Marijuana has analgesic, anti-emetic (anti-nausea), anti-inflammatory, sedative, anticonvulsive, and laxative actions. Clinical studies have demonstrated its effectiveness in relieving **nausea** and **vomiting** following chemotherapy treatments for **cancer**. The herb has also been shown to reduce intra-ocular pressure in the eye by as much as 45%, a beneficial action in the treatment for **glaucoma**. Cannabis has proven anticonvulsive action and may be helpful in treating **epilepsy**. Other research has documented an in-vitro tumor inhibiting effect of THC. Marijuana also increases appetite and reduces nausea and has been used with **AIDS** patients to counter weight loss and wasting that result from the disease. Several chemical constituents of cannabis have displayed antimicrobial action and antibacterial effects in research studies. The components CBC and d-9-tetrahydrocannabinol have been shown to destroy and inhibit the growth of streptococci and staphylococci bacteria.

Cannabis contains chemical compounds known as cannabinoids. Different cannabinoids seem to exert different effects on the body after ingestion. Scientific research indicates that these substances have potential therapeutic value for **pain** relief, control of nausea and vomiting, and appetite stimulation. The primary active agent identified as of 2008 was THC. This chemical may constitute as much as 12% of the active chemicals in the herb and is said to be responsible for as much as 70 to 100% of the euphoric action, or high, experienced when ingesting the herb. The predominance of this mental lightness or euphoria depends on the balance of other active ingredients and the freshness of the herb. THC degrades into a component known as cannabinol, or CBN. This relatively inactive chemical predominates in marijuana that has been stored too long prior to use. Another chemical component, cannabidiol, known as CBD, has a sedative and mildly analgesic effect and contributes to a somatic heaviness sometimes experienced by marijuana users.

In the United States in the early twentieth century, cannabis was recommended for treatment of **gonorrhea**, **angina** pectoris (constricting pain in the chest due to insufficient blood to the heart), and choking fits. It was also used for **insomnia**, **neuralgia**, rheumatism, gastrointestinal disorders, cholera, **tetanus**, epilepsy, strychnine poisoning, **bronchitis**, **whooping cough**, and **asthma**. Other phytotherapeutic (plant-based therapeutic) uses include treatment of ulcers, cancer, **emphysema**, migraine, and **anxiety**.

The federal policy prohibits physicians from prescribing marijuana, even for seriously ill patients because of possible adverse effects, and the disputed belief that cannabis is dangerously addictive. Former U.S. attorney general Janet Reno warned that physicians in any state who prescribed marijuana could lose the privilege of writing prescriptions, be excluded from Medicare, and Medicaid reimbursement, and even be prosecuted for a federal crime, according to a 1997 editorial in the *New England Journal of Medicine*. Yet in 1996, California passed a law legalizing medical use of marijuana. By 2008, 35 states had passed legislation recognizing the medical value of marijuana and about one-third of those had either legalized or decriminalized medical use of the herb. The debate in the United States over medical use of the drug continued as of 2008. Some opponents believe that the movement to legalize marijuana for medicinal purposes is led by those who want the drug legalized for recreational purposes.

Preparations

Marijuana is ingested by smoking, which quickly delivers the active ingredients to the blood system. The dried herb is also variously prepared for eating. The essential oil consists of beta caryophyllenes, humules, caryophyllene oxide, alpha-pinenes, beta-pinenes, limonene, myrcene, and betaocimene. The oil expressed from the seeds is used for massage and in making salves used to relieve muscle strain. THC extract is available legally in some countries in capsule form.

Precautions

Marijuana is considered a Class I narcotic, and federal law in the United States has restricted its use since 1937. Penalties include fines and imprisonment in some states, but the herb has been decriminalized in others. California, for example, issues cards identifying medical marijuana users and allows them to purchase the drug openly at certain clinics.

Research has shown that cannabis acts to increase heart frequency by as much as 40 beats per minute. A

study reported by the American Heart Association in February 2000 concluded that smoking marijuana can precipitate a **heart attack** in persons with pre-existing heart conditions. One hour after smoking marijuana, the likelihood of having a heart attack is four and one-half times greater than if the person had not smoked, according to the research. Marijuana also can cause a drop in blood pressure resulting in **dizziness**.

Marijuana use during **pregnancy** has been found to reduce the newborn's birth weight, a possible indication of problems. Pregnant and breastfeeding women should avoid using marijuana. Other research has shown that marijuana decreases male fertility and increases the number of abnormal sperm found in semen.

An additional health concern is the effect that marijuana smoking has on the lungs. Cannabis smoke carries more tars and other particulate matter than tobacco smoke. Long-term use is also associated with an increase in respiratory diseases such as bronchitis.

Studies have shown that motor coordination and driving ability can be impaired for up to eight hours after smoking marijuana. Individuals should avoid driving and using heavy machinery for several hours after using the herb.

Side effects

The *PDR for Herbal Medicine* reports that the most common side effect of marijuana use is psychotropic, as a euphoric state (pronounced gaiety, laughing fits) occurs almost immediately after smoking the herb. Long-term usage leads to a clear increase in tolerance for most of the pharmacological effects. Chronic use results in **laryngitis**, bronchitis, apathy, psychic decline, and disturbances of genital functions.

Some people may be hypersensitive to marijuana. They may experience paranoia or be allergic or sensitive to the plant. Chronic sinus **fungal infections** have been linked to chronic marijuana smoking. Clinical trials have shown that there is no decrease in cognitive function over time in moderate marijuana users when compared to non-users.

Interactions

Marijuana use may mask the perceived effects of alcohol and cocaine when the drugs are consumed together. Marijuana is said to exert a synergistic effect with other medicinal agents. When used with nitrous oxide it may enhance the nitrous oxide effect.

Marijuana use by individuals taking selective serotonin re-uptake inhibitors (SSRIs, used to treat **depression**) may develop manic symptoms. Use in individuals taking tricyclic antidepressants can produce delirium and racing heart (tachycardia).

KEY TERMS

Edema—Swelling of a body tissue due to collection of fluids.

Glaucoma—An eye disorder caused by damage to the optic nerve resulting in vision loss. Glaucoma is usually accompanied by inflammation and increased pressure in the eye (intraocular pressure). There are several types that may develop suddenly or gradually.

Pharmacopeia—A book containing a list of medicinal drugs and their descriptions of preparation and use.

Marsh mallow

Description

Marsh mallow (*Althaea officinalis*) is a perennial plant that grows in salt marshes, damp meadows, and on the banks of tidal rivers and seas. It originated in

Marsh Mallow. *(© Arco Images / Alamy)*

countries adjoining the Caspian Sea, Black Sea, and in the eastern Mediterranean, and is native to Europe and western Asia. Marsh mallow is found in North America along the eastern seaboard.

The plant stems grow to a height of 3-4 ft (1-1.3 m) and have round, velvety leaves that are 2-3 in (5-7.5 cm) long. Pale pink or white flowers bloom in August or September, and the roots are thick and long. The whole plant is used medicinally. The leaves and flowers are picked when the flowers are blooming. The roots are harvested in the fall, but the plant must be two years old before the root is harvested.

The common name marsh mallow is derived from the environment in which it grows. The Latin name *Althaea* comes from the Greek word *altho*, which means to heal or to cure. The family name Malvaceae comes from the Greek word *malake*, meaning soft. Other names for marsh mallow include mallards, mauls, sweetweed, Schloss tea, and mortification root.

KEY TERMS

Chilblain—Redness and swelling of the skin often accompanied by burning, itching, and blisters. A condition caused by excessive exposure to the cold.

Decoction—An herbal tea created by boiling herbs in water. Roots, bark, and seeds are used in decoctions; boiling the herbs brings out their medicinal properties.

Enteritis—Inflammation of the bowels.

Infusion—An herbal tea created by steeping herbs in hot water. Generally, leaves and flowers are used in infusions.

Perennial—A plant that lives for many years; comes back yearly without replanting.

Tincture—The concentrated solution of an herbal extract, usually made with alcohol.

Marsh mallow's medicinal use dates back 2,000 years. Arabian doctors created a poultice from the leaves to treat inflammation. The father of medicine, Hippocrates, used marsh mallow to remedy **bruises** and blood loss. Dioscorides wrote about the beneficial properties of marsh mallow, while Horace praised the laxative properties of the leaves and roots. Roman doctors used marsh mallow for toothaches, insect **bites**, chilblains, and irritated skin. The Chinese, Egyptians, and Romans ate a variety of marsh mallow for food. The French eat the flowers and leaves in salads. Marsh mallow was used to soothe toothaches, insect bites, **indigestion**, and **diarrhea** in Europe during medieval times. Teething babies were often given marsh mallow root to provide comfort.

Nineteenth century doctors used the roots of marsh mallow to make a **sore throat** lozenge for children and adults. They combined the cooked juice of the root with egg whites and sugar and whipped the mixture into a meringue that later hardened into a candy. The marshmallows eaten today as sweet treats were derived from this candy, but no longer contain any herbal properties.

Marsh mallow contains starch, mucilage, pectin, oil, sugar, asparagin, phosphate of lime, glutinous matter, and cellulose. It is rich in **calcium**, **zinc**, **iron**, **sodium**, **iodine**, **vitamin B complex**, and **pantothenic acid**.

General use

The main therapeutic constituent of marsh mallow is mucilage, a spongy substance of the root that is

composed of large sugar molecules. Mucilage's healing effect stems from its ability to support white blood cells against attacking microorganisms. When liquid is added to mucilage, it acquires a gel-like consistency. This gooey substance coats mucous membranes of the throat, mouth, stomach, and intestinal tract and provides relief from inflammation and **pain**. It also acts to expel phlegm from the lungs and to relax the bronchial tubes.

These anti-inflammatory and anti-irritant properties make marsh mallow a viable remedy for arthritis and joint pain; upper respiratory ailments such as **asthma**, **emphysema**, bronchial **infections**, coughs, sore throats, and lung congestion; inflamed kidneys and urinary tract disorders; and gastrointestinal disturbances including **Crohn's disease**, ulcers, **colitis**, diarrhea, dysentery, and stomach irritation.

The German Commission E has approved marsh mallow as a beneficial treatment for irritated and inflamed throat, pharyngeal, and gastric mucous membranes, and for dry coughs. Teas made from the root and leaf are licensed in Germany as standard medicinal teas. The root is also used as an ingredient in **cough** syrup and as a cough suppressant tea.

The British Herbal Compendium supports the use of marsh mallow for **gastroenteritis**, peptic and duodenal ulcers, colitis, and enteritis. In the United States, marsh mallow is an ingredient in dietary supplements and cough suppressants.

Marsh mallow provides external treatment for **cuts**, **wounds**, abscesses, **boils**, **burns**, and **varicose veins**. A gel created by adding water to finely chopped marsh mallow root may be applied to the affected area to reduce inflammation. A poultice containing **cayenne** and marsh mallow may relieve **blood poisoning**, **gangrene**, burns, bruises, and other wounds.

Preparations

Marsh mallow is available in whole bulk, tincture, and capsule forms. It can be taken internally as a tea, tincture, or capsule, or applied externally as an ointment or poultice.

A decoction may be made from the root to relieve congestion, sore throat, or dry cough. To create a decoction, 1-2 tsp of the finely chopped root is added to 1 cup of water and simmered for 10-15 minutes. The liquid is then cooled and strained. A person can drink 1 cup three times daily or as needed. An infusion can be made by steeping the crushed roots in cold water overnight. The infusion is then drunk as needed for symptomatic relief. For relief of an irritated kidney, boiling water is poured over the flowers and leaves. The mixture is covered and steeped for three hours.

To make a poultice, the leaves and/or the powdered or crushed roots are steeped in water. The mixture is then applied externally to areas of inflamed skin, **eczema**, or **dermatitis**.

For capsules, 5-6 g may be taken daily or as recommended.

For a tincture, 5 ml may be taken three times daily or as recommended.

For insect bites, the leaves are rubbed on wasp or bee **stings** to alleviate pain, inflammation, and swelling.

For sore throat, the flowers are boiled in oil and water, cooled, and used as a gargle to relieve sore throat pain.

Precautions

Diabetics should take marsh mallow with caution since high doses may lower blood sugar levels.

Children and infants may take marsh mallow in low doses.

Side effects

There are no known side effects.

Interactions

Marsh mallow may slow the absorption of other drugs when taken simultaneously.

Martial arts

Definition

Martial arts cover a broad range of activities that involve fighting techniques, physical exercises, and methods of mental discipline, among other skills. Martial arts originated in the ancient cultures of Asia, and are used today around the world for self-defense, **exercise**, health, spiritual growth, law enforcement, and athletic competition.

Origins

Very few activities have as many legends and myths surrounding them as do martial arts. Hundreds of practices are included under the title of martial arts, and some of these were passed down in secrecy for many generations. Furthermore, martial arts developed in countries that have been historically isolated from the Western world. Thus, there are many conflicting theories and opinions concerning the origins of martial arts. What is known is that martial arts began in the ancient cultures of Asia, including China, India, and Japan. In both China and India, artifacts from 2,000 to 4,000 years old have been found with paintings of people striking possible martial arts poses. **Qigong**, one of the oldest systems that may be considered a martial art, is believed by some historians to be 5,000 years old or older, originating in ancient China. Some scholars trace the development of martial arts much later to the sixth century A.D. According to legend, that is when a Buddhist monk from India named Bodhidharma brought Buddhism, **yoga** exercises, and **meditation** techniques to the Shaolin Monastery in China.

Martial arts involve intellectual concepts as well as physical techniques, and have been influenced by many of the religious and philosophical systems of the East. The Taoist philosophy holds that the universe operates within laws of balance and harmony, and that people must live within the rhythms of nature. Martial arts cultivate these concepts of balance and adaptation to the natural flow of events. Buddhism is believed to have introduced breathing methods, meditation, and techniques of mental and spiritual awareness to the early founders of martial arts. Chinese Confucianism was concerned with ethical behavior in daily life, and martial arts often address these concerns. Some martial arts, such as **t'ai chi** and various kung fu methods, developed from qigong. Qigong, which means "energy cultivation," is a system designed to increase the flow of the body's *qi*, the universal life energy responsible for health and strength according to Chinese philosophy. **Traditional Chinese medicine** also incorporates concepts derived from martial arts to better the understanding of the body and health. Because therapeutic exercise is one of the major modalities of treatment in traditional Chinese medicine, some martial arts masters are also expert healers. There is, in fact, a subtype of qigong known as medical qigong in China, used to treat a wide range of diseases and disorders. Although most of the research in medical qigong has been conducted in China, some of this work has been translated into English. A video is available that presents the basic concepts of medical qigong.

KEY TERMS

Dojo—A martial arts school.

Meridian—Channel through which qi travels in the body.

Qi—Basic life energy according to traditional Chinese medicine.

Qigong—Chinese system of energy cultivation techniques.

Yin/Yang—Universal characteristics used to describe aspects of the natural world.

From China, martial arts spread to other Asian countries, and eventually arrived in Japan, where many new variations developed. Karate is the generic term for Japanese martial arts. Martial arts in Japan have been influenced by Zen Buddhism and by the samurai warrior tradition, which refined many weapons as well as methods of fighting. Some Japanese schools of instruction adopted the values of bushido, Japanese for "way of the warrior." This system insists on extreme physical and mental discipline, using martial arts as a means to spiritual enlightenment. Martial arts also flourished in Korea, Vietnam, and Thailand.

Martial arts were largely unknown to the Western world until after 1945, when a few American and British veterans of World War II brought back Japanese martial arts from occupied Japan. During the 1970s, there was a surge of interest in martial arts in America, due to several popular television shows and the charismatic actor Bruce Lee. With better communication and less secrecy among teachers, Chinese martial arts, including t'ai chi and qigong, have made their way to America. Today, there are martial arts schools all across America, and martial arts are a multi-billion dollar industry. Martial arts are a popular activity for self-defense, sport, exercise, **spirituality**, and health around the world. Present-day forms of martial arts include *kalarippayattu* in southern India, *escrima* in the Philippines, *pentjak silat* in Malaysia, *karate* in Okinawa, *aikido* in Japan, and *capoeira* in Brazil.

Benefits

Martial arts teach self-defense, and can improve confidence and self-esteem. When used as exercise, martial arts can improve balance, strength, stamina, flexibility, and posture. They also enhance weight loss and improve muscle tone. On the mental level, martial

arts can teach **stress** management, improve concentration, and increase willpower. Some martial arts, such as qigong and t'ai chi, are used for longevity, disease prevention, and healing purposes, making them effective exercises for those with health conditions and for the elderly. Some teachers claim that martial arts can be used as spiritual practices, bringing balance, peace, and wisdom to dedicated practitioners.

Description

Basic concepts of martial arts

Many martial arts utilize basic concepts of traditional Chinese philosophy. Qi is the fundamental life energy of the universe. In the body, qi is the invisible vital force that sustains life. Qi is present in food, air, water, and sunlight. The breath is believed to account for the largest quantity of human qi, because the body uses air more than any other substance. All martial arts emphasize breathing techniques. Many movements and mental exercises are designed to improve the flow of qi in the body, which improves overall strength. There are many legends concerning martial arts masters who had such control of their qi that they could throw opponents across rooms merely by looking at them. Martial arts that focus on the development and use of qi are termed internal martial arts. In contrast, external martial arts focus on physical exercises, fighting methods, and the use of weapons. Many martial arts combine internal and external methods.

Qi travels through the body along channels of energy called meridians. On the meridians there are certain points (acupoints) where qi accumulates. Some martial arts teach defensive techniques that utilize the knowledge of these points on the body, which, if pressed in the correct manner, can be used to immobilize attackers. Martial arts also teach massage and exercise techniques that are designed to stimulate the energy flow along the meridians to improve health.

The concepts of yin and yang are also central to the martial arts. Yin and yang are the two separate but complimentary principles of the universe, which are always interacting, opposing, and influencing each other. Yin is associated with such qualities as cold, passivity, darkness, yielding, and inward movement. Yang is associated with heat, activity, light, assertiveness, outward movement, and so on. In martial arts, yin and yang movements are used to balance each other. For instance, a strong (yang) attack is taught to be met by a yin, or yielding, response. Martial arts cultivate an awareness and use of yin or passive qualities, which are ignored by many sports and fighting techniques. Another major yin/yang concept used in martial arts is that the more one becomes familiar with violence, the more one learns to avoid and resist it. Some martial arts, such as aikido, teach peace as their ultimate lesson.

Types of martial arts

Although there are hundreds of different martial arts, many of them have more similarities than differences. Within the major categories, there are often many sub-schools and systems developed by different teachers. Martial arts are generally classified as soft or hard, internal or external, yin or yang, but they all need to embrace these complementary aspects. Internal arts such as qigong focus on yielding and inner strength. Hard arts such as karate focus on developing muscular power and speed, and the mastery of breaking and throwing techniques delivered with devastating impact.

Karate means "empty handed." This form of fighting originated on the Japanese island of Okinawa. Karate is now the general term for an entire group of Japanese martial arts. Karate emphasizes offensive and defensive moves, and avoids grappling and wrestling. Students are taught how to deliver quick, powerful blows with nearly every part of the body, including dangerous kicks with the legs. Karate also consists of hard styles and soft styles. Some schools teach "full contact" karate, for which students wear protective equipment to absorb the blows of actual fighting.

Kung fu means "skill" in Chinese, and is the generic term for a whole spectrum of martial arts methods that developed in China. In China, kung fu is called *wushu*. Kung fu consists of thousands of hard and soft techniques, taught for both offensive and defensive positions. Kung fu uses punching, kicking, grappling, and blocking moves in addition to the use of certain weapons. Kung fu may also emphasize internal methods to increase and improve qi energy.

Aikido is a relatively new martial art, developed in the 1930s by a Japanese teacher named Morihei Ueshiba (1883–1969). Ueshiba was a religious man who wanted to invent a martial art that emphasized non-aggression. In Japanese, aikido means "connecting with life energy." Aikido teaches students a variety of techniques to disarm an attacker, including such defense moves as blocks, escapes, grabs, and falling safely to the ground. Aikido also teaches internal methods of cultivating qi energy. Aikido has been called the "way of peace," because it teaches the philosophical ideals of love and harmony as ways of reducing conflict.

Judo means "gentle way" in Japanese and was developed as an educational tool by a teacher named

Jigoro Kano in the 1800s. Judo emphasizes such defensive moves as holds and grappling, and teaches students how to disarm attackers by applying pressure to specific sensitive points on the body. Judo is performed competitively in matches.

T'ai chi chuan, also called t'ai chi, consists of a sequence of flowing movements performed very slowly. These movements emphasize posture and the flow of the body's energy (qi). Although considered a martial art and consisting of fighting postures, tai chi is used more as a meditation and health technique. In China, millions of people, particularly the elderly, use tai chi daily to improve their health and flexibility. T'ai chi developed from qigong and shares many of the same concepts of energy cultivation, making it effective for healing and prevention of illness.

Jujitsu is a Japanese martial art that emphasizes flexibility, quickness, and fluidity of motion. It consists of kicking, punching, holding, and striking moves as well as the use of weapons. *Tae kwon do* is a Korean martial art that means "kick-punch-art." Tae kwon do consists of a variety of powerful kicking and punching techniques. *Kendo* is traditional Japanese sword fighting, teaching students how to use various weapons with agility, speed, and effectiveness. Kendo also emphasizes discipline and ethics.

A martial arts session

Most martial arts classes, held in schools called *dojos*, have similarities. Sessions begin with warm-up exercises and stretches. Then, depending on the school, certain exercises will be performed to improve strength, speed, and stamina. Sparring is often used, with students competing head to head. Some schools require students to stop short of striking one another, while other schools require students to wear equipment to protect them from authentic blows. Exercises for cooling down and for flexibility are performed at the end of class.

Most martial arts use the colored belt system to rank students, although colors and rankings can vary greatly among disciplines. In general, white belts signify beginners, brown belts represent intermediate students, and black belts are given to masters, with other colors in between.

Martial arts classes take between one to two hours. Some schools allow students to attend as many classes per week as they wish, while others limit the number of classes taken. Two to three classes per week are recommended. Schools often charge a monthly fee, ranging from $50 or more. Some schools charge a flat fee for training from beginner to expert. Many schools require students to regularly participate in competitions, and fees for these may begin at $25. Students are required to purchase uniforms and equipment as well. Uniforms may cost $100 or more, and protective equipment may cost roughly the same, depending on the practice.

Preparations

Prospective martial arts students should search for the style of martial arts that best meets their objectives. Students should attend classes at various schools (dojos), and should talk to students and teachers to find the right program. Finding a good instructor may be even more important than finding the right school. Students should search for instructors with such positive qualities as patience, knowledge, and strong communication skills. Prospective students should also search for schools with adequate facilities, including padded or sprung floors, full-length mirrors, and roomy practice spaces without obstructions.

Precautions

Martial arts can be dangerous. Students are often required to take blows and falls as part of the learning process, as well as to fight with weapons. Students should search for teachers and schools who teach these methods as safely as possible. People with health conditions and injuries should consult a physician before attempting a martial art, and should find a teacher familiar with their condition.

Training and certification

Martial arts teachers are usually certified with the achievement of an advanced black belt status. Many large schools of martial arts have organizations which oversee and certify the granting of belt ranks. The Aikido Association of America recognizes training programs and certifies ranking procedures.

The USA Karate Federation is the largest organization for certifying ranking systems and schools of karate. The Chinese Kung-Fu Wu-Su Association works with kung fu schools, ranking systems, and contests.

Massage therapy

Definition

Massage therapy is the scientific manipulation of the soft tissues of the body for the purpose of normalizing those tissues and consists of manual techniques that include applying fixed or movable pressure, holding, and/or causing movement of or to the body.

Origins

Massage therapy is one of the oldest health care practices known to history. References to massage are found in Chinese medical texts more than 4,000 years old. Massage has been advocated in Western health care practices at least since the time of Hippocrates, the "Father of Medicine." In the fourth century B.C. Hippocrates wrote, "The physician must be acquainted with many things and assuredly with rubbing" (the ancient Greek term for massage was rubbing).

Woman having neck and shoulders massaged. *(© Bubbles Photolibrary / Alamy)*

The roots of modern, scientific massage therapy go back to Per Henrik Ling (1776–1839), a Swede, who developed an integrated system consisting of massage and active and passive exercises. Ling established the Royal Central Gymnastic Institute in Sweden in 1813 to teach his methods.

Modern, scientific massage therapy was introduced in the United States in the 1850s by two New York physicians, brothers George and Charles Taylor, who had studied in Sweden. The first clinics for massage therapy in the United States were opened by two Swedish physicians after the Civil War period. Doctor Baron Nils Posse operated the Posse Institute in Boston and Doctor Hartwig Nissen opened the Swedish Health Institute near the Capitol in Washington, D.C.

Although there were periods when massage fell out of favor, in the 1960s it made a comeback in a different way as a tool for **relaxation**, communication, and alternative healing. Today, massage is one of the most popular healing modalities. It is used by conventional, as well as alternative, medical communities and is now covered by some health insurance plans.

Benefits

Generally, massage is known to affect the circulation of blood and the flow of blood and lymph, reduce muscular tension or flaccidity, affect the nervous system through stimulation or sedation, and enhance tissue healing. These effects provide a number of benefits:

- reduction of muscle tension and stiffness
- relief of muscle spasms
- greater flexibility and range of motion
- increase of the ease and efficiency of movement
- relief of stress and aide of relaxation
- promotion of deeper and easier breathing
- improvement of the circulation of blood and movement of lymph
- relief of tension-related conditions, such as headaches and eyestrain
- promotion of faster healing of soft tissue injuries, such as pulled muscles and sprained ligaments, and reduction in pain and swelling related to such injuries
- reduction in the formation of excessive scar tissue following soft tissue injuries
- enhancement in the health and nourishment of skin

- improvement in posture through changing tension patterns that affect posture
- reduction in stress and an excellent stress management tool
- creation of a feeling of well-being
- reduction in levels of anxiety
- increase in awareness of the mind-body connection
- promotion of a relaxed state of mental awareness

Massage therapy also has a number of documented clinical benefits. For example, massage can reduce **anxiety**, improve pulmonary function in young **asthma** patients, reduce psycho-emotional distress in persons suffering from chronic **inflammatory bowel disease**, increase weight and improve motor development in premature infants, and may enhance immune system functioning. Some medical conditions that massage therapy can help are: **allergies**, anxiety and **stress**, arthritis, asthma and **bronchitis**, **carpal tunnel syndrome** and other repetitive motion injuries, chronic and temporary **pain**, circulatory problems, **depression**, digestive disorders, tension **headache**, **insomnia**, myofascial pain, sports injuries, and temporomandibular joint dysfunction.

Description

Massage therapy is the scientific manipulation of the soft tissues of the body for the purpose of normalizing those tissues and consists of a group of manual techniques that include applying fixed or movable pressure, holding, and/or causing movement of or to the body. While massage therapy is applied primarily with the hands, sometimes the forearms or elbows are used. These techniques affect the muscular, skeletal, circulatory, lymphatic, nervous, and other systems of the body. The basic philosophy of massage therapy embraces the concept of *vis Medicatrix naturae*, which is aiding the ability of the body to heal itself, and is aimed at achieving or increasing health and well-being.

Touch is the fundamental medium of massage therapy. While massage can be described in terms of the type of techniques performed, touch is not used solely in a mechanistic way in massage therapy. One could look at a diagram or photo of a massage technique that depicts where to place one's hands and what direction the stroke should go, but this would not convey everything that is important for giving a good massage. Massage also has an artistic component.

Because massage usually involves applying touch with some degree of pressure and movement, the massage therapist must use touch with sensitivity in order to determine the optimal amount of pressure to use for each person. For example, using too much pressure may cause the body to tense up, while using too little may not have enough effect. Touch used with sensitivity also allows the massage therapist to receive useful information via his or her hands about the client's body, such as locating areas of muscle tension and other soft tissue problems. Because touch is also a form of communication, sensitive touch can convey a sense of caring—an essential element in the therapeutic relationship—to the person receiving massage.

In practice, many massage therapists use more than one technique or method in their work and sometimes combine several. Effective massage therapists ascertain each person's needs and then use the techniques that will meet those needs best.

Swedish massage uses a system of long gliding strokes, kneading, and friction techniques on the more superficial layers of muscles, generally in the direction of blood flow toward the heart, and sometimes combined with active and passive movements of the joints. It is used to promote general relaxation, improve circulation and range of motion, and relieve muscle tension. Swedish massage is the most commonly used form of massage.

Deep tissue massage is used to release chronic patterns of muscular tension using slow strokes, direct pressure, or friction directed across the grain of the muscles. It is applied with greater pressure and to deeper layers of muscle than Swedish, which is why it is called deep tissue and is effective for chronic muscular tension.

Sports massage uses techniques that are similar to Swedish and deep tissue, but are specially adapted to deal with the effects of athletic performance on the body and the needs of athletes regarding training, performing, and recovery from injury.

Neuromuscular massage is a form of deep massage that is applied to individual muscles. It is used primarily to release trigger points (intense knots of muscle tension that refer pain to other parts of the body), and also to increase blood flow. It is often used to reduce pain. Trigger point massage and **myotherapy** are similar forms.

Acupressure applies finger or thumb pressure to specific points located on the **acupuncture** meridians (channels of energy flow identified in Asian concepts of anatomy) in order to release blocked energy along these meridians that causes physical discomforts, and re-balance the energy flow. **Shiatsu** is a Japanese form of acupressure.

The cost of massage therapy varies according to geographic location, experience of the massage therapist, and length of the massage. In the United States, the average range is from $35-60 for a one hour session. Massage therapy sessions at a client's home or office may cost more due to travel time for the massage therapist. Most sessions are one hour. Frequency of massage sessions can vary widely. If a person is receiving massage for a specific problem, frequency can vary widely based on the condition, though it usually will be once a week. Some people incorporate massage into their regular personal health and fitness program. They will go for massage on a regular basis, varying from once a week to once a month.

The first appointment generally begins with information gathering, such as the reason for getting massage therapy, physical condition and medical history, and other areas. The client is asked to remove clothing to one's level of comfort. Undressing takes place in private, and a sheet or towel is provided for draping. The massage therapist will undrape only the part of the body being massaged. The client's modesty is respected at all times. The massage therapist may use an oil or cream, which will be absorbed into the skin in a short time.

To receive the most benefit from a massage, generally the person being massaged should give the therapist accurate health information, report discomfort of any kind (whether it's from the massage itself or due to the room temperature or any other distractions), and be as receptive and open to the process as possible.

Insurance coverage for massage therapy varies widely. There tends to be greater coverage in states that license massage therapy. In most cases, a physician's prescription for massage therapy is needed. Once massage therapy is prescribed, authorization from the insurer may be needed if coverage is not clearly spelled out in one's policy or plan.

Preparations

Going for a massage requires little in the way of preparation. Generally, one should be clean and should not eat just before a massage. One should not be under the influence of alcohol or non-medicinal drugs. Massage therapists generally work by appointment and usually will provide information about how to prepare for an appointment at the time of making the appointment.

Precautions

Massage is comparatively safe; however it is generally contraindicated, i.e., it should not be used, if a person has one of the following conditions: advanced heart diseases, **hypertension** (high blood pressure), **phlebitis**, thrombosis, embolism, kidney failure, **cancer** if massage would accelerate metastasis (i.e., spread a tumor) or damage tissue that is fragile due to chemotherapy or other treatment, infectious diseases, contagious skin conditions, acute inflammation, infected injuries, unhealed **fractures**, dislocations, **frostbite**, large hernias, torn ligaments, conditions prone to hemorrhage, and psychosis.

Massage should not be used locally on affected areas (i.e., avoid using massage on the specific areas of the body that are affected by the condition) for the following conditions: **rheumatoid arthritis** flare up, **eczema**, goiter, and open skin lesions. Massage may be used on the areas of the body that are not affected by these conditions.

In some cases, precautions should be taken before using massage for the following conditions: **pregnancy**, high fevers, **osteoporosis**, diabetes, recent postoperative cases in which pain and muscular splinting (i.e., tightening as a protective reaction) would be increased, apprehension, and mental conditions that may impair communication or perception. In such cases, massage may or may not be appropriate. The decision on whether to use massage must be based on whether it may cause harm. For example, if someone has osteoporosis, the concern is whether bones are strong enough to withstand the pressure applied. If one has a health condition and has any hesitation about whether massage therapy would be appropriate, a physician should be consulted.

Side effects

Massage therapy does not have side effects. Sometimes people are concerned that massage may leave them too relaxed or too mentally unfocused. To the contrary, massage tends to leave people feeling more relaxed and alert.

Research and general acceptance

Before 1939, more than 600 research studies on massage appeared in the main journals of medicine in English. However, the pace of research was slowed by medicine's disinterest in massage therapy.

Massage therapy research picked up again in the 1980s, as the growing popularity of massage paralleled the growing interest in complementary and alternative medicine. Well designed studies have documented the benefits of massage therapy for the treatment of acute and chronic pain, acute and chronic inflammation, chronic lymphedema, **nausea**, muscle spasm, various soft tissue dysfunctions, anxiety, depression, insomnia,

and psycho-emotional stress, which may aggravate mental illness.

