–400 mg per capsule. The cost of a bottle of 30 capsules ranges from $8 to $15. The concentrations of GLA in these oils varies and the number of capsules needed depends on the amount of GLA.

Precautions

GLA should not be used by women who are pregnant or breastfeeding without consulting a physician. Hemophiliacs and people who take the blood-thinning drug warfarin (Coumadin) should consult a physician before taking GLA. It should also not be taken before surgery because it may increase bleeding. Persons with high blood pressure or heart or blood vessel conditions should consult a physician before taking GLA.

Side effects

There is no evidence that GLA is toxic in daily doses of up to 2.8 g. There have been no reports of serious side effects by people taking GLA supplements. It is generally well tolerated by most people. Possible minor side effects include upset stomach, **diarrhea**, soft stool, bloating, and **gas**. Persons who take GLA and experience difficulty breathing, chest or throat tightness, chest **pain**, **hives**, rash, or itchy or swollen skin may be allergic to it. They should stop taking it and consult a physician immediately.

Interactions

No adverse interactions between GLA and other medications, vitamins, or nutritional supplements have been reported.

KEY TERMS

Amputation—The surgical removal of a part of the body.

Antitoxin—A vaccine used to stimulate immunity against a specific disease.

Arteriosclerosis—A disease characterized by build-up on the artery walls that can lead to the obstruction of blood flow.

Debridement—The surgical removal of dead tissue.

Raynaud's disease—A condition in which there is poor circulation and decreased oxygen in the hands and feet particularly.

Torsion—The accidental twisting of tissues in the body that may decrease the blood and oxygen supply to the affected area.

Gangrene

Definition

Gangrene is a term used to describe the decay or death of an organ, tissue, or bone caused by a lack of oxygen and nutrients. It is a complication resulting from tissue injuries (such as **frostbite**), the obstruction of blood flow, or the processes of chronic diseases such as **diabetes mellitus**. Externally, the hands and feet are the areas most often affected by gangrene; internally, it is most likely to affect the gallbladder and the intestines. Gangrene is referred to as wet, or moist, if a bacterial infection is involved. In dry gangrene, there is no infection.

Description

Gangrene is often characterized by **pain** followed by numbness. The infection may first go unnoticed, especially in the elderly or those individuals with a loss of sensation. The area affected by gangrene may be cold and pale, especially early in the disease. **Blisters** may be apparent and the patient may experience an increased heart rate and profuse sweating. As the tissue dies, the skin begins to darken. The dead tissue gradually separates and falls away from the healthy tissue.

Dry gangrene is often seen in advanced cases of diabetes and arteriosclerosis. The tissue does not become infected, rather it dries out and shrivels over a period of weeks or months. Wet gangrene progresses much more rapidly. The affected area becomes swollen and gives off a foul smelling discharge. Death may occur within a matter of hours or days. **Fever**, rapid heart rate, rapid breathing, altered mental state, loss of appetite, **diarrhea**, **vomiting**, and vascular collapse may occur as the infection progresses.

Causes and symptoms

The primary cause of gangrene is often an injury to the blood vessels, causing either an interruption of blood flow, the introduction of a bacterial infection, or both. Such injuries may include **burns**, infected **bedsores**, **boils**, frostbite, compound **fractures**, deep **cuts** or gunshot **wounds**. Gangrene can also develop due to the poor circulation and obstructions in the blood vessels associated with abnormal **blood clots**, torsion of organs, and diseases such as diabetes, **heart disease**, and Raynaud's disease. Gangrene of the internal organs may be attributed to a ruptured appendix, internal wounds, or the complications of surgery.

The bloodstream is the body's main transport system. When blood flow is diminished, the flow of the oxygen and nutrients needed to keep tissues healthy is greatly decreased. The white blood cells needed to fight infection are not readily available. In such an environment, invading bacteria thrive and multiply quickly. *Streptococcus* spp. and *Staphylococcus* spp. are the most common agents of external skin infection.

Gas gangrene, also called progressive or clostridial myonecrosis, is a type of moist gangrene most commonly caused by an infection of *Clostridium perfringens*, or other species that are capable of thriving under conditions where there is little oxygen. These bacteria produce gases and poisonous toxins as they grow in the tissues. Gas gangrene causes the death of tissue, the destruction of red blood cells, and the damaging of the walls of the blood vessels and parts of the kidneys. Early symptoms include sweating, fear, and

anxiety. Gas gangrene is a life-threatening condition and should receive prompt medical attention.

Diagnosis

A diagnosis of gangrene will be based on a combination of patient history, a physical examination, blood test results, and other laboratory findings. A physician will look for a history of recent trauma, surgery, **cancer**, or chronic disease. Blood tests will be used to determine whether infection is present and to determine how much the infection has spread. A sample of drainage from a wound or obtained through surgery may be tested to identify the bacteria causing the infection and to aid in determining treatment. In the case of gas gangrene, the gas produced by the bacteria may be detected beneath the skin by pressing into the swollen areas. The crackling sounds of gas bubbles may also be heard in the affected area and the surrounding tissues.

X-ray studies and other imaging techniques, such as computed tomography (CT) scans or magnetic resonance imaging (MRI), may be helpful in making a diagnosis by showing evidence of gas accumulation or muscle tissue death. These techniques, however, are not sufficient alone to provide an accurate diagnosis of gangrene. Precise diagnosis often requires surgical exploration of the wound.

Treatment

Chelation therapy is a treatment that uses an intravenous solution containing the drug ethylenediamine tetra-acetic acid (EDTA), among other substances. In the bloodstream, EDTA binds and removes toxins and plaque formation on arterial walls. It promotes circulation throughout the body, and is reportedly, although not proven, able to reverse the processes leading to gangrene. Early intervention is necessary, however.

Other alternative and complementary treatments are used to treat gangrene. Herbal remedies such as **goldenseal** can be applied topically. **Biofeedback** and hypnosis can increase blood flow. Diabetics receive herbal and **traditional Chinese medicine** remedies and nutritional supplements to help prevent gangrene.

Allopathic treatment

Pain medications and large amounts of intravenous antibiotics are given. Prompt surgical removal of infected and destroyed tissue is required for healing to take place. Gas gangrene is often treated with the antitoxin for clostridium as well. In a number of cases, amputation may have to be used to keep the infection under control.

In hyperbaric oxygen (HBO) therapy the patient is placed in a pressurized chamber and receives 100% pure oxygen to breathe. This has been shown useful in inhibiting the production of toxins in gas gangrene and for getting oxygen quickly to tissues, especially following a crushing injury that might lead to gangrene. HBO therapy must be carried out early in the process and used before any surgical removal. The therapy, though useful, does have adverse side effects. It requires skilled technicians and may not be widely available.

Expected results

The outcomes for gangrene are generally favorable if the infection is recognized and treated early in the progression of the disease. Left untreated, gas gangrene will result in a decrease in blood pressure, kidney failure, and coma. Overall, about 20% of those infected with gas gangrene die from the disease, and another 20% require an amputation. Gangrene is most dangerous to the elderly, those who are immuno-compromised, and those who have internal **infections** and chronic conditions such as diabetes. Individuals suffering from dry gangrene often have multiple health problems that complicate recovery and may prove fatal.

Prevention

Infections and injuries should be thoroughly cleaned and monitored; medical attention should be pursued if symptoms worsen or remain unresolved. Gastrointestinal wounds should be surgically explored, drained, and repaired. Use of antibiotic therapy prior to and directly following surgery has been shown to reduce the rates of infection.

Patients with diabetes or severe arteriosclerosis should take particular care of their hands and feet to avoid the decreased circulation and unchecked infection that may lead to gangrene. Any injury or infection, however slight, should be cared for promptly. There should be a focus on proper foot care, including keeping the feet clean, dry, and warm, wearing well-fitting shoes and not going barefoot. It is important to avoid **smoking**, since tobacco use constricts the blood vessels of the hands and feet, decreasing circulation.

Patience Paradox

Ganoderma

Description

Ganoderma is the name of the fungus *Ganoderma lucidum*. It is also called the **reishi mushroom** or in Chinese *ling zhi*. It is one of the most popular medicinal mushrooms in China, Japan, and the United States.

Ganoderma grows on logs and tree stumps. It has a shiny, hard, asymmetrical cap that ranges in color from yellow to black. The cap, spores, and mycelium are all used medicinally. Wild ganoderma is rare in Asia.

In ancient China, ganoderma was so rare and so highly prized that it was reserved for the emperors and called the "elixir of life." In 1972, Japanese researchers successfully cultivated the mushroom. There are six different colors of cap: red, green, white, black, yellow, and purple. These researchers showed that all colors are the same species and that the color variations are the result of differences in environmental conditions. Despite this information, some herbalists insist that certain colors of reishi mushroom are more potent or effective in healing certain conditions than others.

General use

Ganoderma is considered one of the most important herbs in Asian healing. Its use extends to almost every system of the body. Not only is it believed to heal physical ailments, it is said to bring about a peaceful state of mind and to increase spiritual potency for Taoists and other Asian spiritual seekers.

Ganoderma has been used in China for over 4,000 years. It is the primary shen tonic in Chinese herbalism. In a broad sense, it is used to help a person adapt both physically and mentally to the world. It is used to strengthen and calm the nerves, improve memory, and prevent or delay senility.

***Ganoderma persum* growing on a tree trunk.** *(©David Chapman / Alamy)*

Herbalists consider ganoderma an adaptogen, or natural regulator, suppressing the immune system if it is overactive and boosting it if it is underactive. Many health claims are made on the effect that ganoderma has on the immune system. These claims are based primarily on the presence of high molecular weight polysaccharides and free radical **antioxidants** in ganoderma extracts. Ganoderma also contains the elements **potassium** (K), **magnesium** (Mg), **calcium** (Ca), and germanium (Ge).

Ganoderma is used in Japan and China to treat **cancer** and to stimulate the immune system after radiation or chemotherapy. It is also used to treat myasthenia gravis and **systemic lupus erythematosus** (SLE), both autoimmune diseases. In Japan and China, ganoderma is also used to treat symptoms of viral diseases such as colds, **influenza**, **canker sores**, and **hepatitis**.

Several research studies on ganoderma extracts have been done at universities in Japan, China, and South Korea. Many of these are test-tube or animal

Ganoderma mushroom. *(The Herald, Stephanie S. Cordle / AP Photo)*

studies. The results are not clear-cut, but they seem to indicate that at least in these non-human systems, ganoderma has an effect on the immune system, some anti-tumor properties, and some anti-viral activity.

Subsequent research in Asian universities investigated the effects of ganoderma on human cells or tissues. One study done in Taiwan indicated that ganoderma inhibits apoptosis (cell self-destruction) in human white blood cells. This finding may help to explain ganoderma's beneficial effects on the immune system.

Ganoderma attracted the attention of Western cancer researchers when a case study report from Columbia University indicated that a Japanese dietary supplement containing ganoderma as well as genistein, a soybean derivative, appeared to be useful in the prevention and treatment of **prostate cancer**. Beginning in the mid 2000s, the National Center for Complementary and Alternative Medicine, funded by the United Sates government, began giving grants to researchers to investigate some of the health claims made for ganoderma. Early results suggested that the herb has some antitumor and antiviral properties.

In Eastern medicine, ganoderma is also used in treating conditions of the nervous system. It is used to calm the nerves, cure **insomnia**, reduce **stress**, eliminate nervous exhaustion, and increase determination and focus. Laboratory studies show fairly conclusively that ganoderma does act as a sedative on cells of the central nervous system and possibly has painkilling and anti-convulsive properties.

Ganoderma is frequently used to treat **allergies**, **hay fever**, bronchial **asthma**, and to reduce skin inflammation. Laboratory studies support these uses and show that some components of ganoderma have a strong antihistamine effect that interrupts the development of allergic reactions.

Many conditions of the blood and circulatory system are treated with ganoderma. These include:

- altitude sickness
- atherosclerosis
- cardiac arrhythmia
- coronary heart disease
- high blood pressure

KEY TERMS

Adaptogen—A substance that regulates, either by stimulating or suppressing, a system to bring it back within its normal, healthy range.

Apoptosis—A type of programmed cell death in which a damaged cell shuts down and, in effect, commits suicide. Ganoderma appears to inhibit apoptosis in human white blood cells.

Atherosclerosis—A disease in which deposits of fatty materials build up on the walls of arterial blood vessels, causing them to narrow or become obstructed. Blood pressure increases, leading to heart disease.

Myasthenia gravis—A muscle weakness that occurs because the body makes antibodies to the natural chemical that facilitates transmission of impulses between the nerve and the muscle.

Mycelium—The part of the fungus that grows into the log and supports the fruiting body or cap. It is analogous to the roots of a plant.

Reishi mushroom—Another name for ganoderma.

Shen—One of the five body energies. It influences mental, spiritual, and creative energy. Shen tonics address deficiencies in this type of energy.

Spores—Fine powder-like reproductive bodies of the mushroom.

Systemic lupus erythematosus (SLE)—A multi-symptom disease caused by failure of the immune system to regulate itself.

- high blood sugar
- high cholesterol
- low blood pressure
- stroke

Scientific research shows that compounds found in ganoderma do lower blood sugar and interfere with the clotting of blood platelets. This reduction in clotting may account for ganoderma's effectiveness against **stroke** and **atherosclerosis**.

Ganoderma is also used to treat a variety of other diseases. These uses are generally backed by little or no scientific evidence. They include:

- gastroenteritis
- diarrhea
- constipation
- gallstones
- ulcer
- acne
- hair loss
- inflammation of the kidneys
- menstrual cramps
- erectile dysfunction
- low sex drive

Preparations

Virtually all ganoderma available commercially come from cultivated mushrooms. Different preparations are made using the cap, the spores, and the mycelium. These preparations are available in the form of fresh and dried whole mushrooms, capsules, concentrated drips, extracts, tablets, tea bags, tea granules, and tinctures. A common dose is 1,800–2,400 mg in capsule form per day. However, doses vary hugely depending on the condition being treated and the strength and part of the mushroom being used.

Precautions

Although no toxic reactions to ganoderma have been reported, people with allergies to other mushrooms may also experience allergic reactions to ganoderma.

Side effects

Large doses (2–9 g) of ganoderma taken regularly over the course of 3–6 months may result in **diarrhea**, upset stomach, and **dizziness**. **Nosebleeds** from high doses of ganoderma have also been reported. Some herbalists claim that large doses of **vitamin C** taken with this herb will control the symptoms of diarrhea.

Interactions

Ganoderma and other Chinese herbs are often used together with no reported interactions; in fact, a new health food supplement is made from reishi mushrooms grown on herbs, in the belief that the mushrooms absorb some of the properties of the herbs on which they are grown.

With regard to Western pharmaceuticals, ganoderma has been reported to produce negative interactions with warfarin, a blood-thinning medication. Because ganoderma extract may cause a drop in blood pressure, persons who are taking prescription antihypertensives (medications to lower blood pressure) should use ganoderma only if they are being monitored by a physician.

Garcinia

Description

Garcinia is a plant genus native to much of Asia and Australia. Although there are many members of the genus, the species *Garcinia cambogia*, also known as *Garcinia gummi-gutta*, is the best known. This species has also been known as *Garcinia hanburyi* and by the common names Cambogia and Gamboge. The plant, which is native to the Indian subcontinent, has a long medicinal use and, at various times, has been included in the *United States Pharmacopoeia, United States National Formulary,* and the *British Pharmacopoeia*. As of 2008, garcinia was the source of two compounds of medicinal interest, one for weight reduction and the other for **cancer** therapy.

Traditionally, the gum resin of the plant has been used and has been called *Gutta gamba, Gummigutta, Tom Rong, Gambodia* and *Garcinia Morella*.

General use

Historical use

At the start of the twentieth century gamboge was used as a laxative, for treatment of congestive heart failure, and to lower blood pressure in cases of enlargement of the pelvic veins in women, which may be a cause of **dysmenorrhea**. By mid-century, it was no longer used for cardiovascular purposes, but it was still used as a powerful laxative and for the elimination of intestinal **worms**. By the 1950s, gamboge was still recognized medicinally, but only as an ingredient in compound mild mercurous chloride pills, which themselves were essentially obsolete.

Weight reduction

The active component of garcinia that may be beneficial in weight reduction programs is hydroxycitric acid, which is found in the rind and pulp of the fruit. There have been small studies indicating that hydroxycitric acid may influence fat utilization and creation of new fat cells; however, these studies were not definitive.

A 2003 study compared the effects of hydroxycitric acid against a placebo in men during **exercise** over a 5-day period. The authors concluded that the supplement increased fat oxidation, an indication of increased fat utilization. A team from Maastricht University in the Netherlands compared the effects of hydroxycitric acid with a placebo during periods of overeating and concluded that the hydroxycitric acid inhibited the creation of new fat cells.

A significant study was conducted at Georgetown University and involved 60 volunteer subjects who were given a controlled diet and hydroxycitric acid supplements. The authors reported: "At the end of 8 weeks, body weight and BMI decreased by 5.4% and 5.2%, respectively. Food intake, total **cholesterol**, LDL, triglycerides, and serum leptin levels were significantly reduced, while HDL and serotonin levels and excretion of urinary fat metabolites (a biomarker of fat oxidation) significantly increased. No significant adverse effects were reported. These results demonstrate the safety, bioavailability and efficacy of HCA-SX in weight management."

Flowering garcinia tree. *(Dr. Carleton Ray / Photo Researchers, Inc.)*

Other studies have shown little or no efficacy or have only shown evidence of efficacy when the material was used in conjunction with **caffeine** or other dietary supplements. A study at Purdue University showed no benefit in terms of caloric restriction, while a Creighton University study failed to confirm claims that garcinia preparations increased fat oxidation or metabolic rate. An excellent review of weight loss preparations that appeared in *American Family Physician* in 2004 concluded that there are significant questions about the safety, efficacy, and product quality of supplements containing either garcinia or hydroxycitric acid. The authors recommended that persons using these supplements should be followed carefully, both because of the risk of toxicity and for gaining information regarding whether the preparations are effective or ineffective.

Claims of efficacy for garcinia and hydroxycitric acid may depend on other aspects of the diet. It has been suggested that a high fiber diet, which is recommended by most clinicians, will inhibit the absorption and efficacy of hydroxycitric acid. The reasons for success or failure in clinical studies were not resolved as of 2008.

Cancer therapy

Garcinia has been studied as a possible treatment or preventative for various types of cancer. Although there have been no well documented clinical trials of garcinia in cancer, initial laboratory studies were promising. A study from the Jiangsu Key Laboratory of Carcinogenesis and Intervention reported that gambogic acid, the major active principal of gamboge, inhibits the formation of blood vessels required to support the growth of solid tumors. Another study, from the University of Texas, reported that gambogic acid promotes apoptosis, programmed cell death. This cell death is a normal biological phenomenon, but it is inhibited in cancerous growths permitting the excessive growth of malignant tumors. Laboratory studies have reported on use of garcinia compounds in breast, liver, and gastrointestinal cancers, indicating that the compounds are good candidates for clinical trials.

Preparations

There are no standardized preparations of garcinia. Garcinia extracts, powdered preparations, or hydroxycitric acid have been included in many commercial

KEY TERMS

Apoptosis—Programmed cell death, the death of individual cells.

Carcinogenesis—Production of cancer.

Congestive heart failure—A condition in which the heart is too weak to maintain an adequate supply of blood to the tissues of the body.

Dysmenorrhea—Painful menstruation.

Fiber—Nutrients in the diet that are not digested by the enzymes in the stomach and/or intestine.

Malignant—Meaning cancerous and tending to spread to surrounding tissues.

Oxidation—Combining with oxygen. In fatty acids, is the process is accomplished with the breakdown of the carbon chain in two-carbon segments.

weight loss preparations, but there are no established dose levels, and no purity rubrics for the natural product.

Precautions

Laboratory studies seem to show that both garcinia and hydroxycitric acid are safe in normal doses. The traditional gamboge of medicine fell into disuse because of severe intestinal griping, which was occasionally fatal, but this was in doses far higher than seen in modern products. Consumption of the fruit of garcinia as part of the diet has been linked to formation of gallstones. While severe adverse effects have been associated with weight loss products containing either garcinia or hydroxycitric acid, these were combination products, and the cause of the adverse effects may have been due to some other component.

Safety of hydroxycitric acid may also depend on the formulation used. It has been suggested that salts of hyroxycitric acid have a high margin of safety, including **sodium**, **potassium**, and **calcium** compounds. The free acid and organic salts of hydroxycitric acid may be more prone to adverse effects.

Gardenia

Description

Gardenias are members of the madder, or Rubiaceae, family. Though not native to either North or South America, they were named for an eighteenth-century American physician and naturalist, Alexander Garden. Gardenias were originally found only in China and Japan, but today there are over 200 different species of gardenia, mostly hybrid, in existence throughout the world. Gardenias are most prevalent in China, Japan, tropical regions of Southeast Asia and the Pacific islands, and South Africa. With proper conditions, gardenias grow into shrub-like bushes or small trees that can reach 5 ft (1.5 m) in height.

Most species of gardenia, however, are very tender plants that require an average temperature of at least 60°F (28.9°C), sunlight with some protection, and just the right amount of humidity. They often survive far better in greenhouses than outside. Gardenias are often rambling plants that form mounds of glossy dark green foliage. The leaves are oval in shape and very shiny. The flowers vary in color from pale yellow with purple markings to creamy white, and they have a classic, heavy, sweet scent reminiscent of green apple. All gardenia blossoms have an almost wax-like appearance and can be either single or double, depending on the species. Most gardenias flower in the winter or early spring, and the blossom is followed by the appearance of a large, yellowish-red, bitter-tasting berry that contains a crystalline compound called acrocetin.

The most commonly listed botanical species of gardenia include:

- *Gardenia jasminoides*. This species is easily the most common of these rare, fragile plants. It reaches heights of 2 ft (61 cm) and grows into a tall bushy green shrub that produces white, highly fragrant flowers. *G. jasminoides* is a native of China, and the gardenia most commonly used in Chinese herbal medicine. Its name comes from the fact that it was first introduced to the Western world from Cape Colony in Africa, and the aroma of its large white flowers was said to be very like the scent of jasmine.
- *Gardenia jasminoides fortunata*. This plant is a hybrid version of *G. jasminoides* that is somewhat more hardy.
- *Gardenia nitida*. This gardenia is a slightly taller plant that grows up to 3 ft (93 cm) tall and also produces white blossoms.
- *Gardenia radicans floreplena*. This plant is a low spreading dwarf variety from Japan that grows only to heights of 18 in (46 cm), and has double-blossomed flowers.
- *Gardenia thunbergia*. This gardenia grows to 4 ft (1.2 m) tall, and is often cultivated in American greenhouses. It is found as both tree and shrub, and has white flowers with long tube-like necks.
- *Gardenia rothmania*. This plant is also a particular favorite of American botanists, but does not survive well in North America outside of a greenhouse. It also exists as both tree and shrub, and has pale yellow flowers with short, tube-like necks and purple markings.

KEY TERMS

Astringent—Any substance or medication that causes soft tissue to contract or constrict. Some types of gardenia have astringent properties.

Cold-deficiency diarrhea—In Chinese herbal medicine, this condition is described as cold settling in the abdomen when resistance is low, causing cramping, some gas, and loose, watery stools without any burning sensations.

Expectorant—A substance or medication that promotes the coughing up of phlegm.

Hematuria—A condition in which red blood cells are present in the urine. Blood in the urine may be readily visible or small amounts may give the urine a smoky appearance.

Hemostatic—A drug or medication that stops bleeding. Gardenia is used as a hemostatic agent in traditional Chinese medicine.

General use

Gardenias are widely used as exotic ornamental flowers in corsages, as houseplants, and in some regions, as outdoor plants. A yellow silk dye has been made for centuries from the chemical compound acrocetin extracted from the gardenia berry.

Chinese herbal medicine makes the most extensive use of the gardenia. Its Chinese name is *zhi zi*. The traditional medicinal actions attributed to gardenia include calming irritability; cooling blood and clearing away heat (a yin/yang imbalance often characterized by deficient yin); reducing swelling; and moving stagnant blood that has congealed in one place, usually following trauma. Gardenia is considered to be very effective as a hemostatic agent, which means that it stops bleeding; and also effective in treating injuries to the muscles, joints, and tendons. Gardenia is commonly used in Chinese herbal formulas to treat **infections**, particularly bladder infections; abscesses; **jaundice**; and blood in the urine, sputum, or stool. Because of its perceived ability to ease agitation or irritability, it is also used in formulas to treat **anxiety** or **insomnia**. It is also helpful in correcting menopausal imbalances reflected in insomnia and **depression**, nervous tension, **headache**, and **dizziness**.

The United States Department of Agriculture Agricultural Research Service phytochemical and ethnobotanical database lists the following species of gardenia as having specific medicinal properties:

- *Gardenia gummifera*. This species can be helpful in treating digestive problems, including dyspepsia and

diarrhea; or used as an astringent and expectorant for nervous conditions and spasms.