Premature infants treated with daily massage therapy gain more weight and have shorter hospital stays than infants who are not massaged. A study of 40 low-birth-weight babies found that the 20 massaged babies had a 47% greater weight gain per day and stayed in the hospital an average of six days less than 20 infants who did not receive massage, resulting a cost savings of approximately $3,000 per infant. Cocaine-exposed, preterm infants given massage three times daily for a 10 day period showed significant improvement. Results indicated that massaged infants had fewer postnatal complications and exhibited fewer stress behaviors during the 10 day period, had a 28% greater daily weight gain, and demonstrated more mature motor behaviors.

A study comparing 52 hospitalized depressed and adjustment disorder children and adolescents with a control group that viewed relaxation videotapes, found massage therapy subjects were less depressed and anxious, and had lower saliva cortisol levels (an indicator of less depression).

Another study showed massage therapy produced relaxation in 18 elderly subjects, demonstrated in measures such as decreased blood pressure and heart rate and increased skin temperature.

A combination of massage techniques for 52 subjects with traumatically induced spinal pain led to significant improvements in acute and chronic pain and increased muscle flexibility and tone. This study also found massage therapy to be extremely cost effective, with cost savings ranging from 15-50%. Massage has also been shown to stimulate the body's ability to naturally control pain by stimulating the brain to produce endorphins. **Fibromyalgia** is an example of a condition that may be favorably affected by this effect.

A pilot study of five subjects with symptoms of tension and anxiety found a significant response to massage therapy in one or more psycho-physiological parameters of heart rate, frontalis and forearm extensor electromyograms (EMGs) and skin resistance, which demonstrate relaxation of muscle tension and reduced anxiety.

Lymph drainage massage has been shown to be more effective than mechanized methods or diuretic drugs to control lymphedema secondary to radical mastectomy, consequently using massage to control lymphedema would significantly lower treatment costs. A study found that massage therapy can have a powerful effect upon psycho-emotional distress in persons suffering from chronic inflammatory bowel disease. Massage therapy was effective in reducing the frequency of episodes of pain and disability in these patients.

Massage may enhance the immune system. A study suggests an increase in cytotoxic capacity associated with massage. A study of **chronic fatigue syndrome** subjects found that a group receiving massage therapy had lower depression, emotional distress, and somatic symptom scores, more hours of sleep, and lower epinephrine and cortisol levels than a control group.

Training and certification

The generally accepted standard for training is a minimum of 500 classroom hours. Training should include anatomy, physiology, pathology, massage theory and technique, and supervised practice. Most massage therapists also take additional courses and workshops during their careers.

In the United States, massage therapists are currently licensed by states, the District of Columbia, and a number of localities. Most states require 500 or more classroom hours of training from a recognized training program and passing an examination.

A national certification program was inaugurated in June 1992 by the National Certification Board for Therapeutic Massage and Bodywork (NCBTMB). The NCBTMB program is accredited by the National Commission for Certifying Agencies, the chief outside agency for evaluating certification programs. Those certified can use the title Nationally Certified in Therapeutic Massage and Bodywork (NCTMB). Most states use the NCBTMB exam for their licensing exams.

A national accreditation agency, the Commission on Massage Therapy Accreditation, designed according to the guidelines of the U.S. Department of Education, currently recognizes about 70 training programs. The Accrediting Commission of Career Schools and Colleges of Technology and the Accrediting Council for Continuing Education and Training also accredit massage training programs.

McDougall diet

Definition

The McDougall diet provides the structure of a low-fat, starch-based diet to promote a broad range of such health benefits as weight loss and the reversal of such serious health conditions as heart disease , without the use of drugs.

Origins

The McDougall diet began as a challenge to Dr. John McDougall by one of his patients. The patient simply asked him if he believed that diet is connected to the health problems he saw in his patients. At that time, McDougall believed the answer to this question was a definite no. The patient challenged him to ask his patients what they were eating, in order to see if there might be any relationship between their eating habits and their diseases. McDougall agreed, and the McDougall diet was born.

McDougall was a plantation physician based in the village of Honokaa, Hawaii. In his practice, he handled a variety of medical problems from delivering babies to performing brain surgery on accident victims. Although he felt a lot of satisfaction in saving people's lives, McDougall was bothered by his inability to help patients with such disease conditions as diabetes, heart disease, high blood pressure and strokes. He decided to further his education and took up another residency in internal medicine. During his internal medicine residency, McDougall did countless hours of research on the effects of diet and lifestyle on chronic illnesses. Unfortunately, the literature he read seemed to conflict with the approaches he was being taught in his residency.

McDougall began to change his own diet as he studied the literature. Over a period of a year, he began to cut out meat and dairy products and began to focus on eating more green and yellow vegetables, fruits, and whole grains. He noticed many improvements in his own health, such as lower weight, lower blood **cholesterol** levels, and lower blood pressure. The St. Helena Hospital and Health Center in Deer Park, California offered him an opportunity to present his diet program at their facilities in 1986.

Benefits

Many patients who have undertaken the McDougall diet have found an improvement in such conditions as:

- high blood pressure
- diabetes
- headaches
- constipation
- mild arthritis
- fatigue
- body odor
- oily skin
- allergies

Another possible benefit of the McDougall program is that patients may find themselves spending less for food. In addition, McDougall points to the possibility of saving considerable amounts of money by avoiding serious and costly health problems.

Description

The McDougall diet focuses on adopting a dietary regimen and lifestyle that encourages human beings' natural tendencies to be healthy. The program is based on proper foods, moderate **exercise**, adequate sunshine,

clean air and water, and surroundings that promote psychological well-being.

Specifically, the McDougall diet is a very low-fat, starch-based program. Grains, fruits and such starchy plant foods as beans, corn, pastas, potatoes, and rice provide the major components of this diet. There are some fruits and vegetables used in this program that may be quite unfamiliar to the average person. Some of these include carambola, guava, persimmon, passion fruit, daikon, endive, fava beans, bok choy, kale, kohlrabi, taro root and watercress, to name a few. In addition, some of these foods are more easily obtained and less expensive in Hawaii than they might be in the upper Midwest or Canada.

Dairy products are not used in the McDougall diet. McDougall believes that many **allergies** and such conditions as post-nasal drip are related to people's use of dairy products.

Preparations

Patients should check with their physician before they begin this or any other diet and exercise program if they have any health problems such as **heart disease**, high blood pressure, diabetes, or arthritis. People who have a major health problem, or who are on medication, should request a doctor's examination before starting this program. This examination should include a complete history and thorough medical workup to use as a baseline evaluation for performance on this program.

McDougall recommends that patients spend some time evaluating their reasons for undertaking this program. Patients should determine how well they think they will be able to stick to the program for the initial 12 days as well as whether they can stay with the program for life. Examining any aspects of their lifestyle that are harmful to their health is also important. For example, **smoking** tobacco, drinking coffee, drinking alcohol, and the use of recreational drugs are all very damaging to anyone's health. Since few people can leave their normal environment for 12 days (as people do at the live-in McDougall diet program at the St. Helena Hospital and Health Center), they may find it stressful to work on these lifestyle problems at the same time they are making radical changes in their diet.

Those undertaking this program should also prepare family and friends for the changes this program will cause in their diet. They may find their families unwilling to change, and this fact will require a different approach to the program. On the other hand, McDougall points out that family members often decide to undertake the program themselves when they see the positive changes that result from the diet.

Before undertaking the program, patients will need to stock their pantry with new foods. They will also need to check the availability of the acceptable products in their local grocery and health food stores.

Precautions

Patients should not undertake this diet program without the advice of a physician if they have any health condition or are currently on medication.

Side effects

The primary negative side effect of the McDougall diet usually comes from **caffeine** withdrawal. Many people find they suffer from headaches while abstaining from caffeine. Although giving up caffeine is not required by the program, it is strongly recommended.

Research and general acceptance

There is extensive research about the effect of lifestyle and diet on various health conditions, although research on the McDougall diet specifically has not yet been released. Anecdotal evidence suggests, however, that significant improvement in some health problems can be achieved in a relatively short period of time.

Training and certification

The McDougall diet is self-administered. No training or certification is required.

Measles

Definition

Measles is a viral infection that causes an illness displaying a characteristic skin rash known as an exanthem. Measles is also sometimes called rubeola, five-day measles, or hard measles.

Description

Measles **infections** appear all over the world. Incidence of the disease in the United States is down to a record low and only 86 confirmed cases were reported in the year 2000. Of these, 62% were definitely linked to foreigners or international travel. Prior to the current effective immunization program, large-scale measles outbreaks occurred on a two to three year cycle, usually in the winter and spring. Smaller outbreaks occurred during the off-years. Babies up to about eight months of age are usually protected from contracting measles, due to antibodies they receive from their mothers in the uterus. Once someone has had measles, he or she can never get it again.

Small child with measles. *(Lowell Georgia / Photo Researchers, Inc.)*

Causes and symptoms

Measles is caused by a type of virus called a paramyxovirus. It is an extremely contagious infection, spread through the tiny droplets that may spray into the air when a person carrying the virus sneezes or coughs. About 85% of those people exposed to the virus will become infected with it. About 95% of those people infected with the virus will develop the illness. Once someone is infected with the virus, it takes about seven to 18 days before he or she actually becomes ill. The most contagious time period is the three to five days before symptoms begin through about four days after the characteristic measles rash has begun to appear.

The first signs of measles infection are **fever**, extremely runny nose, red, runny eyes, and a **cough**. A few days later, a rash appears in the mouth, particularly on the mucous membrane that lines the insides of the cheek. This rash consists of tiny white dots (like grains of salt or sand) on a reddish bump. These are called Koplik's spots, and are unique to measles infection. The throat becomes red, swollen, and sore.

A couple of days after the appearance of the Koplik's spots, the measles rash begins. It appears in a characteristic progression, from the head, face, and neck, to the trunk, then abdomen, and next out along the arms and legs. The rash starts out as flat, red patches, but eventually develops some bumps. The rash may be somewhat itchy. When the rash begins to appear, the fever usually climbs higher, sometimes reaching as high as 105°F (40.5°C). There may be **nausea**, **vomiting**, **diarrhea**, and multiple swollen lymph nodes. The cough is usually more problematic at this point, and the patient feels awful. The rash usually lasts about five days. As it fades, it turns a brownish color, and eventually the affected skin becomes dry and flaky.

Many patients (about 5–15%) develop other complications. Bacterial infections, such as ear infections, sinus infections, and **pneumonia** are common, especially in children. Other viral infections may also strike the patient, including **croup**, **bronchitis**, **laryngitis**, or viral pneumonia. Inflammation of the liver, appendix, intestine, or lymph nodes within the abdomen may cause other complications. Rarely, inflammation of the heart or kidneys, a drop in platelet count (causing episodes of difficult-to-control bleeding), or reactivation of an old **tuberculosis** infection can occur.

KEY TERMS

Antibodies—Proteins made by the immune system that have the ability to recognize foreign invaders (bacteria, viruses) and stimulate the immune system to eliminate them.

Antigens—Markers on the outside of organisms (such as bacteria and viruses) which allow antibodies to recognize foreign invaders.

Encephalitis—Swelling, inflammation of the brain.

Exanthem (plural, exanthems or exanthemata)—A skin eruption regarded as a characteristic sign of such diseases as measles, German measles, and scarlet fever.

Koplik's spots—Tiny spots occurring inside the mouth, especially on the inside of the cheek. These spots consist of minuscule white dots (like grains of salt or sand) set onto a reddened bump. Unique to measles.

An extremely serious complication of measles infection is the inflammation and subsequent swelling of the brain. Called encephalitis, this can occur up to several weeks after the basic measles symptoms have resolved. About one out of every 1,000 patients develops this complication, and about 10–15% of these patients die. Symptoms include fever, **headache**, sleepiness, seizures, and coma. Long-term problems following recovery from measles encephalitis may include seizures and mental retardation.

A very rare complication of measles can occur up to 10 years or more following the initial infection. Called subacute sclerosing panencephalitis, this is a slowly progressing, smoldering, swelling, and destruction of the entire brain. It is most common among people who had measles infection prior to the age of two years. Symptoms include changes in personality, decreased intelligence with accompanying school problems, decreased coordination, and involuntary jerks and movements of the body. As the disease progresses, the patient becomes increasingly dependent, ultimately becoming bedridden and unaware of his or her surroundings. Blindness may develop, and the temperature may spike (rise rapidly) and fall unpredictably as the brain structures responsible for temperature regulation are affected. Death is inevitable.

Measles during **pregnancy** is a serious disease, leading to increased risk of a miscarriage or stillbirth. In addition, the mother's illness may progress to pneumonia.

Diagnosis

Measles is almost always diagnosed based on its characteristic symptoms, including Koplik's spots, and a rash that spreads from central body structures out towards the arms and legs. If there is any doubt as to the diagnosis, then a specimen of body fluids (mucus or urine) can be collected and combined with fluorescent-tagged measles virus antibodies. Antibodies are produced by the body's immune cells that can recognize and bind to markers (antigens) on the outside of specific organisms, in this case the measles virus. Once the fluorescent antibodies have attached themselves to the measles antigens in the specimen, the specimen can be viewed under a special microscope to verify the presence of the measles virus.

Treatment

There are a variety of general measures that can be taken to treat measles and help the patient feel more comfortable. These include:

- humidifying the air to ease cough
- drinking plenty of fluids to prevent dehydration
- keeping the room lights dim to relieve sensitivity to light
- getting plenty of rest
- eating nutritious and easily digestible food

Herbals and Chinese medicine

There are specific **acupuncture** and **acupressure** therapies for measles. The following herbals can also help relieve the symptoms associated with measles:

- Chamomile tea for restlessness.
- Echinacea plus goldenseal to clear infection, boost the immune system, and soothe skin and mucous membranes.
- A tea of lemon balm leaf, chamomile flower, peppermint leaf, licorice root, and elder flower to reduce fever and chills and increase perspiration.
- Ginger tea to reduce fever.
- Shiitake mushrooms to boost the immune system.
- Witch hazel (*Hamamelis virginiana*), chickweed (*Stellaria media*), or oatmeal baths to reduce itching.
- Eyebright (*Euphrasia officinalis*) eyewash to soothe eyes.
- Garlic to fight infection and boost the immune system.
- *Flos lonicerae* (10 g) and *Radix glycyrrhizae* (3 g) decoction to wash the mouth, eyes, and nose.

Supplements

Some studies have shown that children with measles encephalitis or pneumonia benefit from relatively large doses of **vitamin A**. Vitamin A may also heal mucous membranes. Bioflavinoids and **vitamin C** boost the immune system. **Zinc** promotes healing and is an immune system stimulant. Zinc can cause nausea and vomiting, and chronic use can cause low levels of **copper** and iron-deficiency **anemia**.

Homeopathy

Homeopathic remedies cater to the patient's specific symptoms. Remedies for common measles symptoms are listed. The patient can take 30x or 9c of the following remedies four times daily for two days:

- Apis mellifica: for swollen throat, breathing difficulty, and painful cough.
- Arsenicum album: for restlessness, feeling worse after midnight, and thirst.
- Belladonna: for high fever, red eyes, flushed face, headache, and swallowing difficulty.
- Gelsemium: for fever, droopy eyes, cough, feeling cold, and runny nose.
- Pulsatilla: for eye problems (tears, drainage, light sensitivity), dark red rash, thick yellow nasal discharge, and dry cough.

Allopathic treatment

There are no medications available to cure measles. Treatment is primarily aimed at helping the patient to be as comfortable as possible, and watching carefully so that antibiotics can be started promptly if a bacterial infection develops. Fever and discomfort can be treated with acetaminophen (Tylenol) or ibuprofen (Advil, Motrin, Nuprin). Children with measles should never be given aspirin, as this increases the risk of the fatal disease Reye's syndrome.

Expected results

The prognosis for an otherwise healthy, well-nourished child who contracts measles is usually quite good. In developing countries, however, death rates may reach 15–25%, as malnutrition, especially protein deficiency, for six months prior to the onset of measles increases the risk of death. Adolescents and adults usually have a more difficult course. Women who contract the disease while pregnant may give birth to a baby with a hearing impairment. Although only one in 1,000 patients with measles will develop encephalitis, 10–15% of those who do will die, and about another 25% will be left with permanent brain damage.

Prevention

Measles is a highly preventable infection. A very effective vaccine exists, made of live measles viruses that have been treated so they cannot cause infection. The important markers on the viruses are intact and cause the immune system to produce antibodies. In the event of a future infection with measles virus the antibodies will quickly recognize the organism and eliminate it. Measles vaccines are usually given at about 15 months of age. Prior to that age, the baby's immune system is not mature enough to initiate a reaction strong enough to ensure long-term protection from the virus. A repeat injection should be given at about 10 or 11 years of age. Outbreaks on college campuses have occurred among non-immunized or incorrectly immunized students.

Measles vaccine should not be given to a pregnant woman, however, in spite of the seriousness of gestational measles. The reason for not giving this particular vaccine during pregnancy is the risk of transmitting measles to the unborn child.

Surprisingly, new cases of measles began being reported in some countries—including Great Britain—in 2001 because of parents' fears about vaccine safety. The combined vaccine for measles, **mumps**, and **rubella** (MMR) was claimed to cause **autism** or bowel disorders in some children. However, the World Health Organization (WHO) says there is no scientific merit to these claims. The United Nations expressed concern that unwarranted fear of the vaccine would begin spreading the disease in developing countries, and ultimately in developed countries as well. Parents in Britain began demanding the measles vaccine as a separate dose and scientists were exploring that option as an alternative to the combined MMR vaccine. Unfortunately, several children died during an outbreak of measles in Dublin because they had not received the vaccine. Child mortality due to measles is considered largely preventable, and making the MMR vaccine widely available in developing countries is part of WHO's strategy to reduce child mortality by two-thirds by the year 2015.

Meditation

Definition

Meditation is a practice of concentrated focus upon a sound, object, visualization, the breath, movement, or attention itself in order to increase awareness of the present moment, reduce **stress**, promote **relaxation**, and enhance personal and spiritual growth.

A young woman meditating. *(© Angela Hampton Picture Library / Alamy)*

Origins

Meditation techniques have been practiced for millennia. Originally, they were intended to develop spiritual understanding, awareness, and direct experience of ultimate reality. The many different religious traditions in the world have given rise to a rich variety of meditative practices. These include the contemplative practices of Christian religious orders, the Buddhist practice of sitting meditation, and the whirling movements of the Sufi dervishes. Although meditation is an important spiritual practice in many religious and spiritual traditions, it can be practiced by anyone regardless of their religious or cultural background to relieve stress and **pain**.

As Western medical practitioners begin to understand the mind's role in health and disease, there has been more interest in the use of meditation in medicine. Meditative practices are increasingly offered in medical clinics and hospitals as a tool for improving health and quality of life. Meditation has been used as the primary therapy for treating certain diseases; as an additional therapy in a comprehensive treatment plan; and as a means of improving the quality of life of people with debilitating, chronic, or terminal illnesses.

Benefits

Meditation benefits people with or without acute medical illness or stress. People who meditate regularly have been shown to feel less **anxiety** and **depression**. They also report that they experience more enjoyment and appreciation of life and that their relationships with others are improved. Meditation produces a

KEY TERMS

Dervish—A member of the Sufi order. Their practice of meditation involves whirling ecstatic dance.

Mantra—A sacred word or formula repeated over and over to concentrate the mind.

Transcendental meditation (TM)—A meditation technique based on Hindu practices that involves the repetition of a mantra.

state of deep relaxation and a sense of balance or equanimity. According to Michael J. Baime, "Meditation cultivates an emotional stability that allows the meditator to experience intense emotions fully while simultaneously maintaining perspective on them." Out of this experience of emotional stability, one may gain greater insight and understanding about one's thoughts, feelings, and actions. This insight in turn offers the possibility to feel more confident and in control of life. Meditation facilitates a greater sense of calmness, empathy, and acceptance of self and others.

Meditation can be used with other forms of medical treatment and is an important complementary therapy for both the treatment and prevention of many stress-related conditions. Regular meditation can reduce the number of symptoms experienced by patients with a wide range of illnesses and disorders. Based upon clinical evidence as well as theoretical understanding, meditation is considered to be one of the better therapies for **panic disorder**, generalized anxiety disorder, **substance dependence** and abuse, ulcers, **colitis**, chronic pain, **psoriasis**, and dysthymic disorder. It is considered to be a valuable adjunctive therapy for moderate **hypertension** (high blood pressure), prevention of cardiac arrest (**heart attack**), prevention of **atherosclerosis** (hardening of arteries), arthritis (including **fibromyalgia**), **cancer**, **insomnia**, migraine, and prevention of **stroke**. Meditation may also be a valuable complementary therapy for **allergies** and **asthma** because of the role stress plays in these conditions. Meditative practices have been reported to improve function or reduce symptoms in patients with some neurological disorders as well. These include people with **Parkinson's disease**, people who experience **fatigue** with **multiple sclerosis**, and people with **epilepsy** who are resistant to standard treatment.

Overall, a 1995 report to the National Institutes of Health on alternative medicine concluded that, "More than 30 years of research, as well as the experience of a large and growing number of individuals and health care providers, suggests that meditation and similar forms of relaxation can lead to better health, higher quality of life, and lowered health care costs." A study of health care professionals published in 2002 indicates that the majority of physicians, nurses, and occupational therapists in the United States accept meditation as a beneficial adjunct to conventional medical or surgical treatments.

Description

Sitting meditation is generally done in an upright seated position, either in a chair or cross-legged on a cushion on the floor. The spine is straight yet relaxed. Sometimes the eyes are closed. Other times the eyes are open and gazing softly into the distance or at an object. Depending on the type of meditation, the meditator may be concentrating on the sensation of the movement of the breath, counting the breath, silently repeating a sound, chanting, visualizing an image, focusing awareness on the center of the body, opening to all sensory experiences including thoughts, or performing stylized ritual movements with the hands.

Movement meditation can be spontaneous and free-form or involve highly structured, choreographed, repetitive patterns. Movement meditation is particularly helpful for those people who find it difficult to remain still.

Generally speaking, there are two main types of meditation. These types are concentration meditation and mindfulness meditation. Concentration meditation practices involve focusing attention on a single object. Objects of meditation can include the breath, an inner or external image, a movement pattern (as in tai chi or **yoga**), or a sound, word, or phrase that is repeated silently (mantra). The purpose of concentrative practices is to learn to focus one's attention or develop concentration. When thoughts or emotions arise, the meditator gently directs the mind back to the original object of concentration.

Mindfulness meditation practices involve becoming aware of the entire field of attention. The meditator is instructed to be aware of all thoughts, feelings, perceptions, or sensations as they arise in each moment. Mindfulness meditation practices are enhanced by the meditator's ability to focus and quiet the mind. Many meditation practices are a blend of these two forms.

The study and application of meditation to health care has focused on three specific approaches: 1. transcendental meditation (TM); 2. The "relaxation response," a general approach to meditation developed by Dr. Herbert Benson; and 3. mindfulness meditation, specifically

the program of mindfulness-based stress reduction (MBSR) developed by Jon Kabat-Zinn.

Transcendental meditation

TM has its origins in the Vedic tradition of India and was introduced to the West by Maharishi Mahesh Yogi. TM has been taught to somewhere between two and four million people. It is one of the most widely practiced forms of meditation in the West. TM has been studied many times; these studies have produced much of the information about the physiology of meditation. In TM, the meditator sits with closed eyes and concentrates on a single syllable or word (mantra) for 20 minutes at a time, twice a day. When thoughts or feelings arise, the attention is brought back to the mantra. According to Charles Alexander, an important TM researcher, "During TM, ordinary waking mental activity is said to settle down, until even the subtlest thought is transcended and a completely unified wholeness of awareness...is experienced. In this silent, self-referential state of pure wakefulness, consciousness is fully awake to itself alone..." TM supporters believe that TM practices are more beneficial than other meditation practices. A group of Australian researchers has recently recommended TM as a preventive strategy for **heart disease**.

The relaxation response

The relaxation response involves a similar form of mental focusing. Dr. Herbert Benson, one of the first Western doctors to conduct research on the effects of meditation, developed this approach after observing the profound health benefits of a state of bodily calm he calls "the relaxation response." In order to elicit this response in the body, he teaches patients to focus upon the repetition of a word, sound, **prayer**, phrase, or movement activity (including swimming, jogging, yoga, and even knitting) for 10–20 minutes at a time, twice a day. Patients are also taught not to pay attention to distracting thoughts and to return their focus to the original repetition. The choice of the focused repetition is up to the individual. Instead of Sanskrit terms, the meditator can choose what is personally meaningful, such as a phrase from a prayer.

Mindfulness meditation

Mindfulness meditation comes out of traditional Buddhist meditation practices. Psychologist Jon Kabat-Zinn has been instrumental in bringing this form of meditation into medical settings. In formal mindfulness practice, the meditator sits with eyes closed, focusing the attention on the sensations and movement of the breath for approximately 45–60 minutes at a time, at least once a day. Informal mindfulness practice involves bringing awareness to every activity in daily life. Wandering thoughts or distracting feelings are simply noticed without resisting or reacting to them. The essence of mindfulness meditation is not what one focuses on but rather the quality of awareness the meditator brings to each moment. According to Kabat-Zinn, "It is this investigative, discerning observation of whatever comes up in the present moment that is the hallmark of mindfulness and differentiates it most from other forms of meditation. The goal of mindfulness is for you to be more aware, more in touch with life and whatever is happening in your own body and mind at the time it is happening—that is, the present moment." The MBSR program consists of a series of classes involving meditation, movement, and group process. There are over 240 MBSR programs offered in health care settings around the world.

Meditation is not considered a medical procedure or intervention by most insurers. Many patients pay for meditation training themselves. Frequently, religious groups or meditation centers offer meditation instruction free of charge or for a nominal donation. Hospitals may offer MBSR classes at a reduced rate for their patients and a slightly higher rate for the general public.

Precautions

Meditation appears to be safe for most people. There are, however, case reports and studies noting some adverse effects. Thirty-three to 50% of the people participating in long silent meditation retreats (two weeks to three months) reported increased tension, anxiety, confusion, and depression. On the other hand, most of these same people also reported very positive effects from their meditation practice. Kabat-Zinn notes that these studies fail to differentiate between serious psychiatric disturbances and normal emotional mood swings. These studies do suggest, however, that meditation may not be recommended for people with psychotic disorders, severe depression, and other severe personality disorders unless they are also receiving psychological or medical treatment.

Side effects

There are no reported side effects from meditation except for positive benefits.

Research and general acceptance

The scientific study of the physiological effects of meditation began in the early 1960s. These studies

MAHARISHI MAHESH YOGI (1911–2008)

(Bernard Gotfryd/Hulton Archvie/Getty Images.)

Maharishi Mahesh Yogi was one of the most recognized spiritual leaders of the world. Almost single handedly, the Maharishi (meaning great sage) brought Eastern culture into Western consciousness. He emerged in the late 1950s in London and the United States as a missionary in the cause of Hinduism, the philosophy of which is called Vedanta a belief that "holds that God is to be found in every creature and object, that the purpose of human life is to realize the godliness in oneself and that religious truths are universal."

By 1967, the Maharishi became a leader among flower children and an anti drug advocate. The Maharishi's sudden popularity was helped along by such early fans as the Beatles, Mia Farrow, and Shirley MacLaine. These people, and many others, practiced Transcendental Meditation (TM), a Hindu influenced procedure that endures in America to this day.

When the 1960s drew to a close, the Maharishi began to fade from public view. The guru still had enough followers, though, to people the Maharishi International University, founded in 1971. One of the main draws of Maharishi International University was the study of TM Sidha, an exotic form of Transcendental Meditation. Sidhas believe that group meditation can elicit the maharishi effect a force strong enough to conjure world peace.

prove that meditation affects metabolism, the endocrine system, the central nervous system, and the autonomic nervous system. In one study, three advanced practitioners of Tibetan Buddhist meditation practices demonstrated the ability to increase "inner heat" as much as 61%. During a different meditative practice they were able to dramatically slow down the rate at which their bodies consumed oxygen. Preliminary research shows that mindfulness meditation is associated with increased levels of **melatonin**. These findings suggest a potential role for meditation in the treatment and prevention of breast and prostrate cancer.

Despite the inherent difficulties in designing research studies, there is a large amount of evidence of the medical benefits of meditation. Meditation is particularly effective as a treatment for chronic pain. Studies have shown meditation reduces symptoms of pain and pain-related drug use. In a four-year follow-up study, the majority of patients in a MBSR program reported "moderate to great improvement" in pain as a result of participation in the program.

Meditation has long been recommended as a treatment for high blood pressure; however, there is a debate over the amount of benefit that meditation offers. Although most studies show a reduction in blood pressure with meditation, medication is still more effective at lowering high blood pressure.

Meditation may also be an effective treatment for coronary artery disease. A study of 21 patients practicing TM for eight months showed increases in their amount of **exercise** tolerance, amount of workload, and a delay in the onset of ST-segment depression. Meditation is also an important part of Dean Ornish's program, which has been proven to reverse coronary artery disease.

Research also suggests that meditation is effective in the treatment of chemical dependency. Gelderloos and others reviewed 24 studies and reported that all of them showed that TM is helpful in programs to stop **smoking** and also in programs for drug and alcohol abuse.

Studies also imply that meditation is helpful in reducing symptoms of anxiety and in treating anxiety-related disorders. Furthermore, a study in 1998 of 37 psoriasis patients showed that those practicing mindfulness meditation had more rapid clearing of

their skin condition, with standard UV light treatment, than the control subjects. Another study found that meditation decreased the symptoms of fibromyalgia; over half of the patients reported significant improvement. Research by a group of ophthalmologists indicates that nearly 60% of a group of patients being treated for **glaucoma** found meditation helpful in coping with their eye disorder. In addition, meditation was one of several stress management techniques used in a small study of HIV-positive men. The study showed improvements in the T-cell counts of the men, as well as in several psychological measures of well-being.

Training and certification

There is no program of certification or licensure for instructors who wish to teach meditation as a medical therapy. Meditation teachers within a particular religious tradition usually have extensive experience and expertise with faith questions and religious practices but may not have been trained to work with medical patients. Different programs have varied requirements for someone to teach meditation. In order to be recognized as an instructor of TM, one must receive extensive training. The Center for Mindfulness in Medicine, Health Care and Society at the University of Massachusetts Medical Center offers training and workshops for health professionals and others interested in teaching mindfulness-based stress reduction. The Center does not, however, certify that someone is qualified to teach meditation. The University of Pennsylvania program for Stress Management suggests that a person have at least 10 years of personal experience with the practice of mindfulness meditation before receiving additional instruction to teach meditation. Teachers are also expected to spend at least two weeks each year in intensive meditation retreats.

Mediterranean diet

Definition

The Mediterranean diet is based upon the eating patterns of traditional cultures in the Mediterranean region. Several noted nutritionists and research projects have concluded that this diet is one of the most healthful in the world in terms of preventing a variety of illnesses including **heart disease** and **cancer**, and increasing life expectancy.

Origins

The countries that have inspired the Mediterranean diet all surround the Mediterranean Sea. These cultures have eating habits that developed over thousands of years. In Europe, parts of Italy, Greece, Portugal, Spain, and southern France adhere to principles

Mediterranean diet

Frequency	Food	Tips
Monthly	Red meats	No more than a few times month
Weekly	Sweets	Opt instead for naturally sweet fresh fruit
	Eggs	Less than 4 per week, including those in processed foods
	Poultry	A few times a week. Take the skin off and choose white meat to lower fat intake
	Fish	A few times a week
Daily	Cheese and yogurt	Cheese and yogurt are good sources of calcium. Choose low-fat varieties
	Olive oil	The beneficial health effects of olive oil are due to its high content of monounsaturated fats and antioxidants. Olive oil is high in calories, consume in moderation to reduce calorie intake
	Fruits	At least a serving at every meal. A serving of fruit is a healthy option for snacks
	Vegetables	At least a serving at every meal. Choose a variety of colors
	Beans, legumes, nuts	Beans are a healthy source of protein, and are loaded with soluble fiber, which has been shown to lower blood cholesterol levels by five percent or more. Most nuts contain monounsaturated (heart-healthy) fat. A handful of nuts is a healthy option for snacks
	Whole grains, including breads, pasta, rice, couscous, and polenta	A grain is considered whole when all three parts—bran, germ and endosperm—are present. Substitute whole wheat for white bread, brown rice for white rice and whole-wheat flour when baking. Mix pasta, rice, couscous, polenta and potatoes with vegetables and legumes
	Water	At least 6 glasses daily
	Wine (in moderation)	The U.S. Department of Agriculture defines moderation as no more than a five-ounce glass of wine daily for women and up to 2 glasses (10 ounces) daily for men
	Physical activity	Thirty minutes of cardiovascular activity a day is recommended to get in shape, burn calories and boost the metabolism

Based on the Mediterranean diet pyramid. *(Illustration by GGS Information Services. Cengage Learning, Gale)*

of the Mediterranean diet, as do Morocco and Tunisia in North Africa. Parts of the Balkan region and Turkey follow the diet, as well as Middle Eastern countries like Lebanon and Syria. The Mediterranean region is warm and sunny, and produces large supplies of fresh fruits and vegetables almost year round that people eat many times per day. Wine, bread, olive oil, nuts, and legumes (beans and lentils) are other staples of the region, and the Mediterranean Sea has historically yielded abundant fish. The preparation and sharing of meals is a very important and festive part of Mediterranean culture as well, and Mediterranean cuisine is popular around the world for its flavors.

The first description of the traditional Mediterranean diet as it became followed in America was in a research study funded by the Rockefeller Foundation and published in 1953. The author was Leland Allbaugh, who carried out a study of the island of Crete as an underdeveloped area. Allbaugh noted the heavy use of olive oil, whole-grain foods, fruits, fish, and vegetables in cooking as well as the geography and other features of the island.

The Cretan version of the Mediterranean diet became the focus of medical research on the Mediterranean diet following the publication of Dr. Ancel Keys's Seven Country Study in 1980. Dr. Keys performed an epidemiological analysis of **diets** around the world. Epidemiology is the branch of public health that studies the patterns of diseases and their potential causes among populations as a whole. The Seven Countries Study is considered one of the greatest epidemiological studies ever performed. It was a systematic comparison of diet, risk factors for heart disease, and disease experience in men between the ages of 40 and 59 in eighteen rural areas of Japan, Finland, Greece, Italy, the former Yugoslavia, the Netherlands, and the United States from 1958 to 1970. (Women were not included as subjects because of the rarity of heart attacks among them at that time and because the physical examinations were fairly invasive). In addition to asking the subjects to keep records of their food intake, the researchers performed chemical analyses of the foods the subjects ate. It was found that the men living on the island of Crete—the location of Leland Allbaugh's 1953 study—had the lowest rate of heart attacks of any group of subjects in the study.

Several other studies have validated Keys' findings regarding the good health of people in the Mediterranean countries. The World Health Organization (WHO) showed in a 1990 analysis that four major Mediterranean countries (Spain, Greece, France, and Italy) have longer life expectancies and lower rates of heart disease and cancer than other European countries and America. The data are significant because the same Mediterraneans frequently smoke and don't have

regular **exercise** programs like many Americans, which means that other variables may be responsible. Scientists have also ruled out genetic differences, because Mediterraneans who move to other countries tend to lose their health advantages. These findings suggest that diet and lifestyle are major factors.

The Mediterranean diet gained more notice when Dr. Walter Willett, head of the **nutrition** department at Harvard University, began to recommend it. Although low-fat diets were recommended for heart disease, Mediterranean groups in his studies had very high intakes of fat, mainly from olive oil. Willett and others proposed that the risk of heart disease could be reduced by increasing one type of dietary fat—monounsaturated fat. This is the type of fat in olive oil. Willett's proposal went against conventional nutritional recommendations to reduce all fat in the diet. It has been shown that unsaturated fats raise the level of HDL **cholesterol**, which is sometimes called "good cholesterol" because of its protective effect against heart disease. Willett has also performed studies correlating the intake of meat with heart disease and cancer.

Willett, other researchers at Harvard, and the WHO collaborated in 1994 and designed the Mediterranean Food Pyramid, which lists food groups and their recommended daily servings in the Mediterranean diet. These nutritionists consider their food groups a more healthful alternative to the food groups designated by the U.S. Department of Agriculture (USDA). The USDA recommends a much higher number of daily servings of meat and dairy products, which Mediterranean diet specialists attribute to political factors rather than sound nutritional analysis.

Benefits

Preventive health care

Most of the scientific research that has been done on Mediterranean diets concerns their role in preventing or lowering the risk of various diseases.

HEART DISEASE. Mediterranean diets became popular in the 1980s largely because of their association with lowered risk of heart attacks and **stroke**, particularly in men, following the publication of the Seven Countries study. Mediterranean diets are thought to protect against heart disease because of their high levels of **omega-3 fatty acids** even though blood cholesterol levels are not lowered.

ALZHEIMER'S DISEASE. A study published in *Annals of Neurology* in 2006 reported that subjects in a group of 2000 participants averaging 76 years of age who followed a Mediterranean-type diet closely were less likely to develop Alzheimer's than those who did not. Further study is needed, however, to discover whether factors other than diet may have affected the outcome.

ASTHMA AND ALLERGIES. A group of researchers in Crete reported in 2007 that the low rate of **wheezing** and allergic **rhinitis** (runny nose) on the island may be related to the traditional Cretan diet. Children who had a high consumption of nuts, grapes, oranges, apples, and tomatoes (the main local products) were less likely to suffer from **asthma** or nasal **allergies**. Children who ate large amounts of margarine, however, were more likely to develop these conditions.

METABOLIC SYNDROME. Research conducted at a clinic in Naples, Italy, suggests that Mediterranean diets lower the risk of developing and can even help in reversing the effects of metabolic syndrome, a condition associated with **insulin resistance** and an increased risk of heart disease and type 2 diabetes. The results from this clinic were corroborated by a study done at Tufts University in Massachusetts, which found that the symptoms of metabolic syndrome were reduced even in patients who did not lose weight on the diet.

Weight loss

Some population studies carried out in Mediterranean countries (particularly Italy and Spain) have found that close adherence to a traditional Mediterranean diet is associated with lower weight and a lower body mass index. Although there are relatively few studies of Mediterranean diets as weight-reduction regimens, a research team at the Harvard School of Public Health reported in 2007 that a Mediterranean-style diet is an effective approach to weight loss for many people. A major reason for its effectiveness is the wide variety of enjoyable foods permitted on the diet combined with a rich tradition of ethnic recipes making use of these foods—which makes it easier and more pleasant for people to stay on the diet for long periods of time.

Description

The Mediterranean diet has several general characteristics:

- The bulk of the diet comes from plant sources, including whole grains, breads, pasta, polenta (from corn), bulgur and couscous (from wheat), rice, potatoes, fruits, vegetables, legumes (beans and lentils), seeds, and nuts.
- Olive oil is used generously, and is the main source of fat in the diet as well as the principal cooking oil. The total fat intake accounts for up to 35% of calories.

Saturated fats, however, make up only 8% of calories or less, which restricts meat and dairy intake.

- Fruits and vegetables are eaten in large quantities. They are usually fresh, unprocessed, grown locally, and consumed in season.
- Dairy products are consumed in small amounts daily, mainly as cheese and yogurt (1 oz of cheese and 1 cup of yogurt daily).
- Eggs are used sparingly, up to four eggs per week.
- Fish and poultry are consumed only one to three times per week (less than 1 lb per week combined), with fish preferred over poultry.
- Red meat is consumed only a few times per month (less than 1 lb per month total).
- Honey is the principle sweetener, and sweets are eaten only a few times per week.
- Wine is consumed in moderate amounts with meals (1–2 glasses daily).

Preparations

Many Mediterranean cookbooks are available that can help with planning and preparing meals. A good first step is eliminating all oils, butter, and margarine and replacing them with olive oil. Meals should always be accompanied with bread and salads. Mediterranean fruits and vegetables are generally fresh and high in quality; American consumers may find equivalents by shopping in farmers' markets and health food stores that sell organic produce. Meat intake should be reduced and replaced by whole grains, legumes, and other foods at meals. The dairy products that are used should be yogurt and cheese instead of milk, which is not often used as a beverage by Mediterraneans.

Researchers have been quick to point out that there may be other factors that influence the effectiveness of the Mediterranean diet. Getting plenty of physical exercise is important, as is reducing **stress**. Researchers have noted that Mediterraneans' attitude toward eating and mealtimes may be a factor in their good health as well. Meals are regarded as important and joyful occasions, are prepared carefully and tastefully, and are shared with family and friends. In many Mediterranean countries, people generally relax or take a short nap (siesta) after lunch, the largest meal of the day.

Precautions

People who are making any major change in their dietary pattern in general should always consult their physician first. In addition, people who are taking monoamine oxidase inhibitors (MAOIs) for the treatment of **depression** should check with their doctor, as these drugs interact with a chemical called tyramine to cause sudden increases in blood pressure. Tyramine is found in red wines, particularly aged wines like Chianti, and in aged cheeses.

People using a Mediterranean diet for weight reduction should watch portion size and monitor their consumption of olive oil, cheese, and yogurt, which are high in calories. Dieters may wish to consider switching to low-fat cheeses and yogurts.

Because olive oil is a staple of Mediterranean diets, consumers should purchase it from reliable sources. The safety of olive oil is not ordinarily a concern in North America; however, samples of olive oils sold in Europe and North Africa are sometimes found to be contaminated by mycotoxins (toxins produced by molds and fungi that grow on olives and other fruits). Some mycotoxins do not have any known effects on humans, but aflatoxin, which has been found in olive oil, is a powerful carcinogen and has been implicated in liver cancer.

KEY TERMS

Cholesterol—A white, waxy, crystalline organic steroid alcohol found in animal foods that is also produced in the body from saturated fat for several important functions. Excess cholesterol intake is linked to many diseases.

Complex carbohydrates—Organic compounds that are broken down by the body into simple sugars for energy; they are found in grains, fruits and vegetables. They are generally recommended in the diet over refined sugar and honey, because they are a steadier source of energy and often contain fiber and nutrients as well.

Legume—A family of plants used for food that includes beans, peas, and lentils. Legumes are high in protein, fiber, and other nutrients.

Organic food—Food grown without the use of synthetic pesticides and fertilizers.

Saturated fat—Fat that is usually solid at room temperature, found mainly in meat and dairy products but also in such vegetable sources as nuts, some seeds, and avocados.

Unsaturated fat—Fat found in plant foods that is typically liquid (oil) at room temperature. They can be monounsaturated or polyunsaturated, depending on their chemical structure. Unsaturated fats are the most highly recommended dietary fats.

Medium-chain triglycerides

Description

Medium-chain triglycerides (MCTs) are a special class of fatty acids. Normal fats and oils contain long-chain fatty acids (LCTs). Compared to these fatty acids, MCTs are much shorter in length. Therefore, they resemble carbohydrates more than fat. As a result, they are more easily absorbed, digested, and utilized as energy than LCTs.

Medium-chain triglycerides are found naturally in milk fat, palm oil, and coconut oil. Commercial MCT oil, available as liquid and capsules, is obtained through lipid fractionation, the process in which MCTs are separated from other components of coconut oil. Medium-chain triglycerides were originally formulated in the 1950s as an alternative food source for patients who are too ill to properly digest normal fats and oils. The long chains of LCTs require a lot of bile acids and many digestive steps to be broken down into smaller units that can be absorbed into the bloodstream. Once in the bloodstream, they are absorbed by fat cells and stored as body fat. In contrast, the medium-chain triglycerides are more water-soluble and are able to enter the bloodstream quicker because of their shorter lengths. Once in the bloodstream, they are transported directly into the liver. Thus, MCTs are an immediately available source of energy and only a tiny percent is converted into body fat.

Medium-chain triglycerides were first used in the mid-1900s to reduce seizures with the help of the ketogenic diet. In the 1980s, MCTs became popular in sports as a substitute for normal dietary fats or oils. They quickly became a favorite energy source for many athletes, such as marathon runners, who participate in endurance sports. These athletes require a quick source of energy, which is readily supplied by carbohydrates. However, **diets** high in carbohydrates may cause rapid increase in insulin production, resulting in substantial weight gain, diabetes, and other health problems. Dietary fats or oils are not a readily available source of energy. In addition, they are believed to make the body fatter. MCT is also a form of fat; therefore, it is high in calories. Yet, unlike normal fats and oils, MCTs do not cause weight gain because they stimulate thermogenesis (the process in which the body generates energy, or heat, by increasing its normal metabolic, fat-burning rate). A thermogenic diet, which is high in medium-chain triglycerides, has been proposed as a type of weight loss regime.

General use

Endurance sport nutrition

Medium-chain triglycerides are often used by athletes to increase their endurance during sports or **exercise** regimes. MCTs are an immediate source of energy, and as such, the body can use them as an alternative energy source for muscle during endurance exercise. However, if consumed in moderate amounts (30 to 45 grams), MCTs are not very effective in either decreasing carbohydrate needs or in enhancing exercise endurance. Increased consumption may help. One study evaluated six athletes at different points during a 25-mile cycling trial. They were given either a medium-chain triglyceride beverage, a carbohydrate drink, or a combined MCT-carbohydrate mixture. The fastest speed was achieved when the athletes used the MCT-carbohydrate blend. The worst performance was associated with sport drinks containing MCT alone (without carbohydrate). Therefore, to gain significant increases in endurance, it is generally recommended

KEY TERMS

Endurance—The ability to sustain an activity over a period of time.

Hepatic encephalopathy—Brain and nervous system damage that occurs as a complication of liver disorders.

Ketones—The potentially toxic by-products of partially burned fatty acids that the body uses as an alternative fuel source when carbohydrates are not available.

Thermogenesis—The production of heat, especially within the body.

that an athlete consume at least 50 grams of MCTs per day in combination with some carbohydrates. However, dosages exceeding 30 grams often cause gastrointestinal upset, which can diminish an athlete's performance.

MCT products available in the market may have high water content or contain unwanted ingredients. Therefore, athletes should buy MCT-only products, and mix a small amount into carbohydrate soft drinks. Alternatively, they can purchase premixed MCT sport drinks, such as a brand known as SUCCEED.

Thermogenic diet

MCTs are popular among body builders because they help reduce carbohydrate intake, while allowing them ready access to energy whenever they need it. MCTs also have muscle-sparing effects. As a result, they can build muscles while reducing fats. However, this does not mean that these athletes will become healthier, because an improvement in body physique does not always correlate with higher fitness levels.

Pre-competition diet

Compared to carbohydrates, medium-chain triglycerides are a better and more efficient source of quick energy. They help conserve lean body mass because they prevent muscle proteins from being used as energy. Therefore, some athletes load up on medium-chain triglycerides the night before a competition. However, MCT intake should be raised gradually to allow the body to adapt to increasing MCT consumption. If MCT consumption abruptly increases, incomplete MCT metabolism may occur, producing lactic acid in the body and a rapid rise of ketones in the blood, which can make the person ill.

Weight-loss diet

Studies have shown that MCT may increase metabolism, which is the rate that the body burns fat. It is believed that sustained increases in metabolic rate cause the body to burn more fat, resulting in weight loss. However, for any kind of meaningful weight loss, a person would have to consume more than 50% of total daily caloric intake in the form of medium-chain triglycerides.

Treatment of seizures

A ketogenic diet, or diet containing mostly medium-chain triglycerides, offers hope for those who have seizures that cannot be controlled by currently available drugs. Excessive consumption of MCTs produces ketones in the body; therefore, this type of diet is called a ketogenic diet. It has proven effective for some epileptic patients.

Nutritional supplements

MCTs are the preferred forms of fat for many patients with fat malabsorption problems. Many diseases cause poor fat absorption. For instance, patients with pancreatic insufficiency do not have enough pancreatic enzymes to break down LCTs. In children with cystic fibrosis, thick mucus blocks the enzymes that assist in digestion. Another fat absorption condition is short-bowel syndrome, in which parts of the bowel have been removed due to disease. Stressed or critically ill patients also have a decreased ability to digest LCTs. Unlike LCTs, medium-chain triglycerides are easily absorbed by patients with malabsorption conditions. These patients benefit most from oral preparations that contain MCTs as the primary source of fat (up to 85% of fat caloric intake). Several scientific studies have shown MCT to be effective in treating fat malabsorbtion, chronic **diarrhea**, and weight loss in patients with Acquired Immune Deficiency Syndrome (**AIDS**).

Many MCT products can be found in local health food stores or ordered through pharmacies. Before purchasing these products, patients should consult their doctors or registered dietitians for advice concerning appropriate dosage and use. MCT oil is not used for cooking. However, it can be used for tube feeding in critically ill patients. Healthy people may take it orally, by itself or mixed with water, juice, ice cream, or pudding.

Preparations

Available medium-chain triglyceride products include:

- MCT oil
- sports drinks
- energy bars
- meal replacement beverages

Precautions

- People with hepatic encephalopathy, brain and nervous system damage that occurs as a complication of liver disorders, should not take MCT.
- High consumption of medium-chain triglycerides can cause abdominal pain, cramps, and diarrhea.
- Long-term high-level MCT consumption is associated with increased risk of heart disease and other conditions. Even moderate consumption of medium-chain triglycerides can increase cholesterol and triglyceride levels. Therefore, no more than 10% of a person's diet should come from MCTs.
- Diabetic athletes and those with liver disease should not use MCT products.
- MCT oil should not completely replace all dietary fats, as this would result in a deficiency of other fatty acids—essential fatty acids— that the human body needs from food sources. To avoid essential fatty acid deficiencies, a person should also include omega-3 and omega-6 fatty acids in their diets. Good sources of omega-3 include fish, fish oils, or flaxseed oil. Omega-6 fatty acids are often found in vegetable oils and evening primrose oil . The omega-3 fats have several additional health benefits, such as alleviating inflammation and protecting the body against heart disease.
- A person should not take medium-chain triglyceride products on an empty stomach, as this may cause gastric upset.
- MCT oil is not for cooking. It is usually consumed in its uncooked form as sport bars, or mixed with a carbohydrate drink, protein shake, or other products.
- MCT oil leaches into plastic bags and containers. Therefore, non-plastic containers should be used for MCT oil storage.

Side effects

There are a few adverse effects associated with MCT use. Eating foods containing medium-chain triglycerides on an empty stomach often causes gastrointestinal upset. Regular consumption of MCTs may increase **cholesterol** and triglyceride blood levels.

Interactions

There have been no reported interactions between MCTs and other drugs.

Melanoma *see* **Skin cancer**

Melatonin

Description

Melatonin is a hormone produced naturally in the pineal gland at the base of the brain. It is important in regulating sleep and may play a role in maintaining circadian rhythm, the body's natural time clock. The hypothalamus keeps track of the amount of sunlight that is taken in by the eye. The less sunlight, the more melatonin that is released by the pineal gland, thereby enhancing and regulating sleep. Melatonin can also be taken in an over-the-counter supplement sold mainly in health food stores and pharmacies.

General use

A variety of medical uses for melatonin have been reported, but in the late 2000s, its popularity resulted from its promotion as a sleep aid and a reducer of **jet lag**. However, medical experts caution that melatonin is not a harmless substance without risks. Natural melatonin production decreases with age, and the decrease is associated with some **sleep disorders**, particularly in the elderly.

A study conducted by the Institute of Medicine in 2005 found that 50 to 70 million Americans suffer from some kind of chronic sleep disorder that hinders their ability to function normally and adversely affects their health and longevity. The use of melatonin supplements became popular in the mid-1990s as a way of dealing with such sleep disorders. Numerous scientific studies have supported this practice, although there are a few studies that cast doubt on its effectiveness. People reporting the most benefit generally are those with mild and occasional **insomnia** and trouble falling asleep. Melatonin is not generally recommended for use on a regular basis since its long-term consequences are not known.

The second most popular use of melatonin is to ease the effects of jet lag, a physical condition caused by the disturbance of circadian rhythms, usually associated with air travel across several time zones. In its 2008 issue of the popular booklet *Health Information for International Travel*, the Centers for Disease Control and Prevention suggests that "limited evidence suggests melatonin is safe and well tolerated, and doses of 0.5 to 5 mg may promote sleep and decrease jet lag symptoms in travelers crossing five or more time zones."

As of 2008, questions remained about the efficacy of melatonin in treating sleep disorders and jet lag. In 2006, researchers at the University of Alberta, Canada, reported that their review of studies on melatonin conducted between 1999 and 2003 led them to conclude that "[t]here is no evidence that melatonin is effective in treating secondary sleep disorders or sleep disorders accompanying sleep restriction, such as jet lag and shift-work disorder."

Some researchers report that melatonin may be effective in reducing the effects of **aging**. In a 2007 study conducted by researchers at the University of Granada, Spain, mice whose diet included melatonin showed significantly fewer effects of aging than did a control group that received no melatonin. Further studies on the benefits, long-term effects, and proper dosage were being conducted through the National Institutes on Aging as of 2008.

In laboratory and animal experiments, melatonin appears to protect cells and boost the immune system. Melatonin supplementation is sometimes part of a holistic treatment regimen for people with HIV or **AIDS**. There have been no human trials that support this claim.

Preparations

Melatonin is available over the counter in varying doses of up to 3 mg per tablet. However, a fraction of this amount is required for insomnia, usually about 0.3 mg or less. Too much melatonin or taking it at the wrong time can interrupt normal circadian patterns. Melatonin is produced at its highest level in the pineal gland during darkness. Since melatonin occurs naturally in some foods, it can be sold as an over-the-counter dietary supplement. It is only one of two hormones (the other is **DHEA**) not regulated by the U.S. Food and Drug Administration (FDA). Natural, animal, and bovine melatonin supplements contain actual extracts from pineal glands. Synthetic melatonin is made from non-animal ingredients and is suitable for vegetarians. It is similar in molecular structure to melatonin produced in the human body.

The proper dosage of melatonin for various applications is not known, but it appears to differ greatly depending on the individual and extent of the sleep disorder. Persons starting the hormone should begin with a very low dose, 100 to 300 mcg (0.1–0.3 mg) or less and gradually increase the dosage if needed. Melatonin is quick-acting and should be taken about 30 minutes prior to bedtime. For jet lag, the general recommendation is 300 mcg just before boarding the flight and 1.5 mg after arrival before going to bed. Melatonin should not be taken during the day.

Researchers have long thought that melatonin is not available from any plant source. However, some

KEY TERMS

Circadian rhythm—The approximately 24-hour period, also known as the body's time clock, that regulates waking and sleeping periods.

Dehydroepiandrosterone (DHEA)—A hormone produced by the adrenal glands that is important in the synthesis of other hormones, especially estrogen and testosterone.

Estrogen—A hormone that stimulates development of female secondary sex characteristics.

Hypertension—Abnormally high blood pressure in the arteries.

Insomnia—A prolonged and usually abnormal inability to obtain adequate sleep.

Lymphoma—Cancer of the lymph nodes.

Pineal gland—A gland about the size of a pea at the base of the brain that is part of the endocrine system.

research showed that this view is not entirely correct. Studies have found that both cherries and walnuts contain small amounts of melatonin. The amounts of very small, however, amounting to no more than a few nanograms (billionths of a gram) of melatonin per gram of natural product. Anyone wanting to ingest melatonin from plants such as cherries or walnuts would, therefore, have to consume very large amounts of the plants.

Precautions

Women who are on estrogen or estrogen replacement therapy should not take melatonin without consulting their doctor. Since the safety of melatonin use during **pregnancy** has not been adequately studied as of 2008, women who are pregnant or breast feeding a child should not take melatonin. Also, women who are trying to get pregnant should avoid using it since some research suggests it may have a contraceptive effect. Studies in animals suggest melatonin can constrict blood vessels, which can raise blood pressure. Therefore, persons with **hypertension** or cardiovascular problems should consult with their doctor before taking the hormone. It is not recommended for people with lymphoma or **leukemia** and should not be used by children.

Side effects

Few studies have been done on the long-term effects or correct dosing of melatonin. In one study of melatonin, about 10% of patients said they experienced minor side effects such as nightmares, headaches, morning **hangover**, **depression**, and impaired sex drive.

Interactions

Melatonin should not be taken by people using certain antidepressants, such as a serotonin inhibitor (Prozac) or a monoamine oxidase inhibitor (Nardil). Interaction between melatonin and these types of antidepressants can cause a **stroke** or **heart attack**. Preliminary symptoms include confusion, sweating, shaking, **fever**, lack of coordination, elevated blood pressure, **diarrhea**, and convulsions.

Memory loss

Definition

Memory loss can be partial or total. Most memory loss occurs as part of the normal **aging** process, but memory loss may also occur as a result of severe emotional trauma or brain damage following disease or physical trauma. Memory loss can be described as amnesia, forgetfulness, or impaired memory.

Description

Memory is often classified as immediate (retention of information for a few seconds); short-term (retention of information for several seconds or minutes); and long-term (retention of information for days, weeks, or years). In short-term memory loss, patients can remember their childhood and past events but fail to remember events that happened in the previous few minutes. In long-term memory loss, patients are unable to recall events in the remote past.

Depending on the cause, memory loss can be sudden or gradual, and it can be permanent or temporary. Memory loss resulting from trauma to the brain is usually sudden and may be either permanent or temporary. By contrast, disease-related memory loss, such as in Alzheimer's disease, occurs gradually and is usually permanent. It is barely noticeable at first but progressively gets worse.

In most cases, memory loss is temporary and usually affects memories relating to a portion of a person's experience. However, severe physical brain trauma, such as that following a severe head injury, can cause total (global) memory loss. Some patients may temporarily lose memory and consciousness, then fully recover after the event.

Causes and symptoms

The following are common causes of memory loss:

- Aging. Even in people who do not have a disease associated with memory loss, the number of new nerve cells produced in the brain's hippocampus progressively decreases with age, and this decrease affects memory.
- Nutritional deficiency. Not enough thiamine (vitamin B_1), vitamin B_{12}, and/or protein contributes to memory loss.
- Depression. Depression can cause memory loss at any age. This is one of the main reasons for forgetfulness in the elderly. Depression-related memory loss is a treatable condition.
- Diseases. Memory loss can result from such chronic disease conditions as diabetes or hypothyroidism.
- Oxygen deprivation. Such conditions as severe head trauma, surgery, strokes, or heart attacks cause a sudden reduction of oxygen to the brain, which causes widespread death of nerve cells and significant memory loss.
- Structural abnormalities in or damage to the parts of the brain associated with memory formation. Two areas of the brain that are involved in memory formation are the hippocampus and the orbitofrontal cortex.
- Free-radical damage. Free-radical molecules are unstable and highly reactive molecules. These molecules destabilize other molecules around them, resulting in damage to the body at the molecular level. Free radicals can damage the blood-brain barrier, a membrane that separates the circulating blood and the brain. A weakened barrier may not be able to prevent toxic chemicals from entering the brain. Widespread brain damage, accelerated cell death, and memory loss occur as a result.
- Chemical poisoning. Daily exposure to toxic chemicals such as alcohol, tobacco, and illicit drugs (heroine, cocaine, and amphetamines) destroys brain cells at a rapid rate. Other environmental toxins, such as lead and mercury, can penetrate the blood-brain barrier. Once inside the brain, these heavy metals kill nerve cells. This action helps explain why exposure to heavy metals has been linked to memory and learning problems in children. Even though aluminum is not considered a heavy metal, its accumulation in the brain is believed to contribute to Alzheimer's disease.
- Central nervous system (CNS) infections and inflammation of the brain. Encephalitis (an inflammatory disease of the brain) can result in the death of nerve cells, which can lead to significant memory loss. CNS infections such as toxoplasmosis and neurosyphilis can also cause significant brain damage and memory loss.
- Stress. Emotional or physical stress stimulates the release of stress hormones such as cortisol and adrenaline. Constant exposure to stress hormones results in nerve-cell death and memory loss.
- Sensory overload. When a person is trying to do too many tasks or is worrying about too many things at the same time, the brain is overloaded with information and cannot process short-term memories. Therefore, if individuals are trying to remember a

lot of information, they may forget such details as where the car keys are or what appointments need to be kept.

- Low blood sugar. Nerve cells require glucose (sugar) to generate energy. If there is not enough glucose in the blood, nerve cells starve and die. Excessively low blood sugar can send a person into shock and/or into a coma.
- Genetic factors. A rare form of Alzheimer's disease is called early-onset familial AD. This form of the disease is inherited and usually strikes between the ages of 30 and 60. Most cases of Alzheimer's disease are described as "late-onset" because they do not occur until later in life. Although late-onset AD does not appear to be an inherited illness, scientists have identified a gene that may be involved. This gene's role is to make a protein known as apolipoprotein E, or ApoE. Although all people have this gene, about 15 percent of individuals have a certain form of the gene that increases the risk for AD. Scientists are also interested in the protein beta-amyloid, which is active in persons who have Alzheimer's disease. According to a study published in 2008, the protein is also very active in healthy young people. They believe the protein helps the brain delete unnecessary memories but causes problems in people with Alzheimer's disease because they lose memories faster than they make new ones. Studies were underway as of 2008 to search for possible other genetic risk factors. In addition, Down syndrome, which is caused by an abnormal form of human chromosome 21, is characterized by memory loss relatively early in life, often when individuals are in their 30s or 40s.
- Seizures. Prolonged seizures, such as in patients with epilepsy, can cause significant memory loss.
- Severe emotional trauma. Extreme emotional trauma has been associated with sudden amnesia. Dissociative amnesia is a type of amnesia that occurs when the brain splits off, or dissociates, extremely distressing memories from conscious recollection.
- Low estrogen levels in postmenopausal women. Women often report a significant decrease in memory function immediately following menopause.

Diagnosis

To find the underlying cause of memory loss, physicians obtain a detailed medical history, which documents the pattern, symptoms, and types of memory loss. They also inquire about contributing factors that may worsen or trigger memory loss. A routine physical and detailed neuropsychological examination with a focus on memory function is conducted. In addition, they may order several diagnostic tests.

Tests used to pinpoint the exact cause of memory loss include neuroimaging; electroencephalography (EEG) for patients with seizures; blood, cerebrospinal fluid, and tissue analysis to rule out specific diseases; and cognitive tests for gauging the patient's recent and remote (long-term) memory, and possibly the patient's attention span, judgment, and word comprehension as well. The most common brief test given to evaluate a person for memory loss and other aspects of cognitive function is the Mini-Mental Status Examination, or MMSE, which is also known as the Folstein.

Available neuroimaging techniques include computed tomography or CT scan, magnetic resonance imaging (MRI), positron emission tomography (PET), and single-photon emission computed tomography (SPECT). A CT scan can detect structural abnormalities, such as brain tumors or lesions. For detection of widespread loss of neurons associated with aging or degenerative diseases, an MRI, PET, or SPECT test can be performed. These tests can show the severity and extent of nerve damage. They can also help doctors pinpoint the cause of the memory loss. A PET scan is especially useful in that it allows doctors to track and record which memory centers are stimulated in a person's brain tissue while the person is functioning.

Treatment

Dietary guidelines

The following dietary changes are recommended to lower the risk of or slow memory loss:

- Reduce sugar intake.
- Avoid eating foods that contain such additives as artificial sweeteners, monosodium glutamate (MSG), preservatives, and artificial colors. These chemicals can accumulate in the body and become toxic, causing brain damage and memory loss.
- Eat organically grown foods. Pesticides and insecticides are toxic chemicals that can affect nerve function and cause memory loss.
- Limit alcohol intake and quit smoking.
- Do not use illicit drugs.
- Drink only filtered water to avoid toxic chemicals in the water system.
- Eat a low-fat, high-fiber diet with emphasis on fresh fruits and vegetables. Raw fruits and vegetables are the best sources of the vitamins, minerals, fiber, and antioxidants that the body needs for detoxifying. Antioxidants also protect and support brain function.

- Get enough protein. Protein is necessary to maintain healthy muscles, organs, and nerve cells; it also helps maintain blood sugar levels.
- Eat cold-water fish, which are a good source of omega-3 fatty acids. Omega-3 fats are believed to reduce the risk of strokes, blood clotting, and heart attacks. These are major causes of sudden memory loss in the elderly.

Nutritional supplements

The following nutritional supplements may help restore and maximize memory:

- L-Acetylcarnitine (LAC). Studies have shown that acetylcarnitine can improve memory function in the elderly. It may even reverse memory loss in some patients who have early Alzheimer's disease.
- Phosphatidylserine (100 mg three times per day). This supplement may help improve brain function in patients suffering from age-related memory loss and appears to be most effective for patients with milder symptoms.
- Vitamin E (400–800 IU per day). A strong antioxidant, vitamin E has been shown to promote memory performance.
- Omega-3 fatty acids. Flaxseed oil (1 tablespoon per day) and fish oil capsules are good sources of omega-3 fatty acids. Omega-3 enriched eggs are also beneficial.
- Thiamine (3–8 g per day). A vitamin B_1 deficiency can be treated with supplements. Thiamine/vitamin B_1 is an antioxidant that may improve mental function in Alzheimer's patients.
- Methylcobalamin (1,000 micrograms twice daily). Methylcobalamine is a supplemental form of cyanocobalamin, or vitamin B_{12}. Many Alzheimer's patients have been found to have a vitamin B_{12} deficiency.