- *Gardenia storckii*. This variety can be used in treating constipation.
- *Gardenia lucida*. This gardenia has antiseptic properties that can kill both bacteria and insects.
- *Gardenia pseudopsidium*. This species has been used to treat smallpox.
- *Gardenia jasminoides*. This gardenia has been found to be helpful in the treatment of pain, nose bleeds, fever, and influenza; in healing wounds and reducing swelling; and in treating mastitis, hepatitis and the hematuria that accompanies bladder infection.
- *Gardenia augusta*. This variety has shown effectiveness in the treatment of headaches, fever, delirium, mastitis, and jaundice related to liver problems.
- *Gardenia campanulata*. This plant is used in healing wounds, burns, and scalds; in reducing swelling; as a treatment for fever and influenza; in treating jaundice associated with liver problems; and in stopping bleeding.
- *Gardenia labifolia*. This gardenia has been found effective in treating the bites of certain snakes.

Preparations

The kernel within the gardenia berry is often removed for use in herbal poultices put on sports injuries such as **sprains**, pulled muscles, or inflammation of nerves. The use of gardenia poultices is particularly common in Chinese medicine. Traditional Chinese practitioners make a paste of the herb with flour and wine. The powdered berry is given in both decoctions and capsules. When gardenia is used to stop bleeding it is usually burned before it is simmered in water.

Precautions

Chinese herbalists state that gardenia should not be used when there is cold deficiency (watery) **diarrhea** present.

It is important to remember that Chinese herbal medicine is based upon individual prescriptions developed for each patient and their unique symptoms. Chinese herbs should not be taken, either individually or in formulas, unless a practitioner of Chinese herbal medicine is first consulted.

Side effects

Gardenia has laxative properties, and can cause loose stools when taken frequently or in large amounts.

Garlic

Description

Garlic (*Allium sativa*) is a plant with long, flat grass-like leaves and a papery hood around the flowers. The greenish white or pink flowers are found grouped together at the end of a long stalk. The stalk rises directly from the flower bulb, which is the part of the plant used as food and medicine. The bulb is made up of many smaller bulbs covered with a papery skin known as cloves. Although garlic is known as the "stinking rose" it is actually a member of the lily family.

The most active components of fresh garlic are an amino acid called alliin and an enzyme called allinase. When a clove of garlic is chewed, chopped, bruised, or cut, these compounds mix to form allicin, which is responsible for garlic's strong smell. Allicin, in turn, breaks down into other **sulfur** compounds within a few hours. These compounds have a variety of overlapping healing properties.

Garlic also contains a wide range of trace minerals. These include **copper**, **iron**, **zinc**, **magnesium**, germanium, and **selenium**. The integrity of the growers and suppliers of garlic are important to the integrity of the garlic used. A soil rich with the presence of trace minerals will produce a healthful bulb of garlic, full of those minerals. Depleted soils produce a depleted product. In addition, garlic contains many sulfur compounds, vitamins A and C, and various **amino acids**.

General use

The ancient Indians, Chinese, Egyptians, Greeks, Romans, and other peoples have used garlic for thousands of years, both as food and as medicine. One of the most famed usages of garlic occurred during the Middle Ages, when garlic was reputed to have been highly effective against the plague.

As early as 1858, Louis Pasteur (1822–1895) formally studied and recorded garlic's antibiotic properties. Dr. Albert Schweitzer (1875–1965) used the herb to successfully treat cholera, typhus, and dysentery in Africa in the 1950s. Before antibiotics were widely available, garlic was used as a treatment for battle **wounds** during both World Wars.

Garlic can be used in the treatment of a variety of bacterial, viral, and **fungal infections**. It has been shown to be effective against staph, strep, *E. coli*, *Salmonella*, Vibrio cholera, *H. pylori*, *Candida albicans*, and other microorganisms. Garlic also helps prevent **heart disease** and strokes. Modern studies show that garlic can improve immune function and may even help in the prevention of **cancer**. To be of benefit in chronic conditions, garlic should be used daily over an extended period of time.

Heart disease

One of the main causes of heart disease is the buildup of plaque on the walls of the blood vessels. This plaque is mostly made up of **cholesterol** and other fatty substances found in the blood. When large amounts of plaque get stuck on artery walls, they block the flow of blood and cause **blood clots** to form. Parts of the artery wall may even be destroyed completely.

In arteriosclerosis, also known as hardening of the arteries, the major arteries may become so stiff and clogged, that the heart cannot get necessary nutrients and oxygen. This condition usually causes a **heart attack**. High serum cholesterol levels are a major risk factor for having a heart attack.

Studies show that people who eat garlic regularly have improved serum cholesterol levels. Some people with high cholesterol have been able to get within normal levels by eating 1–2 cloves per day. In addition, low-density lipoprotein (LDL) and triglyceride levels are decreased and high-density lipoprotein (HDL) levels are increased. This effect correlates with an overall reduced cholesterol level. These benefits are significant in preventing heart disease as well as strokes. While garlic's contribution to reducing levels of harmful plaques has been known for some time, a 2003 study found that garlic also lowered levels of homocysteine, a type of amino acid that in the early 2000s was considered a major risk factor for heart attacks. Manufactured garlic supplements appear to be equally as beneficial as eating fresh cloves. It takes at least one month of using garlic for laboratory results to be seen.

Hypertension

Hypertension, or high blood pressure, is also a significant cause of heart problems. It is one of the leading causes of disability and death due to **stroke**, heart attack, heart failure, and kidney failure. Garlic can help reduce blood pressure through the actions of its sulfur compounds and its ability to reduce the fatty substances, such as cholesterol, found in the bloodstream. Use of garlic also can help normalize low blood pressure.

Platelet aggregation

Platelets clot the blood in order to repair breaks in the blood vessel walls. When there is an injury, platelets are attracted to the damaged area and become attached to the wall and to other platelets. Platelet aggregation, as this process is called, plugs up the break and prevents further blood loss while the injury is being repaired. This is a good and necessary part of healing an injury.

If there are serious problems with the heart and blood vessels and there is too much injury and clotting, the vessels may become clogged with platelets, which can lead to strokes and heart disease. The sulfur compounds in garlic—particularly ajoene—give the platelets a slippery quality. They are less able to clump together, thus slowing down platelet aggregation. Garlic can be used effectively in the same way as a daily dose of aspirin to reduce or prevent platelet aggregation over an extended time.

Cancer

Studies have found that garlic blocks the formation of powerful carcinogens, called nitrosamines, which may be formed during the digestion of food. This may be why in populations in which people consume a large amount of garlic, there is a decreased incidence of all types of cancer. The **antioxidants** found in garlic may also contribute to this effect by protecting against the cell damage by cancer-causing free radicals. Studies show that use of garlic may also inhibit the growth of a variety of tumors. However, cancer-related studies are not conclusive and relate to consumption of raw or cooked garlic, not garlic supplements.

Infectious conditions

Eating garlic is good for helping the body's immune system resist **infections**. While garlic is not as strong as modern antibiotics, it is believed to kill some **strains** of bacteria that have become resistant to antibiotics. Studies have shown garlic treats yeast infections, and it can kill many of the viruses responsible for colds and flu. While daily consumption of garlic was once highly recommended for HIV-positive individuals, the National Institutes of Health (NIH) reported in 2002 that garlic supplements greatly reduced levels of saquinavir, an HIV protease inhibitor, in patients' blood. The NIH began cautioning patients who used garlic to control cholesterol levels who also used saquinavir or combination therapies, since garlic might interfere with their effectiveness.

Modern doctors, in reconsidering the causes of many diseases, have discovered that bacteria and viruses may be the cause of sicknesses that were formerly not thought to be caused by infections. Included are gastric ulcers, **colitis**, and Kaposi's sarcoma. Garlic may be useful in treating or preventing these due to its antimicrobial properties.

Diabetes

Garlic has the ability to lower and help keep blood sugar stable by helping to increase the amount of insulin available in the bloodstream. This action, together with garlic's ability to lower cholesterol and blood pressure, make it an excellent daily supplement for people with diabetes. A 2003 report showed that long-term use of garlic helped improve the blood vessel systems of diabetic rats.

Cancer

Garlic may also be helpful in reducing the risk for a number of cancers, according to a study by Swiss and Italian researchers published in the November 2006 issue of *American Journal of Clinical Nutrition*. The meta-study looked at a number of previous studies of garlic and onion use among approximately 25,000 people in Italy and Switzerland. In people who ate 15–22 portions of onions and garlic per week, the reduced risk of various types of cancer was: oral and pharynx, 84%, esophageal, 88%, colorectal, 56%, laryngeal, 83%, breast, 25%, ovarian, 73%, prostate, 71%, and kidney, 38%.

Other health conditions

Garlic is effective in the treatment of numerous other conditions. The following list provides some examples:

- The consumption of 1–3 cloves per day is useful for immune support and as a preventive against diseases and infection.
- Warmed garlic oil in the ear canal can be used to treat ear infections.
- Garlic can be used to treat respiratory complaints such as asthma and chronic bronchitis.
- Garlic helps increase the body's ability to handle the digestion of meat and fats.
- Garlic can be used to help kill and expel intestinal worms in both animals and humans.
- When added to a pet's food, garlic helps repel fleas.
- Garlic is helpful in getting rid of athlete's foot.
- Garlic relieves gas and other stomach complaints.
- The sulfur compounds found in garlic can bind to heavy metals and other toxins and help remove them from the body.
- Garlic can be used externally for cuts, wounds, and skin eruptions.
- The taste of garlic in mother's milk stimulates improved nursing. Infants eat more and nurse longer. They appear to relish the taste of slightly garlicky milk. The components of garlic that reach the infant through the mother's milk also may be helpful in relieving colic and infections.

Preparations

Used internally

Garlic can be eaten raw or cooked, taken as tablets or capsules, and used as a tincture or syrup.

The suggested dosage for fresh whole garlic is one to three cloves per day. The cloves can be chewed and held in the mouth or swallowed. Consuming raw garlic can actually be a pleasure if the herb is crushed or grated and mixed with food or a tablespoon of honey. The dosage for tinctures is 2–4 ml or 15–40 drops taken twice daily. One tablespoon of the syrup should be taken three times a day, or as needed to relieve coughing. Garlic oil should be slightly warmed, and 1–3 drops should be put in the affected ear 1–3 times per day.

Tablets and capsules are often more convenient to use than raw garlic, and they are more likely to be tolerated by garlic-sensitive individuals. Garlic pills also minimize the garlic taste and odor. Manufacturers vary on which components of the herb are emphasized.

In general, the following dosages are appropriate, but product labels also should be consulted:

- 400–500 mg of allicin, twice daily

- a dose equaling approximately 4,000 mcg of allicin potential, once or twice daily
- 400–1,200 mg of dried garlic powder
- 1,000–7,200 mg of aged garlic
- a dose equivalent to 0.03–0.12 ml of garlic oil, three times per day

Manufactured garlic pills come in a variety of forms, and a great deal of controversy continued in the early 2000s about what type is best. Studying the manufacturers' literature and other information is important to make a good decision about which preparation to use. The types of garlic preparations include:

- garlic oil capsules
- encapsulated powdered garlic
- odorless garlic pills
- allicin-stabilized pills
- aged garlic extract

Used externally

The raw cloves can be directly applied externally. A poultice can be made using grated or crushed fresh garlic. The herb material should be placed directly on the site of injury or eruption, either as is or mixed with enough honey to make a paste. The poultice can be held in place with a cloth or bandage.

A compress of garlic is less messy than a poultice and may be less irritating to the site of the injury. It is made by wrapping grated or crushed fresh garlic in a single piece of cheesecloth. As with the poultice, the compress is placed directly on the affected area.

Garlic oil can be made by putting a whole bulb of grated or finely chopped garlic into a pint jar of olive oil, and letting it sit undisturbed in a warm place, away from direct sunlight, for at least two weeks. Then it can be strained and refrigerated. The garlic oil will stay fresh in the refrigerator for up to two years.

A garlic suppository can be used to treat vaginal yeast or mild bacterial infections. A clove of fresh garlic should be peeled and slightly crushed or bruised. If crushed garlic irritates the vaginal tissue, an alternative that might lessen the desired antimicrobial effect is to use the whole, uncrushed garlic clove. The clove should be wrapped in a single layer of cheesecloth and inserted into the vaginal canal overnight for 5–10 days. Dental floss or a length of the cheesecloth can be used to make the suppository easier to retrieve. If the garlic causes a burning sensation, this can be eased with the insertion of plain yogurt into the vagina.

KEY TERMS

Anticoagulant—Any substance that reduces or prevents the blood's tendency to clot in order to prevent blockages in the arteries.

Antimicrobial—Having the ability to help the immune system resist or destroy a wide spectrum of disease-causing organisms.

Carcinogens—Chemical substances that cause cell mutations and, ultimately, cancer.

Cholesterol—A fatty substance found only in animals; used in the body to build cell walls and in the forming of bile and sex hormones.

Free radicals—Highly reactive toxins in the body that can bind to cells and damage them. Antioxidants are useful in neutralizing these compounds.

HDL—Beneficial lipoprotein molecules that transport cholesterol to the liver to be processed and excreted, thereby lowering cholesterol levels. Also known as good cholesterol.

LDL—Lipoproteins that transport cholesterol to body tissues for storage and thereby raise cholesterol levels. Also known as bad cholesterol.

Plaque—A buildup of fats, cholesterol, calcium, and fibrous tissue in the blood that tends to attach to and weaken artery walls.

Stroke—A condition caused by the blockage of blood flow and oxygen to the brain. Paralysis, coma, and death may result.

Suppository—Any treatment prepared to be inserted into the vagina or the rectum.

Precautions

Consumers will find a wide variety of garlic preparations on the market. Therefore, it is important to study manufacturers' claims, talk to knowledgeable practitioners, and find out which formulations are most effective for a given condition.

Due to the high concentration of sulfur compounds in garlic, it should be avoided by those allergic to sulfur. Garlic inhibits clotting, thereby causing increased bleeding times. Hemophiliacs and those on anticoagulant medication should consult a physician before taking garlic on a daily basis. This caution also applies to individuals who are preparing to undergo surgery. Medicinal use of garlic should be discontinued for at least 1–2 weeks before surgery. HIV patients receiving protease inhibitor or combination therapy

should check with their physicians before using garlic supplements, as garlic may interfere with the therapy's effectiveness.

Side effects

Raw garlic can be very irritating to the digestive system. Excessive intake (usually, more than three or four cloves a day) can cause bloating, **gas**, cramping, **diarrhea**, and may even damage the red blood cells. When applied to the skin, garlic may cause **itching**, redness, and swelling. Garlic that is cooked, aged, or made into pills is not nearly as harsh on the system. However, these forms may not be as suitable as raw garlic in treating some conditions, particularly infections.

Garlic travels through the lungs and the bloodstream, giving a pungent garlic odor to the breath, skin, and perspiration. The odor will be present for at least 4–18 hours, sometimes even when so-called odorless garlic pills are used.

Interactions

Garlic does well when combined with **coltsfoot** or **lobelia** for treating **asthma** and **bronchitis**. Although onion is not as potent as garlic, it has similar actions, and the two often are combined. Use of garlic is contraindicated in individuals using the anticoagulant drug warfarin or certain HIV therapies.

Gas

Definition

Gas, or flatus, is the by-product of the breakdown of food by naturally occurring bacteria in the gastrointestinal tract. Gas can also enter the digestive system when an excess of air is swallowed. The body absorbs some of this air, but the rest is expelled as gas. Gastrointestinal gases include methane, carbon dioxide, nitrogen, and hydrogen.

Description

Gas production is an essential, normal function of the gastrointestinal tract, and most healthy individuals pass up to 1,200 cc (over 40 oz) of gas each day. The odor associated with gas comes from small amounts of **sulfur** released by bacteria. When gas causes excessive **pain** and cramping (**colic**), evaluation and treatment are appropriate.

Causes and symptoms

Gastrointestinal gas production can be increased by certain foods, illnesses, and some medications. Common causes of excessive gas include:

Common remedies for gas

Remedy	Description
Acupressure	Press inward at the point three finger widths below the navel known as Conception Vessel 6.
Exercise	Exercise after meals and regularly to increase digestion and expel gas.
Herbal medicine	Anise water, peppermint or chamomile tea, and fennel may relieve gas.
Homeopathy	Carbo vegetabilis (or vegetable charcoal) is used to relieve gas. Nux vomica is used to treat gas that accompanies constipation. Chamomilla is used to treat gas in infants.
Diet	Increase fiber intake. Do not mix carbohydrates with proteins at the same meal. Avoid beans, peas, cheese, sodas, and alcohol. Do not overeat. Chew food well and eat slowly.
Hydrotherapy	Alternate a warm compress with a vigorous cold friction rub on the abdomen.
Yoga	The Boat, Bow, Cobra, and Pigeon positions all encourage digestion and help relieve gas pain.

(Illustration by Corey Light. Cengage Learning, Gale)

- Gas-producing foods. Onions, beans, the vegetables in the cabbage family, and other fibrous foods can cause excessive gas or intestinal spasms in some individuals. High fat intake also reduces the body's ability to digest carbohydrates and may lead to larger amounts of gas.
- Gastrointestinal diseases and disorders. Increased flatulence is a defining symptom of irritable bowel syndrome, diverticulitis, lactose intolerance, malabsorption problems, dysbiosis (imbalance among the various types of bacteria in the gut), and other gastrointestinal disorders.
- Air swallowing (aerophagia). Swallowing too much air while eating or chewing gum can introduce extra gas to the gastrointestinal tract.
- Medications. Certain prescription and over-the-counter medications may cause gas as a side-effect.
- Stress and food allergies can also cause gas.

Symptoms of excessive gas production include:

- flatulence
- belching or burping
- abdominal cramping or colic
- abdominal pain

Diagnosis

A thorough medical and dietary history and physical examination performed by a healthcare professional can usually identify the cause of gas pains caused by diet or medication. Gas problems triggered by gastrointestinal disease may be harder to diagnose and will typically require additional medical testing such as colonoscopy or an upper and/or lower gastrointestinal (GI) series (x rays of the digestive system).

Treatment

Changes in diet can eliminate most excessive gas caused by a particular food or beverage, reducing the amount of fat in the diet, and eating smaller, more frequent meals. Gas caused by air swallowing can be alleviated by eating more slowly, and avoiding **smoking**, gum chewing, and drinking through a straw.

An herbalist or naturopathic healthcare professional may recommend a preparation of carminative (gas reducing) herbs such as **valerian** (*Valeriana officinalis*) or **peppermint** (*Mentha piperita*). These may be helpful in eliminating discomfort and gas-related bloating.

Homeopathic remedies for excessive intestinal gas include Carbo vegetabilis, Nux vomica, and Chamomilla. The prescription of a specific homeopathic remedy will depend on an individual's overall symptom picture, mood, and temperament, and should be prescribed by a qualified homeopathic physician.

Hydrotherapy, **acupressure**, **acupuncture**, **yoga**, **reflexology**, and mild **exercise** can also help to relieve the pain and discomfort of excessive gas.

Allopathic treatment

Over-the-counter preparations of the enzyme alpha-D-galactosidase (e.g., Beano) can alleviate gas symptoms caused by ingestion of certain foods in some individuals. These preparations are typically

KEY TERMS

Homeopathic—Healthcare practice that uses remedies and treatments that cause similar effects to the symptoms they are intended to treat in an effort to stimulate the natural immune response of the body.

Malabsorption problems—A condition in which the intestinal tract is not able to absorb adequate nutrients from the food that passes through it (e.g., celiac disease, inflammatory bowel disease).

available in liquid or tablet form. Other non-prescription medications such as Gas-X, Phazyme, and Mylanta contain the ingredient simethicone that can reduce gas bubbles within the gastrointestinal tract. Lactase enzyme supplements help some people digest lactose (milk sugar) without producing gas.

Expected results

Mild excess gas is typically easy to treat, especially when triggered by dietary causes. Gas caused by gastrointestinal disease may be more difficult to manage, and successful treatment depends on the type and severity of the disorder.

Prevention

Avoiding fermented foods, drastic increases in fiber intake, and excessive air intake can prevent gas in some individuals. Lactose intolerant individuals should avoid dairy products.

Gastritis

Definition

Gastritis commonly refers to inflammation of the lining of the stomach, but the term is often used to cover a variety of symptoms resulting from this inflammation, as well as symptoms of burning or discomfort. True gastritis comes in several forms and is diagnosed using a combination of tests. In the 1990s, scientists discovered that the main cause of most gastritis is infection by a bacterium called *Helicobacter pylori*.

Description

Gastritis should not be confused with common symptoms of upper abdominal discomfort. It has been associated with ulcers, particularly peptic ulcers, and in some cases, chronic gastritis can lead to more serious complications.

Nonerosive H. pylori gastritis

Under current theory, the main cause of true gastritis is *H. pylori* infection, which is found in an average of 90% of patients with chronic gastritis. *H. pylori* is a bacterium whose outer layer is resistant to the normal effects of stomach acid in breaking down bacteria. The resistance of *H. pylori* means that the bacterium may remain in the stomach for long periods of times, even years, and eventually cause symptoms of gastritis or ulcers when other factors are introduced, such as the presence of specific genes or the use of nonsteroidal anti-inflammatory drugs (NSAIDs). Studies of the role of *H. pylori* in the development of gastritis and peptic ulcers have disproved the former belief that **stress** leads to most stomach and duodenal ulcers. The newer findings have resulted in improved treatment and reduction of stomach ulcers. *H. pylori* is most likely transmitted between humans, although the

KEY TERMS

Apigenin—A bioflavonoid contained in chamomile that appears to inhibit *H. pylori*.

Atrophic—Characterized by a wasting away of a part of the body.

Capsaicin—A crystalline, bitter compound found in peppers. It may be helpful in treating some forms of gastritis.

Demulcent—A medication or substance that is used to soothe irritated mucosa. Some of the herbs recommended to treat gastritis have demulcent properties.

Helicobacter pylori—The bacterium that is implicated in most cases of nonerosive gastritis.

NSAIDs—An abbreviation for nonsteroidal anti-inflammatory drugs. Heavy use of NSAIDs is the most common cause of erosive gastritis.

specific routes of transmission still are under study. Studies are also underway to determine the role of *H. pylori* and resulting chronic gastritis in the development of gastric cancers.

Erosive and hemorrhagic gastritis

After *H. pylori*, the second most common cause of chronic gastritis is the use of NSAIDs. These commonly used **pain** killers, including aspirin, fenoprofen, ibuprofen and naproxen, can lead to gastritis and peptic ulcers. Other forms of erosive gastritis are caused by alcohol or corrosive agents, or by injuries to the stomach tissues from the ingestion of foreign bodies.

Other forms of gastritis

Clinicians differ on the classification of the less common and specific forms of gastritis, particularly since there is so much overlap with *H. pylori* in development of chronic gastritis and complications of gastritis. Other types of gastritis that may be diagnosed include:

- Acute stress gastritis. This is the most serious form of gastritis. It usually occurs in critically ill patients, such as those in intensive care. Stress erosions may develop suddenly as a result of severe trauma or stresses on the stomach lining.
- Atrophic gastritis. This form of gastritis results from chronic gastritis. It is characterized by atrophy, or a decrease in size and wasting away of the gastric lining. Gastric atrophy is the final stage of chronic gastritis and may be a precursor of gastric cancer.
- Superficial gastritis. This term is often used to describe the initial stages of chronic gastritis.
- Uncommon specific forms of gastritis include granulomatous, eosiniphilic, and lymphocytic gastritis.

Causes and symptoms

Nonerosive H. pylori gastritis

H. pylori gastritis is caused by infection from the *H. pylori* bacterium. It is believed that most infection occurs in childhood. Clinicians think that there may be more than one route for the bacterium. Its prevalence and distribution differs in nations around the world. The presence of *H. pylori* has been detected in 86–99% of patients with chronic superficial gastritis. Physicians are still learning about the link of *H. pylori* to chronic gastritis and peptic ulcers, since many patients with *H. pylori* infection do not develop symptoms or peptic ulcers. *H. pylori* is also seen in 90–100% of patients with duodenal ulcers.

The symptoms of *H. pylori* gastritis include abdominal pain and reduced acid secretion in the stomach. The majority of patients with *H. pylori* infection have no symptoms, even though the infection may lead to ulcers and resulting symptoms. Ulcer symptoms include dull, gnawing pain, often two to three hours after meals; and pain in the middle of the night when the stomach is empty.

Erosive and hemorrhagic gastritis

The most common cause of this form of gastritis is the use of NSAIDs. Other causes may be **alcoholism** or stress from surgery or critical illness. The role of NSAIDs in development of gastritis and peptic ulcers depends on the dose level. Although even low doses of aspirin or other nonsteroidal anti-inflammatory drugs may cause some gastric upset, low doses generally will not lead to gastritis. However, as many as 10–30% of patients on higher and more frequent doses of NSAIDs, such as those with chronic arthritis, may develop gastric ulcers. Patients with *H. pylori* already present in the stomach who are treated with NSAIDs are much more susceptible to ulcers and other gastrointestinal effects of these pain killers.

Patients with erosive gastritis may also show no symptoms. When symptoms do occur, they may include **anorexia nervosa**, gastric pain, **nausea**, and **vomiting**.

Other forms of gastritis

Less common forms of gastritis may result from a number of generalized diseases or from complications of chronic gastritis. Any number of mechanisms may cause various less common forms of gastritis and they may differ slightly in their symptoms and clinical signs. However, they all have inflammation of the gastric mucosa in common. Research recently found that severe gastritis may occur rarely as a result of infectious **mononucleosis**.

Diagnosis

Nonerosive H. pylori gastritis

H. pylori gastritis is easily diagnosed through the use of the urea breath test. This test detects active presence of *H. pylori* infection. Other serological tests, which may be readily available in a physician's office, may be used to detect *H. pylori* infection. Newly developed versions offer rapid diagnosis. New stool antigen tests were developed and made available in 2002. The choice of test will depend on cost, availability and the physician's experience, since nearly all of the available tests have an accuracy rate of 90% or better. Endoscopy, or the examination of the stomach area using a hollow tube inserted through the mouth, may be ordered to confirm the diagnosis. A biopsy of the gastric lining also may be ordered.

Erosive or hemorrhagic gastritis

The patient's clinical history may be particularly important in the diagnosis of this type of gastritis, since its cause is most often the result of chronic use of NSAIDs, alcoholism, or abuse of other substances.

Other forms of gastritis

Gastritis that has developed to the stage of duodenal or gastric ulcers usually requires endoscopy for diagnosis. It allows the physician to perform a biopsy for possible malignancy and for *H. pylori*. Sometimes, an upper gastrointestinal x-ray study with barium is ordered. Some diseases such as Zollinger-Ellison syndrome, an ulcer disease of the upper gastrointestinal tract, may show large mucosal folds in the stomach and duodenum on radiographs or in endoscopy. Other tests check for changes in gastric function.

Treatment

Some alternative treatments for gastritis follow mainstream medical practice in distinguishing between gastritis and other digestive disorders; others treat all disorders originating in the stomach in similar fashion.

Dietary supplements

Of all the alternative treatments for gastritis, dietary supplements of various types are the most likely to have been tested in clinical research. Some alternative practitioners have used the following supplements:

- Capsaicin. Capsaicin is the active ingredient in chili peppers. One study in human subjects indicates that capsaicin offers some protection against gastritis caused by aspirin.
- Antioxidants. Vitamin C and beta-carotene given in combination appear to be beneficial to most patients with chronic atrophic gastritis.
- Amino acids. Several studies indicate that cysteine speeds healing in bleeding gastritis related to NSAIDs and in atrophic gastritis. Glutamine appears to protect against the development of stress-related gastritis.
- Vitamins. Preliminary research suggests that large doses of vitamin A may reduce or eliminate erosive gastritis. Vitamin B_{12} is helpful for patients with prenicious anemia related to atrophic gastritis.
- Gamma oryzanol. In one study, 87% of patients with various types of gastritis reported at least some improvement from a daily dose of 300 mg of gamma oryzanol.

Herbal therapy

Herbs that have been recommended for gastritis include:

- Licorice. Licorice is a traditional remedy for stomach inflammation. It also appears to inhibit the growth of *H. pylori*. People who gain water weight or develop high blood pressure as side effects of taking licorice can be treated with licorice that has had the glycyrrhizin removed.
- Goldenseal. This herb contains berberine, a compound with antibiotic properties. There is some evidence that berberine is active against *H. pylori*.
- Chamomile. Chamomile contains apigenin, a bioflavonoid that inhibits *H. pylori*, and chamazulene, a compound that counteracts free radicals.
- Marsh mallow and slippery elm. These herbs have demulcent properties, which means that they soothe irritated mucous membranes.
- Echinacea and geranium. These herbs are recommended by some practitioners for their antiseptic and analgesic (pain-relieving) properties.

Naturopathic practitioners also advise patients with gastritis to eat certain categories of food separately. Patients are advised to eat protein foods by

themselves or with green leafy vegetables; to eat fruits alone; and to avoid combining proteins and starches.

Acupuncture/acupressure

One source recommends applying gentle pressure to a point on the abdomen known as CV (conception vessel) 12, midway between the navel and the breastbone. Pressure should be applied when the stomach is empty. Trained acupuncturists treat stomach problems by releasing energy from the spleen and from other energy points associated with digestion.

Yoga

The Bow Pose is recommended by some teachers of **yoga** for stomach disorders because it puts pressure on a number of acupoints on the abdomen associated with the digestive process and with the stomach meridian.

Chinese herbal medicine

The Chinese traditionally use a tea made from **ginger** (*Zingiber officinale*) as a stomachic, to improve digestive functions.

Reflexology

A trained reflexologist will gently massage the stomach reflexes located on the hands and feet. On the hands, the stomach reflexes are on the palms, below the pads of the middle and index fingers. On the feet, the stomach reflexes are located on the sole just below the pad of the big toe.

Allopathic treatment

H. pylori gastritis

The discovery of *H. pylori's* role in the development of gastritis and ulcers has led to improved treatment of chronic gastritis. Since the infection can be treated with antibiotics, the bacterium can be completely eliminated up to 90% of the time. The treatment, however, may be uncomfortable for patients and relies heavily on patient compliance. No single antibiotic has been found that would eliminate *H. pylori* on its own, so various combinations of antibiotics have been prescribed to treat the infection.

TRIPLE THERAPY. As of early 1998, triple therapy was the preferred treatment for patients with *H. pylori* gastritis. This treatment regimen usually involves a two-week course of three drugs. An antibiotic such as amoxicillin or tetracycline, and another antibiotic such as clarithromycin or metronidazole are used in combination with bismuth subsalicylate, a substance that helps protect the lining of the stomach from acid. This treatment often fails due to poor patient compliance and quadruple therapy is required.

DUAL THERAPY. Dual therapy involves the use of an antibiotic and a proton pump inhibitor. Proton pump inhibitors help reduce stomach acid by halting the mechanism that pumps acid into the stomach. Dual therapy has not been proven to be as effective as triple therapy, but may be ordered for some patients who can more comfortably handle the use of fewer drugs.

OTHER TREATMENTS. Scientists have experimented with quadruple therapy, which adds an antisecretory drug, or one that suppresses gastric secretion, to the standard triple therapy. One study showed this therapy to be effective with only a week's course of treatment in more than 90% of patients. The goal is to develop the most effective therapy combination that can work in one week of treatment or less.

Treatment of erosive gastritis

Patients with erosive gastritis may be given treatments similar to those for *H. pylori*, especially since some studies have demonstrated a link between *H. pylori* and NSAIDs in causing ulcers. The patient will most likely be advised to avoid NSAIDs.

Other forms of gastritis

Specific treatment will depend on the cause and type of gastritis. These may include prednisone or antibiotics. Critically ill patients at high risk for bleeding may be treated with preventive drugs to reduce the risk of acute stress gastritis. Sometimes surgery is recommended, but is weighed against the possibility of surgical complications or death. Once heavy bleeding occurs in acute stress gastritis, mortality is as high as 60%.

Expected results

The results expected from alternative treatments for gastritis include accelerated healing from some of the dietary therapies, and some symptomatic relief from **acupressure**, yoga, and **reflexology**.

The discovery of *H. pylori* has improved the prognosis for patients with gastritis and ulcers. Since treatment exists to eradicate the infection, recurrence is much less common. The prognosis for patients with acute stress gastritis is much poorer, with a 60% or higher mortality rate among those bleeding heavily. Recent studies have shown that infection with *H. pylori* and resulting gastritis may lead to such

complications as chronic gastritis or as serious as gastric adenoma, a form of stomach **cancer**.

Prevention

The widespread detection and treatment of *H. pylori* as a preventive measure in gastritis has been discussed but not resolved. Until more is known about the routes through which *H.pylori* is spread, specific prevention recommendations are not available. It was estimated in late 2002 that the organism was present in 80% of middle-aged adults in developing countries and about 20% of those in industrialized countries. Erosive gastritis from NSAIDs can be prevented with cessation of use of these drugs. An education campaign was launched in 1998 to educate patients, particularly an **aging** population of arthritis sufferers, about the risk of developing ulcers from NSAIDs and alternative drugs.

Gastrodia

Description

Gastrodia is a preparation made from the rhizome or tuber of an orchid, *Gastrodia elata*. It is a member of the Orchidaceae family. *Gastrodia elata* is a native of the Far East; its natural areas of distribution include Tibet, western China, Korea, and Japan. While gastrodia appears in the oldest lists of Chinese medicinal herbs, it was not known to Western herbalists.

Gastrodia is first mentioned in the *Shennong Bencao Jing*, which was compiled around A.D. 100. A later Chinese herbalist named Tao Hong placed gastrodia in the category of superior herbs, which meant that it could be taken for long periods of time, and that it could be used to promote longevity as well as to treat illnesses. It was originally called *chiqian*, which means "red arrow" in Chinese, because its stem is red and arrow-shaped. Later it was named *tian ma*, or "heavenly hemp," which is the name that it still bears in Chinese herbal formularies.

Like other wild orchids, *Gastrodia elata* is rare and has been placed on the list of endangered species. The increasing difficulty of finding wild gastrodia in the 1970s led to an interesting discovery about this plant. Chinese herbalists tried to cultivate gastrodia, but failed until biologists discovered that the plant needs two fungi in order to survive and reproduce. It needs the *Armillaria mellea* mushroom on its tuber in order to grow and mature; and it requires a second fungus called *Mycena osmundicola* to help its seeds to sprout. After this complicated relationship was understood, herbalists were able to grow gastrodia.

Another aspect of this discovery was the finding that most of the medicinal benefits associated with gastrodia are actually produced by the *Armillaria* mushroom. Many growers then decided to cultivate the mushroom by itself without the gastrodia tuber. Some herbalists now use the *Armillaria* mushroom in their preparations instead of wild or cultivated gastrodia.

General use

In the categories of Chinese herbal medicine, gastrodia is classified as having a sweet and slightly warm nature with a neutral taste. Herbalists have traditionally used it to calm the liver and to clear the meridians by invigorating the patient's circulation. In the categories of Western medicine, gastrodia is said to have sedative and analgesic properties. The specific conditions that were treated by gastrodia include migraine headaches, **dizziness** or vertigo due to liver inflammations, convulsions

caused by heat excess, paralysis, general **fatigue**, numbness in the hands or feet, and **pain** in the joints. More recently, gastrodia has been used to relieve nervous headaches, pain in the trigeminal nerve, nocturnal emissions, difficult breathing, **insomnia** due to **stress**, and **hypertension**.

Chemical analysis of gastrodia indicates that it contains significant amounts of **calcium**, **magnesium**, and **potassium**. Its active ingredients include gastrodioside, vanillin (from the rhizome), and vanillyl alcohol (from the tuber). These last two compounds are related to vanilla flavoring, which comes from another orchid called *Vanilla plantifolia*. Research indicates that vanillin has anticonvulsive properties. Other research suggests that the gastrodia tuber has analgesic and sedative effects because the compounds in it decrease the level of dopamine in the brain. Studies have shown that gastrodia reduces epileptic seizures, and suggested that is has a protective effect against neuronal damage and may improve the ability of learning memory. A study in 2007 provided insight into the mechanism of gastrodia's anticonvulsive effects. In addition, a 2006 review of the scientific literature on gastrodia noted that various human and animal studies have reported that it affects smooth muscle tone, protects against oxidative damage in nerve and heart-muscle cells, and may serve as an anticoagulant. One study in 2003 also suggested that gastrodia reduces a certain peptide, called amyloid beta peptide, that is believed to play a role in Alzheimer's disease. Therefore, gastrodia may have implications for the treatment of Alzheimer's disease.

KEY TERMS

Analgesic—A substance or medication given to relieve pain.

Meridians—In Chinese medicine, pathways of subtle energy that link and regulate the various structures, organs, and substances in the human body. Gastrodia is recommended to clear the meridians of obstructions caused by dampness and wind.

Rhizome—A root-like underground plant stem, often horizontal in position.

Sedative—A substance or medication given to calm and soothe. In traditional Chinese herbal medicine, gastrodia is used as a sedative to the liver.

Tuber—The thick, fleshy, underground stem of a plant.

Preparations

Single-herb preparations

Gastrodia preparations are made from the tubers and rhizomes, or underground stems, of the plant. The rhizomes are dug in winter or spring. The bark is then removed and the rhizomes are cleaned and boiled, or steamed and baked. They are soaked in water a second time and sliced. In traditional Chinese herbal medicine, gastrodia is given as a decoction (concentration of herb after boiling down), in doses of 3-10 g per day.

The *Armillaria* mushroom that is necessary for the growth of the gastrodia tuber has been given the Chinese name of *tian ma mihuanjun*. It is more potent than the gastrodia tuber because it is the source of the tuber's active compounds. Although exact comparisons have not yet been determined, most Chinese practitioners use about half the customary dosage of gastrodia when they are replacing it with *Armillaria*. The mushroom or the gastrodia tuber are given in powdered form, in doses of 1.0-1.5 g, two or three times per day.

Herbal formulas

Gastrodia has been a favorite herb to use in combination formulas to treat specific conditions. Most of these formulas come in the form of tablets or capsules. A Chinese pharmacology textbook lists the following herbal mixtures containing gastrodia:

- For dizziness and headache caused by a hyperactive liver: gastrodia combined with uncaria and haliotis.
- For disturbances caused by wind-phlegm: gastrodia with pinellia and atractylodes.
- For migraine: gastrodia combined with cnidium.
- For convulsions caused by liver heat: gastrodia with antelope horn and uncaria.
- To clear the meridians and relieve pain or numbness in the limbs: gastrodia combined with achyranthes, *chin-chiu*, and *chiang-huo*.

Precautions

Gastrodia is considered a mild herb by the Chinese, and therefore generally safe to use. It is best to consult an experienced practitioner of Chinese herbal medicine before using gastrodia either as a single herb or in formulas.

Side effects

One source reports that the side effects of gastrodia include skin **allergies**, **hair loss**, and other allergic reactions.

Interactions

Because gastrodia has not been used by Western herbalists, its potential interactions with standard pharmaceutical preparations have not been studied.

Gastroenteritis

Definition

Gastroenteritis is a general term for infection or irritation of the digestive tract, particularly the stomach and intestine. It is frequently referred to as stomach or intestinal flu, although the **influenza** virus does not cause this illness. Major symptoms include **nausea**, **vomiting**, **diarrhea**, and abdominal cramps. **Fever** and overall weakness sometimes accompany these symptoms. Gastroenteritis typically lasts about three days. Adults usually recover without problem, but children, the elderly, and persons with an underlying disease are more vulnerable to complications such as dehydration.

Description

Gastroenteritis is an uncomfortable and inconvenient ailment, but it is rarely life-threatening in the United States and other developed nations. In the United States an estimated 220,000 children younger than age five are hospitalized annually with gastroenteritis symptoms. Of these children, 300 die as a result of severe diarrhea and dehydration. In developing nations, diarrhea-related illnesses are a major source of mortality.

Viral gastroenteritis

Gastroenteritis is usually caused by infection with one of the following viruses: rotavirus, adenovirus, astrovirus, calicivirus, and small round-structured viruses (SRSVs). These viruses are found all over the world and are particularly problematic where sanitation is poor. Typical exposure to these viruses occurs through the fecal-to-oral route, by ingesting food that is contaminated with fecal material or by coming in contact with an infected person's vomit or diarrhea and then inadvertently bringing the contaminant to the mouth. Other routes of transmission are quite likely because exposure to as few as 100 virus particles can cause an infection.

Typically, children are more vulnerable to rotaviruses—the most common cause of acute watery diarrhea. It is estimated that each year rotaviruses cause 800,000 deaths worldwide in children younger than age five. The Centers for Disease Control and Prevention (CDC) estimates that rotavirus results in 55,000 annual hospitalizations in the United States for young children and infants. Adults can be infected with rotaviruses, but these **infections** typically have minimal or no symptoms.

Adenoviruses and astroviruses are minor causes of childhood gastroenteritis, and children may become infected with caliciviruses and SRSVs. Adults experience illness from astroviruses as well, but the major causes of adult viral gastroenteritis are the caliciviruses and SRSVs. The SRSVs are a type of calicivirus and include the Norwalk, Southhampton, and Lonsdale viruses. SRSVs are the most likely to produce vomiting as a major symptom.

Bacterial gastroenteritis

Bacterial gastroenteritis is frequently a result of poor sanitation, the lack of safe drinking water, or contaminated food—conditions that are common in developing nations. Natural or man-made disasters can worsen underlying sanitation and food-safety problems. In developed nations, modern food production, handling, and distribution systems and methods may expose millions of people to disease-causing bacteria. Common types of bacterial gastroenteritis can be linked to *Salmonella* and *Campylobacter* bacteria. In the United States, *Campylobacter* alone affects more than one million people per year; however, *Escherichia coli* O157 and *Listeria monocytogenes* are creating increased concern in developed nations as of 2008. Cholera and shigella remain two diseases of great concern in developing countries, and research to develop long-term vaccines against them was underway as of 2008.

Causes and symptoms

Gastroenteritis arises from ingestion of viruses, certain bacteria, or parasites. Spoiled food may also cause illness. Certain medications and excessive alcohol can irritate the digestive tract to the point of inducing gastroenteritis. Regardless of the cause, the symptoms of gastroenteritis include diarrhea, nausea, vomiting, abdominal **pain**, and cramps. Patients may also experience bloating, low fever, and overall tiredness. Typically, the symptoms last only two to three days, but some viruses may last up to a week.

A typical bout of gastroenteritis should not require a visit to the doctor. However, medical treatment is essential if symptoms worsen or if there are complications. Infants, young children, the elderly, and persons with underlying disease require special attention in this regard.

Dehydration is the greatest danger presented by gastroenteritis. The loss of fluids through diarrhea and vomiting can upset the body's electrolyte balance, leading to potentially life-threatening problems, such as heart beat abnormalities (arrhythmia). The risk of dehydration increases the longer that symptoms are present. Signs of dehydration include a **dry mouth**, increased or excessive thirst, or scanty urination.

Symptoms that do not clear up within a week may point to an infection or disorder more serious than gastroenteritis. Symptoms of great concern include a fever of 102°F (38.9°C) or above, blood or mucus in the diarrhea, blood in the vomit, and severe abdominal pain or swelling. Persons experiencing these symptoms should seek prompt medical attention.

Diagnosis

The symptoms of gastroenteritis are usually sufficient for identifying the illness. Unless there are complications or there is an outbreak that affects several people, identifying the specific cause of the illness is not a priority. If it is necessary to identify the infectious agent, a stool sample will be collected and analyzed for the presence of viruses, disease-causing (pathogenic) bacteria, or parasites.

Treatment

Gastroenteritis is a self-limiting illness that will resolve by itself. Symptoms of uncomplicated gastroenteritis can be relieved with adjustments in diet, herbal remedies, and **homeopathy**. An infusion of meadowsweet (*Filipendula ulmaria*) may be effective in reducing nausea and stomach acidity. Once the worst symptoms are relieved, **slippery elm** (*Ulmus fulva*) can be used to calm the digestive tract.

The homeopathic remedies *Arsenicum album*, **ipecac**, and ***Nux vomica*** are also believed to relieve the symptoms of gastroenteritis. In Chinese herbal medicine, the patent remedies Po Chai and Pill Curing can be effective for relieving nausea and diarrhea.

Supplementing the bacteria that are beneficial to a person's health (**probiotics**) is recommended during the recovery phase of gastroenteritis. Specifically, live cultures of *Lactobacillus acidophilus* are said to be effective in soothing the digestive tract and returning the intestinal flora to normal. In fact, in 2002, a study found it was reasonably effective in treating children with acute infectious diarrhea. *L. acidophilus* is found in live-culture yogurt and in capsule or powder form at health food stores. **Castor oil** packs applied to the abdomen can reduce inflammation, spasms, and discomfort.

It is important to stay hydrated and nourished during a bout of gastroenteritis. In the absence of dehydration, it should be sufficient to drink generous amounts of nonalcoholic fluids, such as water or juice. **Caffeine** should be avoided, since it increases urine output.

The traditional BRAT diet—bananas, rice, applesauce, and toast—is tolerated by the tender gastrointestinal system, but it is not particularly nutritious. Many, but not all, medical researchers recommend a diet that includes complex carbohydrates (rice, wheat, potatoes, bread, and cereal, for example), lean meats, yogurt, fruit, and vegetables. Milk and other dairy products should not create problems if they are part of the normal diet. Fatty foods or foods with a lot of

sugar should be avoided. These recommendations are based on clinical experience and controlled trials but are not universally accepted.

Allopathic treatment

Over-the-counter medications such as Pepto Bismol are useful in relieving the symptoms of gastroenteritis. These medications work by altering the intestine's ability to move or secrete spontaneously, by absorbing toxins and water, or by altering intestinal microflora. Some over-the-counter medicines use more than one element to treat symptoms, and this information should be included on the label.

If over-the-counter medications are ineffective, a doctor may prescribe a more powerful anti-diarrheal drug, such as motofen or lomotil. If pathogenic bacteria or parasites are found in the patient's stool sample, medications such as antibiotics will be prescribed.

The physician may prescribe odansetron (Zofran) to treat nausea and vomiting. In a study done at the Children's Memorial Hospital in Chicago, one dose of odansetron helped relieve the symptoms and promoted rehydration.

Minimal to moderate dehydration is treated with oral rehydrating solutions that contain glucose and electrolytes. These solutions are commercially available under names such as Naturalyte, Pedialyte, Infalyte, and Rehydralyte. If vomiting prevents patients from taking a full dose of solution, they may better tolerate fluid taken in small, frequent amounts. Should oral rehydration fail or severe dehydration occur, medical treatment in the form of intravenous (IV) therapy is required. IV therapy can be followed with oral rehydration as the patients' condition improves. Once normal hydration is achieved, patients can return to a regular diet.

Sometimes, a child's dehydration is so severe that it requires hospitalization with IV therapy. However, a study published in 2002 informed pediatricians that often, rapid intravenous rehydration and rapid nasogastric hydration in the emergency department are safe and effective alternatives to hospitalization for many children with viral gastroenteritis. Doing so saves money and spares children the more frightening experience of being in a hospital overnight and the routine laboratory testing they would endure in the hospital setting.

Expected results

Gastroenteritis usually clears up within two to three days and there are no long-term effects. If dehydration occurs, recovery is extended by a few days.

KEY TERMS

Dehydration—A condition in which the body lacks the normal level of fluids, potentially impairing normal body functions.

Electrolyte—An ion, or weakly charged element, that conducts reactions and signals in the body. Examples of electrolytes are sodium and potassium ions.

Glucose—A sugar that serves as the body's primary source of fuel.

Influenza—A virus that affects the respiratory system, causing fever, congestion, muscle aches, and headaches.

Intravenous (IV) therapy—Administration of fluids through the veins.

Microflora—The bacterial population in the intestine.

Pathogenic bacteria—Bacteria that produce illness.

Probiotics—Bacteria that are beneficial to a person's health, either through protecting the body against pathogenic bacteria or assisting in recovery from an illness.

Prevention

Gastroenteritis can be avoided by practicing good hygiene, which includes washing hands thoroughly after using the bathroom or coming in contact with an infected person, using disinfectants to clean areas the infected person has come in contact with, and washing infected linens in hot water. Making sure that food is well-cooked and unspoiled can prevent bacterial gastroenteritis but may not be effective against viral gastroenteritis.

In 2006, the United States Food and Drug Administration (FDA) approved RotaTeq, a vaccine to prevent rotavirus in infants. The vaccine is given by mouth in liquid form. It is a live vaccine and is given in three doses between the ages of six weeks and 32 weeks.

KEY TERMS

Alkaloid—One of a group of organic compounds which are generally toxic.

Neuralgia—Severe nerve pain.

Phenacetin—A compound formerly used to ease pain or fever, but withdrawn because of its serious side effects.

Rhizome—A horizontal, underground stem that sends out roots.

Gelsemium

Description

Gelsemium sempervirens is also known as yellow jasmine, false jasmine, wild woodbine, and Carolina jasmine. It is a woody, climbing vine with dark leaves and groups of yellow, bell-shaped flowers that bloom in early spring. The flowers are very fragrant. It is native to the coastal areas extending from Virginia to Florida, and in Mexico, and is the state flower of South Carolina.

Gelsemium contains extremely toxic alkaloid components, and is not in current medical use. Even very small doses may prove lethal. It was reportedly discovered in the nineteenth century as a result of mistaken identity for another herb. A sick farmer took it for an attack of "bilious fever," and became quite ill. When the symptoms resolved, he discovered that his prior illness had also disappeared. It came into use as an agent to treat **fever**, spasmodic disorders, and the **pain** of **neuralgia**.

General use

The herb form of gelsemium has historically been used for migraines resulting from excessive cerebral blood flow, severe **wheezing** attacks of **asthma**, **insomnia**, and nerve pain, particularly trigeminal neuralgia. The latter condition is a disorder of the trigeminal nerve, which causes shooting pain in the area of the lips, gums, cheek, chin, and occasionally around the eye. Use of the herb form has not been recommended for some time due to the extremely toxic potential of the alkaloids this plant contains.