Herbal therapy

Alternative medicine practitioners may recommend one or more of the following herbs to help reverse memory loss and/or improve mental performance:

- *Ginkgo biloba* extract (24% ginkgo flavonglycosides: 80 mg three times per day) is the herb most well-known as a memory booster. A study in 2002, however, indicated that gingko had no effect on memory or on concentration among generally healthy adults aged 60 to 82. Yet, several other studies demonstrated that ginkgo helps improve thinking and concentration in patients with Alzheimer's disease. Ginkgo is a strong antioxidant.
- Gotu kola (*Centella asiatica*: 70 mg taken twice daily). This herb is used to help improve memory by increasing blood circulation to the brain and by keeping blood vessels strong and healthy.
- Ginseng. Studies have shown that ginseng can improve memory and enhance learning ability. The recommended dosage of Korean ginseng is typically 3 to 9 g per day. Because ginseng may elevate blood pressure, patients with heart disease or high blood pressure should consult with their doctor before using this herb.
- Huperzine A. Huperzine A is isolated from a traditional Chinese medicine known as Qian Ceng Ta, which is made from a type of club moss (*Huperzia serrata*). It is sometimes recommended for treating dementia and for improving memory. Limited studied in China indicate that it is indeed useful in the treatment of memory loss due to dementia.
- Brahmi (*Bacopa monniera*). Brahmi is a herb native to India that is used in Ayurvedic medicine and Japanese medicine as a nerve tonic and treatment for insomnia. It is believed to improve a person's ability to retain new learning. Brahmi, which is sometimes called bacopa in Western countries, contains two compounds known as bacosides A and B. It is thought that these chemicals help to prevent memory loss by improving the efficiency of impulse transmission between nerve cells in the brain. An Australian study published in 2002 reported on the effects of brahmi on 76 human subjects. It showed that brahmi has a significant effect on people's ability to remember new information, although it does not affect a person's ability to retrieve information that was known prior to the experiment.

Allopathic treatment

The method of treatment for memory loss depends on underlying causes:

- Age. The elderly can be taught simple techniques to remember things better such as repeating a person's name several times, using word association, or jotting things down in a notebook.
- Depression. Depressed patients often show enhanced memory function after they are successfully treated for depression.
- CNS infections. Patients require effective antimicrobial treatment immediately to save them from death, significant brain damage, and profound memory loss.
- Trauma. Patients' memories usually return as they recover from the accident or injury. In some causes hypnosis is useful in helping patients retrieve traumatic memories without being overwhelmed by them.

KEY TERMS

Alzheimer's disease—A degenerative brain disease caused by physiological changes inside the brain. As a result, the patient experiences impaired memory and thought processes.

Antioxidant—Any substance that reduces the damage caused by oxidation, such as the harm caused by free radicals.

Bacosides—The name of two chemicals found in brahmi that are believed to aid memory by improving the efficiency of nerve impulse transmission.

Brahmi—A herb used in Ayurvedic and Japanese medicine that is believed to improve a person's ability to remember new information. Brahmi is also called bacopa.

Dissociation—A reaction to trauma in which the mind splits off certain aspects of the traumatic event from conscious awareness. Dissociation can affect the patient's memory, sense of reality, and sense of identity.

Dissociative amnesia—A disorder characterized by loss of memory for a period or periods of time in the patient's life.

Down syndrome—A genetic disorder caused by an extra human chromosome 21 (trisomy 21), characterized by mental retardation, muscular weakness, and folds over the patient's eyelids. Individuals with Down syndrome often begin to lose their memory in midlife.

Hippocampus—A horseshoe-shaped ridge in the brain that is part of the limbic system. The hippocampus is associated with the formation of short-term memory and with the sense of spatial orientation.

Mini-Mental Status Examination (MMSE)—A brief test of memory and cognitive function that is used to evaluate the presence and extent of memory loss and to monitor the effects of treatment for memory loss.

Neuron—A nerve cell that receives, processes, saves, and sends messages. It consists of an axon, a body, and dendrites.

- Alzheimer's disease (AD). Such medications as galantamine, rivastigmine, tacrine, or donepezil are often prescribed to improve memory and cognitive functions in patients with mild to moderate AD. Doctors may prescribe memantine to treat individuals with moderate to severe AD.

Expected results

A patient's prognosis depends on the underlying causes of his or her memory loss. Partial or complete recovery can be expected when the memory loss results from treatable causes such as **depression** or nutritional deficiencies. Patients with such degenerative nerve conditions as Alzheimer's disease, however, are expected to have a slow, irreversible decline of both memory and cognitive function. Medical treatment with memory-enhancing medications and long-term care are often required.

Prevention

A person can decrease or slow age-related memory loss by taking several steps. Keeping the mind active by continually learning new information is an important strategy in this regard. By eating healthy and nutritious foods, taking nutritional supplements and **antioxidants**, reducing stresses at home and at work, and avoiding environmental toxins, one can slow or even prevent memory loss.

Ménière's disease

Definition

Ménière's disease is a condition characterized by recurrent vertigo (**dizziness**), **hearing loss**, and **tinnitus** (a roaring, buzzing, or ringing sound in the ears).

Description

Ménière's disease was named for the French physician Prosper Ménière, who first described the illness in 1861. It is an abnormality within the inner ear. A fluid called endolymph moves in the membranous labyrinth or semicircular canals within the bony labyrinth inside the inner ear. When the head or body moves, the endolymph moves, causing nerve receptors in the membranous labyrinth to send signals to the brain about the body's motion. A change in the volume of the endolymph fluid, or swelling or rupture of the membranous labyrinth is thought to result in Ménière's disease symptoms.

KEY TERMS

Myelin—A whitish fatty substance that acts like an electrical insulator around certain nerves in the peripheral nervous system. It is thought that the loss of the myelin surrounding the vestibular nerves may influence the development of Ménière's disease.

T cell—A type of white blood cell produced in the thymus gland that regulates the immune system's response to diseased or malignant cells. It is possible that a subcategory of T cells known as CD4 cells plays a role in Ménière's disease.

Tinnitus—A roaring, buzzing or ringing sound in the ears.

Transcutaneous electrical nerve stimulation (TENS)—A treatment in which a mild electrical current is passed through electrodes on the skin to stimulate nerves and block pain signals.

Vertigo—The medical term for dizziness or a spinning sensation.

Causes and symptoms

Causes

The cause of Ménière's disease is unknown as of 2002; however, scientists are studying several possible causes, including noise pollution, viral **infections**, or alterations in the patterns of blood flow in the structures of the inner ear. Since Ménière's disease sometimes runs in families, researchers are also looking into genetic factors as possible causes of the disorder.

One area of research that shows promise is the possible relationship between Ménière's disease and **migraine headache**. Dr. Ménière himself suggested the possibility of a link, but early studies yielded conflicting results. A rigorous German study published in late 2002 reported that the lifetime prevalence of migraine was 56% in patients diagnosed with Ménière's disease as compared to 25% for controls. The researchers noted that further work is necessary to determine the exact nature of the relationship between the two disorders.

A study published in late 2002 reported that there is a significant increase in the number of CD4 cells in the blood of patients having an acute attack of Ménière's disease. CD4 cells are a subtype of T cells, which are produced in the thymus gland and regulate the immune system's response to infected or malignant cells. Further research is needed to clarify the role of these cells in Ménière's disease.

Another possible factor in the development of Ménière's disease is the loss of myelin from the cells surrounding the vestibular nerve fibers. Myelin is a whitish fatty material in the cell membrane of the Schwann cells that form a sheath around certain nerve cells. It acts like an electrical insulator. A team of researchers at the University of Virginia reported in 2002 that the vestibular nerve cells in patients with unilateral Ménière's disease are demyelinated; that is, they have lost their protective "insulation." The researchers are investigating the possibility that a viral disease or disorder of the immune system is responsible for the demyelination of the vestibular nerve cells.

Symptoms

The symptoms of Ménière's disease are associated with a change in fluid volume within the labyrinth of the inner ear. Symptoms include severe dizziness or vertigo, tinnitus, hearing loss, and the sensation of **pain** or pressure in the affected ear. Symptoms appear suddenly, last up to several hours, and can occur as often as daily to as infrequently as once a year. A typical attack includes vertigo, tinnitus, and hearing loss; however, some individuals with Ménière's disease may experience a single symptom, like an occasional bout of slight dizziness or periodic, intense ringing in the ear. Attacks of severe vertigo can force the sufferer to have to sit or lie down, and may be accompanied by **headache**, **nausea**, **vomiting**, or **diarrhea**. Hearing

tends to recover between attacks, but becomes progressively worse over time.

Ménière's disease usually starts between the ages of 20 and 50 years; however, it is not uncommon for elderly people to develop the disease without a previous history of symptoms. Ménière's disease affects men and women in equal numbers. In most patients only one ear is affected but in about 15% both ears are involved.

Diagnosis

An estimated three to five million people in the United States have Ménière's disease, and almost 100,000 new cases are diagnosed each year. Diagnosis is based on medical history, physical examination, hearing and balance tests, and medical imaging with magnetic resonance imaging (MRI).

In patients with Ménière's disease, audiometric tests (hearing tests) usually indicate a sensory type of hearing loss in the affected ear. Speech discrimination, or the ability to distinguish between words that sound alike, is often diminished. In about 50% of patients, the balance function is reduced in the affected ear. An electronystagnograph (ENG) may be used to evaluate balance. Since the eyes and ears work together through the nervous system to coordinate balance, measurement of eye movements can be used to test the balance system. For this test, the patient is seated in a darkened room and recording electrodes, similar to those used with a heart monitor, are placed near the eyes. Warm and cool water or air are gently introduced into each ear canal and eye movements are recorded.

Another test that may be used is an electrocochleograph (EcoG), which can measure increased inner ear fluid pressure.

Treatment

Because there is no cure for Ménière's disease, most treatments are aimed at reducing its symptoms, especially tinnitus. General measures to mask the tinnitus include playing a radio or tape of white noise (low, constant sound). Exercising to improve blood circulation and reducing the intake of salt, alcohol, aspirin, **caffeine**, and nicotine may relieve Ménière's disease symptoms.

Ayurveda

Ayurvedic practitioners believe that tinnitus is a vata disorder. (Vata is one of three doshas, or body/mental types.) The patient can drink a tea prepared from 1 tsp of a mixture of **comfrey**, cinnamon, and **chamomile** two to three times a day. Yogaraj guggulu in warm water can be taken two or three times a day. Gentle massage of the mastoid bone (behind the ear) with warm **sesame oil** may help relieve tinnitus. Placing three drops of **garlic** oil into the affected ear at night may also be effective.

Homeopathy

Homeopathic remedies are chosen based on each patients specific set of symptoms. Salicylic acidum is indicated for patients who experience a roaring sound, deafness, and giddiness. **Bryonia** is recommended for patients with headache, a buzzing or roaring sound in the ear, and dizziness that is worsened by motion. Cocculus is indicated for those who experience dizziness and nausea. Conium is chosen for the patient who experiences light sensitivity and dizziness that is worsened by lying down. *Carbonium sulphuratum* is recommended for patients who experience a roaring with a tingling sensation and clogged ears. *Kali iodatum* is chosen for patients who have long-term ringing in the ears and no other symptoms. Theridion is indicated for patients who experience sensitivity to noise and dizziness with nausea and vomiting that is worsened by the slightest motion.

Other remedies

Other alternative medicine disciplines which have treatments to help relieve symptoms of Ménière's disease are:

- Acupuncture. The acupuncture ear points neurogate, kidney, sympathetic, occiput, heart, and adrenal may relieve dizziness associated with Ménière's disease. Chronic cases may be treated at the body points on the spleen, triple warmer, and kidney meridians. The World Health Organization (WHO) lists Ménière's disease as one of 104 conditions that can be treated effectively with acupuncture.
- Aromatherapy. The essential oils of geranium, lavender, and sandalwood may be added to bath water. Lavender or German chamomile oils may be used as massage oils.
- Body adjustments. Chiropractors or osteopaths may adjust the head, jaw, and neck to relieve movement restrictions that could affect the inner ear. Craniosacral therapists may gently move bones of the skull to relieve pressure on the head.
- Herbals. Ginkgo (*Ginkgo biloba*) improves circulation which may improve tinnitus and Ménière's disease. Ginkgo is a powerful antioxidant and blood thinner. Ginkgo relieves tinnitus in about half of

the patients who use it. Fenugreek (*Trigonella foenum-graecum*) tea (steeped in cold water) stops cricket noises and ringing in the ears. Chamomile (*Matricaria recutita*) promotes relaxation and may help the patient to sleep.

- Reflexology. Working the cervical spine, ear, and neck points on the hands and feet and the points on the bottoms and sides of the big toes may relieve tinnitus.
- Relaxation techniques. Biofeedback, yoga, massage, and other stress-reduction techniques can promote relaxation and divert the patient's attention away from tinnitus. Stress can worsen tinnitus and bring on an attack of Ménière's disease so relaxation techniques can be beneficial.
- Supplements. Magnesium deficiency may cause tinnitus. Magnesium supplementation may relieve the tinnitus associated with Ménière's disease and protect the ears from damage resulting from loud sounds. Vitamin B_{12} supplementation has improved tinnitus in patients deficient in this vitamin. Other supplements recommended for the treatment of Ménière's disease include vitamins C, B_1, B_2, and B_6 and zinc.
- TENS. Transcutaneous electrical nerve stimulation reduced tinnitus in 60% of the Ménière's disease patients in a study of tinnitus sufferers. Patients received six to 10 treatments biweekly. A few of the study patients reported temporary or permanent worsening of tinnitus, however, the cause of the tinnitus in these patients was not specified.

Allopathic treatment

There is no cure for Ménière's disease, but medication, surgery, and dietary and behavioral changes can help control or improve the symptoms.

A special hearing aid is available which makes a soft noise to mask the ringing and other noises associated with Ménière's disease. This device does not interfere with hearing or speech.

Medications

Symptoms of Ménière's disease may be treated with a variety of oral medicine or through injections. Antihistamines, like diphenhydramine, meclizine, and cyclizine can be prescribed to sedate the vestibular system. A barbiturate medication like pentobarbital may be used to completely sedate the patient and relieve the vertigo. Anticholinergic drugs, like atropine or scopolamine, can help minimize nausea and vomiting. Diazepam has been found to be particularly effective for relief of vertigo and nausea in Ménière's disease. There have been some reports of successful control of vertigo after antibiotics (gentamicin or streptomycin) or a steroid medication (dexamethasone) are injected directly into the inner ear. Some researchers have found that gentamicin is effective in relieving tinnitus as well as vertigo.

A newer medication that appears to be effective in treating the vertigo associated with Ménière's disease is flunarizine, which is sold under the trade name Sibelium. Flunarizine is a **calcium** channel blocker and anticonvulsant that is presently used to treat **Parkinson's disease**, migraine headache, and other circulatory disorders that affect the brain.

Surgical procedures

Surgical procedures may be recommended if the vertigo attacks are frequent, severe, or disabling and cannot be controlled by other treatments. The most common surgical treatment is insertion of a small tube or shunt to drain some of the fluid from the canal. This treatment usually preserves hearing and controls vertigo in about one-half to two-thirds of cases, but it is not a permanent cure in all patients.

The vestibular nerve leads from the inner ear to the brain and is responsible for conducting nerve impulses related to balance. A vestibular neurectomy is a procedure where this nerve is cut so the distorted impulses causing dizziness no longer reach the brain. This procedure permanently cures the majority of patients and hearing is preserved in most cases. There is a slight risk that hearing or facial muscle control will be affected.

A labyrinthectomy is a surgical procedure in which the balance and hearing mechanism in the inner ear are destroyed on one side. This procedure is considered when the patient has poor hearing in the affected ear. Labyrinthectomy results in the highest rates of control of vertigo attacks, however, it also causes complete deafness in the affected ear.

Expected results

Ménière's disease is a complex and unpredictable condition for which there is no cure. The vertigo associated with the disease can generally be managed or eliminated with medications and surgery. Hearing tends to become worse over time, and some of the surgical procedures recommended, in fact, cause deafness.

Prevention

Because the cause of Ménière's disease is not definitely known as of 2002, there are no proven strategies for its prevention. **Stress** reduction and **relaxation** may

prevent attacks of Ménière's disease. Wearing earplugs while exposed to loud sounds will help to prevent hearing damage and worsening of tinnitus.

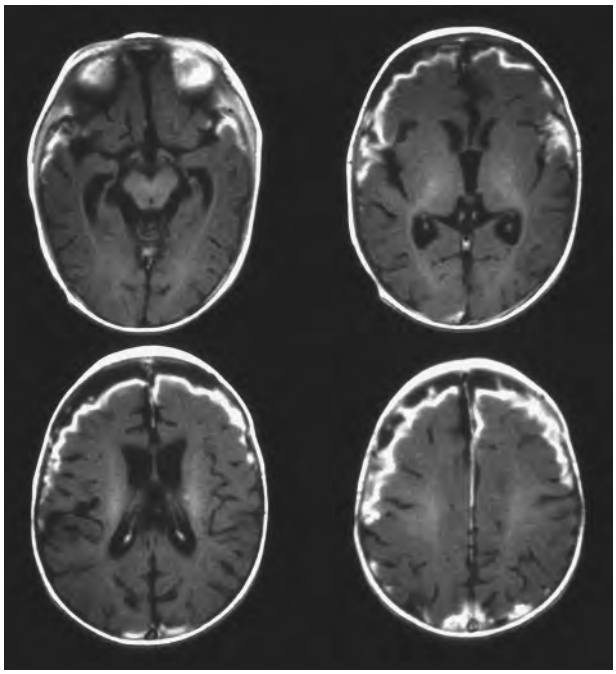
Meningitis

Definition

Meningitis is a potentially fatal inflammation of the meninges, the thin, membranous covering of the brain and the spinal cord. Meningitis is most commonly caused by infection by bacteria, viruses, or



This composite of four contrast-enhanced MRI images shows H. Influenza meningitis. *(Living Art Enterprises, LLC / Photo Researchers, Inc.)*

fungi, although it can also be caused by bleeding into the meninges, **cancer**, diseases of the immune system, and an inflammatory response to certain types of chemotherapy or other chemical agents. The most serious and the most difficult to treat types of meningitis tend to be those caused by bacteria.

Description

Meningitis is a particularly dangerous infection because of the very delicate nature of the brain. Brain cells are some of the only cells in the body that, once killed, will not regenerate themselves. Therefore, if enough brain tissue is damaged by an infection, then serious lifelong handicaps will remain.

In order to learn about meningitis, it is important to have a basic understanding of the anatomy of the brain. The meninges are three separate membranes, layered together, which encase the brain and spinal cord:

- The dura is the toughest, outermost layer, and is closely attached to the inside of the skull.
- The middle layer, the arachnoid, is important because of its involvement in the normal flow of the cerebrospinal fluid (CSF), a lubricating and nutritive fluid that bathes both the brain and the spinal cord.
- The innermost layer, the pia, helps direct blood vessels into the brain.
- The space between the arachnoid and the pia contains CSF, which helps insulate the brain from trauma. Many blood vessels, as well as peripheral and cranial nerves course through this space.

CSF, produced within specialized chambers deep inside the brain, flows over the surface of the brain and spinal cord. This fluid serves to cushion these relatively delicate structures, as well as supplying important nutrients for brain cells. CSF is reabsorbed by blood vessels located within the meninges. A careful balance between CSF production and reabsorption is important to avoid the accumulation of too much CSF.

Because the brain is enclosed in the hard, bony case of the skull, any disease that produces swelling will be damaging to the brain. The skull cannot expand at all, so when the swollen brain tissue pushes up against the skull's hard bone, the brain tissue becomes damaged and the blood supply is compromised, and this tissue may ultimately die. Furthermore, swelling on the right

KEY TERMS

Blood-brain barrier—An arrangement of cells within the blood vessels of the brain that prevents the passage of toxic substances, including infectious agents, from the blood and into the brain. It also makes it difficult for certain medications to pass into brain tissue.

Cerebrospinal fluid (CSF)—Fluid made in chambers within the brain which then flows over the surface of the brain and spinal cord. CSF provides nutrition to cells of the nervous system, as well as providing a cushion for the nervous system structures. It may accumulate abnormally in some disease processes, causing pressure on and damage to brain structures.

Fluouroquinolones—A group of medications used to treat bacterial infections in many different parts of the body. They are often used to treat bacteria that have become resistant to penicillin and other antibiotics.

Lumbar puncture (LP)—A medical test in which a very narrow needle is inserted into a specific space between the vertebrae of the lower back in order to draw a sample of CSF for further examination. Also referred to as a spinal tap.

Meninges—The three-layer membranous covering of the brain and spinal cord, composed of the dura, arachnoid, and pia. It provides protection for the brain and spinal cord, as well as housing many blood vessels and participating in the appropriate flow of CSF.

side of the brain will not only cause pressure and damage to that side of the brain, but by taking up precious space within the tight confines of the skull, the left side of the brain will also be pushed up against the hard surface of the skull, causing damage to the left side of the brain, as well.

Another way that **infections** injure the brain involves the way in which the chemical environment of the brain changes in response to the presence of an infection. The cells of the brain require a very well-regulated environment. Careful balance of oxygen, carbon dioxide, sugar (glucose), **sodium**, **calcium**, **potassium**, and other substances must be maintained in order to avoid damage to brain tissue. An infection upsets this balance, and brain damage can occur when the cells of the brain are either deprived of important nutrients or exposed to toxic levels of particular substances.

The cells lining the brain's tiny blood vessels (capillaries) are specifically designed to prevent many substances from passing into brain tissue. This is commonly referred to as the blood-brain barrier. The blood-brain barrier prevents various substances that could be poisonous to brain tissue (toxins), as well as many agents of infection, from crossing from the blood stream into the brain tissue. While this barrier is obviously an important protective feature for the brain, it also serves to complicate treatment in the case of an infection by making it difficult for medications to pass out of the blood and into the brain tissue where the infection is located.

Causes and symptoms

The most common infectious causes of meningitis vary according to an individual's age, habits, living environment, and health status. While nonbacterial types of meningitis are more common, bacterial meningitis is more potentially life-threatening. Three bacterial agents are responsible for about 80% of all bacterial meningitis cases. These bacteria are *Haemophilus influenzae* type b, *Neisseria meningitidis* (causing meningococcal meningitis), and *Streptococcus pneumoniae* (causing pneumococcal meningitis).

In newborns, the most common agents of meningitis are those that are contracted from the newborn's mother, including Group B streptococci (becoming an increasingly common infecting organism in the newborn period), *Escherichia coli*, and *Listeria monocytogenes*. The highest incidence of meningitis occurs in babies under a month old, with an increased risk of meningitis continuing through about two years of age.

Older children are more frequently infected by bacteria, including *Haemophilus influenzae*, *Neisseria meningitidis*, and *Streptococcus pneumoniae*.

Adults are most commonly infected by either *S. pneumoniae* or *N. meningitidis*, with pneumococcal meningitis the more common. Certain conditions predispose to this type of meningitis, including **alcoholism** and chronic upper respiratory tract infections (especially of the middle ear, sinuses, and mastoids).

N. meningitidis is the only organism that can cause epidemics of meningitis. For instance, cases have been reported when a child in a crowded day care situation or a military recruit in a crowded training camp has fallen ill with meningococcal meningitis.

There have been case reports in recent years of meningitis caused by *Streptococcus bovis*, an organism that is ordinarily found in the digestive tract of such animals as cows and sheep; and *Pasteurella multocida*, an organism that usually infects rabbits. Other atypical

cases of meningitis include several caused by the anthrax bacillus. These cases have a high mortality rate.

Viral causes of meningitis include the herpes simplex virus, the **mumps** and **measles** viruses (against which most children are protected due to mass immunization programs), the virus that causes **chickenpox**, the **rabies** virus, and a number of viruses that are acquired through the **bites** of infected mosquitoes.

A number of medical conditions predispose individuals to meningitis caused by specific organisms. Patients with **AIDS** (acquired immunodeficiency syndrome) are more prone to getting meningitis from fungi, as well as from the agent that causes **tuberculosis**. Patients who have had their spleens removed, or whose spleens are no longer functional (as in the case of patients with sickle cell disease) are more susceptible to other infections, including meningococcal and pneumococcal meningitis.

The majority of meningitis infections are acquired by transmission through the blood. A person may have another type of infection (for instance, infection of the lungs, throat, or tissues of the heart) caused by an organism that can also cause meningitis. If this initial infection is not properly treated, the organism will continue to multiply, find its way into the blood stream, and be delivered in sufficient quantities to invade past the blood-brain barrier. Direct spread occurs when an organism spreads to the meninges from infected tissue next to or very near the meninges. This can occur, for example, with a severe, poorly treated ear or **sinus infection**.

Patients who suffer from skull **fractures** possess abnormal openings to the sinuses, nasal passages, and middle ears. Organisms that usually live in the human respiratory system without causing disease can pass through openings caused by such fractures, reach the meninges, and cause infection. Similarly, patients who undergo surgical procedures or who have had foreign bodies surgically placed within their skulls (such as tubes to drain abnormal amounts of accumulated CSF) have an increased risk of meningitis.

Organisms can also reach the meninges via an uncommon but interesting method called intraneural spread. This involves an organism invading the body at a considerable distance away from the head, spreading along a nerve, and using that nerve as a sort of ladder into the skull, where the organism can multiply and cause meningitis. Herpes simplex virus is known to use this type of spread, as is the rabies virus.

The classic symptoms of meningitis (particularly of bacterial meningitis) include **fever**, **headache**, **vomiting**, sensitivity to light (photophobia), irritability, severe **fatigue** (lethargy), stiff neck, and a reddish purple rash on the skin. Untreated, the disease progresses with seizures, confusion, and eventually coma.

A very young infant may not show the classic signs of meningitis. Early in infancy, a baby's immune system is not yet developed enough to mount a fever in response to infection, so fever may be absent. However, checking an infant's temperature to see if it is high or low could be an indication. Some infants with meningitis have seizures as their only identifiable symptom. Similarly, debilitated elderly patients may not have fever or other identifiable symptoms of meningitis.

Damage due to meningitis occurs from a variety of phenomena. The action of infectious agents on the brain tissue is one direct cause of damage. Other types of damage may be due to the mechanical effects of swelling and compression of brain tissue against the bony surface of the skull. Swelling of the meninges may interfere with the normal absorption of CSF by blood vessels, causing accumulation of CSF and damage from the resulting pressure on the brain. Interference with the brain's carefully regulated chemical environment may cause damaging amounts of normally present substances (carbon dioxide, potassium) to accumulate. Inflammation may cause the blood-brain barrier to become less effective at preventing the passage of toxic substances into brain tissue.

Diagnosis

A number of techniques are used when examining a patient suspected of having meningitis to verify the diagnosis. Certain manipulations of the head (lowering the head, chin towards chest, for example) are difficult to perform and painful for a patient with meningitis.

The most important test used to diagnose meningitis is the lumbar puncture (LP), commonly called a spinal tap. Lumbar puncture involves the insertion of a thin needle into a space between the vertebrae in the lower back and the withdrawal of a small amount of CSF. The CSF is then examined under a microscope to look for bacteria or fungi. Normal CSF contains set percentages of glucose and protein. These percentages will vary with bacterial, viral, or other causes of meningitis. For example, bacterial meningitis causes a smaller than normal percentage of glucose to be present in CSF, as the bacteria are essentially "eating" the host's glucose, and using it for their own **nutrition** and energy production. Normal CSF should contain no infection-fighting cells (white blood cells), so the presence of white blood cells in CSF is another

indication of meningitis. Some of the withdrawn CSF is also put into special lab dishes to allow growth of the suspected infecting organism, which can then be identified more easily. Special immunologic and serologic tests may also be used to help identify the infectious agent.

In rare instances, CSF from a lumbar puncture cannot be examined because the amount of swelling within the skull is so great that the pressure within the skull (intracranial pressure) is extremely high. This pressure is always measured immediately upon insertion of the LP needle. If it is found to be very high, no fluid is withdrawn because doing so could cause herniation of the brain stem. Herniation of the brain stem occurs when the part of the brain connecting to the spinal cord is thrust through the opening at the base of the skull into the spinal canal. Such herniation will cause compression of those structures within the brain stem that control the most vital functions of the body (breathing, heart beat, consciousness). Death or permanent debilitation follows herniation of the brain stem.

Treatment

Because meningitis is a potentially deadly condition, doctors should be contacted immediately for diagnosis and treatment. Alternative treatments should be used only to support the recovery process following appropriate antibiotic treatments, or used concurrently with antibiotic treatments.

General recommendations

Patients should be well rested in bed, preferably in a darkened room. They should be given lots of fluids and nutritious foods. Patients should avoid processed foods and those with high fat and sugar content. Fats are difficult to digest in severely ill patients; sugar tends to depress the immune system and impede recovery process. Patients should also take **vitamin A** (up to 10,000 IU per day), B-complex vitamins (up to 1,500 mg per day), and **vitamin C** (up to 2 g per day) to help keep the body strong and prevent future infections. Additionally, the patient may consider taking other **antioxidants**, **essential fatty acids** (EFAs), and/or participate in therapies, such as **massage therapy** and movement therapies (e.g., **t'ai chi**).

Other treatments

Alternative therapies, such as **homeopathy**, **traditional Chinese medicine**, and Western herbal medicine may help patients regain their health and build up their immune systems. The recovering individual, under the direction of a professional alternative therapist, may opt to include mushrooms into his or her diet to stimulate immune function. Contact an experienced herbalist or homeopathic practitioner for specific remedies.

Allopathic treatment

Antibiotics are the first line of treatment for bacterial meningitis. In recent years, however, doctors have turned to such newer medications as vancomycin or the fluoroquinolones to treat bacterial meningitis because strains of *S. pneumoniae* and *N. meningitidis* have emerged that are resistant to penicillin and the older antibiotics. Because of the effectiveness of the blood-brain barrier in preventing the passage of substances into the brain, medications must be delivered directly into the patient's veins (intravenously) at very high doses. Antiviral drugs (acyclovir) may be helpful in shortening the course of viral meningitis, and antifungal medications are available as well. Patients who develop seizures will require medications to halt the seizures and prevent their return.

Expected results

Viral meningitis is the least severe type of meningitis, and patients usually recover with no long-term effects from the infection. Bacterial infections, however, are much more severe, and progress rapidly. Without very rapid treatment with the appropriate antibiotic, the infection can swiftly lead to coma and death in less than a day's time. While death rates from meningitis vary depending on the specific infecting organism, the overall death rate is just under 20%.

The most frequent long-term effects of meningitis include deafness and blindness, which may be caused by the compression of specific nerves and brain areas responsible for the senses of hearing and sight. Some patients develop permanent seizure disorders, requiring lifelong treatment with antiseizure medications. Scarring of the meninges may result in obstruction of the normal flow of CSF, causing abnormal accumulation of CSF. This may be a chronic problem for some patients, requiring the installation of shunt tubes to drain the accumulation regularly.

Some cases of sudden and unexplained death in adults have been attributed to rapidly developing meningitis.

Prevention

Prevention of meningitis primarily involves the appropriate treatment of other infections an individual may acquire, particularly those that have a track record of seeding to the meninges (such as ear and sinus infections). Preventive treatment with antibiotics

is sometimes recommended for the close contacts of an individual who is ill with meningococcal or *H. influenzae* type b meningitis. A meningococcal vaccine exists, and is sometimes recommended to individuals who are traveling to very high risk areas. A vaccine for *H. influenzae* type b is now given to babies as part of the standard array of childhood immunizations.

Menopause

Definition

Menopause represents the irreversible end of ovulation and **menstruation**. Technically menopause refers to the final menstrual period after which a woman can no longer conceive children. Nevertheless, menopause is not an abrupt event, but a gradual process that involves many physical and hormonal changes before fertility ceases. Menopause is not a disease that needs to be treated, but a natural result of **aging**. However, the changes that occur during the time surrounding menopause can cause symptoms of widely varying severity that a women may wish to treat. Women have many options for managing these symptoms.

Description

Perimenopause is the time surrounding menopause. It can last for several years, and many women have irregular periods and other changes during this time. Although it is not easy to pinpoint when menopause begins, doctors agree that it is complete when a woman has not had a menstrual period for a full year.

There is no method to determine when the ovaries will begin to scale back, but a woman can get a general idea of when she will experience menopause based on her family history, body type, and lifestyle. A woman is likely to enter menopause at about the same age as her mother and sisters. Women who are smokers are more likely to begin menopause earlier than non-smokers. Women who began menstruating early will not necessarily stop having periods early. Eight out of every 100 women stop menstruating before age 40. At the other end of the spectrum, five out of every 100

Signs and symptoms of menopause

- Changes in periods (they may be shorter or longer, heavier or lighter, or have more or less time in between)
- Hot flashes
- Night sweats
- Trouble sleeping through the night
- Vaginal dryness
- Mood changes
- Hair loss or thinning on the head, more hair growth on the face

Although menopause itself is the time of a woman's last period, symptoms can begin several years before that in a stage called peri-menopause. Menopause and peri-menopause affect every woman differently. *(Illustration by GGS Information Services. Cengage Learning, Gale)*

continue to have periods until they are almost 60. The average age of menopause is 51.

Causes and symptoms

Once a woman enters puberty, her body releases one of the more than 400,000 eggs (ova) that are stored in her ovaries, about every 28 days in response to the interaction of several hormones. Blood supply to the womb (uterus) increases, and the lining of the uterus thickens in anticipation of receiving a fertilized egg. If the egg is not fertilized, the level of progesterone, the hormone mainly responsible for this uterine thickening, drops, and the uterine lining is sloughed off along with some blood. This menstrual flow is visible evidence ovulation has occurred.