Homeopathic remedies incorporating gelsemium have specific indications. As with other homeopathic treatments, they contain infinitesimal amounts of the active ingredient, so that toxicity is highly unlikely. Some of the recommendations for the use of homeopathic gelsemium include **migraine headache**, **anxiety**, chemotherapy support, dental support, **influenza**, **nausea**, and recovery from surgery.

Homeopathic gelsemium is thought to relieve anxiety in the form of apprehension about particular events, as well as generalized anxiety. The 30C formulation is recommended for this purpose, taken as needed up to three or four times daily, for no longer than one week. The 6C formulation may be used two or three times prior to undergoing chemotherapy treatment. Similar dosing is recommended prior to a visit to the dentist.

True influenza is a respiratory ailment, although symptoms also include aches, fever, **chills**, and **headache**. Homeopathic recommendations for gelsemium due to flu symptoms include mild fever, dull headache at the nape of the neck, and **dizziness**. Gelsemium 6C can be used for as long as five days, once every three to four hours, during the illness.

Migraine headaches that are felt primarily in the back of the head or as constrictive pain may be helped by homeopathic preparations of gelsemium. Visual aura and aching of the neck and shoulders may accompany this type of headache. For best results, gelsemium 30C is taken as soon as symptoms begin, every 30 minutes, for up to three doses if needed.

Homeopathic gelsemium is also recommended to support surgical recovery, particularly for those who are quite apprehensive and restless. The 6C formulation may be taken for a few days preceding the surgery, up to four doses per day.

Consult a practitioner of **homeopathy** to determine the best indicated doses and combinations of remedies for a particular health issue.

Preparations

The dried root, harvested in autumn, is the usable portion of the plant. Gelsemium is currently unavailable in medicinal formulations due to the narrow safety margins and dangerous toxicity.

Precautions

Gelsemium is an extremely toxic herb because of the alkaloid component, related to strychnine, which exists in all parts of the plant. Symptoms can include sweating, nausea, muscular weakness, dilated pupils, lowered temperature, and convulsions. It can excessively depress the nervous system, and can cause death due to respiratory failure. A lethal dose is approximately 2–3 g for an adult, and 500 mg for a child. Ingestion of as little as a single flower has reportedly resulted in the fatality of a child. Accidental ingestion of the plant under any circumstances warrants emergency treatment.

The safety margin of gelsemium is extremely small. It should never be used, especially in children, or in women who are pregnant or lactating. Oral use of preparations from the rhizome or root are also considered unsafe. It is particularly dangerous for people with any sort of **heart disease**.

Side effects

There are no reported side effects, although individual aggravations may occur.

Interactions

The effects of aspirin and phenacetin may be increased by gelsemium.

Genital herpes

Definition

Genital herpes is a sexually transmitted disease caused by the herpes simplex virus. The disease is characterized by the formation of fluid-filled, painful **blisters** in the genital area.

Description

Genital herpes is a sexually transmitted disease spread by vaginal, anal, and oral contact. The first herpes infection a person has is called a primary infection. It develops about four to seven days after contact with the disease. Once a person has been infected with the herpes virus, it cannot be completely cured. Instead, the virus can lay latent in the sensory nerve ganglia for days, months, or even years between outbreaks. When the virus becomes activated there is a recurrent infection of the skin. An active herpes infection is then obvious because of the sores that develop. However, an active infection may occur without visible sores. Up to 75% of people with herpes may not know they have the infection.

Newborn babies who are infected with herpes virus experience a very severe, and possibly fatal, disease called neonatal herpes. In the United States, one in 3,000–5,000 babies born are infected with herpes virus. Babies usually become infected during passage through the birth canal, but they also can become infected during **pregnancy** if the membranes rupture early.

Causes and symptoms

Genital herpes results from an infection by herpes simplex virus. There are several different kinds of human herpes viruses. Only two of these, herpes simplex type 1 (HSV-1) and type 2 (HSV-2), can cause herpes. HSV-2 is most often responsible for genital **infections**. HSV-1 usually causes oral herpes, but it can also cause genital herpes about 10–30% of the time. While the herpes virus can infect anyone, not everyone shows symptoms. Risk factors include early age at first sexual activity, multiple sexual partners, and a medical history of other sexually transmitted diseases (STDs).

The first symptoms of a primary herpes infection usually occur within two to seven days after contact with an infected person but may take up to two weeks. Symptoms of a primary infection are usually more severe than those of recurrent infections. For up to 70% of people, a primary infection causes general

symptoms such as tiredness, **headache**, **fever**, **chills**, muscle aches, loss of appetite, and painful, swollen lymph nodes. These symptoms are greatest during the first three to four days of the infection and disappear within a week.

Most people with genital herpes experience prodromes, or symptoms of the oncoming disease. Such symptoms might include **pain**, burning, **itching**, or tingling at the site on the genital area, legs, or buttocks where blisters will form. The prodrome stage may occur anywhere from a few hours, to one or two days before an outbreak of the infection. Following that time, small red bumps appear. These bumps quickly become fluid-filled blisters that may also fill with pus and become covered with a scab. The blisters may burst and become painful sores. Blisters may continue to erupt for a week or longer. Pain usually subsides within two weeks, and the blisters and sores heal without scarring by three to four weeks. It is possible to pass the virus to other parts of the body by touching an open sore and then bringing the fingers into contact with the mouth, the eyes, or a break in the skin. The highest risk for spreading the herpes virus is the time during the appearance of blisters up to the formation of scabs. However, an infected person can spread herpes virus to other people even in the absence of sores.

Women can experience a very severe and painful primary herpes infection. In addition to the vaginal area, blisters often appear on the clitoris, at the urinary opening, in the rectum and around the anus, and on the buttocks and thighs. The cervix is almost always involved, causing a watery discharge. About one in 10 women get a vaginal **yeast infection** as a complication of herpes. In men, the herpes blisters usually form on the penis but can also appear on the scrotum, thighs, around the anus, and in the rectum. Men may also have a urinary discharge with a genital herpes infection. Both men and women may experience painful or difficult urination, swelling of the urethra, **meningitis**, and throat infections, with women experiencing these symptoms more often than men.

As of 2008, scientists did not know the factors that trigger a latent herpes virus to activate, but several conditions seem to be connected with the onset of an active infection. These include illness, **stress**, tiredness, sunlight, **menstruation**, skin damage, food **allergies**, and extreme hot or cold temperatures. Most people with genital herpes experience one or more outbreaks per year. About 40% experience six or more outbreaks per year. Active recurrences of herpes are usually less severe than the primary infection. There are fewer blisters, less pain, and the time period from the beginning of symptoms to healing is shorter than the primary infection.

Diagnosis

Because genital herpes is so common, it can be initially diagnosed by symptoms. A Tzanck test can also be used for a quick initial diagnosis. The test is performed using a sample scraped from the base of an active blister. A confirmation of the diagnosis can be done by making a tissue culture of material scraped from the skin lesions, testing the blood for herpes antibodies, or examining fluid and scrapings from the lesions by a method called direct immunofluorescent assay. Since most infants infected with the herpes virus are born to mothers with no symptoms of infection, newborns and pregnant women are often routinely given blood tests called the TORCH antibody panel, which includes a test for herpes. Babies also need to be checked for signs of herpes infection in their eyes. Skin sores and sores in the mouth should be sampled for the presence of herpes simplex.

Treatment

An imbalance in the **amino acidslysine** and **arginine** is thought to be one contributing factor in herpes virus outbreaks. Supplementation with lysine may help maintain the correct balance and prevent recurrences of herpes. Patients may take 500 mg of lysine daily and increase to 1,000 mg three times a day during an outbreak. Intake of foods that are rich in the amino acid arginine should be avoided, including chocolate, peanuts, almonds, and other nuts and seeds.

Clinical experience indicates a connection between high stress and herpes outbreaks. Many people respond well to stress reduction and **relaxation** techniques. **Acupressure** and massage may relieve tiredness and stress. **Meditation**, **yoga**, **t'ai chi**, **acupuncture**, and **hypnotherapy** can also help relieve stress and promote relaxation. Counseling and support groups are often recommended to deal with the emotional and psychological stress of the disease.

An extract of bovine thymus gland can be taken to improve immune function and help the body fight against viral infections such as herpes. Some herbs are also able to serve as antivirals. They include **echinacea** and **garlic** (*Allium sativum*). **Siberian ginseng**, *Eleutherococcus senticosus,* is useful in relieving the stress response that can bring on recurrent herpes outbreaks. Supplementation with beta-carotene and **vitamin E** is recommended during an outbreak. Homeopathic remedies that may be helpful treatments

for genital herpes include *Rhus tox* 6c and *Apis mellifica* 6c.

There are **traditional Chinese medicine** combinations that are useful for herpes outbreaks. One, called Zhi Bai Lui Wai Di Huang, is a mixture of philodendron and other remedies. Another is Long Dan Xie Gan Tang, a soup made to drain the liver. A traditional Chinese medicine practitioner can help create the right combination specific to the outbreak.

Red marine algae, both taken internally and applied topically, is thought to be effective in treating herpes. Other topical treatments may be helpful in inhibiting the growth of the herpes virus, in minimizing the damage it causes, or in helping the sores heal. **Zinc** may also be used both internally and externally. Oral supplementation coupled with an application of zinc sulfate ointment may help heal sores and fight recurrent outbreaks. Lithium succinate ointment may interfere with viral replication. An ointment made with glycyrrhizinic acid, a component of **licorice** (*Glycyrrhiza glabra*), seems to inactivate the virus. Topical applications of vitamin E oil or **tea tree oil** (*Melaleuca* spp.) help dry up the sores.

Allopathic treatment

There is no cure for a herpes infection. Aspirin may be used to reduce pain and inflammation. Antiviral drugs are available that may lessen the symptoms and decrease the length of outbreaks. There is evidence that some may also help prevent the spreading of the disease and reduce recurrence of future outbreaks. For the best results, treatment with antiviral drugs has to begin during the prodrome stage, before blisters are visible. Depending on the length of the outbreak, drug treatment may continue for up to 10 days.

Acyclovir (Zovirax) is the drug of choice for herpes infection and can be given intravenously, taken by mouth, or applied directly to sores as an ointment. Intravenous acyclovir is given to patients who require hospitalization, usually due to severe primary infections or complications of herpes such as aseptic meningitis or sacral ganglionitis, an inflammation of nerve bundles. Acyclovir reduces the virus shedding period, the duration of the blisters, and the healing time. Patients with herpes outbreaks happening more than six to eight times per year may be given a long-term course of treatment with acyclovir. This is referred to as suppressive therapy. Patients on suppressive therapy have longer periods between herpes outbreaks. Alternatively, patients may use short-term suppressive therapy to lessen the chance of developing an active infection during special occasions such as weddings or holidays. Side effects of acyclovir include **nausea**, **vomiting**, itchy rash, and **hives**. Other drugs that may be used include famciclovir (Famvir), valacyclovir (Valtrex), vidarabine (Vira-A), idoxuridine (Herplex Liquifilm, Stoxil), trifluorothymidine (Viroptic), and penciclovir (Denavir).

Neonatal herpes is a serious condition. Even with treatment, babies may not survive or they may suffer serious damage to the nervous system. Newborns with herpes infections are normally treated with intravenous acyclovir or vidarabine for 10 days. However, infected babies may have to be treated with long-term suppressive therapy. These drugs have greatly reduced deaths and have also increased the number of babies who are relatively healthy by one year of age.

Expected results

Genital herpes is usually not a serious disease, with several major exceptions. Sometimes, a primary infection can be severe and may require hospitalization for treatment. Complications that may arise include aseptic meningitis and nervous system damage. There may also be **constipation**, **impotence**, and difficulty with urination. In addition, people who are immunosuppressed due to disease or medication are at risk for a very severe, and possibly fatal, herpes infection. And even with antiviral treatment, neonatal herpes infections can be fatal or cause permanent nervous system damage.

Prevention

The only way to definitely prevent a genital herpes infection is to avoid contact with infected people, which is not an easy solution because many people are not aware that they are infected. Use of condoms and spermicidal jellies or foams with monoxynol-9 is recommended with all partners whose disease status is questionable or unknown. However, condoms may not protect against herpes when there is skin contact with someone with an open sore that cannot be covered by a condom. Use of dental dams or squares of non-microwaveable plastic wrap is also recommended. Sexual contact should be avoided altogether during a herpes outbreak. Touching affected areas should be avoided, since this can spread the infection to other sites. In order to prevent a child from contracting a herpes infection through contact in the birth canal, doctors usually perform Caesarean sections on women who have active herpes sores when they go into labor.

KEY TERMS

Culture—A laboratory test in which colonies of microorganisms are grown from tissue samples of an infected individual in order to identify the pathogen.

Immunofluorescent assay—A laboratory technique using a fluorescent dye and a special microscope to identify the cause of an infection.

Meningitis—An infection or inflammation of membranes of the brain and spinal cord.

Sensory root ganglion—A bundle of nerves that help conduct physical sensations.

Tzanck test—A laboratory test using a microscope to examine tissue samples that have been stained with certain dyes.

Urethra—The small tube that drains urine from the bladder.

Genital warts

Definition

Genital **warts**, or condylomata acuminata, are also called venereal warts. These warts are painless, pink or grayish growths on the skin and mucous membranes of the genitals and anal area. They are usually found in clusters. Genital warts are very contagious and are spread through sexual contact with an infected person.

Description

Genital warts are the second most common sexually transmitted disease (STD), after **chlamydia**, in the general population of the United States. Public health officials estimate that 1% of sexually active people between the ages of 18 and 45 have genital warts. However, studies indicate that approximately 50% of sexually active adults may carry the virus that causes genital warts. Certain **strains** of the virus that cause genital warts may also cause cervical changes and **cancer**.

Causes and symptoms

Genital warts are caused by several subtypes of human papillomavirus (HPV), the same virus that causes warts on other parts of the body. Symptoms develop about one to six months after being exposed to the virus. Once contracted, the virus remains in the infected person's body even though the warts are not visible. In addition to the visible warts, symptoms of the disease may include bleeding, **pain**, odor, **itching**, and redness in affected areas. These symptoms may appear without the warts, and the warts may appear without other symptoms. **Stress** may contribute to recurrent outbreaks.

Genital warts may be difficult to detect. At any given time, at least a quarter of all HPV **infections** are in a state of remission, in which the infection remains dormant in the body, and there are no outbreaks of warts or other readily detected symptoms. In addition,

Man with genital warts. *(Custom Medical Stock Photo. Reproduced by permission.)*

warts that occur deep inside the vagina, on the cervix, or within the anus may go undetected.

HPV can be transmitted through oral, anal, or genital contact with an infected person, even if warts are not visible. The virus may also be transmitted via objects that have been recently exposed to the virus. These objects may include unwashed or improperly cleaned medical equipment, as well as underwear, tanning beds, and sex toys.

Risk factors for contracting genital warts include:

- multiple sex partners
- infection with another sexually transmitted disease (STD)
- pregnancy
- anal intercourse
- poor personal hygiene
- heavy perspiration

Genital warts vary somewhat in appearance. They may either be flat or resemble raspberries in appearance. The warts begin as small, red or pinkish growths. They may grow in clusters as large as 4 in (10 cm) across, and may interfere with intercourse and **childbirth**. The warts grow on warm, moist tissue. In women, they occur on the external genitalia, the cervix, and the walls of the vagina. In men, they develop in the urethra and on the shaft of the penis. The warts may also spread to the area surrounding the anus.

Diagnosis

Genital warts are usually identified and diagnosed by their characteristic appearance. A sexual history should be taken, and tests for other STDs may be administered. If cervical warts are suspected, a colposcopy exam to view the cervix is necessary for diagnosis. A Papanicolaou (Pap) smear may be performed, and the doctor may order a biopsy of the warts to rule out cancer.

Treatment

Genital warts are contagious and should be assessed and treated under the supervision of a healthcare practitioner. A **traditional Chinese medicine** practitioner or an acupuncturist will probably recommend treatments to cleanse the liver and enhance immune functioning. A generally recommended homeopathic remedy is the application of a tincture of *Thuja occidentalis* (common names **thuja**, northern white cedar, and arborvitae, or tree-of-life) directly to the warts. A homeopathic physician should be consulted for a work-up for further treatment.

The direct topical application of **vitamin A**, thuja, **lomatium** (*Lomatium dissectum*) isolate, or **tea tree oil** (*Melaleuca alternifolia*) helps resolve warts and prevent recurrence of outbreaks. With the exception of the tea tree oil, these herbs should also be taken internally in addition to direct application. Some evidence suggests that deficiencies of **folic acid** and vitamins A and C contribute to genital warts. Such deficiencies may be risk factors for a progression to abnormal cervical cells and cancer; therefore, supplementation is recommended. Beta carotene is often suggested as an alternative to taking high dosages of vitamin A.

Treatments that focus on emotional and psychological factors have been shown to be effective in reducing or eliminating outbreaks of warts. **Hypnotherapy** and techniques of stress reduction and **relaxation** are highly recommended.

Allopathic treatment

There is no cure for genital warts, as the virus cannot be destroyed once it enters the body. The warts themselves may be burned off with electrocautery or lasers, frozen with liquid nitrogen for easy removal, or surgically removed. Podophyllum resin, trichloroacetic acid, interferon inducers, 5-fluorouracil cream, bichloroacetic acid, or trichloroacetic acid can be used as a topical treatment. These medications require several weeks of treatment and may irritate the skin. Pregnant women should be sure to inform their healthcare provider of this condition, as some of the medications for warts may cause fetal abnormalities. Genital warts can also be treated with injections of interferon, either into muscle tissue or directly into the lesions.

Unfortunately, regardless of the treatment regime, genital warts have a high rate of recurrence. Several

KEY TERMS

Cervix—The entrance to the uterus that protrudes into the vagina.

Electrocautery—A procedure in which heat from an electric current is used to perform surgical procedures.

Mucous membranes—Thin sheets of tissue that cover and protect body passages that open to the outside. These membranes secrete mucus and absorb water and various salts.

Papanicolaou (Pap) smear—A diagnostic test using a sampling of tissue from the cervix.

Papilloma—A benign growth on the skin or mucous membrane.

courses of treatment may be required. Sexual partners should be diagnosed and treated as well. Because of the connection between certain strains of HPV and cervical cancer, infected women should also have yearly Pap smears.

Expected results

As with many warts, genital warts may spontaneously disappear over time. Although the warts are not cancerous by themselves, HPV infection in women appears to increase the risk of later cervical cancer. Recurrence is common with all methods of treatment.

Prevention

The only reliable method of prevention is sexual abstinence. The use of condoms is often recommended; however, condoms protect only a limited area and should not be relied upon for complete protection from genital warts. Circumcision may sometimes prevent recurrence of the visible warts.

Gentiana

Description

Gentiana is a plant extract made from gentians, which are a group of perennial plants belonging to the Gentianaceae family. There are about 180 species of gentians worldwide. They have a long history of use in healing both in Asian and **Western herbalism**. In the West, the common gentian used in healing is *Gentiana lutea*, or yellow gentian. In China, two different gentians are used in healing, *Gentiana macrophylla*, known in Chinese as *qin jiao*; and *Gentiana scabra*, known in Chinese as *long dan cao*.

G. lutea grows wild or cultivated in many places from Europe to India. It is also cultivated in North America. It grows to a height of about 4 ft (1.2 m), primarily in temperate alpine and subalpine meadows. The plant produces a spike of showy yellow-orange flowers. *G. macrophylla* grows in China and Siberia, and *G. scabra* grows in China and Japan.

There are some differences in height, leaf size, and flower among these three gentians, but the roots and rhizomes (underground stems) used to make gentiana are very similar. Gentians have a single long, strong taproot that can extend as far as 3 ft (1 m) into the earth. The top of the taproot can be as thick as a child's arm and is surrounded by a cluster of rhizomes. The root has an extremely bitter taste. Other names for gentiana include bitter root, bitterwort, and gall weed.

KEY TERMS

Amargogentin—An extremely bitter substance found in gentian that makes it an effective digestive stimulant.

Rhizome—A rootlike underground stem of a plant.

Stomachic—A substance or medication that sharpens the appetite or stimulates digestion.

Tincture—An alcohol-based extract prepared by soaking plant material.

Tonic—Any medicine given to strengthen and invigorate the body or a specific organ.

General use

Gentiana has been used for centuries. It gets its name from Gentius, King of Illyria (a part of Greece) from 180–167 B.C., who is said to have discovered the medicinal value of these plants. Gentian is one of the most intensely bitter herbs ever discovered. It is an ingredient in Angostura™ **bitters**. At one time it was used as a substitute for **hops** in making beer. Gentiana is also used in small amounts as a food flavoring, and is added to many anti-smoking products.

In Western herbalism, gentiana is used for digestive problems. It is an ingredient in aperitifs that are drunk a half-hour or so before eating to stimulate the appetite and digestion. Liqueurs made using fresh gentiana have been used for generations in Europe; in the eighteenth century gentian wine was served before eating as a stomachic, or aid to digestion.

In addition to stimulating digestion and appetite, gentiana is used to relieve **heartburn** and stomach ache, and to treat **vomiting**, **diarrhea**, abdominal fullness, and intestinal **gas**. Western herbalists also use gentiana for treating **fever**, **sore throat**, **jaundice**, and arthritis. It is used externally to treat **wounds**.

In **traditional Chinese medicine**, *G. macrophylla*, or *qin jiao*, is considered to have a neutral nature and a bitter, pungent taste. It is associated with the liver, stomach, and gallbladder. It is used as a tonic for the digestive system, and to treat arthritis; chronic low-grade fever; jaundice; **hepatitis**; and **constipation**. It is also an ingredient of several common formulas.

According to Chinese herbalists, another gentian, *Gentiana scabra*, or *long dan cao*, has a cold nature and a bitter taste. It is associated with the liver, stomach, gallbladder, and bladder. *Long dan cao* is used in formulas to treat pink eye (**conjunctivitis**); high blood pressure; acute urinary **infections**; testicular **pain**; leucorrhea (whitish vaginal discharge); vaginal pain; tantrums in children; fever; and balance problems.

A long history of folk use coupled with modern scientific investigation shows that gentiana works well as a stomach tonic and digestive stimulant. The German Federal Health Agency's Commission E, established in 1978 to independently review and evaluate scientific literature and case studies pertaining to herb and plant medications, has approved gentiana for use in Germany. It is considered safe and effective in treating such digestive complaints as loss of appetite, abdominal bloating, and gas.

In laboratory studies gentiana was found to contain a substance called amargogentin, which is possibly the bitterest compound ever found. It can be tasted at dilutions of 1:50,000. Its bitterness triggers the secretion of saliva, thus stimulating the production of gastric juice and bile and preparing the digestive system to process food. This reaction makes gentiana effective in treating almost all conditions related to sluggish digestion.

Other research shows that gentiana has selective antifungal, anti-inflammatory, and antispasmodic activity in laboratory experiments. There is much less scientific evidence to support such other traditional uses as treating pain and fever.

Preparations

Gentian roots are harvested in the autumn. They are used fresh in the production of liqueurs, but are dried for medicinal use. The better roots are dried quickly and remain whitish for several months before they darken. Roots that are dried too slowly will ferment.

Gentiana is available in many forms including an extract, dried powdered rhizome, tea, tincture, and decoction. The liquid remedies are very bitter, and sweetening is often added to make them more palatable. Gentian tea can be made by adding 1 tsp of powdered dried rhizome to every 3 cups (750 ml) of water. One tablespoon of this tea is taken about half an hour before eating. Smaller amounts of tincture and decoction can also be taken before eating.

In traditional Chinese medicine, gentiana is used in a formula (*long dan xie gan wan*) to treat chronic bladder infections, herpes, **blisters** in the mouth, and **dizziness**.

Precautions

German health authorities recommend that gentiana not be used by people who have stomach

(gastric) or intestinal (duodenal) ulcers. In a few sensitive people, gentiana can cause stomach irritation and **headache**. Chinese herbalists recommend that gentiana not be used when there is frequent urination and chronic pain with weight loss.

Side effects

Overdoses of gentiana may cause **nausea** and vomiting.

Interactions

A long history of use in both East and West suggests that there are no interactions with either herbs or modern pharmaceuticals. Few studies, however, have been done to verify these observations.

Geriatric massage

Definition

Geriatric massage is a form of massage designed to meet the specific needs of the elderly population. It involves the use of hands to manipulate the soft tissues of the body to improve blood circulation, relieve **pain**, and increase range of motion. Active or passive movement of the joints may also be part of geriatric massage.

Old people often have a variety of such age-related diseases as **Parkinson's disease**, arthritis, diabetes, or **heart disease**. As a result, they have poor blood circulation and limited physical activity. Many of them are also anxious, depressed and lonely. Geriatric massage can help them maintain and improve their overall health, as well as regain certain physical functions that have been reduced or lost due to **aging**. In addition, it can relieve **anxiety** and **depression** and provide comfort to touch-deprived elderly patients.

Origins

Modern massage techniques were brought into the United States from Sweden in the 1850s by two brothers, Dr. Charles and Dr. George Taylor. Their massage technique was invented by a Swedish fencing instructor named Per Henrik Ling in the 1830s. When he was injured in the elbows, he reportedly cured himself using tapping movements around the affected area. He later developed the technique currently known as **Swedish massage**. This massage technique involves the application of long gliding strokes, friction, kneading and tapping movements on the soft tissues of the body. Passive or active joint movements are also used.