By the time a woman reaches her late 30s or 40s, her ovaries begin to produce less of the female hormones estrogen and progesterone and to release eggs less regularly. As the levels of hormones fluctuate, the menstrual cycle begins to change. Some women may have longer periods with heavy flow followed by shorter cycles and very little bleeding. Others will begin to miss periods entirely. These irregular menstrual cycles make it more difficult for a woman to become pregnant. The gradual decline of estrogen also causes a wide variety of changes in tissues that respond to estrogen including the vagina, vulva, uterus, bladder, urethra, breasts, bones, heart, blood vessels, brain, skin, hair, and mucous membranes. Less immediately, the long-term lack of estrogen can make a woman more vulnerable to **osteoporosis**.

The most common symptom of perimenopause include:

- changes in the menstrual cycle
- hot flashes
- night sweats
- insomnia
- mood swings and increased irritability
- memory or concentration problems
- vaginal dryness
- heavy bleeding
- fatigue
- depression
- changes in the thickness and texture of hair
- headaches
- heart palpitations
- sexual disinterest
- urinary changes
- weight gain

Diagnosis

The clearest indication of menopause is the absence of a period for one full year. If it has been at least three months since a woman's last period, a follicle-stimulating hormone (FSH) test might be helpful in determining whether menopause has occurred. FSH levels rise steadily as a woman ages. The FSH test alone cannot be used as proof that a woman has entered early menopause. A better measure of menopause is to determine the levels of FSH, estrogen, progesterone, testosterone, and related hormones at mid-cycle. These tests are not routinely performed as most women can recognize the symptoms of perimenopause and menopause. They can, however, be helpful diagnostic tests in younger women who are showing symptoms of perimenopause.

Treatment

Decisions about if and how to treat symptoms associated with perimenopause should be made by a woman and her health care provider after taking into consideration her medical history and current research findings. Some women report success in using natural remedies to treat the unpleasant symptoms of menopause, although alternative therapies have only received significant attention in the United States in the last decade or so. Debate continues until scientific studies can prove these treatments' effectiveness on menopausal symptoms.

For women nearing menopause, alternative medical practitioners and traditional healthcare professionals generally recommend a diet high in fresh fruits, fresh vegetables, whole grains, nuts, seeds, and fresh vegetable juices and low in sugary treats and fats, especially animal fats. Calorie and portion control becomes more important as metabolism slows. Because a decrease in estrogen accelerates bone loss, women should make sure they get enough **calcium**. Most often a calcium supplement is recommended in addition to dairy products that provide calcium. Women generally need less **iron** after menopause because they no longer bleed monthly.

Herbs

Herbs have been used to relieve menopausal symptoms for centuries. In reasonable quantities, many herbs are relatively safe. Often adverse reactions to herbs come not from the herbs themselves, but from contaminants. Because the United States Food and Drug Administration (FDA) does not regulate herbal products as strictly as pharmaceutical medicines, contamination, mislabeling, or accidental overdose is

possible. Herbs should be purchased from a recognized company or through a qualified herbal practitioner. Herbal practitioners recommend a dose based on a woman's history, body size, lifestyle, diet, and reported symptoms. Women who choose to take herbs for menopausal symptoms should learn as much as possible about herbs and work with a qualified practitioner such as an herbalist, a traditional Chinese doctor, or a naturopathic physician.

The following list of herbs include those that herbalists recommend to treat menopausal symptoms:

- black cohosh (*Cimicifuga racemosa*): >): hot flashes and other menstrual complaints
- black currant (*Ribes migrum*): breast tenderness
- chaste tree/chasteberry (*Vitex agnus-castus*): hot flashes, excessive menstrual bleeding, moodiness
- chickweed (*Stellaria media*): hot flashes
- evening primrose oil (*Oenothera biennis*): mood swings, irritability, breast tenderness
- fennel (*Foeniculum vulgare*): hot flashes, digestive gas, bloating
- flaxseed (*Linum usitatissimum*): excessive menstrual bleeding, breast tenderness, and other symptoms, including dry skin and vaginal dryness
- ginkgo (*Ginkgo biloba*): memory problems
- ginseng (*Panax ginseng*): hot flashes, fatigue, vaginal thinning
- hawthorn (*Crataegus laevigata*): memory problems, fuzzy thinking
- horsetail (*Equisetum arvense*): osteoporosis
- lady's mantle (*Alchemilla vulgaris*): excessive menstrual bleeding
- Licorice (*Glycyrrhiza glabra*) root: general menopausal symptoms
- Mexican wild yam (*Dioscorea villosa*) root: vaginal dryness, hot flashes, general menopause symptoms
- motherwort (*Leonurus cardiaca*): night sweats, hot flashes
- oat straw (*Avena sativa*): mood swings, anxiety
- passionflower (*Passiflora incarnata*): insomnia, pain
- raspberry leaf (*Rubus idaeus*): normalizes hormonal system
- sage (*Salvia officinalis*): mood swings, headaches, night sweats
- skullcap (*Scutellaria lateriflora*): insomnia
- sesame oil (*Sesamum orientale*): vaginal dryness (applied topically)
- valerian (*Valeriana officinalis*): insomnia
- violet (*Viola odorata*): hot flashes.

Natural estrogens (phytoestrogens)

Phytoestrogens are estrogen compounds found in plants. Proponents of plant estrogens (including soy products) believe that plant estrogens are better than synthetic estrogens, but science has not yet proved this. The results of small preliminary trials suggest that the estrogen compounds in soy products (soy is very high in plant estrogens) can relieve the severity of **hot flashes** and lower **cholesterol**. In one study at Bowman-Gray Medical School in North Carolina, women were able to ease their menopausal symptoms such as hot flashes by eating a large amount of fruits, vegetables, and whole grains, together with 4 oz of tofu four times a week. However, no one has shown that plant estrogens can provide these benefits without causing the same negative side effects as estrogen replacement therapy. In addition, it is difficult to judge how much estrogen is in various plant products as there is no requirement for standardization. Many women believe that natural or plant-based means harmless. In large doses, phytoestrogens can promote the abnormal growth of cells in the uterine lining. Unopposed estrogen of any type can lead to an increased risk of **cancer**.

Several studies have shown that a **black cohosh** extract (Remifemin) relieved menopausal symptoms as well as or better than estrogen and that it showed the greatest promise among alternative treatments. In a 2007 study conducted at the University of Pennsylvania and published in *International Journal of Cancer*, Remifemin was also shown to reduce the risk of **breast cancer**. The United States Office of Dietary Supplements considers the evidence from studies of black cohosh promising but cautions that the long-term safety of this herb has not been established and recommends that if women choose to use black cohosh extract, they do so for no more than six months.

Flaxseeds also are a good source of phytoestrogens. Other sources include **red clover** leaf, **licorice**, wild yam, chickpeas, pinto beans, lima beans, and pomegranates. In 2003, red clover leaf was thought to offer relief for hot flashes, but in two short clinical trials, it failed to demonstrate hot flash relief.

Homeopathy

Women interested in homeopathic remedies for menopausal symptoms should consult a homeopathic physician. The following homeopathic remedies are often recommended to alleviate specific groups of symptoms:

- lachesis: hot flashes, irritability, talkativeness, tightness around abdomen, dizziness, fainting

- sepia: bleeding between periods, chilliness, tearfulness, withdrawal from loved ones, sinking feeling in stomach
- pulsatilla: tearfulness, thirstless, feels better with others, avoids heat, hot flashes, varicose veins, hemorrhoids
- sulfur: philosophical personality, feeling hot, itching and burning of vagina and rectum
- lycopodium: low self esteem, bloated after eating, infrequent menstruation, low blood sugar, weak digestion, belching
- *Argentum nitricum:* gas, indigestion, craving for sweets and chocolate, panic attacks, fear of crossing bridges
- Magnesium phosphoricum: severe cramping
- transitional formula: hot flashes, night sweats, insomnia, skin-crawling sensation
- women's formula: perimenopause, PMS, irregular cycles, infertility, absent or excessive bleeding, menopausal discomfort
- vital formula: anxiety, headaches, palpitations, PMS, mood swings

Yoga

Many women find that **yoga** can ease menopausal symptoms. Yoga focuses on helping women unite the mind, body, and spirit to create balance. Because yoga has been shown to balance the endocrine system, some experts believe it may affect hormone-related problems. Studies have found that yoga can reduce **stress**, improve mood, boost a sluggish metabolism, and slow the heart rate. Specific yoga positions deal with particular problems, such as hot flashes, mood swings, vaginal and urinary problems, and other pains.

Exercise

Exercise helps ease hot flashes by lowering the amount of circulating FSH and by raising endorphin levels (which drop during a hot flash). Even exercising 20 minutes three times a week can significantly reduce hot flashes. Weight bearing exercises help to prevent osteoporosis. Regular exercise also provides many health benefits unrelated to menopause.

Acupuncture

This ancient Asian art involves placing very thin needles into different parts of the body to stimulate the system and unblock energy. It is usually painless and has been used for many menopausal symptoms including **insomnia**, hot flashes, and irregular periods. Practitioners believe that **acupuncture** can facilitate the opening of blocked energy channels, allowing the life force energy (chi) to flow freely. This allows the menopausal woman to keep her energy moving. Blocked energy usually increases the symptoms of menopause.

Acupressure and massage

Therapeutic massage involving **acupressure** can bring relief from a wide range of menopause symptoms by placing finger pressure at the same meridian points on the body that are used in acupuncture. There are more than 80 different types of massage, including foot **reflexology**, **Shiatsu** massage, and **Swedish massage**, but they all are based on the idea that boosting the circulation of blood and lymph benefits health. Breast massage (rubbing **castor oil** or olive oil on the breasts for five minutes three times a week) is claimed to help balance hormone levels, help the uterus contract during menstruation, and prevents cramping pains.

Biofeedback

Some women have been able to control hot flashes through **biofeedback**, a painless technique that helps a person train her mind to control her body. A biofeedback machine provides information about body processes (such as heart rate) as the woman relaxes her body. Using this technique, it is possible to control the body's temperature, heart rate, and breathing.

Other treatments

Therapeutic touch, an energy-based practice, may relieve menopausal symptoms. Cold compresses on the face and neck can ease hot flashes. Sound or **music therapy** may relieve stress and other menopausal symptoms. **Prayer** or **meditation** can help improve coping ability.

Dietary supplements

Women should discuss the use of dietary supplements with their health care provider. Some supplements interfere with the action of traditional pharmaceuticals and herbal remedies. Other supplements are harmful in large quantities. Supplementation with calcium, **vitamin D**, **vitamin K**, **boron**, **manganese**, **magnesium**, and phosphorous may aid in preventing osteoporosis. **Vitamin E** supplementation may reduce hot flashes and risk of **heart disease**.

Allopathic treatment

When a woman enters menopause, her levels of estrogen drop and symptoms, such as hot flashes and vaginal dryness, begin. Before 2002, many physicians treated these symptoms with hormone replacement

therapy (HRT). HRT treats these symptoms by increasing estrogen and progesterone levels enough to suppress symptoms. However, in the summer of 2002, preliminary results from a large Women's Health Initiative study were released that showed HRT could have significantly harmful effects (harmful enough that the study was stopped early). The study found that a combination of estrogen and progestin (a form of progesterone) HRT caused the following when compared to a placebo (no hormones):

- increased risk of heart attack, stroke, and blood clots
- increased risk of invasive breast cancer
- increased risk of dementia
- decreased risk of colorectal cancer
- decreased risk of bone fractures

Treatment with estrogen alone produced the following results:

- no change in the risk of heart attacks
- increased risk of stroke and blood clots
- unclear changes in the risk of breast cancer
- no change in the risk of colorectal cancer
- decreased risk of bone fractures
- no data available on changes in risk of dementia

At the time the results of the Women's Health Initiative became available, about 9 million American women were using HRT. Most physicians now no longer routinely recommend HRT to treat menopausal symptoms. Nevertheless, under certain circumstances when symptoms associated with menopause are so severe as to interfere with activities of daily life, a short course of HRT may be prescribed. Some doctors believe that short-term use of estrogen for those women with severe symptoms of hot flashes or night sweats is a sensible choice as long as they do not have a history of breast cancer. However, other doctors believe that in almost all cases the risks of HRT outweigh the benefits. The decision should be made by a woman and her doctor after taking into consideration her medical history and situation. Women who choose to take hormones should have an annual mammogram, breast exam, and pelvic exam and should report any unusual vaginal bleeding or spotting (a sign of possible **uterine cancer**).

Postmenopausal treatment for osteoporosis

Raloxifene (Evista, Keoxifene) is a drug that is used to treat osteoporosis (bone loss) in postmenopausal women. It does not increase the risk breast cancer, although it may increase breast tenderness. It may also worsen hot flashes and cause uterine bleeding. It is not a treatment for symptoms associated with

KEY TERMS

Endometrium—The lining of the uterus that is shed with each menstrual period.

Estrogen—Female hormone produced by the ovaries and released by the follicles as they mature. Responsible for female sexual characteristics, estrogen stimulates and triggers a response from at least 300 tissues, and may help some types of breast cancer to grow. After menopause, the production of the hormone gradually stops.

Follicle-stimulating hormone (FSH)—The pituitary hormone that stimulates the ovary to mature egg capsules (follicles). It is linked with rising estrogen production throughout the cycle. An elevated FSH (above 40) indicates menopause.

Hormone—A chemical messenger secreted by a gland that is released into the blood, and that travels to distant cells where it exerts an effect.

Hormone replacement therapy (HRT)—The use of estrogen and progesterone to replace hormones that the ovary no longer supplies. HRT is no longer used as long-term therapy for postmenopausal women.

Hot flash—A wave of heat that is one of the most common perimenopausal symptoms, triggered by the hypothalamus' response to estrogen withdrawal.

Hysterectomy—Surgical removal of the uterus.

Ovary—One of the two almond-shaped glands in the female reproductive system responsible for producing eggs and the hormones estrogen and progesterone.

Phytoestrogen—An estrogen-like substance produced by plants.

Placebo—a pill or liquid given during the study of a drug or dietary supplement that contains no medication or active ingredient. Usually study participants do not know if they are receiving a pill containing the drug or an identical-appearing placebo.

Progesterone—The hormone that is produced by the ovary after ovulation to prepare the uterine lining for a fertilized egg.

Testosterone—Male hormone produced by the testes and (in small amounts) in the ovaries. Testosterone is responsible for some masculine secondary sex characteristics such as growth of body hair and deepening voice.

Uterus—The female reproductive organ that contains and nourishes a fetus from implantation until birth. Also known as the womb.

menopause. Several other drugs are also available to help reduce the risk of **fractures** in postmenopausal women with osteoporosis. In 2002, the FDA approved teriparatide (Forteo) for the treatment of osteoporosis. Ibandronate (Boniva) and alendronate (Fosamax) are also used to treat osteoporosis in postmenopausal women.

Testosterone replacement

The ovaries also produce a small amount of male hormones (about 300 micrograms), which decrease slightly as a woman enters menopause. Most women never need testosterone replacement. Testosterone can improve the libido, and decrease **anxiety** and **depression**. Adding testosterone is especially beneficial to women who have had hysterectomies. Testosterone also eases breast tenderness and helps prevent bone loss. Side effects include mild **acne** and some facial hair growth.

Expected results

Menopause is a natural condition of aging. Some women have no problems with menopause, while others notice significant unpleasant symptoms. Results of allopathic and alternative treatments vary from one woman to another.

Prevention

Menopause cannot be prevented, although some of the symptoms can be relieved by the treatments listed above.

Menstrual cramps *see* **Dysmenorrhea**

Menstruation

Definition

Menstruation is the monthly discharge through the vagina of the blood and tissues that are laid down in the uterus in preparation for **pregnancy**.

Description

The cyclic production of hormones that culminates in the release of a mature egg (ovum) is called the menstrual cycle, which begins during puberty and ends at **menopause**. The first menstrual cycle is called menarche. Hormones that control the menstrual cycle are produced by the hypothalamus, pituitary gland, and ovaries. The beginning of a menstrual cycle is marked by the maturation of an egg in an ovary and preparation of the uterus (womb) to establish

pregnancy. Menstruation occurs when pregnancy has not been achieved.

The menstrual cycle is divided into four phases and is, on average, 28 days long (21–45 days). The onset of menstruation, called a period, monthly, menses, or menstrual period, begins a new menstrual cycle and is considered day one. This first phase usually lasts five days. Menstruation occurs in response to drops in the level of the hormone progesterone. It is estimated that a woman has 500 menstrual periods in her lifetime.

The second phase of the menstrual cycle is called the follicular or proliferative phase. The ovary, in response to increasing levels of follicle stimulating hormone, begins the egg maturation process. Although 10–20 eggs begin to develop within follicles of the ovaries, usually only one egg reaches maturity. Follicles are clusters of cells that encase a developing egg, hence the name "follicular phase." Developing follicles release the hormone estrogen that stimulates the lining of the uterus, called the endometrium, to grow (proliferate) in preparation to receive an embryo (an egg that has been fertilized and begun dividing) and establish pregnancy. This phase usually lasts through day 13.

The ovulation phase occurs in response to a surge in luteinizing hormone and is marked by the release of a mature egg from the follicle. Ovulation usually occurs on day 14.

The fourth phase is called the luteal, secretory, premenstrual, or postovulatory phase, and usually lasts from days 15–28. During this phase, the empty follicle, now called the corpus luteum, releases the hormone progesterone which further prepares the uterus for implantation of an embryo. The endometrium thickens because of cell growth, changes in blood vessels and glands, and increases in fluid. If pregnancy does not occur, the fall in progesterone levels initiates the onset of a new menstrual cycle. However, if pregnancy does occur, progesterone levels remain high, and the endometrium is not shed.

In the United States, menstruation typically begins at 12.8 years of age in Caucasian girls and 12.4 years of age for African American girls. Factors that help to dictate the age at which menarche occurs include race, mother's age at menarche, nutritional status, body fat, as well as climate and elevation. Studies have shown that a body fat level of 17% is necessary for menstruation to begin.

Women who live together or work in close proximity tend to find that their cycles begin to coincide. During the menstrual cycle, the body releases hormones called pheromones, which may signal surrounding women's cycles to begin.

Puberty signals the maturation of a young woman's reproductive hormones. As a girl reaches puberty, the pituitary gland in the brain starts to produce the hormones that signal the ovaries to begin functioning. The interaction between these hormones and the hormones estrogen and progesterone causes the lining of the uterus to swell and thicken in anticipation of a fertilized egg. If the egg is not fertilized, the lining is discharged through the vagina, resulting in menstrual bleeding.

Menstrual problems

Women may experience menstrual cycles that fall outside the norm as described above. Menstrual problems include missing a period; change in the length of the cycle; changes in the flow, color, or consistency of menstrual blood; and extreme **pain** or other menstrual symptoms.

Women may also experience emotional distress or wide mood swings during the luteal phase of the menstrual cycle. The fourth edition of the *Diagnostic and Statistical Manual of Mental Disorders*, or DSM-IV, lists premenstrual dysphoric disorder (PMDD) in an appendix of criteria sets for further study. To meet full criteria for PMDD, a patient must have at least five out of 11 emotional or physical symptoms during the week preceding the menses for most menstrual cycles over the previous 12 months. Although the DSM-IV definition of PMDD as a mental disorder is controversial because of fear that it could be used to justify prejudice or job discrimination against women, there is evidence that a significant proportion of premenopausal women suffer emotional distress or impairment in job functioning in the week before their menstrual period. One group of researchers estimates that 3–8% of women of childbearing age meet the strict DSM-IV criteria for PMDD, with another 13–18% having symptoms severe enough to interfere with their normal activities.

Causes and symptoms

Menstruation is not an illness, but a normal part of the menstrual cycle. However, menstrual problems do occur, and are due to varying causes.

Amenorrhea

Amenorrhea, the absence of menstruation, can be either primary or secondary. Primary amenorrhea is failure to menstruate by age 16 years in girls who have normal puberty or two years after sexual maturation

has occurred. Primary amenorrhea may be caused by genetic disorders, hormonal imbalance, brain defects, or physical abnormality of the reproductive organs. In 2003, a group of researchers reported on a new genetic mutation associated with primary amenorrhea. In addition, certain systemic diseases may delay puberty and menstruation. Delayed menstruation may occur in athletes, especially gymnasts, ballerinas, and long-distance runners because of insufficient body fat. Amenorrhea associated with athletic training and professional dance is a growing health concern, however, because it often occurs together with eating disorders and a loss of bone mass that can lead to early **osteoporosis**.

Secondary amenorrhea refers to the absence of menstruation after an interval of normal menstruation. It is identified as not menstruating for three months in females with irregular menstrual cycles, six months in females with normal menstrual cycles, and 18 months in females who had just started menstruating. Secondary amenorrhea can be caused by pregnancy, weight loss, excessive **exercise**, breast feeding, disease, or menopause. Menopause takes place when the ovaries stop producing estrogen, causing periods to become irregular and then stop. It generally occurs when a woman is between 48 and 52 years of age.

Dysfunctional and abnormal uterine bleeding

Dysfunctional uterine bleeding is excessive or irregular bleeding from the uterus. It is caused by uncontrolled estrogen production that leads to excessive build up of the endometrium.

Abnormal uterine bleeding is excessive bleeding during menstruation, frequent bleeding, and/or irregular bleeding. Abnormal bleeding can be caused by fibroids (noncancerous uterine growths), **endometriosis** (when endometrium spreads outside of the uterus), uterine **infections**, **hypothyroidism**, clotting problems, intrauterine devices (IUD), or **cancer**.

Dysmenorrhea

Dysmenorrhea is painful and difficult menstruation. Studies have found that 60–92% of adolescents suffer from dysmenorrhea. It usually begins six to 12 months following menarche. Symptoms may be severe enough to cause missed work or school and prevent participation in normal activities. Risk factors for developing dysmenorrhea may include long menstrual periods, **obesity**, early age at menarche, **smoking**, and alcohol use.

Primary dysmenorrhea is believed to be caused by high levels of prostaglandins (fatty acids that stimulate muscle contractions, among other activities) which cause painful uterine **muscle spasms**. Symptoms of primary dysmenorrhea occur when bleeding starts and may include moderate to severe menstrual pain (cramping, spasmodic, and labor-like or a dull ache), **nausea**, **vomiting**, **headache**, **fatigue**, **low back pain**, thigh pain, and **diarrhea**.

Secondary dysmenorrhea is caused by conditions such as endometriosis, abnormalities of the pelvic organs, **pelvic inflammatory disease**, fibroids, **ovarian cysts**, tumors, **inflammatory bowel disease**, and salpingitis (inflammation of the fallopian tube). Symptoms of secondary dysmenorrhea usually occur a few days before bleeding starts. The symptoms depend upon the specific cause of dysmenorrhea, but pain is the hallmark symptom.

A study released in 2003 found that oral contraceptives did not impact the mood of most women during the premenstrual timeframe. The study found that, among those taking oral contraceptives, mood declined in women who had a history of **depression** and that mood improved in women with early-onset premenstrual disturbances of mood as well as those with painful menstruation.

Heavy periods

Many women experience heavy menstrual bleeding during their periods, called menorrhagia. Heavy periods cause more blood loss than normal periods or may last longer than seven days. Women suffering from menorrhagia may lose up to 92% of their total fluid and tissue in the first three days of their cycle. Heavy menstruation is common in young girls who have just started their periods.

Menorrhagia is often caused by a failure to ovulate, which leads to a deficiency of progesterone. Without progesterone, the uterine lining becomes unstable and periods tend to be longer and unpredictable. Toxins in the bloodstream tend to settle in the endrometrial tissue. When this tissue is shed each month, so are the toxins. Heavy periods may be a toxin-excretion technique.

A deficiency in **vitamin A** or **iron**, or hypothyroidism may also cause heavy periods. Painful heavy periods may be linked to endometriosis, fibroids, pelvic inflammatory disease, or the use of an intrauterine device (IUD). A single heavy period that takes place later in the cycle may be a miscarriage.

Tampon use

Many women use tampons to absorb their monthly flow. There has been much controversy over the safety

of tampons. The use of high-absorbency tampons has been shown to cause **toxic shock syndrome** (TSS), a bacterial infection caused when tampons left in too long create tiny breaks in the vaginal lining and allow bacteria to enter the blood stream. Symptoms of TSS are high **fever**, rash, muscle and joint aches, and diarrhea. In the 2000s TSS has become uncommon, but women have died from it.

To reduce the risk of TSS, the United States Food and Drug Administration (FDA) recommends that women use the lowest absorbency tampon required to meet their needs. It is also suggested that tampons be left in for no longer than four to eight hours. Alternatives to tampons are sanitary pads, reusable menstrual collection cups, and washable cloth pads.

One controversy was sparked in the early 1990s over the use of dioxin in tampons. Dioxin is a chemical byproduct of bleach that is a carcinogen. Tampons in the United States are bleached with chlorine during production so they will have a fresher appearance. Research conducted using monkeys showed that dioxin exposure may be linked to endometriosis.

In 1992, an investigation revealed that FDA scientists had found trace amounts of dioxin in some tampons. Further FDA research determined that the tampons subsequently manufactured were produced in a dioxin-free process. However, trace amounts of dioxin may be absorbed from the air, water, or ground. These levels are generally nondetectable and, according to the FDA, do not pose a health risk.

Premenstrual syndrome

Premenstrual syndrome (PMS) is a condition that occurs during the premenstrual phase of the menstrual cycle. The cause is unclear but theories include: abnormal hormone levels, other biochemical abnormalities, inappropriate diet, nutrient deficiencies, psychological factors, or a combination of many factors.

Emotional and mental symptoms include fatigue, mood swings, irritability, nervousness, confusion, depression, tearfulness, and **anxiety**. Physical symptoms are bloating, discomfort, breast tenderness, cravings, weight gain, **acne**, change in bowel movements, joint pains, and **dizziness**.

Other menstrual problems

- A missed period can be caused by pregnancy, stress, increased exercise, emotions, grief, and illness, among others.
- Metrorrhagia is bleeding in between normal episodes of menstruation. It may be caused by ovulation, hormonal factors, cervical lesions, or uterine cancer.
- Polymenorrhoea is bleeding associated with menstrual cycles that are shorter than 21 days. It may be caused by hormonal or ovulatory problems.
- Oligomenorrhea is infrequent menstruation with 35 days to six months between menstrual cycles. Researchers discovered that women with a menstrual cycle of 40 days or longer are twice as likely as women with average-length cycles to develop type II (adult-onset) diabetes mellitus. It is thought that long or highly irregular menstrual cycles may be associated with insulin resistance.

Diagnosis

Menstrual problems can be diagnosed and treated by gynecologists. Most menstrual problems would be diagnosed by taking a detailed medical history (with an emphasis on menstrual history) and performing a physical exam, which would include a pelvic exam. Pelvic exams have two components: the manual exam and the speculum exam. During the manual exam, the doctors insert one or two fingers into the vagina and press their other hand on the lower abdomen to feel the uterus and ovaries. A speculum exam involves inserting a speculum (a metal or plastic tool for opening the vagina) to allow viewing of the vagina and cervix, and to obtain smears for Pap testing (sampling of cervical cells) or culture if an infection is suspected.

Ultrasound exam, in which internal organs are visualized using sound waves, may be performed. Abnormal findings from the examination and laboratory tests may warrant laparoscopy in which a thin, wand like instrument is inserted into an incision in the navel to visualize abdominal organs.

Urine tests may be performed to diagnose pregnancy or infection. Blood tests to determine hormone levels, as well as other blood parameters, may be performed. Patient history and physical exam findings may suggest specific illnesses that would require additional laboratory testing.

The patient may be asked to fill out a diary in which daily menstrual symptoms are recorded over a period of three to six months. In some cases, the patient may be referred to a psychiatrist for evaluation for PMDD.

Treatment

There are many alternative treatments for menstrual problems. Because menstrual difficulties may be

due to a serious condition, patients should consult a doctor before self-treating.

Diet

Phytoestrogens are estrogen-like compounds produced by certain plants. Food sources of phytoestrogens include soy products, flaxseeds, chick peas, pinto beans, french beans, lima beans, and pomegranates. Phytoestrogens can lighten menstruation and lengthen menstrual cycles. By contrast, researchers have found that women who were fed soy-based formulas in infancy instead of cow's milk are more likely to report heavy menstrual bleeding and painful periods in adult life.

PMS symptoms may be relieved by avoiding **caffeine**, sugar, salt, white flour, red meat, dairy, butter, monosodium glutamate (MSG), fried foods, and processed foods during the two weeks prior to menstruation. Foods that help to fight PMS include steamed green vegetables, salad, beans, grains, and fruit. To obtain **essential fatty acids** (omega-3 and omega-6) women can eat flaxseeds, sesame seeds, pumpkin seeds, salmon, mackerel, and tuna.

Herbal remedies and Chinese medicine

A variety of herbal remedies may alleviate symptoms associated with menstrual problems. These include:

- black cohosh (*Cimicifuga racemosa*): mood swings, tension, establishing ovulation (an important source of phytoestrogens). The German Commission E, however, states that women should not take black cohosh for menstrual problems for longer than six months because of the risk of side effects.
- black haw (*Viburnum prunifolium*): cramps
- chamomile (*Matricaria recutita*): mood swings, tension, and cramps
- cramp bark (*Viburnum opulus*): cramps
- dandelion (*Taraxacum dang gui*): fluid retention and bloating
- dong quai (*Benincasa cerifera*): PMS symptoms, cramps, irregular cycles, heavy bleeding, or bleeding in between cycles
- fenugreek (*Trigonella foenum-graecum*): irregular bowel movements
- feverfew (*Chrysanthemum parthenium*): headaches and PMS symptoms
- ginger (*Zingiber officinale*): cramps, irregular cycles, heavy bleeding, or bleeding in between cycles
- goldenseal (*Hydrastis canadensis*): heavy bleeding
- horsetail (*Equisetum arvense*): heavy bleeding
- licorice: PMS symptoms
- milk thistle (*Silybum marianum*) extract: heavy bleeding
- nettle (*Urtica dioica*) extract: heavy bleeding
- peppermint (*Mentha piperita*): mood swings and tension
- raspberry tea: cramps, irregular cycles, heavy bleeding, or bleeding in between cycles
- red clover (*Trifolium pratense*): phytoestrogen source
- rosemary (*Rosmarinus officinalis*): cramps
- shepherd's purse (*Capsella bursa–pastoris*): heavy bleeding
- St. John's wort (*Hypericum perforatum*): depression associated with PMS
- valerian (*Valeriana officinales*): mood swings and tension
- vitex: PMS symptoms
- wild yam: phytoestrogen source
- yarrow (*Achillea millefolium*): cramps

Supplements

The following supplements may treat menstrual problems:

- Calcium deficiency may be associated with PMS.
- Iron supplementation can treat anemia.
- Magnesium pidolate supplementation reduced dysmenorrhea symptoms by up to 84%, especially on days two and three.
- Niacin may help to relieve cramps.
- Omega-3 fatty acids deficiency is associated with dysmenorrhea pain (in one small study, patients taking omega-3 fatty acids had lower pain scores).
- Thiamine (vitamin B_1) cured dysmenorrhea in 87% of the patients for up to two months after treatment.
- Vitamin A may be useful to treat heavy bleeding in women who have vitamin A deficiencies.
- Vitamin B complex may help hormonal function, prevent anemia, reduce water retention, and relieve stress.
- Vitamin E may reduce mood swings and menstrual cramps.

Other treatments

Other treatments for menstrual problems include:

- Acupressure. Acupressure can relieve pain, reduce stress, and improve circulation.
- Acupuncture. This treatment is associated with improvement or cure of dysmenorrhea and PMS and decreased use of pain medications. A National Institutes of Health

(NIH) panel concluded that acupuncture may be a useful treatment for menstrual cramps. A study released in 2008 found that acupuncture is an effective treatment for patients suffering from dysmenorrhea. In the study, acupuncture was associated with improvements in both pain and quality of life.

- Aromatherapy. Massage with essential oils: rose, ylang-ylang, bergamot, and/or geranium oils for mood swings; lavender, sandalwood, and clary sage oils for menstrual cramps; and chamomile, cypress, melissa, lavender, and jasmine oils for irregular menstruation or amenorrhea.
- Biofeedback. Weekly biofeedback therapy for 12 weeks led to significant reduction in PMS symptoms.
- Chiropractic. Spinal manipulation may help to ease cramps.
- Exercise. Regular, moderate aerobic exercise reduces or eliminates menstrual pain, improves PMS, reduces the amount of menstrual bleeding, reduces the risk for endometriosis, and reduces cyclic breast pain and cysts. Yoga stretching can relieve back and thigh pain.
- Homeopathy. Homeopathic remedies include: lachesis or sepia for PMS, cimicifuga, colocynthis, or magnesia phosphorica for cramps, and pulsatilla or aconitum for irregular menstruation or amenorrhea.
- Hydrotherapy. Soaking in a hot tub or using a moist heating pad relaxes uterine muscles which relieves cramping.
- Reflexology. Ear, hand, and foot reflexology led to a significant decrease in PMS symptoms that lasted for several months following treatment.
- Transcutaneous electric nerve stimulation (TENS). In four small studies using TENS for the treatment of dysmenorrhea, 42%–60% of the patients experienced at least moderate relief of symptoms. TENS worked faster than naproxen and there was less need for NSAIDs.

Allopathic treatment

The treatment for amenorrhea depends upon the cause. Primary amenorrhea may require hormonal therapy.

Patients with dysfunctional or abnormal uterine bleeding may be prescribed iron supplements to treat **anemia**. Naproxen **sodium** (Aleve) reduces excessive blood loss. Oral contraceptives are often prescribed to treat abnormal bleeding. High doses of estrogens may cause vomiting, which means that anti-emetics (drugs to prevent vomiting) may also be necessary. Excessive bleeding may require hospitalization for observation and treatment.

KEY TERMS

Amenorrhea—Lack of menstruation.

Dysmenorrhea—Painful menstruation.

Endometrium—The lining of the uterus that is shed during menstruation.

Follicle—The cluster of cells that surround the developing egg.

Hormones—Chemical messengers that control the events associated with the menstrual cycle.

Menarche—The first menstrual period or the establishment of the menstrual function.

NSAIDs—Nonsteroidal anti inflammatory drugs such as ibuprofen and naproxen.

Oligomenorrhea—Scanty or infrequent menstrual periods.

Phytoestrogens—Estrogen-like compounds derived from plants.

Toxic shock syndrome (TSS)—A potentially serious bacterial infection associated with the use of tampons to absorb menstrual flow.

Uterus—The organ that carries and provides nutrition to a developing baby. Also called the womb.

Primary dysmenorrhea is usually successfully treated with nonsteroidal anti-inflammatory drugs (NSAIDs); aspirin is not strong enough to be effective. NSAIDs are numerous and include ibuprofen (Advil, Motrin, Nuprin), Naproxen (Aleve), and fenamates (Meclomen). Oral contraceptives (birth control pills) may be used if NSAIDs fail. Treatment of secondary dysmenorrhea involves treating the causative condition and may involve medications or surgery.

Because the cause(s) of PMS are unclear, treatment usually focuses on relieving symptoms. A study released in 2007 found that both acetaminophen and ibuprofen were effective in treating the pain associated with menstruation. Ibuprofen was found to be the more potent pain reliever.

With regard to PMDD, medications that have been reported to be effective in treating it include the tricyclic antidepressants and the selective serotonin reuptake inhibitors (SSRIs). Effective treatments other than medications include cognitive **behavioral therapy** (CBT), aerobic exercise, and dietary supplements containing **calcium**, **magnesium**, and vitamin B_6.

Expected results

Most menstrual problems can be successfully treated using conventional or alternative treatments.

Prevention

Avoiding sodium and caffeine may reduce some menstrual symptoms. Regular moderate aerobic exercise or **yoga** is often beneficial for menstruation difficulties. Getting yearly pelvic exams and Pap smears help to identify problems before they become advanced.

Mercurius vivus

Description

Mercurius vivus is the Latin name for a homeopathic remedy made from elemental mercury. The English word quicksilver is a literal translation of the Latin. Although Samuel Hahnemann, the founder of homeopathic medicine, also formulated a soluble preparation of mercury that he called *Mercurius solubilis*, most contemporary American homeopaths regard these two preparations as essentially the same remedies and use them to treat the same symptom profiles.

General use

Homeopathic medicine operates on the principle that "like heals like." This means that a disease can be cured by treating it with substances that produce the same symptoms as the disease, while also working in conjunction with the homeopathic law of infinitesimals. In opposition to traditional medicine, the law of infinitesimals states that the *lower* a dose of curative, the more effective it is. To achieve a low dose, the curative is diluted many, many times until only a tiny amount remains in a huge amount of the diluting liquid.

The homeopathic *Materia Medica* indicates that, *Mercurius vivus* is the remedy of choice for acute disorders of the skin and mucous membranes characterized by severe inflammation with pus formation and possibly areas of broken or raw skin. Disorders with this symptom profile include:

- eye infections with discharges of pus
- bacterial infections with pus behind the eardrum
- sore throats with open patches of skin and pus formation
- urinary tract infections
- diseases of the skin such as herpes and boils

Other disorders that are treated with *Mercurius vivus* include backache, **chickenpox**, colds, **diarrhea**, **influenza**, **indigestion**, mouth ulcers, and **toothache** accompanied by heavy salivation.

The general symptoms that would suggest *Mercurius vivus* treatment to a homeopath include heavy, foul-smelling perspiration, foul-smelling breath and **body odor**, and copious, drooling salivation. *Mercurius vivus* patients are easily irritated by temperature or other environmental changes, and they are comfortable only within a narrow range of moderate circumstances. They tend to tremble or shake, are generally weak, and easily tired by activity. These patients are slow to respond to treatment and infected parts of the body take a long time to heal and often appear severely diseased.

A female *Mercurius vivus* patient is likely to have heavy periods with painful cramps and **anxiety**. A nursing mother will produce milk that has a bad taste to the infant. A male patient may have burning

pain on urination accompanied by thick mucus or pus from the urethra. The inflammatory sensations associated with *Mercurius vivus* symptoms are present throughout the body. The mouth and gums are typically sore and inflamed, and the patient may complain of a metallic taste in the mouth. The gums may ooze blood when touched, and the patient often has lost several teeth. If the patient has a **headache**, it will have a burning quality. The *Mercurius vivus* patient may also have feelings of gnawing or burning in the chest and abdomen. There may be little appetite for food, but often an intense thirst or desire for cold drinks.

In **homeopathy**, certain remedies are thought to be especially effective in people with specific personality and physical traits. The mental and psychological symptoms of *Mercurius vivus* patients include restlessness, an agitated quality, and a tendency toward impatience and willfulness. The patient may jabber or chatter rather than talking at a normal pace and may act on impulse. These impulses sometimes lead to violence; *Mercurius vivus* patients may act out suicidal or murderous thoughts. Other personality traits of the *Mercurius vivus* patient are quarrelsomeness and dissatisfaction.

In homeopathic practice, the circumstances or factors that make the patient feel better or worse are considered as important a part of the symptom profile as the physical indications. These circumstances, which include weather, time of day, level of activity, light or noise, body position, sleeping patterns, etc., are known as modalities. With *Mercurius vivus* patients, the modalities that make the patient's condition worse include temperature extremes, open air, drafts, a warm bed, evening, being touched, lying on the right side, feeling sweaty, or eating something sweet. Those that make the patient feel better include moderate temperatures, dry weather, and sitting up while at rest.

Preparations

There are two homeopathic dilution scales, the decimal (x) scale with a dilution factor of 1:10 and the centesimal (c) scale with a dilution factor of 1:100. The most common form of *Mercurius vivus* preparation on the market is 30c or 30x tablets, although the remedy is also available in liquid form. The abbreviation 30c means that one part of mercury has been diluted with 99 parts of water or alcohol. This process of dilution, along with vigorous shaking of the remedy, has been repeated 30 times to achieve the desired potency. A potency of 30x means that one part of the medicine is mixed with nine parts of alcohol or water; thus 30x means that this decimal dilution has been repeated 30 times. In homeopathic practice, the strength of the remedy is in inverse proportion to the amount of chemical or plant extract in the alcohol or water; thus a 30c preparation of *Mercurius vivus* is considered a much higher potency than a 30x preparation. The tablet form of a homeopathic remedy is made by pouring the diluted liquid over sugar pills.

Precautions

Taken by itself, mercury is poisonous to humans and can cause irreversible damage to the nervous system even if the patient survives. Other symptoms of **mercury poisoning** include burning thirst, swelling and discoloration of the membranes lining the mouth, abdominal pain, bloody diarrhea, and shock. Samuel Hahnemann's interest in accidental poisonings from medicines that were commonly used in the eighteenth century is one reason why mercury was one of the first substances that he studied. Since ancient times, mercury had been used for medicinal purposes to cleanse **fever** victims of toxins. In the modern world, however, mercury poisoning is more likely to result accidentally from breathing metallic vapors given off in certain industrial processes rather than from mercury-based medicines. Standard homeopathic preparations of *Mercurius vivus* are so dilute that they are highly unlikely to cause mercury poisoning even if the patient takes a sizable overdose.

Side effects

Homeopathic remedies rarely have side effects in the usual sense of the phrase because they are so dilute. On the other hand, a homeopathic remedy may sometimes appear to be making a patient's symptoms temporarily worse as part of the healing process. This worsening is called an aggravation. Aggravations are regarded by homeopaths as an indication that the remedy is effectively stimulating the patient's body to heal itself. *Mercurius vivus* patients appear to be more likely to experience aggravations than patients given other remedies.

Interactions

Homeopathic preparations are so dilute that the chances of their interacting with conventional prescription medications are minimal to nonexistent. On the other hand, a typical homeopathic *Materia Medica* will include some brief notes about the interactions of some remedies. The action of *Mercurius vivus* is thought to be intensified by **belladonna**, **silica**, and *Hepar sulphuricum*.

KEY TERMS

Aggravation—In homeopathy, a temporary worsening or intensification of the patient's symptoms prior to improvement and healing.

Materia medica—A Latin phrase that means "the materials of medicine." In homeopathy, a *materia medica* is a book that lists the various homeopathic remedies together with the symptoms that they treat.

Modality—A factor or circumstance that makes a patient's symptoms better or worse. Modalities include such factors as time of day, room temperature, external stimuli, the patient's level of activity, sleep patterns, etc.

Mercury poisoning

Definition

Mercury poisoning occurs when a person has ingested, inhaled, or had skin or eye contact with the toxic (poisonous) heavy metal mercury and suffers damage to the nervous system and other systems of the body. Mercury, which has the chemical symbol of Hg, is liquid at room temperature, like a few other elements. Because it easily converts to a gas, it is extremely volatile. There are three forms of mercury circulating throughout the environment, and all three forms are toxic to humans and many other living organisms to varying degrees.

Elemental mercury, also known as quicksilver, is mercury in its metallic (solid) elemental form. Elemental mercury is also referred to as mercury-zero. It is frequently found in the home in glass thermometers. It is also found in fluorescent light bulbs, thermostats, some pesticides, switches, preservatives, some paints, and in some dental amalgam fillings—although there are often mercury-free options available. In the past, according to a State of Michigan publication *Mercury Poisoning*, it was used as the active ingredient in ointments, animal worming medicines, antiseptics, disinfectants, diuretics and fungicides. As of 2008, the publication states, it is present in seed fungicides, anti-slime fungicides used by the pulp and paper industries, by-products of burning coal, mining tailings (residue), and wastes from chlorine-alkali industries. In its solid state, elemental mercury is less toxic than some of its other forms, but it is still very volatile. The most toxic effect of elemental mercury occurs when its extremely dangerous vapor is inhaled, which is most likely to occur in an industrial setting.

Elemental mercury can be converted by bacteria into a charged ion (an electrically charged atom or group of atoms) known as mercury-two. There are two dangerous aspects to this form. First, unlike elemental mercury, it readily dissolves in water and combines with other ions to form new compounds. Second, bacteria can change mercury-two into one of mercury's most toxic organic compounds, methylmercury, which is capable of being dissolved in water and thus finds its way into the food chain, where it enters fish and other animals. Large, long-lived fish such as swordfish are most likely to have high levels of methylmercury. The mercury found in fish can be dangerous for a developing fetus, for babies, and young children. It can be passed to infants through breast milk. Breastfeeding women, pregnant women, and women who may become pregnant are advised by the United States Food and Drug Administration (FDA) to avoid eating large, long-lived fish such as shark and swordfish, and to limit other fish consumption to an average of 12 ounces a week (an average portion of fish is about six ounces). The FDA also recommends that the fish eaten be varied regularly and

that the same type of fish or shellfish not be eaten more than once a week.

Inorganic mercury takes the form of various compounds known as mercuric salts. Mercuric salts are used in various folk medicines, particularly in some Chinese herbal preparations and in some Mexican remedies. Exposure to mercuric salts over a long term can cause kidney and nerve damage.

Description

Many people do not take the risk of mercury poisoning seriously because they have played with elemental or liquid mercury or broken thermometers containing mercury without experiencing negative health effects. While these "small" mercury exposures can appear to be free of detectable health consequences, even a small spill can have serious effects, including hospitalization and even death, if improperly cleaned up, if there is poor ventilation, or the mercury is exposed to heat. It is extremely important, therefore, that any mercury spill, even a small one, be properly cleaned up. If not, the home, school, or workplace may be contaminated. Poisoning from elemental mercury is most likely to occur during inhalation of mercury vapors. The danger lies in the fact that after it is inhaled into the lungs in vapor form, mercury passes into the blood stream. The person who inhales mercury requires immediate medical treatment.

Inhalation of mercury vapor might happen in a factory where mercury is used. Most small household spills of elemental mercury are not dangerous if cleaned up correctly. Elemental mercury usually passes right through the body if swallowed, so this is usually not poisonous to a person with a healthy digestive system. Elemental mercury is not easily absorbed by the skin, so touching elemental mercury is usually not enough to cause poisoning. But if elemental mercury is spilled in the home, from a broken thermometer or fluorescent light, for example, it must be correctly and carefully cleaned up. It should not be swept up with a broom or vacuumed because doing so can break the mercury into small particles and spread it. Spilled mercury should be sucked up with an eyedropper, scooped up with paper, or picked up with sticky tape. Then the mercury should be sealed in three layers of plastic bags and disposed of according to local hazardous waste procedures. Any clothes or rags that have been exposed to mercury should also be discarded, rather than washed in a washing machine, which would further spread the mercury. The area of the spill should be ventilated for several days.

Inorganic mercury, or mercury salts, have long been used in folk medicines. Exposure to inorganic mercury through folk medicines can cause poisoning, which can lead to kidney damage, tissue death, and nerve damage. Calomel, or mercurous chloride, and cinnabar, or mercuric sulfide, are two common toxic inorganic mercury compounds that should not be ingested. Folk medicines containing calomel, cinnabar, or other mercuric salts should also not be used on the skin.

Several Chinese herbal medicines have been identified as containing dangerous amounts of mercury and arsenic. These are usually prepared as an herbal ball. Known Chinese herbal medicines to avoid are: An Gong Niu Huang Wan, Da Huo Luo Wan, Niu Huang Chiang Ya Wan, Niu Huang Chiang Hsin Wan, Ta Huo Lo Tan, Tsai Tsao Wan, and Dendrobium Moniliforme Night Sight Pills.

Poisoning from organic mercury is perhaps the most troubling form of mercury exposure. Organic mercury is widespread in the environment, and there is a lot of debate about how it can most safely and cost-effectively be cleaned up. Some mercury finds its way into the atmosphere naturally, from volcanoes for example. But much of the mercury that finds its way into the food supply comes from industrial pollution. Mercury is emitted by power plants that burn fossil fuel and travels through the air. It deposits in bodies of water, where it is first taken up by plankton (floating animal and plant life). Fish that feed on plankton accumulate organic mercury in their bodies, and fish that eat those fish accumulate even more. This process, called bioaccumulation, concentrates the mercury in animals at the top of the food chain.

Because mercury can travel great distances through the air, the problem of mercury pollution affects all of North America and is a global environmental issue. As of 2008, the debate continued on how much mercury is safe and how it should be regulated. In the United States, the Environmental Protection Agency (EPA) is responsible for monitoring mercury emissions. In 2004, the EPA promulgated new rules on mercury emissions, which were criticized by some politicians and environmental groups as too lenient. The FDA, the United States government agency responsible for food safety, revised its findings on the mercury in fish several times during the early 2000s.

Some studies suggest that mercury exposures of up to four times the limits in the FDA guidelines may be safe for people. There are many health benefits to eating fish, and the mercury level in any individual fish meal may vary greatly. Most states in the United

States post warnings on consuming fish or certain types of fish caught in lakes and streams. Specific bodies of water or specific species of fish may have been found to be more dangerous than others. People who fish for sport or for subsistence should check with local government agencies about warnings for eating local fish.

Causes and symptoms

Common home products that contain elemental mercury, such as lights, thermostats, thermometers, and appliances are not dangerous to humans unless they are broken, mercury is released, and there is exposure to mercury vapors because of improper cleanup.

In June 1997, Karen Wetterhahn, 48, a Dartmouth College **cancer** research scientist whose specialty was dangerous heavy metals, died of dimethylmercury poisoning, ten months after she spilled one to several drops of it on her rubber gloves while she was studying how mercury prevents cells from repairing themselves. Tests after the spill revealed that the mercury could pass quickly through the rubber latex gloves without damaging them. Three months after the spill, Wetterhahn experienced two episodes of **nausea** and **vomiting**. Two months later, she began losing her balance and having speaking and hearing difficulties. At the time she was hospitalized, tests showed 80 times the lethal dose of mercury in her blood. She then went into a coma and died. The chairman of the Dartmouth chemistry department, John S. Winn, explained that although methylmercury looks like water, it is three times as dense and is readily absorbed by the body. He also said that about 100 laboratories around the world work with dimethylmercury. Dartmouth officials in a letter to the American Chemical Society urged those who work with dimethylmercury to wear neoprene gloves with long cuffs and to have frequent blood and urine testing.

In 1963, a new filling for dental cavities, non-gamma-two amalgam, was introduced as a solution to conventional amalgam being prone to corrosion and mechanical weakness. Non-gamma-two amalgam quickly caught on, despite the fact that it caused a much-increased mercury emission, and replaced conventional amalgam. In the early 1980s, dentists were regularly using elemental mercury amalgam for dental fillings. However, dentists and other health professionals who had turned to holistic or alternative medicine began to publicize the toxicity of amalgam fillings and advocate their replacement with a non-toxic composite material. One study reported that people with amalgam filings had mercury vapors in their mouths that were nine times greater than people without the filings. If the person with the amalgam filing chewed, the level of vapor increased six-fold, giving the people with amalgam filings vapor levels that were 54 times greater than those without amalgam filings. The level continued to increase as the people brushed their teeth or after they drank hot beverages. Although these findings may seem extreme, they come from only one study. The American Dental Association (ADA) has not found sufficient evidence of the dangers of amalgam fillings to recommend against them. Starting January 1, 2008, Norway banned the use of amalgam fillings in most circumstances. This ban, however, pertained to environmental effects of mercury, not concerns about the safety of the fillings.

Environmental mercury can be extremely dangerous. Walter Crinnion described the effects of the pollution of Minamata Bay in Japan by methylmercury and the neurotoxicity suffered by inhabitants of the area that came to be known Minamata disease: ataxia (lack of normal coordination of voluntary muscles), speech impairment, constriction of visual fields, hypoesthesia (reduced capacity to feel sensation), dysarthria (slurred, slow speech from inability to coordinate mouth muscles), hearing impairment, and sensory disturbances. As the mercury contamination spread, these symptoms did also. Forty years after the spill and almost 30 years since a fishing ban was put into effect in the area, problems continued predominantly in the fishing villages. Males complained of stiffness, poor ability to feel sensation, hand tremors, **dizziness**, loss of **pain** sensation, cramping, atrophy (wasting away) of upper arm muscles, arthralgia (pain in the joints), **insomnia**, and lumbago (back pain). Females had significantly higher complaints of leg tremors, **tinnitus** (ringing in the ears or head), loss of touch sensation, atrophy of leg muscles, and muscular weakness.

The symptoms of poisoning from inorganic mercury may include nausea and vomiting, abdominal pain, bloody **diarrhea**, and decreased urination. If inorganic mercury is applied to the skin, the skin may eventually redden or discolor. Skin contact with inorganic mercury can lead to nerve damage. The symptoms of nerve damage are weakness, numbness, and tingling.

The symptoms of poisoning from organic mercury include **fatigue**, **headache**, **depression**, memory problems, **hair loss**, tremors, and/or a metallic taste in the mouth. These symptoms are also caused by many other common conditions, so organic mercury poisoning can be difficult to diagnose. The doctor will ask the individual questions about possible workplace, home, or dietary exposure to mercury to help make a diagnosis.

Diagnosis

Measurement of mercury in the urine is the recommended method of diagnosing metallic and inorganic mercury poisoning. Organic mercury cannot be measured by urinalysis because it does not leave the body in urine. If the urine collection cannot be done over 24 hours, spot urine samples should be collected at the same time each day.

Extent of exposure to organic mercury, including methylmercury and metallic and inorganic mercury, can be measured by a blood test. Unexposed people usually have less than 2 µg/100mL of mercury in their blood. Early effects of toxicity are indicated when the blood concentration exceeds 3 µg/100 mL.

Treatment

It is worth noting that some herbal and folk treatments for health problems can be a source of mercury. The herbal preparations listed under the "Description" heading above are known to have large concentrations of inorganic mercury. A person prescribed a Chinese herbal ball preparation may want to ask the practitioner about mercury and be alert for symptoms of mercury exposure. Some Mexican skin creams and stomach remedies may also be sources of mercury.

Fish oil supplements are a popular non-prescription treatment used by many people who hope to lower the risk of **heart disease**, lower **cholesterol** levels, and improve mental function. Because in the United States, the manufacture of nutritional supplements is not regulated like pharmaceuticals are, fish oil supplements may vary greatly from maker to maker and so exposure to organic mercury from fish oil supplements is not readily quantifiable. It makes most sense for a person taking fish oil supplements to determine—if necessary by contacting the manufacturer directly—what kinds of fish are used for the oil, and if mercury levels have been tested for that brand.

Alternative treatment—by a naturopathic physician, a holistic medical doctor or osteopathic physician, or a homeopathic practitioner—is based on physical examination, biochemical testing, and an extensive history, including a history of family illness. After the doctor evaluates all of this information, treatment may include a comprehensive diet tailored to the individual patient; vitamins, minerals, enzymes, **amino acids** and or homeopathic remedies tailored to the individual; removal of toxins from patient's environment and diet; removal of amalgam fillings; necessary **chiropractic** adjustments; counseling; supplementary physical treatment; **stress** reduction and proper **exercise**; a stress-free home with help, if needed; a **detoxification** program; use of a sauna; and chelation, a recognized treatment for **heavy metal poisoning**, the intravenous injection of ethylenediamine tetraacetic (EDTA) that will chemically bind with the heavy metal and allow it to be removed from the body in the urine.

KEY TERMS

Bioaccumulation—The buildup of a toxin or other substance within a food chain, as larger predators retain the substance from the bodies of prey they eat.

Allopathic treatment

A person diagnosed with mercury poisoning may be prescribed a drug that binds the mercury and thus helps the body excrete it quickly. The body naturally excretes metallic and inorganic mercury in the urine even without treatment. A doctor may recommend that a person diagnosed with mercury poisoning avoid eating any fish or shellfish. Further monitoring of blood and urine can determine whether mercury levels are falling. The nervous system, mouth, lungs, eyes and skin, target organs for exposure, should also be periodically checked.

Expected results

For adults, small levels of mercury poisoning typically constitute a reversible problem. The body can rid itself of mercury if the exposure to mercury is halted. Symptoms such as fatigue and memory problems seem to go away as mercury levels fall. However, large doses of mercury can cause permanent organ, brain, and neurological damage, or be fatal. For children and developing fetuses, even very low levels of mercury poisoning can cause long-term neurological problems. Mercury exposure before birth has been linked to lower intelligence and delays in learning motor skills.

Prevention

Avoiding mercury is the best way to prevent mercury poisoning. Folk remedies that may contain mercury should not be consumed or rubbed on the skin. People should follow local guidelines about eating fish caught in local waters and should follow federal guidelines for consumption of commercial fish. Much of the scientific literature on long-term exposure to mercury from fish is still mixed, and consumers should try to stay up to date on the FDA recommendations for consumption.

Mesoglycan

Description

Mesoglycan is a mucopolysaccharide complex that is extracted from calf aorta or synthetically created and taken in pill or capsule form as a dietary supplement. Mucopolysaccharides are long molecular chains of sugar. They are used by the body in the building of connective tissues, such as cartilage, tendons, and ligaments. The substance is related to the blood-thinning drug heparin, and the supplements **glucosamine** and **chondroitin**. Both are used to treat joint pain and arthritis.

General use

Aortic glycosaminoglycans and mucopolysaccharides such as mesoglycan are used to treat diseases of blood vessels, joints, and cartilage such as:

- atherosclerosis
- varicose veins
- phlebitis
- hemorrhoids
- arthritis
- bursitis
- headaches
- ulcers
- angina
- allergies

There is some evidence that mucopolysaccharides and the related aortic glycosaminoglycans may slow the development of **atherosclerosis** (hardening of the arteries) by lowering **cholesterol** levels in the blood. In one study, a group of men with early atherosclerosis was given a 200 mg daily dose of aortic glycosaminoglycans, while another group received no treatment. After 18 months, the layering of the vessel lining in the untreated group was 7.5 times greater than in the treated group.

Heparan sulfate and dermatan sulfate are the two main components of mesoglycan. These substances have a protective effect on the walls of blood vessels.

Mesoglycan is an active ingredient found in the aloe vera plant. There have been studies that have found mesoglycan to be effective in treating inflammation, AIDS, and **cancer**. One clinical trial conducted in the 1980s showed that **AIDS** patients who took oral mucopolysaccharides showed a 70% improvement in their symptoms.

Mucopolysaccharides have also been shown to reduce inflammation in diseases such as arthritis, gastric reflux, and ulcerative **colitis**. There is also evidence suggesting that mesoglycan can slow the progression of arthritic diseases.

Preparations

Dosage ranges from 24-200 mg per day for one to six months, depending on the condition being treated. In a study patients with deep vein thrombosis, a dosage of 72 mg per day was found to be effective. An oral dosage of mesoglycan of 72-96 mg per day for 10-13 weeks has been used to treat hyperlipidemia. A dosage of 24-50 milligrams per day is used to treat patients with arterial disease.

Initially, mesoglycan and other mucopolysaccharides were only available through injections. They are now available in oral form.

Some common names for preparations containing mucopolysaccharides include chondroitin and glucosamine. Glucosamine stimulates the production of glycosaminoglycans and proteoglycans, the building blocks of cartilage. If the body does not produce enough glucosamine on its own, the joints can dry out, crack, or wear away completely. If the joints have no protection from glucosamine, they can become swollen, inflamed, and very painful, a common condition known as **osteoarthritis**.

Researchers believe that taking glucosamine can help the body stimulate its own production of protective cartilage around joints. Combining glucosamine together with chrondroitin is thought to increase the overall effectiveness, although some practitioners prescribe glucosamine alone.

Precautions

Mesoglycan and other aortic glycosaminoglycans are basically compounds found naturally in the body, so they are generally considered to be safe to take, even in large quantities. There is some ability, however, for aortic glycosaminoglycans to reduce blood clotting. Maximum safe dosages for young children, pregnant or nursing women, or in those with liver or kidney disease have not been determined.

The Dietary Supplement Health and Education Act of 1994 permits the marketing of a product labeled as a "dietary supplement" without the approval of any government agency as long as the labeling includes a disclaimer stating that it has not been evaluated by the Food and Drug Administration (FDA), and that the product is not intended to diagnose, treat, or prevent any disease. Purity of dietary supplements cannot be guaranteed. Because of this, consumers should **exercise** caution when using any dietary supplement and be sure to discuss the use of dietary supplements with their physician or health practitioner. Currently, the only known medical condition that precludes the use of mesoglycan is hemorrhagic disease.

Side effects

In many studies, mesoglycan was found to be tolerated well. Gastrointestinal discomfort and **nausea** are side effects sometimes reported. With intramuscular injections of mesoglycan, injection site reactions may occur.

Interactions

If you are taking any type of prescription or other medication that decreases blood clotting such as coumadin (warfarin), heparin, trental (pentoxifylline) or aspirin, do not use aortic glycosaminoglycans or mucopolysaccharides without the advice of a physician.

Metabolic therapies

Definition

Metabolic therapies differ considerably according to practitioner; however they typically involve a belief that **cancer** and certain other diseases are caused by imbalances in a patient's metabolism. These imbalances are caused by accumulations of toxins in the body. Treatment involves removing these toxins and strengthening the immune system and biochemical processes.

Origins

The origins of metabolic therapies are as varied as the therapies themselves. One of the best-known proponents was Harold Manners, a biology professor who claimed in 1977 to have cured cancer in mice using injected laetrile, **vitamin A**, and **digestive enzymes**. Manner left the academic world and started a clinic in Tijuana, Mexico before he died in 1988.

Benefits

In addition to cancer, metabolic therapies have also been used against arthritis, **multiple sclerosis**, and other diseases believed linked to metabolic imbalances.

Description

Metabolic therapies are an eclectic and controversial mix of treatment protocols, including the following:

- American biologics: Abstinence from caffeine, sugar and refined carbohydrates, as well as excess animal protein; enemas and colonic irrigation; laetrile; embryonic live cell therapy involving adrenal and cerebral tissues; vitamin C and other dietary supplements.
- Evers therapy: Laetrile; magnetic field therapy; hyperbaric oxygen; diet; Eversol chelation therapy; shark cartilage; Koch vaccination; injections of frozen thymus and other cells; detoxification.

KEY TERMS

Laetrile—The chemical amygdalin, obtained from apricots, peaches, and bitter almonds.

Metabolism—The physical and chemical changes that allow the body to grow, function, and to convert food into energy.

- Gerson therapy: Low-salt vegan diet; hourly intake of fresh fruit and vegetable juices; three or four coffee enemas a day; dietary supplements including thyroid extracts, pancreatin, pepsin, niacin, and potassium.
- Issels' whole body therapy: Removal of mercury dental fillings and infected teeth; vaccines; organic diet with acidophilus support; abstinence from coffee, tea, tobacco; hyperthermia (provoking a fever to strengthen the immune system); hemotogenic oxidation therapy (to stimulate an immune response within the blood); informal psychotherapy.
- Kelley-Gonzalez diet: Individualized diet, often including large quantities of raw fruits, juices, raw and steamed vegetables, cereals, and nuts; abstinence from red meat, white sugar, chicken, refined grain products, and soy; freeze-dried pancreatic enzymes; frequent coffee enemas and laxative purging; as many as 150 dietary supplements a day.
- Manner metabolic diet therapy: Laetrile; enzymes; daily coffee enemas; vitamins, minerals, and other supplements; direct injections of enzymes into tumors; psychological counseling.
- Revici therapy: Intravenous doses of selenium, oxygen, copper, calcium, and other substances intended to balance body chemistry.

Precautions

Generally the controversial and unproven nature of these therapies, combined with the seriousness of the diseases they are intended to treat, make the ongoing involvement of a competent medical professional strongly advisable. One major drawback to trying alternative cancer therapies is that opportunities may be lost for timely application of other, more effective therapies.

Side effects

Concern has been expressed that patients on some metabolic **diets** may risk electrolyte imbalances or even death. Further concern exists about the safety of enzyme injections and the toxicity of megavitamin therapy. Laetrile has been linked to life-threatening cyanide toxicity.

Research and general acceptance

Most metabolic therapies for cancer are well outside the comfort zone of traditional medical practitioners. Some proponents have experienced considerable opposition from regulators and law-enforcement officials.

Training and certification

Metabolic therapies are usually offered in small medical clinics that have developed their own treatment protocols. A number of these clinics are clustered in northwestern Mexico, just a few miles from the United States border. There, practitioners are easily accessible to visiting Americans, yet outside the jurisdiction of United States regulators.

David Helwig

Methionine

Description

Methionine ($C_5H_{11}NO_2S$) is an essential, sulfur–containing amino acid. It is the source of **sulfur** for numerous compounds in the body, including the **amino acids** cysteine and taurine. The body uses sulfur in the development of hair follicles and to promote healthy hair, skin, and nail growth. Sulfur also increases the liver's production of **lecithin** (which reduces **cholesterol**), reduces liver fat, protects the kidneys, helps the body to excrete heavy metals, and reduces bladder irritation by regulating the formation of ammonia in the urine. Methionine is a lipotropic—a nutrient that helps prevent fat accumulation in the liver, and usually helps detoxify metabolic wastes and toxins.

S–adenosyl–L–methionine (SAM, or SAMe) is an active compound made from methionine and adenosine triphosphate (ATP), an enzyme found in muscle tissue. SAMe is manufactured within the body and is found in almost every tissue, but it can also be made synthetically. It acts as a methyl donor in a variety of biochemical pathways. Methylation reactions are essential for the **detoxification** of harmful products

of metabolism, and the synthesis of numerous physiological agents including neurotransmitters, cartilage, and **glutathione**. (Glutathione is a chemical that plays an important role in biological oxidation–reduction processes, and as a coenzyme. It can combine with toxic substances to form water soluble compounds that can be excreted through the kidneys.)

Methionine is considered essential because it cannot be manufactured in the body and must be obtained through diet. This particular amino acid is found only in meat, fish, eggs, and dairy products. Natural and synthetic methionine supplements are available, as well as supplements containing SAMe.

General use

Acetaminophen overdose

Methionine is used to treat acetaminophen (paracetamol) poisoning that may result in liver damage. Preparations containing both methionine and acetaminophen have been formulated for use in situations where overdose may occur.