Benefits

Geriatric massage offers the following benefits:

- Increase in blood circulation, thus preventing such complications of diabetes as leg ulcers or gangrene.
- Improvement in lymphatic flow, which increases the excretion of toxic substances from the body.
- Alleviation of headache and pain.
- Speeding up of healing from injury and illness.
- Partial restoration of mobility lost due to Parkinson's disease or arthritis.
- Mental and physical relaxation.
- Improvement in length and quality of sleep.
- Relief of stress, anxiety, depression, and loneliness.
- Improvement of the patient's quality of life and self-esteem.

Description

Geriatric massage uses the same basic massage techniques as general massage. It is, however, tailored to the specific health conditions and needs of the elderly population. Geriatric massage has the following characteristics:

- Short sessions. A geriatric massage session usually lasts no longer than 30 minutes, as a longer session may be too much for an elderly person.
- Use of gentle hand motions. These motions are comfortable and soothing to the body. They are designed to improve blood circulation and heart function,

KEY TERMS

Massage—A rubbing or kneading with hands or other parts of the body to stimulate circulation, make joints more supple, and relieve tension.

Parkinson's disease—A progressive disease caused by degeneration of the basal ganglia of the brain. Its most common symptoms are tremors and muscular rigidity.

Varicose veins—Swollen and distended veins in the superficial skin layer of the legs.

prevent diabetic complications, relieve muscle tension, and relax the body and the mind.

- Passive movement and gentle stretching of shoulders, legs and feet to improve joint mobility and flexibility.
- Gentle massaging of the hands and feet (if the joints are not inflamed) to prevent stiffness and relieve pain.
- Occasional use of stronger movements such as friction and pressure strokes. These are sometimes used to massage such areas as the shoulders to improve flexibility.

Precautions

Geriatric massage should not be used as a replacement for **exercise** programs or medical treatment in nursing homes. In addition, it should not be given to elderly patients with the following conditions:

- broken bones or body areas that are inflamed, swollen or bruised
- open or unhealed bed sores
- varicose veins
- recent surgery
- severe acute pain
- certain heart conditions
- certain kinds of cancer
- a history of blood clots (The blood clots may become dislodged and travel to the lungs as a result of massage.)
- drug treatment with blood thinners (These medications increase the risk of bleeding under the skin.)

Side effects

Geriatric massage is very gentle and rarely causes adverse effects. More vigorous forms of massage, however, have been associated with bleeding in such vital organs as the liver or with the formation of **blood clots**.

Research and general acceptance

Geriatric massage is gaining acceptance in the medical community. It is being prescribed to elderly patients to improve blood circulation and relieve arthritic symptoms. It is sometimes prescribed for Parkinson's disease patients to help improve mobility. While most patients have to pay for this service, some insurance companies do reimburse prescribed massage treatment.

Training and certification

There are 58 school programs accredited by the Commission for **Massage Therapy** Accreditation/Approval in the United States. The schools provide a minimum of 500 hours of massage training. Certified therapists are graduates of these programs who have passed the national certification examination in therapeutic massage. They are also required to participate in continuing education programs to keep their skills current.

Gerson therapy

Definition

Gerson therapy aims to treat the whole person, not just symptoms. It is a general cleansing therapy for the entire body. The therapy can achieve the following: **detoxification**, restoration of metabolic functions, enabling the digestion and elimination of **cancer** masses through the bloodstream, and recovery of the organs, especially the liver.

Origins

Max Gerson was a pioneer in the world of alternative medicine. His therapy proved itself by providing a cure for just about every degenerative disease that plagues modern society, at a time when the first rumblings of disenchantment with so-called "modern medicine" were being heard. Among his initial successes was a 99% cure rate at a sanitarium for **tuberculosis**, unheard of with allopathic medicine. Beginning his work in the 1920s in Germany, he later immigrated to the United States, where in 1938 he was licensed to practice in New York. In 1946 he became the first physician to demonstrate recovered cancer patients before a U.S. Congressional Committee. Gerson had a 50% success rate even with terminal cancer patients that allopathic medicine had given up on. Albert Schweitzer referred to him as "a medical genius that walked among us."

Gerson first began to develop his therapy when he discovered that he could cure himself from terrible migraines by eating nothing but fresh fruit and vegetables.

Benefits

Gerson therapy has reported successes with the following: cancer, migraine, ulcers, **asthma**, **glaucoma**, edemas, **eczema**, diabetes, **schizophrenia**, **emphysema**, **epilepsy**, **allergies**, **psoriasis**, tuberculosis, arteriosclerosis, heart diseases, **rheumatoid arthritis**, kidney diseases, lupus erythematosus, **multiple sclerosis**, and high blood pressure; all of them common diseases and conditions. Gerson demonstrated that dramatic initial improvements can be expected within one week of starting his therapy, which involves taking nothing but absolutely fresh fruit and vegetable juices, coffee, **chamomile** and **castor oil** enemas, and additional nutrients according to the prescription of a practitioner who is conversant with the principles of the Gerson therapy.

KEY TERMS

Healing crisis—When the body is supplied with nutrients it needs to heal itself, the first thing it does is to flush out toxins from the cells. When these toxins are circulating in the bloodstream, they produce symptoms such as nausea, fevers, and extreme sensitivity.

Metabolic—Pertaining to chemical processes within the body that result in growth, production of energy and elimination of waste.

Oxidize—When oxygen reacts with a substance, it causes a decomposition of its living elements.

Toxification—When the body is unable to eliminate poisonous substances, they remain clogged in the system and eventually cause a breakdown of normal function.

Description

Gerson described how our food has been affected by the lowering of the quality of soil with the use of artificial fertilizers and pesticides. He went on to describe the growing of fruits and vegetables as the human being's "external metabolism." He lists numerous examples in his book of people from around the world who were living the same existence that they have lived for centuries, untouched by "civilization." These people, he noted, were living free of the diseases that modern societies considered commonplace.

It is essential that the juices for this therapy are organic; any traces of pesticides will prevent success with diseases such as cancer, for it is only when complete detoxification can be achieved that the body will be able to overcome such scourges.

The length of therapy will probably be between two weeks and two months, depending on the illness. For cancer patients, it may be necessary to follow with an easier form of the diet in order to prevent a recurrence. The cost of therapy varies. If carried out at home under the supervision of a physician, the major expenses will be doctor's visits and organic fruit and vegetables. If clinic treatment is preferred, the Gerson Institute can help and advise.

Preparations

The central theory of the Gerson therapy is fresh juices, which should be drunk immediately after they are prepared. When they are left for longer than 20 minutes, the vital enzymes begin to oxidize, and after

about 40 minutes, will no longer be suitable for the therapy. The following should also be observed:

- A press type juicer should be used; centrifuges do not produce satisfactory juice for this treatment.
- Fresh veal liver should be juiced (under 4 lb) and the juice drunk raw (Gerson could find nothing better for replacing vital enzymes necessary for repairing the human organism).
- Cooking and enema water should be free of chemicals.
- Salt, tobacco, alcohol, and black tea are forbidden.
- No drugs should be taken except aspirin. Gerson's prescription for pain relief consisted of the following: coffee enemas (given every two hours if necessary), 5 g of aspirin, 100 mg of vitamin C and 50 mg of niacin, up to four times in the course of 24 hours. He noted that this also produced restful sleep in even the worst cases.
- Toothpaste or anything containing fluoride should be eliminated.
- Aerosol sprays, air fresheners, insecticides, paint fumes etc., should be avoided completely.
- Deodorants, hair dye, perms, cosmetics and aluminum cooking pans should be eliminated.
- Proteins, fats and oils must be eliminated, along with all smoked, canned and processed foods.
- The diet should be strictly adhered to, along with all medication, and the prescribed enemas.
- Chemotherapy, radiation therapy etc., must be avoided as they damage the immune system and hinder healing.

Precautions

The Gerson therapy is a powerful tool for detoxification, and can produce healing crises. Most patients experience **nausea** and fevers when the initial flush of toxins is released into the bloodstream. Enemas are designed to help with this, and **peppermint** tea is also recommended. In the case of seriously ill patients, it is advisable to have an understanding practitioner on hand to help with this difficult process. Some of the methods used in Gerson therapy have produced bad outcomes. Coffee enemas have been known to cause deaths and patients undergoing Gerson therapy have been admitted to the hospital with bacterial **infections** most likely caused by ingesting raw calf's liver.

Side effects

Patients are warned that after detoxification by the Gerson therapy, the body becomes hypersensitive to drugs, particularly anesthetic. Dentists should be advised of this, and no drugs should be taken without the advice of a physician.

Research and general acceptance

In 1946 Gerson's therapy was out-voted in congress by four votes in favor of surgery, radiation, and chemicals. This situation remains today, despite increased popularity of alternative and complementary medicine. In 1990, two agencies reviewing patient records could find no evidence that the method was effective in treating cancer. However, many alternative practitioners have shown that detoxification can improve the effectiveness of healing techniques.

Training and certification

The Gerson Institute maintains a list of practitioners specializing in the Gerson method.

Ginger

Description

Ginger (*Zingiber officinale*) belongs to the Zingiberaceae plant family, which also includes **turmeric** and cardamom. Ginger comes from the Sanskrit word "hornroot." It grows in Jamaica, India, Haiti, Hawaii, and Nigeria. This perennial plant grows 3-4 ft (0.9-1.2 m) tall. It has thin, sharp leaves 6-12 in (15-30 cm) long. The tangled, beige root is used medicinally, and can be 1-6 in (2.5-15 cm) in length. The root has a sharp, pungent taste and aroma.

Ginger contains several chemical components:

KEY TERMS

Atherosclerosis—Artery disorder where plaque forms on the arteries. The plaque is usually made up of cholesterol and lipids.

Duodenum—The beginning of the small intestine.

Eclectics—Nineteenth century herbal scientists in the United States who founded the Reformed Medical School. Their outlook was based on herbal medicines of Europe, Asia, and Indian.

Lactobacillus—The healthy bacteria found in the intestine.

Lipids—Groups of oily substances, such as fatty acids, stored in the body as energy reserves.

Perennial—A plant that lives for many years; comes back yearly without replanting.

Protease—The enzyme that digests proteins.

Protein—Complex groups of substances (including nitrogen, carbon, oxygen, iron, and hydrogen) that contain amino acids. Protein is vital to all animals because it makes up the hormones and enzymes controlling the body's actions.

Starch—Complex carbohydrates.

- starch (50%)
- protein (9%)
- lipids (including glycerides, phosphatidic acid, lecithins, and fatty acids; 6-8%)
- protease (2.26%)
- volatile oils (including gingerol, shogoal, zingiberene, and zingiberol; 1-3%)
- pungent principles
- vitamins A and B_3 (niacin)

The pungent principles (including the volatile oil gingerol) are the most medicinally potent because they inhibit prostaglandin and leukotriene formations (products in the body that influence blood flow and inflammation). They also give ginger its pungent aroma.

General use

Historically, ginger has been used to aid digestion. According to Michael Castleman in *The Healing Herbs*, ancient Greeks wrapped ginger inside their bread and ate it as an after-dinner digestive. This practice led to their invention of gingerbread. English society concocted ginger beer to soothe the stomach. In the 1800s, the Eclectics used ginger powder and tea for several digestive complaints, including **indigestion**, **gas**, **nausea**, and infant **diarrhea**.

Beginning in the 1980s, several studies have shown that ginger is useful in aiding digestion. A 1999 German study reported the results from 12 volunteers who took 100 mg twice daily of ginger extract when **fasting** and then with a meal. In both instances, ginger was linked to increased digestive movement through the stomach and duodenum.

A study in India published in 2000 reported the effects of ginger (in combination with other spices including cumin, **fenugreek**, and mustard) on pancreatic action in rats. During the eight-week study, the combination of spices in more than a single dose stimulated several **digestive enzymes** in the pancreas.

The Japanese use ginger as an antidote for fish poisoning, especially with sushi. Ginger is thought to fight harmful intestinal bacteria (like *E. coli*, *Staphylococcus*, and *Streptococcus*) without killing beneficial bacteria. Ginger aids *Lactobacillus* growth in the intestines while killing the *Schistosoma* and *Anisakis* parasites.

Because ginger is an antibacterial, it can work against ulcers caused by *Helicobacter pylori*. Ginger creates an anti-ulcer environment by multiplying the stomach's protective components. Ginger's anti-inflammatory abilities have also been shown to help reduce hip and **knee pain** in some **osteoarthritis** patients.

According to a 1998 report that reviewed the results from 10 clinical studies, ginger also helps to suppress the nausea and **vomiting** associated with **pregnancy**. However, a 2002 conference presentation cautions family physicians to reconsider recommending ginger to their pregnant patients because of the possibility for miscarriage.

Ginger lowers **cholesterol** levels by impairing cholesterol absorption, helping it convert to bile acids and then increasing bile elimination. In a 1998 study, rabbits were fed both cholesterol and 200 mg of ginger extract. The rabbits had a smaller amount of **atherosclerosis**. Ginger also enhances blood circulation and acts as a blood thinner.

Coughs can be relieved by drinking ginger tea made from dried or powdered ginger. It is ginger's pungent taste that releases secretions to help throat congestion.

Preliminary studies also show ginger may have potential cancer-fighting properties. No definitive results have been reported and research continues.

Preparations

Ginger is used in teas, ginger ale, ginger beer, capsules, broths, and as a spice when cooking Asian and Jamaican dishes. Ginger tea for coughs, nausea, digestion, and arthritis can be made by adding 2 tsp (10 ml) of freshly grated root or powdered root to 1 cup (250 ml) of boiling water and steeping for 10 minutes. A cup of the ginger tea, while still warm, should be sipped every 2-2.5 hours.

A compress for arthritic **pain** can be made by grating an unpeeled ginger root in a clockwise direction, then tying it in a moistened muslin cloth, dropping it in a pot of boiling water, and letting it simmer. When the broth is removed from the stove, a cotton cloth is dipped into the broth and the excess moisture squeezed into the pot. While lying flat on the back, the person places the cloth on the aching body part. The broth can also be added to the bath for soaking.

Ginger comes in 250-500 mg capsules of dried ginger root. One to 2 grams of dry powered ginger equals about 1/3 oz of fresh ginger (10 g). A cup of ginger tea contains 250 mg; an 8 oz glass of ginger ale contains 1,000 mg, and a spiced dish contains 500 mg. To prevent **motion sickness**, German health authorities recommend 2-4 g of powdered ginger daily. Another recommended dose is 250 mg four to six times a day.

To bring more blood circulation to arthritic joints, one to two capsules (250 mg each) per day are recommended initially. If results are good, the amount can be increased to six per day, taken between meals.

Ginger can be taken with onions and **garlic**. These agents work in harmony to stimulate the pancreas and decrease cholesterol.

As a blood thinner, two 250 mg capsules of ginger can be taken between meals up to three times a day.

Precautions

Despite studies showing ginger's aid for pregnancy nausea, the German Commission E has recommended that pregnant women not use ginger. Some studies indicate that high amounts of ginger might cause miscarriages. Researchers cannot follow up their suspicions with human clinical trials because of the danger posed to unborn fetuses. Dosages over 6 g could cause gastric problems and possibly ulcers. Ginger may slow down blood clotting time. Before taking ginger, consumers should check dosages with a healthcare provider.

Consumers should not ingest the whole ginger plant; it has been found to damage the liver in animals. Ginger root is not recommended for people with **gallstones**.

Side effects

Ginger may cause **heartburn**.

Interactions

Ginger can interfere with the digestion of iron- and fat-soluble vitamins. Ginger also interacts with several medications. The herb can inhibit warfarin **sodium**, which is a blood thinner. Ginger can also interfere with absorption of tetracycline, digoxin, sulfa drugs, and phenothiazines. Consumers should check with their healthcare provider for drug or other interactions.

Ginkgo biloba

Description

Ginkgo biloba, known commonly as the maidenhair tree, is one of the oldest trees on Earth, once part of the flora of the Mesozoic period. The ginkgo tree is the only surviving species of the Ginkgoaceae family. This ancient deciduous tree may live for thousands of years. Ginkgo is indigenous to China, Japan, and Korea, but it also thrived in North America and Europe prior to the Ice Age. That drastic climate change destroyed the wild ginkgo tree throughout much of the world. In China, ginkgo was cultivated in temple gardens as a sacred tree known as *bai gou*, thus assuring its survival there for more than 200

million years. Ginkgo fossils found from the Permian period are identical to the living tree, which is sometimes called a living fossil.

Ginkgo trees may grow to 122 ft (37.2 m) tall and measure 4 ft (1.2 m) in diameter. The female trees have a somewhat pointed shape at the top, like a pyramid. The male trees are broader at the crown. The bark of the ornamental ginkgo tree is rough and fissured and may be ash to dark-brown in color. Distinctive, fan-shaped leaves with long stalks emerge from a sheath on the stem. Leaves are bright green in spring and summer and turn golden yellow in the fall. Ginkgo trees may take as long as 30 years to flower. Ginkgo is dioecious, with male and female flowers blooming on separate trees. Blossoms grow singly from the axils of the leaf. The female flowers appear at the end of a leafless branch. The yellow, plum-shaped fruits develop an unpleasant scent as they ripen. They contain an edible inner seed that is available in Asian country marketplaces. Ginkgo's longevity may be due, in part, to its remarkable resistance to disease, pollution, and insect damage. Ginkgo trees are part of the landscape plan in many urban areas throughout the world. Millions of ginkgo trees, grown for harvest of the medicinal leaves, are raised on plantations in the United States, France, South Korea, and Japan, and are exported to Europe for pharmaceutical processing.

General use

Ginkgo leaves, fresh or dry, and seeds, separated from the outer layer of the fruit, are used medicinally. Ginkgo has remarkable healing virtues that have been recorded as far back as 2800 B.C. in the oldest Chinese materia medica. Ginkgo seeds were traditionally served to guests along with alcohol drinks in Japan. An enzyme present in the ginkgo seed has been shown in clinical research to speed up alcohol metabolism in the body, underscoring the wisdom of this folk custom. The leaf extract has been used in Asia for thousands of years to treat **allergies**, **asthma**, and **bronchitis**. It is also valued in Chinese medicine as a heart tonic to aid in the treatment of cardiac arrhythmia. Ginkgo was first introduced to Europe in 1730 and to North America in 1784 where it was planted as an exotic garden ornamental near Philadelphia. Ginkgo medicinal extracts are the primary prescription medicines used in France and Germany.

Ginkgo acts to increase blood flow throughout the body, particularly cerebral blood flow. It acts as a circulatory system tonic, stimulating greater tone in the venous system. The herb is a useful and proven remedy for numerous diseases caused by restricted blood flow. European physicians prescribe the extract for treatment of Raynaud's disease, a condition of impaired circulation to the fingers. It is also recommended to treat intermittent claudication, a circulatory condition that results in painful cramping of the calf muscles in the leg that impairs the ability to walk. German herbalists recommend ingesting the extract for treatment of leg ulcers, and large doses are used to treat **varicose veins**. Ginkgo is widely recommended in Europe for the treatment of **stroke**. The dried leaf extract may also act to prevent hemorrhagic stroke by strengthening the blood capillaries throughout the body. In studies of patients with atherosclerotic clogging of the penile artery, long-term therapy with ginkgo extract has provided significant improvement in erectile function. Ginkgo extract also acts to eliminate damaging free radicals in the body and has been shown to be effective in treatment of **premenstrual syndrome**, relieving tender or painful breasts. Other demonstrated benefits include improved long-distance vision and possible action to reverse damage to the retina of the eye. In addition, the ginkgo extract may provide relief for persons with **headache**, sinusitis, and vertigo.

Ginkgo extract is believed to benefit the elderly. This ancient herb is believed by some to enhance oxygen utilization and thus improve memory, concentration, and other mental faculties, and to relieve mild **depression**. Researchers in Germany, working with patients with mild or severe impairment from **Alzheimer's disease** linked ginkgo use to improvement on certain cognitive tests, and in a French study in 2003, researchers credited ginkgo supplements with long-term benefits that could aid in delaying or preventing the development of Alzheimer's disease. However, in a 2007 Tufts University study, reported in *Tufts University Health and Nutrition Letter*, researchers concluded that ginkgo supplements did not improve the mental performance of elderly persons who were not experiencing **dementia**. Researchers acknowledged that the "null findings" in the study might be due to the already high cognitive functioning of study participants.

The active constituents in the ginkgo tree, known as ginkgolides, interfere with a blood protein known as the platelet activating factor (PAF). Other phytochemicals in ginkgo include flavonoids, **bioflavonoids**, proanthocyanidins, trilactonic diterpenes (including the ginkgolides A, B, C, and M), and bilabolide, a trilactonic sesquiterpene. The therapeutic effects of this herb have not been attributed to a single chemical constituent; rather, the medicinal benefits are due to the synergy between the various chemical constituents. The standardized extract of ginkgo must be taken

consistently to be effective. A period of at least 12 weeks of use may be required before the beneficial results are evident.

Preparations

Ginkgo's active principles are diluted in the leaves. The herb must be processed to extract the active phytochemicals before it is medicinally useful. It would take an estimated 50 fresh ginkgo leaves to yield one standard dose of the extract. Dry extracts of the leaf, standardized to a potency of 24% flavone glycosides and 6% terpenes, are commercially available. A standard dose is 40 mg, three times daily, though dosages as high as 240 mg daily are sometimes indicated.

Ginkgo extracts are widely used in Europe where they are sold in prescription form or over the counter as an approved drug. This is not the case in the United States, where ginkgo extract is sold as a food supplement in tablet and capsule form.

Precautions

Ginkgo is generally safe and non-toxic in therapeutic dosages. Exceeding a daily dose of 240 mg of the dried extract may result in restlessness, **diarrhea**, and mild gastrointestinal disorders. Those on anticoagulants should have their doctor adjust their dose or should avoid ginkgo in order to avoid over-thinning their blood and hemorrhaging. Ginkgo should be avoided two days before and one to two weeks after surgery to avoid bleeding complications. Pregnant women should avoid ginkgo supplements because scientists have discovered a compound called colchicine in the placental blood of women who took ginkgo biloba. A 2002 report cautioned that the compound could cause problems for the growing fetus.

In 2002, a case of ginkgo seed poisoning was reported in a toddler in Japan, but she had ingested 50 or more pieces of roasted ginkgo seeds. She experienced severe **vomiting** and seizures.

Side effects

Severe allergic skin reactions, similar to those caused by poison ivy, have been reported after contact with the fruit pulp of ginkgo. Eating even a small amount of the fruit has caused severe gastrointestinal irritation in some persons. People with persistent headaches should stop taking ginkgo. Some patients on medications for nervous system disease should avoid ginkgo. It can interact with some other medicines, but clinical information is still emerging.

Interactions

The chemically active ginkgolides present in the extract, specifically the ginkgolide B component, act to reduce the clotting time of blood and may interact with antithrombotic medicines, including aspirin.

A study reported in 2007 by Gregory Reed of the Kansas Medical Center examined the possible interactions of ginkgo and ginseng supplements with prescription or over-the-counter drugs with regard to how these drugs are metabolized and eliminated by the body. The scientists concluded that these herbal supplements are "unlikely to alter the pharmacokinetics of the majority of prescription or over-the counter drugs."

Ginseng, American

Description

American ginseng, scientific name *Panax quinquefolius*, is a close relative of **Korean ginseng** (*Panax ginseng*), and belongs to the Araliaceae family, which is the same as **Siberian ginseng** (*Eleutherococcus senticosus*). It is a perennial herb, distinguished by its dark green leaves and clusters of red berries, that grows wild in eastern North America. The root of the plant is used medicinally, particularly in China, where **traditional Chinese medicine** places a high value on it.

Of the traditional ginsengs, American ginseng is probably the least used and researched variety. Americans have never been large consumers of American ginseng. In the past, American ginseng was an uncommon folk remedy used as a mild stimulant, tonic, and digestive aid. Most of this herb was exported to China, where most ginseng is consumed, American ginseng is considered a less potent member of the ginseng family, but it is a highly prized tonic and herbal remedy.

American ginseng was used medicinally by many Native American tribes as a health stimulant and sexual tonic and for various health problems including headaches, female **infertility**, digestive problems, **fever**, and **earache**. American ginseng was introduced by Native Americans to European settlers in North America in the early 1700s. A French Jesuit priest named Jartoux had traveled through China and was convinced of the medicinal powers of Korean ginseng. In 1714, he published a paper in Britain about Korean ginseng and its healing powers, and theorized that the plant may grow wild in the favorable climate of North America. Another Jesuit missionary in Canada, Joseph Lafitau (1681-1746), read the article and began searching the woods near his dwelling. Lafitau found American ginseng plants, which bear a close resemblance to their Asian cousins, and sent samples of them to China. A thriving trade of American ginseng began around 1718, it was sent to the Orient, gathered by Native Americans, French fur traders, and early frontiersmen including Daniel Boone.