Arthritis

Most people with arthritis rely on continuous doses of non–steroidal, anti–inflammatory drugs (NSAIDs) such as ibuprofen, aspirin, and naproxen for **pain** relief. SAMe has several advantages over these standard painkillers. It provides effective pain relief and has fewer side effects than these drugs. Users are generally able to tolerate SAMe better than they can other drugs, which is a significant issue for arthritis sufferers. While NSAIDs can cause gastrointestinal bleeding, SAMe can protect against injury to the stomach. Another advantage is that SAMe may actually have a protective effect on joints and even repair cartilage.

Depression

SAMe is beneficial for most forms of **depression**. In Europe, SAMe is prescribed more often than any other type of antidepressant. Many studies have shown SAMe to be as effective as other antidepressant drugs. It works more quickly and has fewer side effects. SAMe may boost the activity of several brain chemicals involved in mood, such as norepinephrine, dopamine, and serotonin.

Liver function

Methionine levels help determine the liver's concentration of sulfur–containing compounds and SAMe improves and normalizes liver function. SAMe is used in Europe in the treatment of **cirrhosis** and liver damage caused by alcohol. It is essential for the production of glutathione. Methionine itself has a protective effect on glutathione and prevents depletion during toxic overload, which can protect the liver from the damaging effects of toxic compounds.

Through methylation, SAMe is able to inactivate estrogens to prevent estrogen–induced cholestasis (suppressed bile flow) in pregnant women and those on oral contraceptives. It also increases membrane fluidity, restoring several factors that promote bile flow. Treatment with SAMe can also help decrease serum bilirubin (pigment in the blood that can cause **jaundice**) in patients with Gilbert's syndrome, a condition characterized by a chronically elevated serum bilirubin level.

Neurological disorders

SAMe improves the binding of neurotransmitters to receptor sites in the brain. It is essential for the regeneration of neuron axons following injury, and for the formation of myelin sheaths (a fatty substance) that surround axons. Alzheimer's and Parkinson's patients have very low levels of SAMe, and methionine may help treat some symptoms of **Parkinson's disease**.

Persons with **AIDS** have low levels of methionine, which may explain some of the nervous system deterioration that can occur to cause symptoms such as **dementia**. Methionine may improve memory recall in persons with AIDS–related nervous system degeneration, and SAMe may be used in the treatment of HIV–related motor and sensory changes in the extremities.

Low levels of methionine in pregnant women are related to an increased risk of neural tube defects (NTDs) in the fetus. Neural tube defects are caused by the failure of the neural tube to close properly during the formation of the central nervous system in the developing embryo. Mothers whose methionine intake is adequate during the period from three months prior to conception through the first trimester of **pregnancy** have a significantly lowered risk of having a baby with a neural tube defect.

Other uses

In Europe, SAMe has been used in clinical studies to treat **anxiety**, **schizophrenia**, demyelination diseases, and dementia. Oral doses of methionine have also been given to lower urinary pH and to help in the treatment of liver disorders. SAMe's ability to inactivate estrogens supports the use of methionine in conditions of presumed estrogen excess such as PMS.

Methionine in combination with several **antioxidants** may reduce pain and recurrences of attacks of **pancreatitis** (inflammation of the pancreas). SAMe also improves the symptoms of **fibromyalgia** patients, who suffer from chronic muscle pain, non–restorative sleep, and profound **fatigue**.

Cancer researchers are also studying the role of methionine in a special diet for patients diagnosed with colon cancer.

Preparations

Amino acid requirements vary according to body weight. Most average–size adults require approximately 800–1,000 mg of methionine per day. Infants require five times that amount, and children need twice that amount. Dosage rates of SAMe for conditions such as depression, fibromyalgia, liver ailments, migraines, and **osteoarthritis** are 200–400 mg, two or three times per day. Before taking SAMe supplementation, a physician or qualified health practitioner should be consulted.

The usual oral dose of methionine for acetaminophen poisoning is 2.5 g every four hours for four doses starting less than 10–12 hours after acetaminophen ingestion. It may also be given intravenously.

Precautions

Homocysteine is an amino acid that the liver produces after ingesting methionine. Increased methionine intake, in the presence of inadequate intake of **folic acid**, vitamin B_6, and **vitamin B_{12}**, may increase the homocysteine in the blood and increase the risk of **heart disease**, or **stroke**. A doctor should be consulted to determine if any nutrient supplementation is needed.

Homocystine is the amino acid formed by the oxidation of homocysteine; homocystinuria is an inherited disorder in which there is excess homocystine in the plasma that is excreted in the urine. People with homocystinuria may benefit from a diet low in methionine, and should consult a physician before taking a supplement.

Patients with acidosis (condition of increased acidity in body fluids) or established liver insufficiency should not take methionine, and it should be used with caution in patients with severe liver disease.

A person who is already taking prescription medications for depression should not attempt to take SAMe, since it increases the efficiency of these medications. Those suffering from bipolar (manic–depressive) disorders should not take SAMe, since its antidepressant properties may induce or heighten the manic phase of this condition.

Women who are healthy and eat a well–balanced diet do not require methionine supplementation during pregnancy or while breastfeeding. They should talk to their doctors before using any kind of supplement.

KEY TERMS

Amino acids—Raw materials used by the body to manufacture proteins, which are vital components of all human cells.

Antioxidant—A substance that inhibits oxidation of another substance, such as low density lipoprotein (LDL). LDL can cause plaque build up and hardening of the arteries.

Methionine—An essential sulfur containing amino acid, found in protein foods.

Methylation—The process by which a methyl group (CH_3) is added to some compound, ion, or other chemical species.

Neural tube defects (NTDs)—A group of birth defects caused by failure of the neural tube to close completely during the formation of the baby's central nervous system. Recent research indicates that methionine deficiency in pregnant women increases the risk of NTDs in their newborns.

SAMe—An active compound made from methionine and adenosine triphosphate (ATP), an enzyme found in muscle tissue.

Side effects

No toxic dosage of methionine has been determined, but it may cause **nausea**, **vomiting**, drowsiness, and irritability in moderate amounts. Supplementation of up to 2 g methionine daily for long periods of time has not produced any serious side effects.

Interactions

There are no well–known drug interactions with methionine.

Mexican yam

Description

Mexican yam is one of some 850 species of yam in the Dioscoreaceae family. It is a perennial plant with twisting, climbing vines that grows in warm tropical climates. There are also some twists and turns related to this plant's identity and its use as a herbal remedy.

The wild yam (*Dioscorea villosa*) is a climbing plant that is native to the southeast United States and Canada. Such wild yam species as *Dioscorea floribunda* as well as *Dioscorea villosa* are native to Mexico. These plants are used for the herbal preparations known as Mexican yam and Mexican wild yam. Mexican wild yam also grows in the southeastern United States and Appalachia.

An extract of this plant is used as a herbal remedy called Mexican yam, wild yam, and Mexican wild yam. It is sold as a "natural hormone" cream and oral remedy. Mexican wild yam is also known as **colic** root, China root, rheumatism root, devil's bones, and yuma.

There is another twist to this plant's identity. Although the Mexican yam has fleshy edible roots, this is not the yam that people associate with Thanksgiving dinner. That yam is actually the sweet potato, a vegetable that is the root of a trailing plant. It is a member of the morning glory family. The identification of the sweet potato as a yam is can be traced to the pre-Civil War era of slavery in the United States. The sweet potato reminded slaves from sub-Saharan Africa of the yam plants in their homeland.

General use

Mexican yam has long had a reputation as a woman's herb. During the eighteenth and nineteenth centuries, wild yam was used to treat menstrual **pain** and conditions related to childbirth . Pregnant women used wild yam to combat nausea , ease aching muscles, and prevent miscarriages.

Wild yam was also used as a colic remedy. Furthermore, the plant's anti-inflammatory properties were thought to be effective in the treatment of rheumatoid arthritis.

Most of those uses were forgotten after Japanese researchers in 1936 discovered that wild yam contained diosgenin, a chemical that scientist Russell Marker used in the 1940s to create synthetic progesterone and the hormone **DHEA**.

Synthetic progesterone

Marker worked with species of Mexican yams. Others used his technique for manufacturing progesterone to develop such products as the birth control pill and steroid drugs. During the 1990s, companies began marketing Mexican yam products as a source of natural progesterone and DHEA.

Mexican yam products are also advertised as treatments for menstrual problems and **osteoporosis**. They are sometimes recommended for hormone replacement therapy during menopause, and sometimes the natural hormones are said to slow down the aging process. In addition, Mexican yam and wild yam products are said to boost progesterone effects that fall during the last half of the month. A rise in hormones could help a woman conceive.

This marketing, in terms of the progesterone content and the results, has drawn criticism for misleading consumers. Herbal expert Varro Tyler described this campaign as a "wild yam scam" in his book, *Tyler's Honest Herbal.*

Mexican yam. *(©PlantaPhile, Germany. Reproduced by permission.)*

Contemporary uses of Mexican yam

Although Mexican yam cream does not provide natural progesterone, the herb can be used for cramping conditions like menstrual pain. It can help to build up good **cholesterol** levels while alleviating poor circulation, nervousness and restlessness. In addition, wild yam root tea has been suggested as a means of increasing a woman's ability to conceive.

Preparations

Mexican yam cream is marketed with the promise that it is natural progesterone. The cream is applied to the skin based on a woman's condition. Dosages are based on the outcome expected.

Mexican yam's other uses

Mexican yam is sold as a powdered herb, liquid extract, tincture, and in capsule form. While there are general dosage recommendations for wild yam, instructions on commercial packages should be followed since product strength can vary.

Wild yam tea, which is also known as an infusion, is made by pouring 1 cup (240 mL) of boiling water over 1–2 tsp (1.5–2.5 g) of the dried herb. The mixture is steeped for 10–15 minutes and then strained. Wild yam tea can be drunk three times a day.

A tincture of wild yam in an alcohol solution can be taken 3–4 times a day. A single dosage consists of 2–3 mL (approximately 1.2 tsp) of wild yam.

Wild yam capsules contain the dried root. The average dosage is 1–2 pills, taken three times daily.

Mexican yam combinations

Mexican yam can be combined with other herbs to treat a range of conditions. The following conditions can be treated by these combination remedies:

- Menstrual cramps can be treated with a tea made with wild yam and cramp bark. Those herbs can also be blended into a tea with such herbs as motherwort, fresh oats, and chamomile.
- Relief for rheumatoid arthritis may come from a combination of wild yam and black cohosh.

KEY TERMS

Diosgenin—A compound found in wild yam that has been used to make synthetic progesterone.

- For kidney stones, wild yam can be combined in a tea with such herbs as cramp bark, hydrangea root, and yarrow.

Precautions

Mexican wild yam is safe if taken within prescribed therapeutic dosages, according to the *PDR (Physician's Desk Reference) for Herbal Medicines*. The book draws on the findings of Germany's Commission E, a government agency that studies herbal remedies for approval as over-the-counter drugs. An English version of the German Commission E *Monographs* was published in 1997.

Pregnant and nursing women, as well as patients with hormone imbalances, **depression**, or hormone-sensitive cancers should avoid wild yam unless they are under the guidance of a clinical herbalist or physician.

Furthermore, although wild yam root tea has been suggested as a method for a woman to become pregnant, the herb should not be used during the last half of a menstrual period.

Side effects

Large doses of Mexican yam may produce **nausea**. There is also a risk of poisoning.

Interactions

There are no known interactions when Mexican yam is taken with standard medications, other herbs, or dietary supplements.

Middle ear infection *see* **Ear infection**

Migraine headache

Definition

Migraine is a type of **headache** marked by severe head **pain** lasting several hours or more.

Description

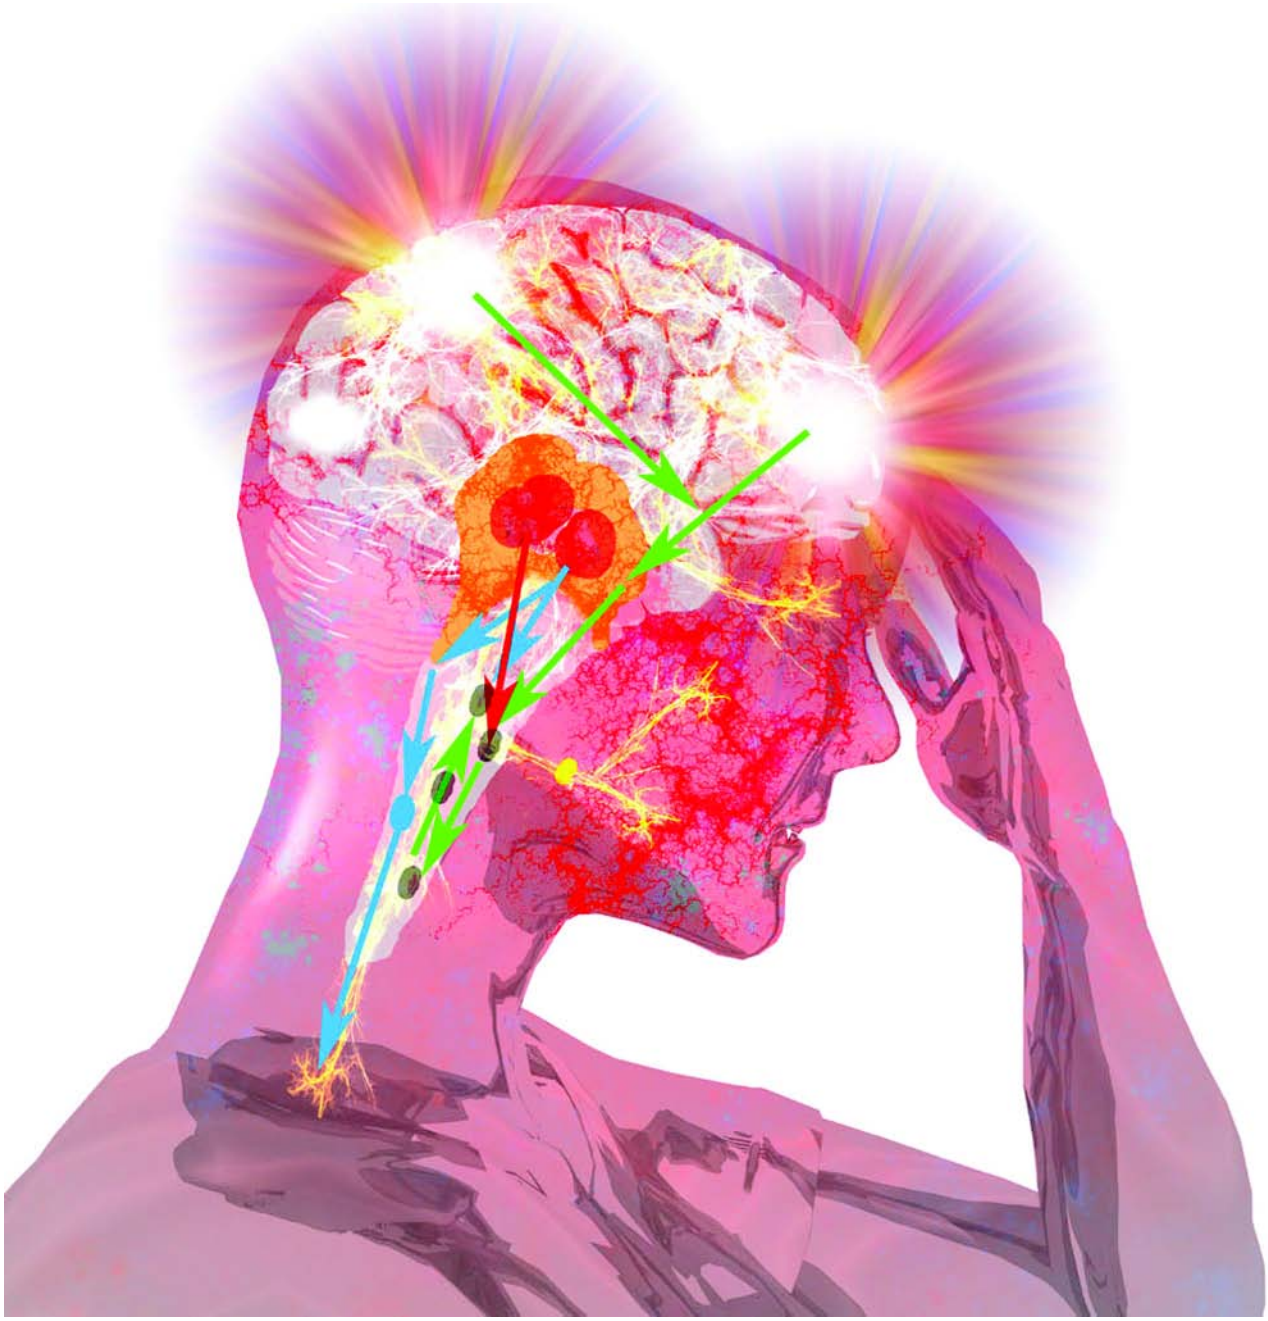
Migraine is an intense and often debilitating type of headache. The term *migraine* is derived from the Greek word *hemikrania*, meaning "half the head," because the classic migraine headache affects only one side of the person's head. Migraines affect as many as 24 million people in the United States, and are responsible for billions of dollars in lost work, poor job performance, and direct medical costs. Approximately 18% of women and 6% of men experience at least one migraine attack per year. Currently, one American in 11 now suffers from migraines, more than three times as many are women, with most of them being between the ages of 30 and 49. Migraines often begin in adolescence, and are rare after age 60.

Two types of migraine are recognized. Eighty percent of migraine sufferers experience "migraine without aura" (common migraine). In "migraine with aura," or classic migraine, the pain is preceded or accompanied by visual or other sensory disturbances, including hallucinations, partial obstruction of the visual field, numbness or tingling, or a feeling of heaviness. Symptoms are often most prominent on one side of the head or body, and may begin as early as 72 hours before the onset of pain.

Causes and symptoms

Causes

The physiological basis of migraine has proved difficult to uncover. There are a multitude of potential triggers for a migraine attack, and recognizing one's own set of triggers is the key to prevention.



Anatomy of a migraine. Sensory triggers cause the thalamus to interact with the trigeminal nucleus and nerve (red arrow) and dilate blood vessels in face and brain. Pain signals sent to the brainstem nuclei (green arrows). The hypothalamus may also send signals to the brainstem and gut to induce pain, nausea, and vomiting (blue arrows). *(© PHOTOTAKE Inc. / Alamy)*

PHYSIOLOGY. The most widely accepted hypothesis of migraine suggests that a migraine attack is precipitated when pain-sensing nerve cells in the brain (called nociceptors) release chemicals called neuropeptides. At least one of the neurotransmitters, substance P, increases the pain sensitivity of nearby nociceptors. This process is called sensitization.

Other neuropeptides act on the smooth muscle surrounding cranial blood vessels. This smooth muscle regulates blood flow in the brain by relaxing or contracting, thus dilating (enlarging) or constricting the enclosed blood vessels. At the onset of a migraine headache, neuropeptides are thought to cause muscle **relaxation**, allowing vessel dilation and

KEY TERMS

Aura—A group of visual or other sensations that precedes the onset of a migraine attack.

Autogenic training—A form of self-hypnosis developed in Germany that appears to be beneficial to migraine sufferers.

Coenzyme Q_{10}—A substance used by cells in the human body to produce energy for cell maintenance and growth. It is being studied as a possible preventive for migraine headaches.

Nociceptor—A specialized type of nerve cell that senses pain.

Transcutaneous electrical nerve stimulation (TENS)—A treatment in which a mild electrical current is passed through electrodes on the skin to stimulate nerves and block pain signals.

increased blood flow. Other neuropeptides increase the leakiness of cranial vessels, allowing fluid leak, and promote inflammation and tissue swelling. The pain of migraine is thought to result from this combination of increased pain sensitivity, tissue and vessel swelling, and inflammation. The aura seen during a migraine may be related to constriction in the blood vessels that dilate in the headache phase.

GENETICS. Susceptibility to some types of migraine is inherited. A child of a migraine sufferer has as much as a 50% chance of developing migraines. If both parents are affected, the chance rises to 70%. In 2002, a team of Australian researchers identified a region on human chromosome 1 that influences susceptibility to migraine. It is likely that more than one gene is involved in the inherited forms of the disorder. Many cases of migraine, however, have no obvious familial basis. It is likely that the genes that are involved set the stage for migraine, and that full development requires environmental influences, as well.

Two groups of Italian researchers have recently identified two loci on human chromosomes 1 and 14 respectively that are linked to migraine headaches. The locus on chromosome 1q23 has been linked to familial hemiplegic migraine type 2, while the locus on chromosome 14q21 is associated with migraine without aura.

TRIGGERS. A wide variety of foods, drugs, environmental cues, and personal events are known to trigger migraines. It is not known how most triggers set off the events of migraine, nor why individual migraine sufferers are affected by particular triggers but not others.

Common food triggers include:

- alcohol
- caffeine products, as well as caffeine withdrawal
- chocolate
- foods with an extremely high sugar content
- dairy products
- fermented or pickled foods
- citrus fruits
- nuts
- processed foods, especially those containing nitrites, sulfites, or monosodium glutamate (MSG)

Environmental and event-related triggers include:

- stress or time pressure
- menstrual periods, menopause
- sleep changes or disturbances, including oversleeping
- prolonged overexertion or uncomfortable posture
- hunger or fasting
- odors, smoke, or perfume
- strong glare or flashing lights

Drugs that may trigger migraine include:

- oral contraceptives
- estrogen replacement therapy
- Theophylline
- Reserpine
- Nifedipine
- Indomethicin
- Cimetidine
- oversuse of decongestants
- analgesic overuse
- benzodiazepine withdrawal

Symptoms

Migraine without aura may be preceded by elevations in mood or energy level for up to 24 hours before the attack. Other pre-migraine symptoms may include **fatigue**, **depression**, and excessive yawning.

Aura most often begins with shimmering, jagged arcs of white or colored light progressing over the visual field in the course of 10–20 minutes. This may be preceded or replaced by dark areas or other visual disturbances. Numbness and tingling are common, especially of the face and hands. These sensations may spread, and may be accompanied by a sensation of weakness or heaviness in the affected limb.

Migraine pain is often present only on one side of the head, although it may involve both, or switch sides during attacks. The pain is usually throbbing, and may

range from mild to incapacitating. It is often accompanied by **nausea** or **vomiting**, painful sensitivity to light and sound, and intolerance of food or odors. Blurred vision is also common.

The pain tends to intensify over the first 30 minutes to several hours, and may last from several hours to a day, or longer. Afterward, the affected person is usually weary, and sensitive to sudden head movements.

Diagnosis

Ideally, migraine is diagnosed by a careful medical history. Unfortunately, migraine is underdiagnosed because many doctors tend to minimize its symptoms as "just a headache." According to a 2003 study, 64% of migraine patients in the United Kingdom and 77% of those in the United States never receive a correct medical diagnosis for their headaches.

So far, laboratory tests and such imaging studies as computed tomography (CT scan) or magnetic resonance imaging (MRI) scans have not been useful for identifying migraine. However, these tests may be necessary to rule out a brain tumor or other structural causes of migraine headache in some patients.

Treatment

At the onset of symptoms, the migraine sufferer should seek out a quiet, dark room and attempt to sleep. Placing a cold, damp cloth or a cold pack on the forehead may help. Additionally, tying a headband tightly around the head can relieve migraines.

Migraine headaches are often linked with food **allergies** or intolerances. Identification and elimination of the offending food or foods can decrease the frequency of migraines and/or alleviate these headaches altogether.

Alternative treatments for migraine include:

- Acupressure. Pressing on the Gates of Consciousness (GB 20) points can relieve migraine.
- Acupuncture. A National Institutes of Health (NIH) panel concluded that acupuncture may be a useful treatment for headache.
- Aromatherapy. The essential oil rosemary eases migraine pain.
- Autogenic training. Autogenic training is a form of self-hypnosis developed in Germany in the 1930s that has been shown in several studies to relieve the pain of migraine.
- Cognitive behavior therapy.
- Herbals. Valerian (*Valeriana officinalis*), passionflower (*Passiflora incarnata*), feverfew (*Chrysanthemum parthenium*), ginger, ginkgo (*Ginkgo biloba*), goldenseal (*Hydrastis canadensis*), hawthorn (*Crataegus oxyacantha*), linden, wood betony (*Stachys officinalis*), skullcap (*Scutellaria lateriflora*), or cramp bark (*Viburnum opulus*) may relieve migraines.
- Hydrotherapy. Contrast showers, in which a short hot shower is followed by a longer cold shower, may halt an oncoming migraine. A hot enema can temporarily relieve migraine pain.
- Naturopathy. Migraine headaches are one of the most common reasons for consulting naturopathic practitioners. Naturopaths typically treat migraine with a combination of nutritional therapy and mind/body techniques.
- Relaxation techniques. Meditation, yoga, hypnosis, visualization, breathing exercises, or progressive muscular relaxation may halt the progression of a migraine.
- Supplements. Clinical studies have shown that vitamin B_2 (riboflavin), magnesium, 5-HTP, or melatonin can reduce the severity of migraines.
- Transcutaneous electrical nerve stimulation (TENS).

Allopathic treatments

Nonsteroidal anti-inflammatory drugs (NSAIDs) acetaminophen (Tylenol), ibuprofen (Motrin), and naproxen (Aleve) are helpful for early and mild headache. Excedrin Migraine is a combination product that is indicated for migraine headache.

More severe or unresponsive attacks may be treated with ergotamine (botulinum toxin), dihydroergotamine, sumatriptan (Imitrex), beta-blockers and **calcium** channel-blockers, antiseizure drugs, antidepressants (SSRIs), meperidine, or metoclopramide. Some of these drugs are also available as nasal sprays, intramuscular injections, or rectal suppositories when vomiting prevents taking the drug by mouth.

Sumatriptan and other triptan drugs (zolmitriptan, rizatriptan, naratriptan, almotriptan, and frovatriptan) should not be taken by people with any kind of vascular disease because they cause coronary artery narrowing. Otherwise these drugs have been shown to be very safe.

Continued use of some antimigraine drugs can lead to "rebound headache," marked by frequent or chronic headaches, especially in the early morning hours. Rebound headache can be avoided by using antimigraine drugs under a doctor's supervision, with the minimum dose necessary to treat symptoms. Tizanidine (Zanaflex) has been reported to be effective in treating rebound headaches when taken together with an NSAID.

Expected results

Most people can control migraines through recognizing and avoiding triggers, and by using effective treatments. Some people with severe migraines do not respond to preventive or drug therapy. Migraines usually wane in intensity by age 60 and beyond.

Prevention

The frequency of migraine headaches may be lessened by avoiding triggers. It is useful to track these triggers by keeping a headache journal.

One substance that is being studied as a possible migraine preventive is **coenzyme Q_{10}**, a compound used by cells to produce energy needed for cell growth and maintenance. Coenzyme Q_{10} has been studied as a possible complementary treatment for **cancer**. Its use in preventing migraines is encouraging and merits further study.

A study published in early 2003 reported that three drugs currently used to treat disorders of muscle tone are being explored as possible preventive treatments for migraine. They are botulinum toxin type A (Botox), baclofen (Lioresal), and tizanidine (Zanaflex). Early results of open trials of these medications are positive.

Anti-epileptic drugs, which are also known as anticonvulsants, are also being studied as possible migraine preventives. As of 2003, **sodium** valproate (Epilim) is the only drug approved by the Food and Drug Administration (FDA) for prevention of migraine. Such newer anticonvulsants as gabapentin (Neurontin) and topiramate (Topamax) are presently being evaluated as migraine preventives.

A natural preparation made from butterbur root (*Petasites hybridus*) has been sold in Germany since the 1970s as a migraine preventive under the trade name Petadolex. Petadolex has been available in the United States since December 1998 and has passed several clinical safety and postmarketing surveillance trials.

Other possible preventive measures include: eating at regular times, not skipping meals, reducing the use of **caffeine** and pain-relievers, restricting physical exertion (especially on hot days), and keeping regular sleep hours, but not oversleeping. Other measures include:

- Aerobic exercise, which can reduce the frequency of migraines.
- Biofeedback thermal control was found to be as effective as medications in preventing migraines.
- Celery juice consumed twice daily may help to prevent migraines.
- Feverfew was shown to reduce the severity and frequency of migraines. This herb should not, however, be used during pregnancy or by people taking blood-thinning medications.
- Ginger may help prevent migraines.
- Pulsing electromagnetic fields. A preliminary study found that pulsing electromagnetic fields reduced the frequency of migraines.
- Relaxation techniques can reduce migraine frequency.
- Supplementation with magnesium and riboflavin was shown to prevent migraines.

Milk Thistle. *(© blickwinkel / Alamy)*

Milk thistle

Description

Milk thistle (*Silybum marianum* or *Cardus marianum*) is a plant used for treating liver disorders, breast-feeding problems, and other illnesses. The active ingredient of the herb, silymarin, is found in the ripe seeds of the plant. The milk thistle plant has a long stem, green leaves with white spots, and pink to purple spiky flowered head (which true to its name, resembles a thistle). The plant is native to Europe and grows in the wild in the United States and South America. Other common names for the plant include Mary thistle, St. Mary thistle, Marian thistle, and lady's thistle.

The medicinal benefits of milk thistle have been valued for more than 2,000 years. Written records show that as early as the first century, Romans were using the plant as a liver-protecting agent. The plant was also frequently used throughout the Middle Ages, and it is in the herbal literature of this period that the medicinal properties of milk thistle seeds are first noted. Nicholas Culpepper, a British herbalist, wrote about the value of the herb in treating diseases of the liver and spleen in the late eighteenth century, and by the end of the next century, records show that American physicians were also prescribing the substance. Silymarin was first isolated from the milk thistle plant by German scientists in the 1960s.

The leaves and stem of the milk thistle plant are edible, and can be used in salads or eaten raw. The plant was cultivated as a vegetable in Europe through the end of the nineteenth century.

General use

Milk thistle is prescribed for a number of medicinal uses, including liver disease treatment and prevention, HIV treatment, lactation problems, gallbladder

KEY TERMS

Antioxidants—Enzymes that bind with free radicals to neutralize their harmful effects.

Free radicals—Reactive molecules created during cell metabolism that can cause tissue and cell damage like that which occurs in aging and with disease processes such as cancer.

Flavonoid—Any of a group of aromatic compounds that includes many common pigments, such as the anthocyanins and flavones.

Tincture—A liquid extract of an herb prepared by steeping the herb in an alcohol and water mixture. Tinctures can also be prepared using vinegar or glycerin instead of alcohol.

disorders, mushroom poisoning, and **psoriasis**, a chronic skin disease characterized by reddish patches.

Liver disease

Milk thistle is thought to promote the growth of new liver cells, and to prevent toxins from penetrating through healthy liver cells by binding itself to the cell membranes. It is prescribed for **cirrhosis**, **hepatitis**, and other liver disorders. Several clinical studies have demonstrated that individuals with cirrhosis who take daily doses of milk thistle extract have a lower mortality rate than those who took a placebo (or sugar pill). While further research needs to be completed, a 2001 article reports that clinical trials show that milk thistle (at 140 mg three times per day) did indeed improve survival among cirrhosis patients.

In addition, milk thistle may have a protective effect on the liver, and is sometimes prescribed for patients who take medications that can cause liver damage (e.g., Thorazine, Haldol), or those who are exposed to liver-damaging substances such as lead. A large, controlled trial sponsored by the National Center for Complementary and Alternative Medicine (NCCAM) and the National Institutes of health (NIH) of milk thistle's medicinal value in the treatment of hepatitis and liver injury was scheduled to begin in the year 2000.

HIV treatment

Milk thistle is sometimes prescribed for HIV-positive patients to protect the liver from diseases such as hepatitis and from the hepatotoxic effects of other medications prescribed for HIV treatment.

Lactation problems

Milk thistle is frequently prescribed for breast-feeding mothers to promote increased breast milk secretion. Although the herb is considered safe for nursing mothers, it should be acquired from a reputable source and prescribed by an herbalist, naturopathic physician, or other healthcare professional familiar with its use.

Cancer prevention

The active chemical components of the milk thistle, silymarin (a complex of flavonoids) and its constituent, silibin, act as **antioxidants**. These substances have been shown to slow cell growth in some types of **cancer**.

Gallbladder disorders

Milk thistle may prevent inflammation of the gallbladder ducts and clear up **jaundice**.

Death cap mushroom poisoning

Milk thistle is the only known antidote for death cap mushroom (*Amanita phalloides*) poisoning. Ingesting this deadly mushroom can destroy the liver by shutting down protein production in liver cells. Milk thistle neutralizes these toxins and protects the liver. Milk thistle may also be helpful in acetaminophen overdosage.

Psoriasis

Because the liver neutralizes certain toxins associated with psoriasis attacks, milk thistle is believed to help prevent psoriasis outbreaks by promoting proper liver function.

Several other dermatological uses for the herb are currently under investigation. The antioxidant properties of the herb may have a healing effect on skin **wounds** and **burns**. Milk thistle has also been proposed as a cosmetic agent to retain skin tone and quality. Further studies are needed to prove the efficacy of the herb for these applications.

Preparations

Milk thistle is available in seed form, in capsules, and in extracts and tinctures. A tincture is an herbal preparation made by diluting the herb in alcohol. Tinctures of milk thistle can be taken in 1 or 2 ml doses three times a day.