American ginseng grows wild in the forests of the eastern United States and southeastern Canada. It grows in shady, moist and hilly regions, but the plant is becoming increasingly scarce due to over-harvesting and logging practices. In Kentucky, Tennessee, Virginia, and Illinois, American ginseng holds status as a threatened or an endangered species. Some botanists believe that pollution and a thinning ozone layer are contributing to its decline. Efforts at protecting wild American ginseng have not been successful, as the demand for it in the Far East makes it a lucrative crop for poachers. It sometimes sells for as much as $600-800 per pound.

The majority of American ginseng on the market is now cultivated, although it is a sensitive plant and difficult to farm. In the United States, Wisconsin grows 80% of the American ginseng crop. Canada grows more American ginseng than any country, and is second only to China in total ginseng production.

Scientific research

The majority of research performed on ginseng has been done on the Korean and Siberian varieties. Clinical and chemical research on American ginseng is yet to be done. One reason for this is the American medical establishment's skepticism of herbal remedies.

American ginseng is classified as an adaptogen, which is a substance that helps the body adapt to **stress** and improves immune response. Adaptogens must also be non-toxic and cause no major physiological changes or side effects. American ginseng root has an array of complex chemicals, and scientists have determined that the active ingredients are saponin triterpenoid glycosides, or chemicals commonly called ginsenocides. American ginseng contains nearly 30 ginsenocides. However, American ginseng has been found to contain higher levels of ginsenocide Rb1, which has a sedative effect on the central nervous system, than other species of ginseng. Thus, scientific research has been consistent with Chinese herbalists' claims that American ginseng is less stimulating than Korean ginseng. The research implies that American ginseng can provide the strengthening and immune-enhancing effects of other ginseng without overstimulation to those people with high levels of stress and mental stimulation. American ginseng may be the best ginseng for Americans, whose fast-paced and energetic lifestyles may call for more calming and balancing herbs.

KEY TERMS

Adaptogen—Substance that helps the body adapt to any stress.

Ginseng intoxication—Possible side effects of taking *Panax ginseng* products.

Ginsenocides—Active chemicals found in American ginseng.

General use

American ginseng can be used by those people who seek the adaptogenic effects (toning, strengthening, and immune enhancing effects) of *Panax ginseng* without the highly stimulating aspects. Chinese herbalists consider American ginseng to be a cooling herb, so it can be used as a tonic and immune strengthener for people who are over-stressed or who have hot conditions like high blood pressure, excess nervous energy, or ulcers. American ginseng, according to Chinese herbalists, is more suitable and balancing for women and children than *Panax ginseng*, and is more applicable for the elderly who wish to avoid stimulants. American ginseng is also used in Chinese medicine for chronic fevers; to aid in the recovery of infectious diseases; for strengthening the lungs in cases of **tuberculosis**, **bronchitis** and **asthma**; and for the loss of the voice associated with respiratory disorders.

Preparations

American ginseng can be purchased as whole roots, powder, capsules, or a liquid tincture. For whole roots, wild ginseng is the highest quality and also the most

expensive. Also available are organically grown cultivated roots, which are free from pesticides and chemicals. The easiest way to prepare ginseng roots is to make a tea from them. Ginseng roots are very hard and brittle. They should be sliced and simmered in water for 45 minutes or longer to extract the majority of ginsenocides. Experts recommend avoiding metal pots, which can reduce its antioxidant properties. Some herbalists recommend boiling **ginger** or **licorice** root with American ginseng to increase its effectiveness. For each serving of tea, two or more teaspoons of ginseng root are recommended.

Ginseng root can also be made into a tincture using alcohol, as ginsenocides are soluble and well-preserved in alcohol. Vodka or clear alcohol can be used, and the ginseng roots should be chopped finely or put in a blender with the alcohol. Enough alcohol should be used to completely saturate and cover the roots, and the solution should be kept in a sealed glass bottle for a month or longer. The solution should be shaken frequently to promote the extraction process. The liquid can be strained from the roots after distilling, and kept for up to three years. Half a teaspoon or more of the solution can be taken as a daily serving.

Ginseng powder is also available and can be made into tea or taken with water or juice. One half to one teaspoon is recommended per serving. Extracts of American ginseng are also available in liquid or tablet form, some of which offer standardized quantities of ginsenocides. Packages of standardized products should be labeled with the appropriate dosage.

American ginseng is usually taken two to three times per day between meals. It should not be taken continuously for long periods of time, unless prescribed by a doctor.

Precautions

Pregnant women should use American ginseng only under a doctor's orders and avoid any products that contain *Panax ginseng*.

Consumers should assure that the American ginseng product they purchase is a reputable one. Because of the high price and demand of American ginseng, some questionable products are on the market. Generally wild American ginseng is of higher quality than the cultivated plant, and the older and larger the root, the higher the quantity of ginsenocides present. In addition, consumers should be careful not to confuse American ginseng with *Panax ginseng*, which has been shown to produce more serious adverse side effects. A 2002 report stated that the effects of *Panax ginseng* seemed more likely when the herb was used in combination with other products than when it was used alone.

Side effects

In general, American ginseng is gentle and side effects are rare. Side effects may occur with American ginseng when taken in the wrong dosages, over too long a time, or by people whose constitutions, **allergies**, or health conditions disagree with the herb. Also, products combining Korean ginseng with American ginseng may increase the chances for side effects.

Interactions

Due to the lack of research done on American ginseng, no known interactions are reported.

Ginseng, Korean

Description

Korean ginseng is one of the most widely used and acclaimed herbs in the world. Its scientific name is *Panax ginseng*, which is the species from which Chinese, Korean, red, and white ginseng are produced. Chinese and Korean ginseng are the same plant cultivated in different regions, and have slightly different

Dried Korean ginseng. *(Custom Medical Stock Photo. Reproduced by permission.)*

properties according to Chinese medicine. White ginseng is simply the dried or powdered root of Korean ginseng, while red ginseng is the same root that is steamed and dried in heat or sunlight. Red ginseng is said to be slightly stronger and more stimulating in the body than white, according to Chinese herbalism.

Korean ginseng has had a long and illustrious history as an herb for health, and has been used for thousands of years throughout the Orient as a medicine and tonic. Early Chinese medicine texts written in the first century A.D. mention ginseng, and ginseng has long been classified by Chinese medicine as a "superior" herb. This means it is said to promote longevity and vitality. Legends around the world have touted ginseng as an aphrodisiac and sexual tonic. Researchers have found a slight connection between sex drive and consuming ginseng, although a direct link and the mechanism of action are still researched and disputed.

Korean ginseng grows on moist, shaded mountainsides in China, Korea, and Russia. It is a perennial herb that reaches heights of 2 ft (0.8 m) or more, and is distinguished by its dark green leaves and red clusters of berries. The root of the plant is the part valued for its medicinal properties. The root is long and slender and sometimes resembles the shape of the human body. Asian legends claim that this "man-root" has magical powers for those lucky enough to afford or find it, and the roots bearing the closest resemblance to the human body are still the most valuable ones. The word *ren shen* in Chinese means roughly "the essence of the earth in the shape of a man."

Korean ginseng has historically been one of the most expensive of herbs, as it has been in high demand in China and the Far East for centuries. Wars have been fought in Asia over lands where it grew wild. Wild Korean ginseng is now nearly extinct from many regions. Single roots of wild plants have recently been auctioned in China and New York City for sums approaching $50,000. Most of the world's supply of Korean ginseng is cultivated by farmers in Korea and China.

KEY TERMS

Adaptogen—Substance that improves the body's ability to adapt to stress.

Ginsenocide—Active substances found in ginseng.

Because of the number of herbs sold under the name of ginseng, there can be some confusion for the consumer. Korean ginseng is a member of the *Araliaceae* family of plants, which also includes closely related **American ginseng** (*Panax quinquefolius*) and **Siberian ginseng** (*Eleutherococcus senticosus*). Both American and Siberian ginseng are considered by Chinese herbalists to be different herbs than Korean ginseng, and are said to have different effects and healing properties in the body. To add more confusion, there are eight herbs in Chinese medicine that are sometimes called ginseng, including black ginseng, purple ginseng, and prince's ginseng, some of which are not at all botanically related to *Panax ginseng*, so consumers should choose ginseng products with awareness.

General use

The word *panax* is formed from Greek roots meaning "cure-all," and *Panax ginseng* has long been considered to be one of the great healing and strengthening herbs in natural medicine. Ginseng is classified as an *adaptogen*, which is a substance that helps the body adapt to **stress** and balance itself without causing major side effects. Korean ginseng is used as a tonic for improving overall health and stamina, and Chinese herbalists particularly recommend it for the ill, weak, or elderly. Korean ginseng has long been asserted to have longevity, anti-senility, and memory improvement effects in the aged population. As it helps the body to adapt to stress, athletes may use ginseng as herbal support during rigorous training. Korean ginseng generally increases physical and mental energy. It is a good tonic for the adrenal glands, and is used by those suffering from exhaustion, burnout, or debilitation from chronic illness.

Traditional Chinese medicine also prescribes Korean ginseng to treat diabetes, and research has shown that it enhances the release of insulin from the pancreas and lowers blood sugar levels. Korean

ginseng has been demonstrated to lower blood **cholesterol** levels. It has also been shown to have antioxidant effects and to increase immune system activity, which makes it a good herbal support for those with **cancer** and **AIDS** and other chronic conditions that impair the immune system. Further uses of Korean ginseng in Chinese medicine include treatment of **impotence**, **asthma**, and digestive weakness.

Research

Scientists have isolated what they believe are the primary active ingredients in ginseng, chemicals termed *saponin triterpenoid glycosides*, or commonly called *ginsenocides*. There are nearly 30 ginsenocides in Korean ginseng. Much research on Korean ginseng has been conducted in China, but controlled human experiments with it have not been easily accessible to the English-speaking world. Recent research in China was summarized by Dr. C. Lui in the February 1992 issue of the *Journal of Ethnopharmacology*, where he wrote that *Panax ginseng* was found to contain 28 ginsenocides that "act on the central nervous system, cardiovascular system and endocrine secretion, promote immune function, and have effects on anti-aging and relieving stress."

To summarize other research, Korean ginseng has been shown in studies to have significant effects for the following:

- Physical improvement and performance enhancement for athletes: A study performed over three years in Germany showed athletes given ginseng had favorable improvement in several categories over a control group who took a placebo. Another 1982 study showed that athletes given ginseng had improved oxygen intake and faster recovery time than those given placebos.
- Mental performance improvement and mood enhancement: In general, studies show that ginseng enhances mental performance, learning time, and memory. One study of sixteen volunteers showed improvement on a wide variety of mental tests, including mathematics. Another study showed that those performing intricate and mentally demanding tasks improved performance when given Korean ginseng. Finally, a study has shown improvement of mood in people with depression with the use of ginseng.
- Antifatigue and antistress actions: Patients with chronic fatigue who were given ginseng showed a statistically significant improvement in physical tests and in mental attention and concentration, when compared with those given placebos.
- Lowering blood sugar: Animal studies have shown that ginseng can facilitate the release of insulin from the pancreas and increase the number of insulin receptors in the body.
- Antioxidant properties: Scientific analysis of ginseng has shown that it has antioxidant effects, similar to the effects of vitamins A, C, and E. Thus, ginseng could be beneficial in combating the negative effects of pollution, radiation, and aging.
- Cholesterol reduction: Some studies have shown that Korean ginseng reduces total cholesterol and increases levels of good cholesterol in the body.
- Anticancer effects and immune system stimulation: Several tests have shown that Korean ginseng increases immune cell activity in the body, including the activity of T-cells and lymphocytes, which are instrumental in fighting cancer and other immune system disorders like AIDS. A Korean study indicates that taking ginseng may reduce the chances of getting cancer, as a survey of more than 1,800 patients in a hospital in Seoul showed that those who did not have cancer were more likely to have taken ginseng regularly than those patients who had contracted cancer.
- Physical and mental improvement in the elderly: One study showed significant improvement in an elderly test group in visual and auditory reaction time and cardiopulmonary function when given controlled amounts of Korean ginseng. Korean ginseng has also been shown to alleviate symptoms of menopause.
- Impotence: Studies of human sexual function and Korean ginseng have been generally inconclusive, despite the wide acclaim of ginseng as a sexual tonic. Tests with lab animals and ginseng have shown some interesting results, indicating that Korean ginseng promotes the growth of male reproductive organs, increases sperm and testoterone levels, and increases sexual activity in laboratory animals. In general, scientists believe the link between ginseng and sex drive is due to ginseng's effect of strengthening overall health and balancing the hormonal system.

Preparations

Korean ginseng can be purchased as whole roots, powder, liquid extracts, and tea. Roots should be sliced and boiled in water for up to 45 minutes to extract all the beneficial nutrients. One to five grams of dry root is the recommended amount for one serving of tea. Herbalists recommend that ginseng not be boiled in metal pots, to protect its antioxidant

properties. Ginseng should be taken between meals for best assimilation.

Some high quality Korean ginseng extracts and products are standardized to contain a specified amount of ginsenosides. The recommended dosage for extracts containing 4–8% of ginsenosides is 100 mg once or twice daily. The recommended dosage for non-standardized root powder or extracts is 1–2 g daily, taken in capsules or as a tea. It is recommended that ginseng be taken in cycles and not continuously; after each week of taking ginseng, a few days without ingesting the herb should be observed. Likewise, Korean ginseng should not be taken longer than two months at a time, after which one month's rest period should be allowed before resuming the cycle again. Chinese herbalists recommend that ginseng be taken primarily in the autumn and winter months.

Precautions

Consumers should be aware of the different kinds of ginseng, and which type is best suited for them. Red Korean ginseng is considered stronger and more stimulating than white, wild ginseng is stronger than cultivated, and Korean ginseng is generally believed to be slightly stronger than Chinese. Furthermore, American and Siberian ginseng have slightly different properties than Korean ginseng, and consumers should make an informed choice as to which herb is best suited for them. Chinese herbalists do not recommend Korean ginseng for those people who have "heat" disorders in their bodies, such as ulcers, high blood pressure, tension headaches, and symptoms associated with high stress levels. Korean ginseng is generally not recommended for those with symptoms of nervousness, mental imbalance, inflammation, or **fever**. Korean ginseng is not recommended for pregnant or lactating women, and women of childbearing age should use ginseng sparingly, as some studies imply that it can influence estrogen levels. Also, Chinese herbalists typically only prescribe ginseng to older people or the weak, as they believe that younger and stronger people do not benefit as much from it and ginseng is "wasted on the young."

Because of the number of and demand for ginseng products on the market, consumers should search for a reputable brand, preferably with a standardized percentage of active ingredients. To illustrate the mislabeling found with some ginseng products, *Consumer Reports* magazine analyzed 10 nationally-distributed ginseng products in 1995. They found that several of them lacked significant amounts of ginsenocides, despite claims on the packaging to the contrary. Ginseng fraud has led the American Botanical Council to initiate the Ginseng Evaluation Program, a comprehensive study and standardization of ginseng products on the American market. This study and its labeling standards are still under development, and consumers should watch for it.

Side effects

Korean ginseng acts as a slight stimulant in the body, and in some cases can cause overstimulation, irritability, nervousness and **insomnia**, although strong side effects are generally rare. Taking too high a dosage of ginseng, or taking ginseng for too long without a break, can cause *ginseng intoxication*, for which symptoms might include headaches, insomnia, seeing spots, **dizziness**, shortage of breath and gastrointestinal discomfort. Long-term use may cause menstrual abnormalities and breast tenderness in some women.

Interactions

Those taking hormonal drugs should use ginseng with care. Ginseng should not be taken with **caffeine** or other stimulants as these may increase its stimulatory effects and cause uncomfortable side effects. In early 2002, researchers reported that adverse effects and drug interactions from ginseng were more likely to occur when it was used in combination with other products than when ginseng was used alone.

Ginseng, Siberian

Description

Siberian ginseng, *Eleutherococcus senticosus*, is also known as eleuthero ginseng or eleuthero. It is in the same botanical family as **Korean ginseng** (*Panax ginseng*) and **American ginseng** (*Panax quinquefolius*). Siberian ginseng is one of the most widely used herbs in the world.

Siberian ginseng is a thin, thorny shrub that grows up to 15 ft (4.6 m) high. It is native to forests in southeastern Russia, northern China, Japan, and Korea. The root of the plant is used medicinally.

The family of ginseng plants has historically been used for medicinal purposes. Korean ginseng, also called Asian, red, or white ginseng, has been used in China for thousands of years. In China, it is a celebrated herb known to promote strength, energy, and longevity. American ginseng was discovered in North America in the early 1700s, and has since been used as a medicine and tonic. Siberian ginseng has been used in Chinese medicine for more than 2,000 years, to increase energy and vitality and to treat respiratory and other **infections**, although Chinese herbalists use Korean and American ginseng much more frequently. Siberian ginseng was used in Eastern Europe as a folk remedy for hundreds of years, but it was not until the 1940s that it became a popular herb in Russia and Europe.

The Russian physician I. I. Brekhman is credited with making Siberian ginseng popular. Brekhman had studied Korean ginseng in the 1940s and documented some of its effects on the body. He determined that ginseng was an adaptogen. To be classified as an adaptogen, an agent must be shown to help the body adapt to **stress**, improve balance and overall immune function, be non-toxic and cause minimal side effects. Brekhman searched his native Russian forests for an alternative to expensive Korean ginseng, and concentrated on Siberian ginseng. Brekhman discovered that Siberian ginseng was also an adaptogen, offering some of the same benefits of Korean ginseng, although containing a different chemical composition.

During the next 30 years in the Soviet Union, Siberian ginseng became the focus of many studies. It was found to increase endurance and performance of athletes, and many famous Soviet Olympic champions included Siberian ginseng as part of their training programs. Siberian ginseng was so touted that Soviet astronauts carried it into space with them, as opposed to the amphetamines carried by American astronauts.

KEY TERMS

Adaptogen—Substance that helps the body adapt to stress.

Eleutheroside—Active chemical found in Siberian ginseng.

Soviet scientists found that Siberian ginseng strengthened the immune system, and gave Siberian ginseng to highly stressed workers as herbal support. After the Chernobyl nuclear accident, Siberian ginseng was given to people who had been exposed to radiation.

Research

Siberian ginseng's active ingredients are a complex group of chemicals called *eleutherosides*. Eleutherosides are different than the ginsenocides found in the *Panax* varieties of ginseng, which is consistent with Chinese herbalists' claims that Siberian ginseng acts differently in the body than Korean or American ginseng. There has been some debate among herbalists whether Siberian ginseng should be considered a true ginseng at all, due to this difference in active ingredients.

Much of the research done on Siberian ginseng was performed by Soviet scientists in the former Soviet Union. Many of the study results are still unavailable in English. Those that have been translated and more recent studies have corroborated the benefits of Siberian ginseng.

- Siberian ginseng has been documented in many studies to improve physical endurance, oxygen uptake, recovery, and overall performance in athletes, ranging from runners to weightlifters. A 1986 study in Japan showed that eleuthero ginseng improves oxygen uptake in exercising muscle.
- Siberian ginseng normalized blood pressure in patients with high and low blood pressure. Siberian ginseng has been shown to reduce stress symptoms in general. A 1996 study in Japan concluded that Siberian ginseng can protect against gastric ulcers.
- Animal studies showed Siberian ginseng helped fight against toxic chemicals and exposure to harmful levels of radiation. A 1992 Russian study showed that Siberian ginseng reduced the occurrence of tumors in rats when exposed to radiation. Another Russian study showed that women undergoing radiation for breast cancer had a significant reduction of side effects when given Siberian ginseng.

- A 1987 German study, using human subjects in a double-blind test, demonstrated that eleuthero ginseng boosts immune system response and enhances the body's overall resistance to infection. Other studies have shown that Siberian ginseng increases activity of lymphocytes and killer cells in the immune system.

General use

Siberian ginseng can be used as an overall strengthener for the body and immune system. It is an effective herbal support for stress, **fatigue**, and exhaustion; for athletes in training; for prevention of colds and flus; for those undergoing chemotherapy or radiation treatment; and for people with chronic diseases such as chronic fatigue, **fibromyalgia**, or **AIDS**. Siberian ginseng is also used to aid recovery from nervous conditions like **depression**, **anxiety**, or nervous breakdown.

A group of Armenian researchers reported in 2003 that a compound containing Siberian ginseng is safe and effective in treating familial Mediterranean **fever**, an inherited disorder characterized by recurrent attacks of fever and severe abdominal **pain**.

Preparations

Siberian ginseng is available as a fresh root or dried root powder, tea, liquid extract, or capsule/tablet form. The recommended dosage for root powder is 1–2 g daily, taken in capsules or mixed with water or juice. Dosages should be divided and taken two or three times per day, between meals. The dosage for the liquid extract is1–2 ml twice daily. Recently, Siberian ginseng products have been made available that contain standardized percentages of eleutherosides. Siberian ginseng can be taken continuously, but it is generally recommended that for every three months of ginseng use, two- to four-week rest periods should be observed. Siberian ginseng is sometimes combined with other adaptogens, like Korean or American ginseng, **astragalus**, or **schisandra**, to increase its effectiveness.

Precautions

Pregnant women and children should use Siberian ginseng with caution, consulting a practitioner prior to use. Those taking hormonal drugs should use ginseng with care. Furthermore, consumers should be aware of the different medicinal properties of Korean, American, and Siberian ginseng, in order to choose the herb best suited for their constitution and health conditions.

Consumers should choose only high-quality ginseng products made by reputable manufacturers. In a 1995 *Consumer Reports* magazine analysis of 10 nationally distributed ginseng products, several brands were lacking in active ingredients. Ginseng product fraud has led the American Botanical Council to initiate the Ginseng Evaluation Program. Started in 1993, this program provides a comprehensive study of ginseng products and has enacted measures to reduce mislabeling and increase consumer confidence in ginseng products. In 1999, however, the Center for Food Safety and Applied Nutrition of the Food and Drug Administration (FDA) reported several instances of Siberian ginseng products that contained pieces of the roots and leaves of a hazardous plant, *Periploca sepium*.

Side effects

In general, side effects with Siberian ginseng are rare and more mild than those that occur with American and Korean ginseng. Mild **diarrhea** has been reported with its use, and **insomnia** may occur if it is taken too close to bedtime.

Siberian ginseng appears to be less likely than most herbs to interact with other medications. Researchers in South Carolina reported in 2003 that Siberian ginseng did not affect the body's metabolism of such drugs as dextromethorphan and benzodiazepine tranquilizers when the ginseng was taken in recommended dosages.

Glaucoma

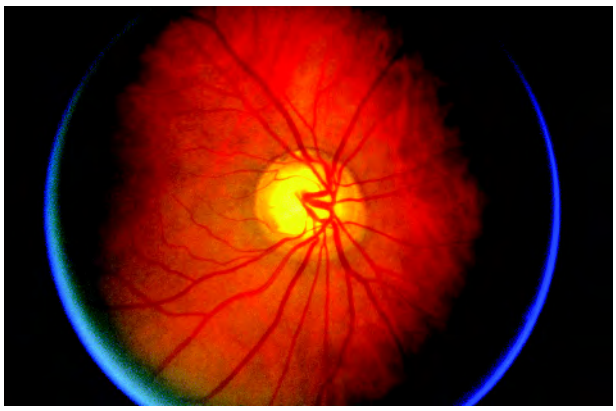
Definition

Glaucoma is a group of slowly progressive disorders that affects the eye and can result in irreversible damage to the optic nerve. Glaucoma represents one of the leading causes of irreversible blindness in the United States and world-wide. It is the leading cause of blindness among African Americans and older adults in the United States. Because there are usually no symptoms early on in the disease, about half of the people with glaucoma do not even know they have it.

Description

More than two million people in the United States have glaucoma, and 80,000 of those are legally blind as a result of the disease. Glaucoma can strike any age group, even newborn infants. Susceptibility to the disease, however, increases with age. African Americans are at a three times higher risk of glaucoma than the rest of the population.

There are at least 20 different types of glaucoma. These can be divided into four main types:



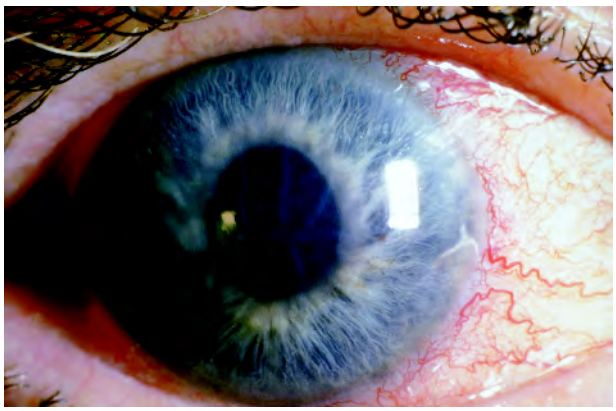
Opthalmoscope view of the retina of an eye with glaucoma. *(Stanford Eye Clinic / Photo Researchers, Inc.)*

- Open-angle glaucoma, which accounts for over 60–70% of all cases, and is usually chronic and often bilateral.
- Closed-angle glaucoma, which is usually an acute condition, as opposed to open-angle glaucoma, which is chronic.
- Congenital glaucoma, which occurs in infants, usually under the age of one.
- Secondary glaucoma, which may be associated with eye diseases, other diseases, and certain types of medications.

Causes and symptoms

Glaucoma is the result of disruptions of normal processes to maintain pressure within the eye tissue. The iris, cornea, and lens of the eye are bathed in a nutritive liquid called the aqueous humor, which is made by cells within the eye. Excess fluid is continually removed by a spongy meshwork of drainage canals. Glaucoma occurs if there is a build up of the aqueous humor due to poor drainage or overproduction. As the fluid builds up there is increased pressure on the retina at the back of the eye. This increased pressure reduces the blood supply to the nerves of the retina and causes the nerves to die, which may distort and destroy the optic nerve. As nerve cells are destroyed, blind spots develop, and there is a progressive loss of vision. A change in the production and strength of collagen may also contribute to the onset of the disease. Collagen is a protein that helps maintain the structure and function of eye tissue. **Stress** and **allergies** may aggravate glaucoma symptoms.

It is probable that most cases of glaucoma are partially due to a genetic predisposition. At least 10 defective genes have been identified that may cause



Acute glaucoma. *(© Medical-on-Line / Alamy)*

glaucoma. Although there are still many unknown factors that trigger the disease, a number of processes have been implicated. They include age-related changes, congenital abnormalities, injuries to the eye tissue, and problems related to other eye diseases. Vision loss in all forms of glaucoma is caused by damage to the optic nerve, the retina, and the collagen protein that makes up eye tissue. Use of certain medications, including antihypertensives, antihistamines, anticholinergics, and antidepressants may also contribute to the development of glaucoma. Corticosteroid eye drops, which are often used for other eye disorders, may destroy the integrity of eye tissue. Other types of eye drops may cause the pupils to dilate, increasing intraocular eye pressure (IOP), which may also lead to glaucoma in those who have a tendency to the disease.

Chronic open-angle glaucoma at first develops without noticeable symptoms. The pressure buildup is gradual, and it does not bring on discomfort. Moreover, the vision loss is too gradual to be noticed at first, and the brain compensates for blind spots. Over an extended period of time, though, the elevated pressure pushes against and damages the optic nerve and the retina. If glaucoma is left untreated, vision loss becomes evident, and the condition becomes painful.

Acute closed-angle glaucoma is obvious from the beginning. The symptoms are blurred vision, severe eye **pain**, sensitivity to light, **nausea** and **vomiting**, dilated pupils, reddened eyes, and halos visualized around lights. The corneas may become hazy in appearance. Acute closed-angle glaucoma is an emergency situation. It needs to be treated immediately. Congenital glaucoma is evident at birth. Symptoms are bulging eyes, cloudy corneas, enlarged corneas, excessive teariness, and sensitivity to light.

Risk factors that increase the probability of developing glaucoma include:

- ocular hypertension, a slightly increased IOP
- age over 40
- diabetic conditions
- high blood pressure
- migraine headaches
- nearsightedness, farsightedness, and other visual disturbances
- a family history of glaucoma
- being of African American or Hispanic ethnicity

Diagnosis

Sometimes glaucoma can be diagnosed with a routine eye exam by an ophthalmologist, who can make a definitive diagnosis of glaucoma. IOP, defects in the field of vision, and the appearance of the optic nerve, are all considered in the diagnosis of glaucoma. Visual field tests can detect blind spots in a patient's field of vision before the patient is aware of them. An instrument, known as a tonometer, is used to measure eye pressure. Since IOP can vary throughout the day, a person may have to return for several visits to measure eye pressure at different times of the day. An ophthalmoscope is used to examine the inner aspects and the back of the eyes, including the optic nerve, for changes and damage. A slit lamp may be used to allow the doctor further examination of the eye. Another test, gonioscopy, can distinguish between narrow-angle and open-angle glaucoma. A gonioscope allows visualization of the angle between the iris and the cornea. A subsequent technology is optical coherence tomography (OCT) that produces high-resolution images of the anterior segment of the eye and is a non-invasive procedure. As of 2007, it was primarily used in conjunction with gonioscopy in diagnosing and assessing glaucoma.

Treatment

There is no cure for glaucoma; however, it can be treated with both traditional and alternative medicine. **Vitamin C**, taken in dosages up to bowel tolerance, is reported to reduce pressure within the eye and restore collagen balance. A vitamin C supplement with **bioflavonoids**, especially rutin and **lutein**, are particularly recommended. **Bilberry** (*Vaccinium myrtillus*) helps maintain collagen balance and prevents the breakdown of vitamin C. Many people with glaucoma have been shown to have deficiencies of **chromium** and **zinc**. Supplementation with these two minerals may, therefore, deter the onset or progression of the disease. Alpha lipoic acid and other **antioxidants** may improve visual functioning.

A naturopathic approach called contrast **hydrotherapy** can be used to stimulate circulation in the eyes. Compresses can be applied over the eyes, alternating three minutes with hot water and one minute with cold water, always ending with the cold. **Biofeedback** can be used to reduce the pressure in the eyes by increasing **relaxation**. **Meditation**, stress reduction, **t'ai chi**, **yoga**, **exercise**, and **acupuncture** also may lower IOP. Remedies used to lower IOP must be taken continually to avoid optic nerve damage. In addition to other treatments, a glaucoma patient should always remain under the care of an ophthalmologist or optometrist who is licensed to treat glaucoma, so that IOP and optic nerve damage can be monitored.

Since the early 1970s, a number of scientific studies reported that the active agents in **marijuana** (*Cannabis sativa*) are effective in lowering intraocular pressure (IOP) in people with glaucoma. One study reported that people with glaucoma who smoked marijuana had a 25% to 30% drop in IOP that lasted three to four hours. Under federal law, the use, possession, or sale of marijuana is illegal in the United States. However, as of 2007, twelve states had legalized the medical use of marijuana. In 2005, the U.S. Supreme Court ruled that federal laws against medical marijuana take precedence over state laws, allowing for continued federal prosecution against people who use marijuana for medical purposes. Despite the ruling, medical marijuana programs continue in several states, including California. The active agents in marijuana are cannabinol, cannabidiol, and delta-9-tetrahydrocannabinol (THC). A synthetic version of THC, dronabinol (Marinol), is available in the United States and can be legally prescribed for a number of conditions, including glaucoma.

KEY TERMS

Alpha-2 agonist—A class of drugs that bind to and stimulate alpha-2 adrenergic receptors, causing responses similar to those of adrenaline and noradrenaline, by inhibiting aqueous humor production.

Beta-blocker—A class of drugs that bind beta-adrenergic receptors and thereby decrease the ability of the body's own natural epinephrine to bind to those receptors, leading to the reduction of aqueous humor secretion.

Cornea—The clear, bowl-shaped structure at the front of the eye located in front of the colored part of the eye. The cornea lets light into the eye and partially focuses it.

Gonioscope—An instrument that consists of a magnifier and a lens equipped with mirrors and sits on the patient's cornea.

Miotic—A drug that causes pupils to contract.

Ophthalmoscope—An instrument, with special lighting, designed to view structures in the eye.

Optic nerve—The nerve that carries visual messages from the retina to the brain.

Retina—The light-sensitive layer of the eye.

Allopathic treatment

The objective of glaucoma treatment is usually to decrease IOP. When glaucoma is diagnosed, drugs, typically given as eye drops, are usually tried before surgery. Several classes of medications are effective at lowering IOP and, thus, at preventing optic nerve damage in chronic and neonatal glaucoma. These include beta-blockers, such as Timoptic, and carbonic anhydrase inhibitors, such as acetazolamide. Alpha-2 agonists, such as Alphagan, inhibit the production of aqueous humor. Miotics, such as pilocarpine, and prostaglandin analogues, such as Xalatan, increase the drainage of aqueous humor. Different medications lower IOP different amounts, and a combination of medications may be necessary. Attacks of acute closed-angle glaucoma are medical emergencies. In such cases, IOP is rapidly lowered by use of acetazolamide, hyperosmotic agents, a topical beta-blocker, and pilocarpine. All of these drugs have side effects, some of which are rare, but serious and potentially life threatening. Patients taking them should be monitored closely, especially for cardiovascular, pulmonary, and behavioral symptoms. IOP should also be monitored and measured three to four times per year.

Laser peripheral iridiotomy or other microsurgery is used to open the drainage canals or to make an opening in the iris to increase the outflow of aqueous humor. These surgeries are usually successful, but effects often last less than a year. Nevertheless, they are an effective treatment for patients whose IOP is not sufficiently lowered by drugs or for those who cannot tolerate the drugs. Surgery is usually used in cases of congenital glaucoma, since the medications are often too harsh for children. Youngsters often respond to surgery better than adults, and have an excellent chance for preserving lifelong good vision.

Expected results

If glaucoma is left untreated, optic nerve damage will result in a progressive loss of vision. Once blindness develops due to glaucoma, it cannot be reversed.

With early treatment and monitoring serious vision loss can usually be prevented.

Prevention

While glaucoma is not preventable, early detection and treatment can help to prevent serious damage to vision. Those with risk factors should have regular eye exams and avoid medicines that tend to be implicated in the development of glaucoma, including some over-the-counter cold and allergy medications. All medications should be checked for their ingredients. Alternatives for drugs that aggravate glaucoma should be discussed with a healthcare provider.

Patience Paradox
Ken R. Wells

Glucosamine

Description

Glucosamine is an amino sugar that occurs naturally in the body. This one-molecule substance consists of glucose and a hydrogen and nitrogen amine. Amino sugars are different from other body sugars, as they form part of carbohydrates. Their function is also different as they are not a source of energy, but rather are included in body tissue structure. Therefore, glucosamine plays a role in forming and maintaining the body's tissues, for example, constructing nails, skin, eyes, bones, ligaments, tendons, heart valves; and discharging mucus from the respiratory system, digestive system, and urinary tract. Glucosamine helps blend **sulfur** into the cartilage. When people grow older, their bodies may lose the capacity to make enough glucosamine, so the cartilage in such weight-bearing joints as the hips, knees, and hands is destroyed. The remaining cartilage then hardens and forms **bone spurs**, causing **pain**, deformed joints, and limited joint movement.

Glucosamine is not readily available from any primary food source. Commercial preparations of glucosamine are derived from chitin, which is a substance found in the outer covering of such shellfish as lobster, crab, and shrimp, as well as in such animal connective tissues as the marrow of chicken bones. Commercially prepared glucosamine comes in three formats: glucosamine sulfate, glucosamine hydrochloride, and N-acetyl-glucosamine (NAG).

General use

Glucosamine works to stimulate joint function and repair. It is most effective in treating **osteoarthritis** (OA), the most prevalent type of arthritis. A number of studies between 1980 and the early 2000s showed that glucosamine is helpful in relieving arthritis

symptoms. For example, a 1982 clinical study compared usage of the NSAID ibuprofen with glucosamine sulfate, for osteoarthritis of the knee. During the first two weeks, ibuprofen decreased pain faster, but by the fourth week the glucosamine group was well ahead in pain relief. The overall results showed 44% of the glucosamine group had pain relief compared to 15% for ibuprofen. A British study published in 2002 reported similar findings regarding the effectiveness of glucosamine in relieving pain associated with arthritis. A team of Japanese researchers suggested that glucosamine relieves the pain of arthritis by suppressing the functions of neutrophils, which are white blood cells that contribute to the joint inflammation found in arthritis. Other researchers speculated that the sulfur content of glucosamine contributes to its healing properties.

Several studies have concluded that over-the-counter preparations of glucosamine sulfate are safe for long-term treatment of osteoarthritis. These are readily available in the dietary supplement sections of most pharmacies. Glucosamine preparations are sometimes classified as nutraceuticals, a term used to refer to foods or food ingredients that are thought to provide medical or health benefits.

Harvard Medical School conducted a somewhat unorthodox study in which patients scheduled for hip surgery were given ground chicken bone supplements. After two weeks of taking these supplements, their pain was reduced considerably.

Glucosamine supplements can also aid in treating sports injuries, **bursitis**, food and respiratory **allergies**, **asthma**, **osteoporosis**, **tendinitis**, **vaginitis**, some skin problems, and candidiasis.

As of 2002, however, updated guidelines issued by the American College of Rheumatology for the treatment of osteoarthritis continued to list glucosamine along with **acupuncture** and electromagnetic therapy as treatments that were still under investigation for treating OA. Although there was considerable clinical experience with glucosamine, the mechanism of action was not determined, and, and analysis of published studies was inconclusive. In one study, sponsored by the National Institutes of Health (NIH), the Glucosamine/Chondroitin Arthritis Intervention Trial (GAIT), which enrolled 1,583 patients with painful knee osteoarthritis, 39 individuals failed to reveal an effect of glucosamine or **chondroitin** alone or in combination when compared to placebo. However, this study tested glucosamine hydrochloride, while more favorable studies have used glucosamine sulfate. Also, the favorable placebo response of 60% made analysis of the data difficult. When so many patients respond favorably to the placebo, it can be difficult to show a significant difference between the active drug and the inactive control. A review by the Arthritis Center of Boston University School of Medicine warned: "Trials of glucosamine and chondroitin preparations for (osteoarthritis) symptoms demonstrate moderate to large effects, but quality issues and likely publication bias suggest that these effects are exaggerated."

One study from the Rheumatology Unit, Department of Clinical and Experimental Medicine of the University of Padova, Italy, offered a mechanism of action explaining the observed physiologic effects of glucosamine. In their observation, glucosamine sulfate has anti-oxidant properties and inhibits natural oxidative stress that can cause unfavorable alterations of cartilage. These observations would explain the clinical reports of glucosamine activity and differentiate it from a placebo response.

Preparations

Although commercially prepared glucosamine comes in three formats (glucosamine sulfate, glucosamine hydrochloride, and N-acetyl-glucosamine (NAG)), not all three work the same. There are also differing opinions on which is best.

One claim states that glucosamine hydrochloride works 50% better than glucosamine sulfate because hydrochloride is the main stomach acid helping the digestive system to put more active ingredients into the body. Another prefers glucosamine sulfate because of its high absorption rate of 98% documented in human studies and its sulfur content. Studies as far back as the 1930s show that people with arthritis usually have low levels of sulfur.

N-acetyl-glucosamine (NAG) can be beneficial to individuals with **Crohn's disease** or ulcerative **colitis**. Individuals with these diseases cannot change glucosamine to NAG as fast as those without the diseases. In one study, cells from patients' intestines were soaked in a solution with a 10:1 ratio of radioactive NAG to glucosamine. These cells consolidated more NAG than did the cells from the intestines of patients without Crohn's disease or ulcerative colitis.

Glucosamine is also sold mixed in formulas with **devil's claw**, pregnenolone, methylsulfonylmethane (**MSM**), and chondroitin sulfate. Chondroitin sulfate is one of the main glycosaminoglycans (GAGs) that is contained in shark cartilage and sea cucumber. Although studies show that chondroitin sulfate has benefits, it is hard to absorb because it contains large molecules.

Further confusion can arise because glucosamine is classified and sold as a dietary supplement, meaning

KEY TERMS

Amino acids—Organic acids containing nitrogen that are the building blocks of proteins.

Carbohydrates—Organic substances, usually from plant sources. They are made up of carbon, hydrogen, and oxygen and are the diet's major source of energy.

Chitin—A transparent horny substance found in the outer coverings of shellfish. Chitin is used to make commercial preparations of glucosamine.

Glucose—Simple sugar that serves as the main energy source for cells.

NSAIDs—Nonsteroidal anti-inflammatory drugs given to suppress inflammation. Ibuprofen is a typical NSAID.

Nutraceutical—A food or food ingredient that is thought to provide medical or health benefits. Glucosamine preparations are classified as nutraceuticals.

Osteoarthritis—Degenerative joint disease that affects the hips, knees, or spine. Pain occurs after exercise and the joints can become stiff and swell. This common type of arthritis occurs in 80% of people over 50.

Placebo—A substance that has no therapeutic effect. A placebo may be prescribed for the psychological benefit of the patient, or it may be used as a control in testing new drugs.

Rheumatology—The medical specialty that studies and treats disorders of the joints and muscles.

Tendinitis—Inflammation of tissues that connect muscles to bones. Tendinitis is usually caused by strain or an injury.

that it had not gone through the FDA approval process.As with any dietary supplement, patients with arthritis who are considering glucosamine formulations should consult their healthcare practitioner.

The standard dosage is 500 mg three times daily. Obese people may need to take higher dosages based on their weight.

Precautions

Persons on potassium-reduced **diets**, with **heart disease**, renal diseases, or high blood pressure related to salt intake should avoid either the regular or salt-free glucosamine supplements.

Diabetics should be aware that glucosamine contains the sugar glucose and can raise blood sugar and insulin levels. A 2000 study of 15 nondiabetic patients at the Los Angeles College of Chiropractic and Meta-Response Science showed that those who took 1,500 mg of glucosamine a day for 12 weeks had raised insulin levels. The conclusion was that the insulin rise would probably be more in diabetics. However, researchers cautioned diabetics that so far there was no need to discard their glucosamine supplements as more controlled studies were required.

Despite the concern regarding the use of glucosamine sulfate in persons with allergies to the sulfa drugs or the sulfite additives in food, sulfur itself is a necessary mineral and human blood contains large amounts of sulfur's sulfate form. Studies show that glucosamine sulfate is safe for long-term use to treat osteoarthritis, with the exception of some medical conditions.

Side effects

High dosages of glucosamine may cause gastric problems, **nausea**, **diarrhea**, **indigestion**, and **heartburn**. Glucosamine should be taken with meals to help avoid these problems

Interactions

Glucosamine should not be taken with heart medications or insulin. Those taking diuretics may require higher amounts of glucosamine on a daily basis.

Glutamine

Description

In healthy individuals, glutamine is a neutral, nonessential amino acid. **Amino acids** are critical to humans, since they form the proteins that are the building blocks for many body tissues, including muscles. Glutamine is the most abundant amino acid in the human body. It performs several important functions in the body and is particularly important when the body is stressed. If not enough glutamine is being created by the body, the body's natural supply can be supplemented with outside sources. Glutamine is sometimes recommended by physicians, and sometimes it is taken as a dietary supplement without physician advice.

General use

Researchers continued as of 2008 to study glutamine's properties and effects. It is the most plentiful amino acid in the bloodstream. In cases of extreme **stress** the body's ability to produce glutamine can be overwhelmed by the body's demand for it. **Cancer**, **burns** or trauma, excessive **exercise**, and other stressors may cause glutamine levels to drop.

Research suggests that when glutamine levels fall and are not replaced, several body functions are affected, particularly within the digestive tract. Glutamine is also believed to be important to overall immunity. Between 1970 and 2000, interest grew for use of glutamine in helping cancer patients. Research continued as of 2008 on using glutamine therapy to help patients with sepsis, burns, trauma, **inflammatory bowel disease**, acquired immune deficiency syndrome (**AIDS**), bone marrow transplants, and many other diseases and conditions.

Some clinical research has reported glutamine aided patients with multiple trauma and burns by helping them fight off **infections**. It may help AIDS patients put on weight at a much lower cost, and with fewer complications, than human growth hormone. Athletes who overtrain have higher rates of infectious diseases and **allergies**; it is thought that a diet high in glutamine can help improve these athletes' immune functions.

As more people began looking for ways to enhance fitness, they turned to protein supplements. Every year, more than one million athletes use some type of performance-boosting supplement. Glutamine is used in the fitness industry as a supplement by bodybuilders who want to reduce muscle breakdown and by athletes on vigorous training schedules who believe the supplement boosts their immune systems.

Preparations

As a protein, glutamine occurs naturally in some foods, including meat, fish, legumes, peanuts, eggs, tofu, and dairy products. It also is highly concentrated in raw cabbage and beets. Cooking can destroy glutamine, particularly in vegetables. Much of a person's glutamine needs, even when exercising hard, can come from food sources. A 3-oz. serving of meat contains about 3 to 4 g of glutamine.

Glutamine supplements come in several forms. Some manufacturers sell tablets that also contain vitamins. The most common forms of glutamine supplements are protein powders that can be added to liquids and prepared protein drinks and shakes. Another amino acid called alanine may be combined with glutamine. The combined protein supplement is called alanyl-glutamine. When glutamine is used for medical purposes in a hospital setting, it may be administered through a tube directly into the intestine.

Recommended doses of glutamine for fitness uses such as bodybuilding vary but generally are 8 to 20 g a day and average about 15 g a day. Cancer patients on glutamine therapy may take a higher dose, about 30 g per day. An average daily dose for the general public is 1.5 to 6 g.

Precautions

The powdered form of glutamine should be dissolved in a liquid and consumed quickly before it breaks down. Some literature recommends taking glutamine immediately before or after meals or at the same time as eating protein, usually twice per day.

Glutamine is marketed as a dietary supplement and, therefore, is not regulated in the same way as prescription drugs. The United States Food and Drug Administration (FDA) is the regulatory body responsible for regulating dietary supplements. Because supplements are regulated in the same way as food, and

KEY TERMS

Digestive tract—The long tubular structure that handles all digestion and the structures that connect to it, including the mouth, esophagus, stomach, and intestines.

Goiter—An enlarged thyroid gland (a hormone-producing gland at the front of the neck). Goiters usually appear as obvious swelling in the neck.

Hypothyroidism—A condition that is characterized by decreased activity of the thyroid gland (a hormone-producing gland at the front of the neck) that often results in weight gain, tiredness, dry skin, and other symptoms.

Sepsis—A bacterial infection of the bloodstream or tissues of the body.

not as medicine, the products do not have to be proven safe or effective before being put on the market. Most FDA regulation of supplements involves only ensuring that false health claims are not made by the supplements. No supplement is allowed to claim that it treats or cures any disease or condition without undergoing scientific study and clinical trials to prove the statement is true. Individuals who take glutamine must be cautioned to carefully read product labels and the research on the products that are being considered. Investigations of dietary supplements have revealed discrepancies between the quantities of active ingredient present in the product and the quantity indicated as present on the label.

While many fitness promoters tout glutamine's effects, some researchers disagree with the science behind the claims. More and larger clinical trails may be able to clear up the controversy over glutamine's ability to increase muscle size and strength in recreational athletes.

Side effects

No side effects are generally reported with glutamine use; however, as of 2008 no significant scientific studies had been done to investigate possible side effects.

Interactions

Glutamine has not been shown to interact with any particular drugs or with other supplements. Before beginning to take glutamine individuals should talk to their physician, pharmacist, or other medical health professional. No significant scientific studies have been done to determine if glutamine negatively interacts with medications, other supplements, or herbs. A medical professional can help individuals determine if the supplement is likely to be safe for them. Consumption of cabbage can worsen goiters and a condition called **hypothyroidism**.

Glutathione

Description

Glutathione is a tripeptide, a chemical compound consisting of three **amino acids**, cysteine, glycine, and glutamic acid. It is produced in the human liver and plays a key role in metabolism, immune response, and general health. The precise mechanisms of its biological functions are not, as of 2008, fully understood. Glutathione is also known as gamma-glutamylcysteineglycine and GHS. Glutathione occurs in two forms, a monomer consisting of a single molecule of the tripeptide and a dimmer consisting of two molecules joined through a disulfide bond. The monomer is sometimes called reduced glutathione, while the dimmer is also called oxidized glutathione. The monomer is the active

form of glutathione. Oxidized glutathione is broken down to the single molecule by an enzyme called glutathione reductase.

Glutathione, in purified extracted form, is a white powder that is soluble in water and in alcohol. It is found naturally in many fruits, vegetables, and meats. However, absorption rates of glutathione from food sources in the human gastrointestinal tract are low.

General use

Glutathione was first isolated in yeast by English biochemist Sir Frederick Hopkins (1861–1947) in 1929. Its metabolism in the body was described in 1984, and its role in **cancer** treatment dates from 1984.

Glutathione is a major antioxidant highly active in human lungs and many other organ systems and tissues. It has many reported uses. It has a critical role in protecting cells from oxidative **stress** and maintaining the immune system. Higher blood levels of glutathione have been associated with better health in elderly people, but the exact association between glutathione and the **aging** process has not been determined.

Among the uses that have been reported for glutathione are:

- treatment of poisoning, particularly heavy metal poisons
- treatment of idiopathic pulmonary fibrosis
- increasing the effectiveness and reducing the toxicity of *cis-platinum*, a drug used to treat breast cancer
- treatment of Parkinson's disease
- lowering blood pressure in patients with diabetes
- increasing male sperm counts in humans and animals
- treatment of liver cancer
- treatment of sickle cell anemia

Claims made for glutathione include that it increases energy, improves concentration, slows aging, and protects the skin.

The importance of glutathione is generally recognized, although its specific functions and appropriate clinical use remain under study. Similarly, because ingested glutathione has little or no effect on intracellular glutathione levels, questions remained as of 2008 as to the optimal method for raising the intracellular levels.

In addition to studies ongoing in the late 2000s of the role of glutathione in cancer and cancer therapy, there were clinical trials of glutathione in the treatment of amyotrophic lateral sclerosis (ALS). The U.S. National Cancer Institute included glutathione in a study to determine whether nutritional factors can inhibit development of some types of cancer.

European researchers, with support from the Cystic Fibrosis Foundation, examined the potential uses of inhaled glutathione in cystic fibrosis. Some physicians also use inhaled glutathione in treating airway restriction and **asthma**. Other studies investigated whether administration of alpha-lipoic acid, a material that can elevate intracellular glutathione, may be beneficial in restoring the immune system in **AIDS** patients.

Preparations

Although glutathione is marketed as a nutritional supplement, it does not appear that glutathione supplements actually increase the levels of glutathione inside cells. In human studies, oral doses of glutathione had little effect in raising blood levels of the substance. Further, glutathione is so widely distributed in common foods that supplements are not normally required. Supplements of **vitamin C** are more effective at increasing intracellular glutathione than taking oral glutathione supplements. Oral supplements of whey protein and of alpha-lipoic acid appear to help restore intracellular levels of glutathione.

Glutathione is available as capsules of 50, 100, and 250 mg. It is also included in many multivitamin and multi-nutrient formulations.

Precautions

As of 2008, the only established precautions were sensitivity to any of the inactive ingredients in the preparations of glutathione or the products used to stimulate glutathione levels.

Side effects

There were no established side effects to glutathione or to the substances used to elevate glutathione levels.

Training and certification

Glutathione has been classified as an orphan drug for treatment of AIDS. For this purpose, medical licensure is required. Glutathione has been given intravenously for amelioration of the side effects of cisplatin therapy. Specific training is required to order, prepare, start, and monitor intravenous therapy. No specific training is required to use glutathione or the compounds that have been reported to raise glutathione levels for other purposes.

KEY TERMS

Antioxidant—A substance, such as vitamin E, vitamin C, or beta carotene, thought to protect body cells from the damaging effects of oxidation.

Dimmer—A molecule consisting of two identical simpler molecules.

Heavy metal poison—A metal with a specific gravity greater than about 5.0, that is poisonous, such as lead or mercury.

Intracellular—Inside a cell.

Monomer—A molecule that can combine with others to form a dimmer or a polymer.

Gluten-free diet

Definition

A gluten-free diet is a diet that is completely free of gluten, which is a generic term for storage proteins found in grains. In **celiac disease** (also referred to as celiac sprue), persons develop an inflammatory immune system response to gluten that results in damage to the small intestine, which inhibits absorption of nutrients. Some persons also develop **dermatitis** herpetiformis, an itchy and blistering skin condition. Because of gluten intolerance, affected persons must completely avoid foods that contain gluten.

Origins

Guidelines for this diet have been developed by dietitians for several organizations associated with celiac disease and dermatitis herpetiformis, including the Gluten Intolerance Group, the Celiac Sprue Association, and the Celiac Disease Foundation. The American Dietetic Association also sponsored the development of a gluten-free diet through a cooperative effort of dietitian experts in celiac disease in Canada and the United States, which was published in October, 2000.

Description

The gluten-free diet is the prescribed medical treatment for gluten intolerance diseases, including celiac disease and dermatitis herpetiformis. Celiac disease is a genetically inherited, chronic digestive disease that results in damage to parts of the small intestine that are responsible for absorption of nutrients. Celiac disease affects almost three million people in the United States, about one percent of the population. Celiac disease is found among North American and European populations, where wheat is a staple food, but is found infrequently among descendants of China and Japan and persons with an African-Caribbean background, where wheat is not as widely consumed.

In addition, dermatitis herpetiformis is an important disorder or complication of gluten-sensitive enteropathy, which is manifested in the form of a skin rash. Approximately 10% of persons with celiac disease have dermatitis herpetiformis, but about 85% of persons with dermatitis herpetiformis also have celiac disease.

When a person with celiac disease consumes gluten, the villi of the small intestine, where absorption of key nutrients takes place, become damaged, resulting in nutrients passing through the digestive system

KEY TERMS

Antibodies—Any of numerous protein molecules produced by the immune system as a primary immune defense to destroy or neutralize foreign objects. Each antibody recognizes a specific target, referred to as the antigen. These antigens may include foreign proteins, microorganisms, or toxins. Some antibodies attack the body's own tissues.

Autoimmune disease —An illness that occurs when the body tissues are attacked by its own immune system.

Enteropathy—A disease of the intestinal tract.

Lymphoma—Any of various usually malignant tumors that arise in the lymph nodes or in other lymphoid tissue.

Osteomalacia—Softening of bone, particularly bone weakened by demineralization (loss of mineral) and most notably by the depletion of calcium from bone. Osteomalacia may be caused by poor dietary intake or poor absorption of calcium and other minerals needed to harden bones. Osteomalacia is a characteristic feature of vitamin D deficiency in adults.

Osteopenia—Mild thinning of the bone mass, but not as severe as osteoporosis. Osteopenia results when the formation of bone is not enough to offset normal bone loss. Osteopenia is generally considered the first step to osteoporosis.

Osteoporosis—A decrease in bone mass and bone density and an increased risk and/or incidence of fracture.

Tropical sprue—A condition of unknown cause whereby abnormalities in the lining of the small intestine prevent the body from absorbing food normally. This disease is not associated with gluten enteropathy. It has been associated with travel and residence in tropical areas.

Villi—The tiny, finger-like projections on the surface of the small intestine that help absorb nutrients.

without being absorbed. The person exhibits gastrointestinal distress and eventually malnutrition. In infancy, celiac disease manifests itself as failure to thrive, **diarrhea**, abdominal distention, developmental delay, and in some infants, as severe malnutrition.

After infancy, the symptoms of celiac disease are less dramatic. Older children may be short or exhibit dental enamel defects. Women comprise about 75% of newly diagnosed adult cases of celiac disease. Symptoms of celiac disease include diarrhea, **constipation** alternating with diarrhea, intestinal **gas**, fatty, greasy, foul-smelling stools, bloating, **nausea**, **vomiting**, skin irritation, weight loss, **anemia**, neurological effects (including seizures, and possibly migraine headaches), **fatigue**, concentration and memory problems. In some cases, there may be intestinal damage without significant gastrointestinal symptoms. Celiac disease is diagnosed by blood tests for certain antibodies and small intestine biopsy. A positive small intestine biopsy, followed by an improvement in health after following a gluten-free diet, is confirmation of celiac disease. A gluten-free diet should not be started before diagnosis is confirmed.

Some individuals may exhibit gluten intolerance, with gastrointestinal symptoms similar to those seen with celiac disease, but without its resulting intestinal damage. Gluten intolerance is diagnosed by following a gluten-free diet, followed by reintroduction of gluten- containing foods, to evaluate health improvement associated with elimination or reduction of gluten from the diet. Some individuals with gluten intolerance maybe be able to tolerate a low-gluten diet under the supervision of a physician or dietitian.

A gluten-free diet may also be helpful for persons with **multiple sclerosis** and other autoimmune disorders, as well as for persons with **autism** spectrum disorders, Attention Deficit Hyperactivity Disorder (ADHD), and some behavioral problems.

The foods of concern for individuals with, or susceptible to, celiac disease are the cereal grains that contain the storage proteins prolamin and glutelin (commonly referred to as glutens in wheat), all varieties of wheat (e.g., durum, spelt, kamut), barley (where the storage proteins are called hordiens), rye (where the storage proteins are called secalins), and their cross-bred hybrids (such as triticale).

Grains and starches that are allowed in a gluten-free diet include: rice, corn, soy, potato, sweet potato, tapioca, beans, garfava, sorghum, quinoa, millet, **arrowroot**, amaranth, tef, nut flours, and buckwheat. However, some commercial buckwheat products are mixtures of wheat and buckwheat flours and should be avoided. Other foods that are allowed (only a partial list) include fresh, canned, and frozen fruit or fruit juices, fresh vegetables, canned and frozen vegetables without gluten-containing additives, milk, aged cheese, all unprocessed meats, poultry, fish, eggs, dried beans, nuts, and seeds. A dietitian should be consulted to develop and monitor a gluten-free diet.

Gluten-free foods can be found in health food stores, through mail order sources, and in some supermarkets. Cookbooks are available to help in food preparation. Many food manufacturers maintain lists of gluten-free products. The Gluten-Free Certification Organization (GFCO) of the Gluten Intolerance Group, in cooperation with the Food Services, Inc., a subsidiary of the Orthodox Union, a kosher certification agency, has developed a gluten-free certification program. This program benefits consumers by giving them confidence that a product is gluten-free through a process whereby products have been tested and the manufacturing site inspected. The program also saves the consumer time that would have been spent calling the manufacturer for the gluten-free status of the product. Certification is a yearly process based on ingredient review, on-site inspection and product testing. The Celiac Sprue Association (CSA) also has the CSA Recognition Seal Program that certifies gluten-free products. Requirements for obtaining the CSA Seal for products include:

- ingredient review and verification by testing to assure products are free of wheat, barley, rye and oats
- provision of written facility procedures and on-site facility audits to assure that procedures are in place to control any cross or outside contamination in processing and packaging

Foods may contain gluten, although gluten will not be indicated on the ingredient list, because it was not included in the formulation of the product. For example, a conveyer belt may be dusted with a gluten-containing material to prevent foods from sticking and may contaminate the finished food product.

Function

The gluten-free diet is used by persons who are gluten-sensitive to prevent damage to their small intestines and to prevent serious complications such as gastrointestinal cancers, iron-deficiency anemia, and decreased bone mineral density.

Benefits

A gluten-free diet has been shown to greatly reduce the risk for **cancer** and overall mortality for individuals with symptomatic celiac disease.

For many people with celiac disease, following a gluten-free diet will stop the symptoms of the disease and result in improved health, usually within several months (for some persons, recovery may take up to one year). However, the health of some people with extensive damage to their small intestines may not improve. Refractory celiac disease (RCD) is a rare syndrome with a poor prognosis, defined by malabsorption due to gluten-related enteropathy after initial or subsequent failure of a strict gluten-free diet and after exclusion of any other disease or disorder mimicking celiac disease. Other treatments may be necessary to treat the RCD, such as the use of corticosteroids and immunosuppressant drugs, but data on their effectiveness is lacking.

Precautions

In addition to gluten-containing grains, gluten can be found in a large variety of foods including soups, salad dressings, processed foods, candy, imitation bacon and seafood, marinades, processed luncheon meats, sauces and gravies, self-basting poultry, soy sauce or soy sauce solids, thickeners, communion wafers, and natural flavorings. Unidentified starch, binders and fillers in medications, supplements, or vitamins and adhesives in stamps and stickers can also be unsuspected sources of gluten. Playdough, which contains wheat, can be harmful if hands are put on or in the mouth after contact or hands are not washed after play.

An individual following a gluten-free diet must read labels every time a food item is purchased or consumed. Ingredients that may contain hidden sources of gluten include unidentified starch, modified food starch, hydrolyzed vegetable or plant protein (HVP or HPP), texturized vegetable protein (TVP), and binders, fillers, and extenders. In addition, manufacturers can change ingredients at any time, and a product may no longer be gluten-free. Ingredients may be verified by contacting a manufacturer and specifying the ingredient and lot number of a food item. If a person cannot verify ingredients in a food product or if the ingredient list is unavailable, the food should not be eaten, to avoid damage to the small intestine that occurs every time gluten is consumed.

Gluten-free recommendations can be difficult to follow. It is recommended that an affected person keeps the diet simple at the beginning by eating fresh fruits and vegetables, milk, unprocessed protein foods such as fresh beef, pork, poultry, fish, and eggs, natural nuts, seeds, and vegetable oils without additives.

Pure, uncontaminated oats eaten in moderation (one cup cooked daily) may be safe for persons with celiac disease. However, in many cases oats can become cross-contaminated with grains containing gluten during growth, harvest, transport, storage, or processing. Some persons with celiac disease who introduce oats to their diet may experience abdominal discomfort, gas, and stool changes until they become

accustomed to the increased fiber levels from the oats. Others with celiac disease may exhibit a hypersensitivity to oats and should avoid their consumption. Recent research published between 2000 and 2004 has indicated that oats may contain a protein similar to gluten that has caused intestinal inflammation in many persons with celiac disease. At this time, because of conflicting information on the effects of oats on persons with celiac disease, excluding oats from the diet may be the best and most risk-free choice. In all cases, persons with celiac disease should consult their health care provider or dietitian before including oats in their diet and should have their antibody levels monitored regularly.

Almost all beers are brewed with barley (some are brewed with wheat) and should not be consumed by a person following a gluten-free diet. Sorghum and buckwheat beers are available but are a specialty product. Most distilled forms of alcohol are gluten-free, unless additives and colorings have been added, which may contain glutens. Wines are also usually gluten-free.

Since celiac disease is an inherited autoimmune disease, screening of family members is recommended. The chances of developing gluten-sensitive enteropathy increases to 10 to 20% in persons who have a first-degree relative with celiac disease. Celiac disease is also associated with other autoimmune syndromes such as Type 1 diabetes.

Risks

A gluten-free diet is difficult to follow, and continued health problems are usually associated with problems adhering to the gluten-free diet. A person can exhibit celiac-related symptoms for months after a single gluten intake. Persons with gluten-sensitivity who do not treat their disease are at a higher risk for enteropathy-associated T-cell lymphoma and other gastrointestinal cancers. However, the maintenance of a long-term gluten-free state reduces the risk of lymphoma to the level seen in the general population. Other complications of gluten-sensitivity include decreased mineral bone density and iron-deficiency. Persons with celiac disease and dermatitis herpetiformis must maintain a gluten-free diet for the rest of their lives, for these diseases cannot be cured.

Persons are more likely to adhere to the diet if a dietitian and support group are involved. If a person is not responding well to a gluten-free diet, the doctor should:

- investigate whether the initial diagnosis of celiac disease was correct
- check for other conditions that can be causing symptoms, such as pancreatic insufficiency, irritable bowel syndrome, bacterial overgrowth, lymphocytic colitis, T-cell lymphoma, fructose intolerance, or tropical sprue
- refer the person to a dietician to check for errors in the diet or for compliance with the diet

To monitor dietary adherence to the gluten-free diet, the dietitian will examine the person's dietary history and habits. Blood tests will be conducted to see if gluten antibody levels have returned to normal levels. If there is clinical concern that a person is not adhering to the gluten-free diet or that the diet is not effective, a biopsy of the small intestine may be conducted.

The gluten-free diet is complex and it cannot be assumed that chefs in restaurants or others who prepare food (including friends and family) are aware of potential sources of gluten contamination. Education of family and friends is important in accomplishing a lifestyle change. In restaurants, simple dishes without sauces should be ordered, and the person should inquire whether grain products are prepared with the same equipment or utensils used to prepare other foods. Although a food may be considered to be gluten-free by the ingredients it contains, it may be gluten-contaminated by the way in which it is prepared or stored. Other difficulties associated with following a gluten-free diet include lifestyle changes such as avoiding travel, finding gluten-free foods (especially those of good quality), determining whether foods are gluten-free, not being invited out because of the diet, with resulting social isolation, and maintaining a gluten-free diet when in the hospital.

As with any restrictive diet, the gluten-free diet has potential for nutritional inadequacy. Persons who are sensitive to gluten are at increased risk for **osteoporosis** and osteomalacia, due to malabsorption of **calcium** and **vitamin D**. Most persons with celiac disease have some degree of osteopenia or osteoporosis. Calcium and vitamin D supplementation along with strict adherence to a gluten-free diet usually results in remineralization of the skeleton. **Iron** or other vitamin deficiencies may also be present and must be treated appropriately. The consumption of gluten-free fiber-rich foods (for example, brown rice, fruits, and vegetables) and adequate fluid intake is recommended to assist in the prevention of constipation.

Women with untreated celiac disease often exhibit a history of miscarriages, anaemia, low birth weight babies, and unfavorable outcome of **pregnancy**. It is suggested that testing for celiac disease be included in

the battery of tests prescribed for pregnant women. Celiac disease is considerably more common than most of the diseases for which pregnant women are routinely screened. Unfavorable events associated with celiac disease may be prevented by a gluten-free diet.

Research and general acceptance

The gluten-free diet is recognized as the required treatment for persons exhibiting gluten-sensitivity.

The National Institutes of Health noted in 2004 that the strict definition of a gluten-free diet remains controversial due to the lack of an accurate method to detect gluten in food products and the lack of scientific evidence for what constitutes a safe amount of gluten ingestion. No international agreement has yet been developed on how much gluten a person with gluten-sensitivity can tolerate. Research is on-going to better identify levels that are acceptable, and health professionals involved in the therapy of celiac disease should keep up-to-date on the latest research. As of 2007, the United States Food and Drug Administration is proposing to set a standard of 20 part per million as the maximum acceptable level of gluten allowed for a product to be labeled as gluten-free.

Research continues on the benefits of a gluten-free diet for persons with multiple sclerosis and other autoimmune disorders, as well as for persons with autism spectrum disorders, ADHD, and some behavioral problems.

In addition, a new enzyme that was being developed for commercial food processing has been found to break down gluten molecules quickly and almost completely. The enzyme is made from *Aspergillis niger*, a common fungus that is the source of other food grade enzymes already being manufactured for human consumption. Fritz Koning of Leiden University Medical Center in the Netherlands is leading the research. He stated that if the enzyme proves itself in clinical trials to eliminate the need for a gluten-free diet, it could be mass produced at a reasonable cost.

Goatweed *see* **St. John's wort**

Goldenrod

Description

Averaging about 4 feet (1.2 m) in height, goldenrod is a perennial with clusters of bright yellow flowers. It has been used for centuries in the treatment of **kidney stones**, urinary tract **infections**, and a variety of other medical conditions. One legend has it that a 10-year-old boy who received an infusion of goldenrod for several months in the late eighteenth century passed 50 gravel stones larger than a pea. Native Americans used goldenrod to alleviate **sore throat**,

Rough-leaf goldenrod. *(© Arco Images / Alamy)*

and blue mountain tea made from goldenrod leaves is sometimes used to combat **fatigue** in the Appalachian Mountains. Goldenrod varieties belong to the plant family Asteraceae. While European goldenrod (*Solidago virgaurea*) is perhaps the most well known variety, other species of the plant (there are over 100 and counting) appear to have roughly equivalent medicinal properties—in particular, the ability to increase the flow of urine. In Europe, *Solidago virgaurea* is often used interchangeably with other species of goldenrod such as *Solidago serotina* and *Solidago canadensis* in the drug of commerce. Only the aboveground parts of the plant, mainly the flowers and leaves, are considered to have medicinal value.

Goldenrod grows in Europe, Asia, northern Africa, and North America, but most medicinal goldenrod originates in Bulgaria, Hungary, Poland, and other eastern European countries. It thrives in a wide variety of habitats, including hills, woods, meadows, and rocky terrain. Contrary to popular belief, goldenrod does not play a significant role in triggering **hay fever** reactions. This myth probably developed due to the fact that goldenrod blooms around the same time and in the same places as the ragweed responsible for most seasonal **allergies**. Studies of goldenrod pollen indicate that it is not a potent allergen for most people. Goldenrod is also a very potent anti-allergic herb for people with hay **fever**.

The genus name *Solidago* is derived from the Latin verb *solidare*, which can be translated "to make whole." Goldenrod received this appellation due to its reputation through the ages as a wound-healing drug. This also explains why goldenrod has sometimes been referred to as "woundwort" during its long history as a folk remedy. While not valued much today as a wound healer, goldenrod has been approved by the authoritative German Commission E as a diuretic, anti-inflammatory, and antispasmodic for the treatment of urinary tract disorders. Research suggests that goldenrod can increase the production of urine, which is often helpful in cases of urinary tract infection or kidney stones, without reducing levels of important electrolytes, such as **sodium** and chloride, the way that some man-made diuretics do. While it is not known exactly how goldenrod produces its therapeutic effects, researchers have focused on several naturally occurring chemicals in the plant. Most experts believe that goldenrod's ability to increase urine production is due to the presence of flavonoids and saponins, which stimulate the kidneys to release fluid. Another chemical in goldenrod, a phenolic glycoside called leiocarposide, may be responsible for goldenrod's anti-inflammatory effects. In one study of *Solidago virgaurea* involving rodents, researchers from Cairo University found that the anti-inflammatory activity of goldenrod was comparable to that of diclofenac, a nonsteroidal anti-inflammatory drug (NSAID) prescribed for conditions such as **rheumatoid arthritis**. The tannins in goldenrod have been associated with astringent properties. The herb also contains a small amount of essential oil.

General use

While not yet popular in the United States or approved for use by the United States Food and Drug Administration (FDA), goldenrod is used widely in Europe to treat urinary tract infections and help eliminate kidney or bladder stones. The Commission E has approved goldenrod as flushing-out therapy for inflammatory diseases of the lower urinary tract and for helping to eliminate and prevent stones. Goldenrod is considered useful in treating these disorders for several reasons. The herb can help to eliminate bacteria and stones by increasing the flow of urine and thereby "washing" them out. As an anti-inflammatory and

KEY TERMS

Antispasmodic—An agent with the ability to prevent or relieve convulsions or muscle spasms.

Astringent—An agent that helps to contract tissue and prevent the secretion of internal body fluids such as blood or mucus. Astringents are typically used to treat external wounds or to prevent bleeding from the nose or throat.

Diuretic—An agent that increases the production of urine.

Edema—Abnormal swelling of tissue due to fluid buildup. Edema, which typically occurs in the legs, liver, and lungs, is often a complication of heart or kidney problems.

Electrolytes—Substances in the blood, such as sodium and potassium, that help to regulate fluid balance in the body.

antispasmodic, goldenrod may help to soothe irritated tissue in the urinary tract and prevent **muscle spasms**.

Goldenrod is not used as a cure for any of these disorders—for example, antibiotics are considered the primary therapy in cases of urinary tract infections—but it can be a helpful component of treatment. In Germany, where goldenrod has government approval as an aid in treating urinary tract disorders, the plant is often combined with java tea leaf, birch leaf, or **uva ursi** leaf. Compared to other herbal diuretics, goldenrod is considered well tolerated due to its lack of side effects and contraindications.

Throughout its history, goldenrod has been used to treat a variety of other medical problems. These include **hemorrhoids**, diabetes, **tuberculosis**, liver enlargement, **gout**, internal bleeding, **diarrhea**, **asthma**, rheumatism, enlarged prostate, infections of the mouth and throat, and external **wounds**. In the Appalachian Mountain region of the United States, goldenrod leaves have been used to prepare blue mountain tea, which is recommended by folk practitioners there to combat fatigue and physical exhaustion. Sufficient scientific evidence to support these additional uses is lacking.

Preparations

Dosage of goldenrod generally ranges from 6–12 g of cut herb per day. The drug, which is recommended for internal use only, can be taken as a tea, liquid extract, or tincture. No matter which preparation is used, it is important to drink plenty of fluids (6–8 glasses a day) while using goldenrod in order to increase its effectiveness as a diuretic.

Goldenrod tea can be prepared by steeping 3–5 g (1 or 2 teaspoonfuls) of the herb in 150 ml of simmering water. The mixture should be strained after about 15 minutes. Dosage is two to four cups of tea a day, taken between meals. The liquid extract preparation is usually taken two to three times a day in doses of 0.5–2.0 ml. Dosage for the tincture is 0.5–1.0 ml two to three times a day.

Precautions

While self-care measures such as goldenrod may be an effective component of treatment for disorders of the urinary tract, these medical conditions can be serious and require consultation with a doctor. People who have **edema** due to reduced heart or kidney function should not use goldenrod without medical supervision. Due to lack of sufficient medical study, goldenrod should be used with caution in children, women who are pregnant or breastfeeding, and people with kidney disease. To ensure optimum effectiveness, protect goldenrod from direct sunlight and moisture during storage.

Most studies of goldenrod's effects as a diuretic, anti-inflammatory, and antispasmodic have been conducted in the test tube or in rodents. Goldenrod's effectiveness in humans is not well demonstrated.

Side effects

When taken in recommended dosages, goldenrod has not been associated with any significant or bothersome side effects. Allergic reactions may occur in some people.

Interactions

No drugs are known to interact adversely with goldenrod. In Germany, goldenrod has been combined with java tea leaf, birch leaf, and uva ursi leaf without apparent harm.

Goldenseal

Description

Goldenseal (*Hydrastis canadensis*) is a perennial North American native plant found wild in eastern deciduous woodlands and damp meadows as far north as Vermont and Minnesota, and south to Georgia and Arkansas. This versatile herb is sought for its valuable rootstock and inner twig bark. Goldenseal is a member of the Ranunculaceae, or buttercup family. It is a mainstay of **Native American medicine**, and a popular folk remedy. Goldenseal has multiple uses, both internally and externally. It is sometimes called poor man's ginseng. This traditional medicinal herb has been known by many names, including yellow paint root, orange root, eye root, Indian plant, tumeric root, eye balm, jaundice root, yellow puccoon, and ground raspberry. Native American tribes valued this natural antiseptic herb for many medicinal uses and as a clothing dye. Early colonists soon came to appreciate its infection-fighting action. The Native American use of goldenseal as a **cancer** treatment was first mentioned in the herbal, *Essays Toward a Materia Medica of the United States* first published by Benjamin Smith Barton in 1798.