Milk thistle seed has a low level of water solubility, so infusions (or teas) made from the herb are weaker than milk thistle tinctures and extracts. An

infusion of milk thistle can be prepared by pouring a cup of boiling water over one teaspoon of seeds that have been ground to a fine texture. After the mixture steeps for 10-20 minutes, the herb is strained out and the mixture can be drunk. Instead of straining, the herb can also be placed into an infuser ball, tea bag, or a piece of cheesecloth or muslin and removed after steeping. Individuals can drink two to three cups of the infusion daily.

Milk thistle seed can also be taken by mouth in a dose of 1 tsp of fresh ground seeds daily. The herb should always be stored in an airtight container in a cool location away from bright light to maintain its potency.

Precautions

Individuals who suspect they have a liver disorder should always seek care from a healthcare professional.

Milk thistle should always be obtained from a reputable source that observes stringent quality control procedures and industry-accepted good manufacturing practices. Consumers should look for the designations "U.S.P." (*U.S. Pharmacopeia*) or "NF" (*National Formulary*) on milk thistle labeling. Herbal preparations prepared under USP or NF guidelines meet nationally recognized strength, quality, purity, packaging, and labeling standards as recommended by the U. S. Food and Drug Administration (FDA).

Botanical supplements are regulated by the FDA; however, they currently do not have to undergo any approval process before reaching the consumer market, and are classified as nutritional supplements rather than drugs. Legislation known as the Dietary Supplement Health and Education Act (DSHEA) was passed in 1994 in an effort to standardize the manufacture, labeling, composition, and safety of botanicals and supplements, and in January 2000, the FDA's Center for Food Safety and Applied **Nutrition** (CFSAN) announced a 10-year plan for establishing and implementing these regulations by the year 2010.

Pregnancy

Milk thistle is considered safe to use during **pregnancy** and in women who breastfeed. However, there are currently no long-term studies on use of the herb during pregnancy or lactation. A woman should speak with her healthcare practitioner before taking any herbs and/or medications during pregnancy.

Side effects

Milk thistle may cause mild **nausea** and **diarrhea**, or loose stools. The herb may also cause an allergic reaction in some individuals, particularly those with known **allergies** to plants in the Asteraceae family (thistles, daisies, artichokes). No other widely reported side effects are known when milk thistle is taken in proper therapeutic dosages. However, people with chronic medical conditions should consult with their healthcare professionals before taking the herb.

Interactions

There are no reported negative interactions between milk thistle and other medications and herbs, although certain drugs with the same therapeutic properties as milk thistle may enhance the effect of the herb. Again, individuals should consult their healthcare provider if they are taking other medications concurrently with milk thistle.

Mind/body medicine

Definition

Mind/body medicine, also known as behavioral medicine, is the field of medicine concerned with the ways that the mind and emotions influence the body and physical health.

Origins

There was a time not long ago when Western medicine believed that health depended solely upon the physical mechanisms of the body. That is, a person is made up only of physical and chemical reactions that can be measured and manipulated scientifically. The notion that the mind and body live in separate compartments, so to speak, goes back to certain philosophers of classical antiquity. This concept of mind/body separation was also present in such religious groups as the Gnostics and some sects on the fringes of medieval Christianity. The scientific version of this split between mind and body is generally traced back to the seventeenth-century French philosopher Rene Descartes, whose thinking aided the development of science. It has taken a lot of time and research, three centuries after Descartes, for mainstream medicine to begin to accept that the mind plays a major role in health and disease.

The idea that the mind and body interact is not new, however. It can be traced to the Wisdom literature in the Old Testament and to Hippocrates, the father of Western medicine. The ancient Hebrews attributed some physical illnesses to grief or anger. Hippocrates believed that health depends upon a balance of the body, mind and environment, and that disease is caused by imbalances in these areas. As modern science progressed, the mind and emotions became neglected, since researchers found it difficult to measure and quantify mental states with the scientific methods and equipment that were so highly valued.

In the early 1900s, Harvard physiologist Walter Cannon coined the term "fight-or-flight response" for the body's reaction to threats, a response that causes increases in heart rate, blood pressure, blood sugar, muscle tension and respiration. During the 1950s, Hans Selye of McGill University pioneered research in what he called **stress**. Selye determined that the fight-or-flight response could be triggered by psychological factors as well as by physical threats. Stress includes having fight-or-flight reactions in situations where there is no immediate threat except mental perceptions and worries. Stress is not necessarily negative, except when people fail to cope with it effectively. Selye's work laid the groundwork for researchers to determine that stress and reactions to it play an integral role in health and disease.

Other mind/body relationships became apparent to medical researchers. The so-called **placebo effect** has been studied by doctors and psychologists for years. In clinical experiments, people who are given inert substances made to look like medicines, such as sugar pills, often experience the same improvements as those patients who are given real medications. It is estimated that nearly one out of every three patients improves with medication simply because of the placebo effect, and not because of the drug itself. Researchers have also noted that some conditions and illnesses have no physical explanations. Doctors termed these conditions psychosomatic illnesses, as they seem to be caused by the psyche, or mind.

Researchers then theorized that certain personality types are susceptible to particular conditions. For instance, "Type A" personalities tend to be aggressive, ambitious, and always rushed. They tend to cope with stress by getting angry and upset. Researchers have found that these personalities are more prone to **heart disease**, high blood pressure, and other stress-related conditions. "Type B" personalities are those who cope with stressful situations with communication and balance instead of anger and aggression, and have been found to be less prone to stress-related conditions. Researchers have added a "Type C" personality, who tends to suppress emotions and has trouble with self-expression. Some clinicians have proposed a link between suppressed emotions and the development of **cancer**.

In the past few decades, researchers have begun to unravel the complex ways in which the mind and body interact. Many findings have demonstrated that the

KEY TERMS

Behavioral medicine—The branch of medicine that studies mind/body relationships.

Fight-or-flight response—The body's reaction to threats.

Mantra—A sacred word or formula repeated over and over to concentrate the mind.

Placebo—A pharmacologically inactive substance disguised as a real medication.

Psychoneuroimmunology—The study of the relationships among mind, nervous system, and immune response.

Psychosomatic—A type of physical illness caused by mental factors.

Relaxation response—The calming of bodily responses through relaxation techniques.

Vipassana—A Buddhist meditative practice that emphasizes deep attentiveness to the present moment.

mind and body are intimately interconnected. Medical science has shown that the nervous system works closely with the immune system, systems that were at one time believed to be separate. Nerve endings have been found that connect directly to important components of the immune system called lymph nodes. This connection demonstrates that there is a physical link between the mind and the immune system. Studies have also shown that thoughts and emotions alone can influence the activity of immune system cells.

In the 1970s, Dr. Herbert Benson at Harvard Medical School discovered what he called the "relaxation response." Benson observed that trained **yoga** specialists (yogis) could control bodily functions that had previously been believed to be autonomic, or beyond the control of the mind. During **meditation**, these yogis could reduce their heart rates, blood pressure, metabolism, body temperature, and other physiological processes to surprising levels. Other people who were then taught meditation were able to reach deep states of **relaxation** and calmness as well. This relaxation response, as Benson termed it, is essentially the opposite of the fight-or-flight response. The relaxation response reduces blood pressure, respiration, heart rate, oxygen consumption, muscle tension, and other bodily processes that are elevated by stress. Researchers soon began to theorize that if stress could have harmful effects on health, then the relaxation response might have the opposite effect. It wasn't long before the Harvard Mind/Body Medical Institute was founded, and other major medical clinics followed by integrating mind/body practices and studies into their health programs. A new field opened up in academic medicine called **psychoneuroimmunology** (PNI), which is the study of how the mind and nervous system affect the immune system. Studies have since shown that the mind and emotions play roles in many diseases, including cancer, diabetes, heart disease, gastrointestinal problems, and **asthma**.

In 1993, Dr. David Eisenberg wrote in the *New England Journal of Medicine* about a study that showed that one out of every three adults in America had used some form of unconventional medicine. Of those alternative treatments, mind/body practices were used most often. The popular PBS series by journalist Bill Moyers, called *Healing and the Mind*, brought mind/body medicine into millions of homes. Dr. Benson of Harvard claims that mind/body medicine should no longer be considered alternative. Despite the acclaim and success, however, there is still resistance to the simple idea that the mind is an important part of health, and many mainstream doctors still adhere to the belief that medicine is just a matter of "drugs killing bugs."

Benefits

Mind/body therapies have shown promise in treating cancer, heart disease, **hypertension**, asthma, and mental illness. They have been used as effective complementary therapies alongside such conventional treatments as surgery and chemotherapy. Mind/body therapies have also been shown to increase quality of life, reduce **pain**, and improve symptoms for people with chronic diseases and health conditions. They may also help control and reverse certain diseases, particularly those that are stress-related. By reducing stress, mind/body therapies may even prevent many diseases. Another benefit of mind/body therapies is that they pose very little risk. Some are inexpensive, and most have few side effects.

Description

There are many alternative techniques that draw upon the interconnections between mind and body. These include **art therapy**, assertiveness training, autogenic training, bioenergetics, **biofeedback**, **breath therapy**, mental imagery, dance and **movement therapy**, dreamwork, Gestalt therapy, group therapy, hypnosis, meditation, mindfulness training, Jungian psychoanalysis, postural integration, **prayer** and faith healing, progressive relaxation, psychodrama, **psychotherapy**, Reichian therapy, support groups, and yoga. Some of the most widely used techniques are meditation, mindfulness training, biofeedback, breath therapy, hypnosis, mental imagery, and movement therapies, which are discussed below.

Costs can vary widely for mind/body treatments, depending on the type and the medical training of the practitioner. Many insurance companies will reimburse some mind/body treatments and training sessions; consumers should be aware of their insurance provisions.

Meditation

There are many forms of meditation, but they all have the same goal, which is to calm and focus the mind. As beginning meditators find out, however, calming and clearing the mind of thoughts and worries is easier said than done. When performed on a regular basis, meditation is an efficient way of promoting the relaxation response. Meditation is used to ease the discomfort of many health problems, including stress-related conditions, chronic pain, panic disorders, tension headaches, and asthma. A 2002 report stated research shows that transcendental meditation can reduce hardening of the arteries, eventually helping reduce risk of **heart attack** and **stroke**.

Meditation can be practiced anywhere, but a quiet and peaceful setting is recommended. Meditators should sit or lie in a comfortable position. Sitting with the spine as straight as possible without straining is the most commonly recommended position. Breathing during meditation should be deep, calm and slow. The meditator may concentrate on the breath or on a still object such as a flower or candle flame. The meditator often may repeat a soft sound, word, or phrase, known as a mantra. Mantras can be affirmative statements, prayers, or humming sounds. The goal of the meditator is to concentrate deeply in order to reduce the amount of thinking, and to calm the worries and thoughts that typically fill the mind. When thoughts or distractions arise, the meditator should allow them to pass without directing attention toward them.

Meditation should be done twice a day, for 20 minutes at a time, preferably at consistent times to develop discipline. It can be learned from books or tapes, but instruction is widely available and recommended, as beginners can find properly meditating and quieting the mind to be difficult at first.

Mindfulness training

This form of mental discipline was made popular by Dr. Jon Kabat-Zinn, a psychologist at the University of Massachusetts Medical Center, who has written some popular books on mind/body medicine. Kabat-Zinn uses mindfulness training to help patients deal with chronic illnesses and pain. Mindfulness training is also good for stress-related conditions, and those undergoing difficult treatments like surgery or chemotherapy. Practitioners of mindfulness claim it helps them experience more pleasure and less stress in their everyday activities.

Mindfulness training originates from a Buddhist practice called *vipassana*. Its basic idea is that deep awareness of the present moment is the essential discipline. Lack of awareness and attention can lead to stress and bad health habits. To be mindful is to participate fully in whatever one is doing at the present moment, whether reading, walking, working, eating, exercising, relaxing, etc. When a person pays full attention to the present moment without judgment, then worries about the past and future tend to disappear, and stress levels are also significantly reduced.

Mindfulness training teaches that painful situations and emotions should be experienced with full attention as well, which helps people to confront and accept them. Mindfulness training also uses techniques like the body scan, in which the patient focuses full attention on each part of the body in succession. This technique helps people become more aware of their bodies and learn to control their reactions to stress, change, and illness.

Biofeedback

Biofeedback uses special instruments that measure and display heart rate, perspiration, muscle tension, brain wave activity, body temperature, respiratory patterns, and other indicators of stress and physiological activity. Patients can observe their measurements and learn to consciously control functions that were previously unconsciously controlled. Biofeedback also helps people learn how to initiate the relaxation response quickly and effectively.

Biofeedback is used to treat hypertension, stress-related headaches, migraine headaches, attention-deficit disorder, and diabetes. Biofeedback is used often in physical therapy to rehabilitate damaged nerves and muscles. It is also an approved treatment for a vascular disorder called **Raynaud's syndrome**. Patients with this syndrome experience blanching and numbness in their hands and feet in response to cold or emotional stress. A 2002 study showed that biofeedback helped children with a disease called vesicoureteral reflux (an abnormal backflow or urine from the bladder to the ureter) learn to correct reflux. This helped the children avoid surgery and prolonged antibiotic therapy.

Breath therapy

Breath therapy works on the premise that breathing plays a central role in the body and mind. People who are under stress tend to breathe rapidly and shallowly, whereas slow and deep breathing has been shown to reduce stress and promote the relaxation response. In **Ayurvedic medicine** and **traditional Chinese medicine**, the breath is considered the most important metabolic function. In yoga, there is a science of breathing techniques known as pranayama, which is designed to reduce stress and promote health.

Breath therapy is often used in conjunction with meditation and other mind/body techniques. It can be learned from books and tapes, or can be learned from a yoga or mind/body specialist. It is an inexpensive treatment, and once learned can be practiced easily anywhere.

Hypnosis

Hypnosis is deeply focused attention that brings about a trance state that is somewhere between waking and sleeping. During hypnosis, the mind is very open to suggestion. Mental imagery is often used in conjunction with hypnosis to maximize positive thinking and healing.

Hypnosis, or **hypnotherapy**, is used to reduce stress, **anxiety**, and pain, and help patients suffering from chronic diseases. It is also used to assist people in overcoming bad health habits, and addictions to nicotine, alcohol and drugs. Some dentists use hypnosis to help patients relax during dental procedures. Research continues to show the benefits of hypnosis. In 2002, a summary of recent studies included one that evaluated the effectiveness of self–hypnosis for patients undergoing angioplasty and other medical procedures. They required half the sedation of patients in control groups, and their procedures took less time. Pregnant adolescents who were counseled on hypnosis needed less anesthesia during delivery, needed less pain medication after delivery, and left the hospital sooner than patients in the control groups. Hypnosis is best performed by trained hypnotherapists, who can teach techniques of self-hypnosis to the patient.

Mental imagery

This technique uses the imagination to stimulate healing responses in the body, as studies have shown that the imagination can cause the same activity in the brain and immune system as real events. Patients are taught to imagine places or situations in which they have felt happy, healthy, or safe. Patients can also focus on images that increase confidence, reduce stress, and promote healing. Cancer patients are taught to imagine that their immune cells are eliminating cancer cells from their bodies. Heart attack sufferers are taught to imagine their hearts getting healthy and strong. Women can mentally rehearse **childbirth**, and patients imagine themselves successfully going through surgery as preparation for the real event.

Mental imagery has shown promise treating immune system problems, and is used often in cancer treatment and **AIDS** cases. It has been used to treat **irritable bowel syndrome** and asthma. Mental imaging techniques are also used in conjunction with many other mind/body techniques like meditation and hypnosis, as it is an efficient means of promoting positive mental attitudes. Mental imaging techniques can be learned from books, audiotapes, videos, and from professional therapists and teachers.

Movement therapy

Movement routines such as **dance therapy** have been shown to have a significant mind/body element. In these therapies, which also include **martial arts**, yoga, and tai chi, strict routines of physical movements are designed to involve high levels of mental concentration and awareness of the body. Movement therapies are good for people who have trouble sitting still for meditation, and are an excellent way of improving physical strength and mental health at the same time.

Precautions

Mind/body practices are safe and have few side effects. They should not, however, be relied upon solely when other medical care is required, particularly for serious conditions like heart disease, cancer, or diabetes. Consumers should also seek out reliable and properly trained practitioners, particularly in those practices and states for which certification is not required by law.

Research and general acceptance

Because of its increasing acceptance by mainstream medicine, mind/body medicine has been the subject of intense research. Studies have shed new light on everything from the minute interactions of the immune and nervous systems to the effective results of individual therapies like meditation and **guided imagery**. Other studies have indicated relationships between stress and disease. Some eye-opening results have been observed as well, such as studies that have shown that cancer and heart disease patients utilizing mind/body techniques had significantly longer survival rates on average than those patients who did not use mind/body therapies. Despite increasingly proven benefits to mind–body medicine, few health plans pay for the treatments.

Training and certification

Training programs and certification criteria tend to vary with individual therapies and states.

The Biofeedback Certification Institute of America lists certified biofeedback practitioners. Address: 10200 W. 44th Ave., Suite 304. Wheatridge, CO 80033. (303) 420-2902.

The American Society of Clinical Hypnosis is the largest organization for certifying hypnotherapists. Address: 2200 East Devon Ave., Suite 291. Des Plaines, IL 60018. (708) 297-3317.

The Wellness Community provides information on support groups organized throughout the country. Address: 2716 Ocean Park Blvd., Suite 1040. Santa Monica, CA 90405. (310) 314-2555.

The Academy for Guided Imagery provides resources for mental imaging treatments. Address: PO Box 2070. Mill Valley, CA 94942. (800) 726-2070.

ANDREW WEIL (1942–)

Dr. Andrew Weil, a Harvard educated physician, adds credibility and expertise to the natural healing methods he espouses in his best selling books, on his Internet Web site, in his talk show appearances, and in his popular audio CD of music and meditation. Weil's *Spontaneous Healing* spent more than a year on the best seller list, and his 1997 book, *Eight Weeks to Optimum Health*, also was a runaway best seller. Perhaps the best known proponent of naturalistic healing methods, Weil has been trying to establish a field he calls integrative medicine. He is director of Tucson's Center for Integrative Medicine, which he founded in 1993. In 1997, he began training doctors in the discipline at the University of Arizona, where he teaches.

After getting his bachelor's degree in botany from Harvard University, Weil applied for admission to Harvard Medical School in 1964. During his second year, he led a group of students who argued they could succeed better studying on their own than going to classes; in fact, the group got higher scores on their final exams than their classmates. After graduating from Harvard Medical School, he volunteered at the notorious counter cultural Haight Asbury Free Clinic in San Francisco, CA. Later in 1969, Weil got a job in Washington, DC, with the National Institute of Mental Health's Drug Studies Division. From 1971 to 1975, he traveled extensively in South America and Africa, soaking up information about medicinal plants, shamanism, and natural healing techniques. He never returned to the practice of conventional medicine.

His approach to alternative medicine is eclectic, mingling traditional medicine with herbal therapy, acupuncture, homeopathy, chiropractic, hypnotism, cranial manipulation, and other alternative healing methods. Though his books discuss the benefits of everything from healing touch to herbal cures, Weil doesn't dismiss the benefits of standard Western medicine when appropriate.

The Vipassana Meditation Center is a resource for those interested in mindfulness training and meditation. Address: PO Box 24. Shelbourne Falls, MA 01370. (413) 625-2160.

Mistletoe

Description

Mistletoe is a parasitic evergreen plant that lives on trees such as oaks, elms, firs, pines, apples, and elms. The parasitic plant has yellowish flowers; small, yellowish green leaves; and waxy, white berries. There are many species of this plant in the Viscacea and Loranthacea plant families. European mistletoe (*Viscum album*) and American mistletoe (*Phoradendron leucarpum*) are used as medical remedies. In addition to Europe and North America, mistletoe is also found in Australia and Korea.

Mistletoe berries are poisonous to cats and other small animals. There is, however, some debate about

Mistletoe. *(© Holt Studios International Ltd. / Alamy)*

KEY TERMS

Amenorrhea—Abnormal absence or suppression of menstruation.

Chorea—A nervous system disorder that causes involuntary jerking or spasms. Also known as St. Vitus dance.

Orthostatic—Related to or caused by an upright position.

Pharmacognosist—A person involved in pharmacognosy, the science concerned with the medical products of plants in their natural state.

Subcutaneous—Beneath the skin.

Vertiginous attacks—Attacks of vertigo or dizziness.

how toxic the berries are to humans, and there is controversy about whether it is safe to use mistletoe as a remedy. Mistletoe is also known as mystyldene, all-heal, bird lime, golden bough, and devil's fuge.

General use

Mistletoe is known popularly as the plant sprig that people kiss beneath during the Christmas season. That custom dates back to pagan times when, according to legend, the plant was thought to inspire passion and increase fertility.

In the centuries since then, mistletoe has acquired a reputation as a nearly all-purpose herbal remedy. In the seventeenth century, French herbalists prescribed mistletoe for nervous disorders, epilepsy, and the spasms known as the St. Vitus dance.

Mistletoe has also been used in folk medicine as a digestive aid, heart tonic, and sedative. It was used to treat arthritis, hysteria and other mental disturbances, **amenorrhea**, **wounds**, asthma, bed wetting, infection, and to stimulate glands.

For centuries, mistletoe also served as a folk medicine treatment for **cancer**, and the plant is currently used in Europe to treat tumors. Iscador is an extract of the European mistletoe plant that is said to stimulate the immune system and kill cancer cells. It reportedly reduces the size of tumors and improves the quality of life. One team of researchers in France has found evidence that mistletoe extracts increase the efficiency of the body's natural killer cells in destroying cancer cells. A German study published in 2002 indicates that Iscador does indeed inhibit tumor growth. Another recent German case study of an 80-year-old woman with metastasized **breast cancer** documented that the patient lived for 41 months after first being given Iscador, with good quality of life. Iscador is one brand name of the mistletoe extract in Europe, and other brand names include Helixor and Eurixor.

Other contemporary uses of mistletoe include treatment of rheumatism, **anxiety**, migraine headaches, dizziness, high blood pressure, relief of spasms, **asthma**, rapid heartbeat, **diarrhea**, hysteria, and amenorrhea. Research continues on the use of mistletoe to treat **AIDS** patients.

There are some differences among the species. American mistletoe is said to cause a rise in blood pressure, while its European counterpart is believed to lower blood pressure.

Although mistletoe appears to be a multipurpose remedy, there is disagreement among medical experts about the safety and effectiveness of this herb. The

number of possible interactions with other medications described below indicates that mistletoe should be used with caution.

Preparations

In alternative medicine, the leaves, twigs, and sometimes the berries of mistletoe are used. In Europe, mistletoe remedies range from tea made from mistletoe leaves to injections of Iscador. While European research indicates that mistletoe is safe and effective, sources in the United States maintain that the berries are poisonous and that the herb can cause liver damage.

Since mistletoe has not been tested by the United States Food and Drug Administration (FDA), many experts urge caution until more research is completed. European research includes work completed by Germany's Commission E, a governmental agency that studies herbal remedies for approval as over-the-counter drugs. An English version of the German Commission E monographs was published in 1997 and was the basis for the *PDR (Physicians' Desk Reference) for Herbal Medicines*.

Home remedies

Mistletoe tea may be taken for high blood pressure, asthma, epilepsy, nervousness, diarrhea, hysteria, whooping cough, amenorrhea, vertiginous attacks, and chorea. The tea is prepared by adding 1 tsp (5 g) of finely cut mistletoe to 1 cup (250 ml) of cold water. The solution is steeped at room temperature for 12 hours and then strained. Up to 12 cups of tea may be consumed each day.

Mistletoe wine is prepared by mixing 8 tsp (40 g) of the herb into 34 oz (1 L) of wine. After three days, the wine can be consumed. Three to four glasses of medicinal wine may be consumed each day.

Mistletoe must be stored away from light and kept above a drying agent.

Cancer treatment

Iscador, the European extract, may be injected before surgery for cancers of the cervix, ovary, breast, stomach, colon, and lung. Cancer treatments can take several months to several years. The treatment is given by subcutaneous injection, preferably near the tumor. Iscador may be injected into the tumor, especially tumors of the liver, cervix, or esophagus.

The dosage of Iscador varies according to the patient's age, sex, physical condition, and type of cancer. The treatment usually is given in the morning three to seven days per week. As treatment continues, the dosage may be increased or adjusted.

European cancer research has been conducted since the 1960s, and most has involved European mistletoe. However, researchers believe there may be some similar active components in other species. In the United States, some cancer patients may qualify for participation in clinical trials of Iscador.

Advocates of Iscador believe it can stimulate the immune system, kill cancer cells, inhibit the formation of tumors, and extend the survival time of cancer patients. They maintain that mistletoe can help prevent cancer and serve as companion therapy for standard cancer treatments. They also think that mistletoe could possibly repair the DNA that is decreased by chemotherapy and radiation.

In general, however, American researchers are skeptical about European claims regarding mistletoe as an effective cancer remedy. The latest information summary on mistletoe extracts, updated in May 2002 and available from the National Cancer Institute web site, states that "There is no evidence from well-designed clinical trials that mistletoe or any of its components are effective treatments for human cancer."

AIDS treatment

Mistletoe extract has been used to combat AIDS. In 1998 European studies, Iscador injections were used to improve the immune response. Experts reported from early results that when patients were given Iscador, no additional progression of HIV was seen. The combination of Iscador with standard therapy could be potentially beneficial, but more research is needed.

In 1996, the first United States patent was issued for T4GEN, a pharmaceutical version of the mistletoe extract. ABT Global Pharmaceutical of Irvine, California (the patent owner) has developed the synthetic version to be tested and potentially approved as a drug by the FDA. As of summer 2000, there have been no further announcements about T4GEN research.

Precautions

Opinions are sharply divided on how safe and effective the herb is as a home remedy and in the treatment of conditions like cancer and AIDS. There is controversy about which parts of the plants are poisonous. Although the berries are classified as poisonous in the United States, some sources say that eating berries is only dangerous for babies, and only if handfuls are consumed. Pregnant or breast-feeding women, however, should not use the plant.

According to a report from the **Hepatitis** Foundation International, mistletoe is toxic to the liver. However, the *PDR for Herbal Medicines* advises that there are no health hazards when mistletoe is taken properly and in designated therapeutic dosages. Other sources state that mistletoe's toxicity could cause cardiac arrest.

People considering mistletoe should consult with their doctor or practitioner. Until there is definitive proof otherwise, there is a risk that the herbal remedies will conflict with conventional treatment.

Herbal experts including Varro Tyler advise against using mistletoe as a beverage or home remedy until more definitive research is completed. Tyler, a respected pharmacognosist, is the coauthor of the *Tyler's Honest Herbal*.

Side effects

Mistletoe may be potentially toxic to the liver. For people diagnosed with hepatitis, use of an herb like mistletoe may cause additional liver damage. However, advocates of mistletoe point out that the herb has been tested in Europe. That research indicated less severe side effects. Mistletoe extracts can produce **chills**, **fever**, **headache**, chest **pain**, and orthostatic circulatory disorders.

Commercial mistletoe extracts may produce fewer side effects. The body temperature may rise and there may be flu-like symptoms. The patient may experience **nausea**, abdominal pain, and (if given the extract injection) inflammation around the injection sight. In a slight number of cases, allergy symptoms have resulted.

Interactions

Mistletoe shouldn't be used by people who take monoamine oxidase (MAO) inhibitor antidepressants like Nardil. Potential reactions include a dangerous rise in blood pressure and a lowering of blood **potassium** levels (hypokalemia). In addition, mistletoe appears to interfere with the action of antidiabetic medications; to increase the activity of diuretics; and to increase the risk of a toxic reaction to aspirin or NSAIDs. Cancer patients considering mistletoe treatment should first consult with their doctor or practitioner.

Monkshood *see* **Aconite**

Mononucleosis

Definition

Infectious mononucleosis is caused by the Epstein-Barr virus, which in teenagers and young adults may result in acute symptoms that last for several weeks. **Fatigue** and low energy can linger for several months.

Remedies for mononucleosis

Therapy	Description	Target symptom
Aromatherapy	Add lavender or eucalyptus to a warm bath	Fatigue
Herbal medicine	Echinacea; yarrow or edler flower tea	Fight infection and fever, strengthen immune system
Home remedies	Rest, drink fluids; gargle with salt water; and massage lower back	Fatigue, dehydration, and sore throat
Mind/body	Meditation, biofeedback, and guided imagery	Stress-induced fatigue
Diet	Eat fresh fruits and vegetables. Avoid caffeine, sugars, and animal proteins	Strengthen immune system and increase energy
Yoga	Cobra pose	Fatigue

(Illustration by Corey Light. Cengage Learning, Gale)

Description

Infectious mononucleosis (IM), also called mono or glandular **fever**, is commonly transmitted among teenagers and young adults by kissing; hence, it is sometimes called the kissing disease.

By age 35 to 40, approximately 95% of the population has been infected with the Epstein-Barr virus (EBV) that causes IM. Although anyone can develop mononucleosis, primary (first) **infections** commonly occur in young adults between the ages of 15 and 35. Symptoms of IM are particularly common in teenagers. In the developed world, 15 to 20% of people are infected during adolescence and about half of these teens become ill. Among adults, 30 to 50% of those contracting IM become ill. Males and females are equally susceptible, and in the United States whites are 30 times more likely than blacks to contract IM.

Typically IM runs its course in about four weeks. However, people with weakened or suppressed immune systems, such as **AIDS** or organ-transplant patients, are especially vulnerable to potentially serious complications from mononucleosis.

Following IM, the EBV remains dormant (latent) in a few cells in the throat and blood for the remainder of one's life. Periodically the virus may reactivate and be transmitted through saliva; however, IM symptoms rarely reoccur.

Causes and symptoms

Causes

Infectious mononucleosis is caused by the first infection with the Epstein-Barr virus, also called herpes virus 4. It is one of the most common human viruses and is endemic throughout the world. EBV is a member of the herpes family of DNA viruses. This family of viruses includes those that cause cold sores, **chickenpox**, and **shingles**. Most people are infected with multiple strains of EBV. The different EBV strains are found in separate parts of the body: the circulating lymphocytes (white blood cells), cell-free blood plasma, or the oral cavity.

EBV is spread by contact with viral-infected saliva through coughing, **sneezing**, kissing, or the sharing of items such as drinking glasses, eating utensils, straws, toothbrushes, or lip gloss. However, EBV is not highly contagious, and household members have only a very small risk of infection unless there is direct contact with infected saliva.

Symptoms

Less than 10% of children under age ten develop symptoms with EBV infection. The incubation period after exposure to EBV is generally about four to six weeks. An infected person can transmit EBV during this period and for as long as five months after symptoms disappear.

The first symptoms of IM are usually general weakness and extreme fatigue. An infected person may require 12 to 16 hours of sleep daily prior the development of other symptoms. IM symptoms are similar to cold or flu symptoms:

- Fever and chills occurs in about 90% of IM cases. EBV is most contagious during this stage of the illness.
- An enlarged spleen, causing pain in the upper left of the abdomen, occurs in about 50 to 60% of infections.
- Sore throat and/or swollen tonsils occurs in less than 50% of mononucleosis infections.
- Swollen lymph glands (nodes) in the neck, armpits, and/or groin develop in less than 50% of infections.
- Jaundice (yellowing of the skin and eyes) develops in more than 20% of patients, depending on age, and indicates an inflamed or enlarged liver.
- A red skin rash, particularly on the chest, occurs in about 5% of infections.

Acute symptoms include the following:

- loss of appetite
- stomach pain and/or nausea
- muscle soreness and/or joint pain
- headache
- chest pain
- coughing
- rapid or irregular heartbeat These acute symptoms usually last one to two weeks.

Splenic enlargement generally peaks during the fourth week after symptoms appear and then subsides. However, an enlarged spleen may rupture in 0.1 to 0.2% of cases, causing sharp **pain** on the left side of the abdomen. Additional symptoms of a ruptured spleen include light-headedness, a fast heart rate, and difficulty breathing. Splenic rupture most often occurs within the first three weeks and is the most common cause of death from mononucleosis. It requires immediate medical attention and may require emergency surgery to stop the bleeding.

There are other rare—but potentially life-threatening—complications of mononucleosis:

- Neurological complications affecting the central nervous system may develop in 1 to 2% of infections. Bell's palsy is a temporary condition caused by weakened or paralyzed facial muscles on one side of the face.
- The heart muscle may become inflamed.
- A significant number of the body's red blood cells or platelets may be destroyed and there may be reduced numbers of circulating red and white blood cells.

Diagnosis

A variety of conditions can produce symptoms similar to those of IM; however, if cold or flu-like symptoms persist for longer than two weeks, mononucleosis may be suspected. Mononucleosis is usually diagnosed by a blood test called a mono spot test that measures antibodies to EBV. Antibodies may not be detectable until the second or third week after the onset of symptoms. The antibodies peak between weeks two and five and can persist at low levels for up to a year.

About 90% of IM cases show a positive mono spot. Infants and young children do not make the type of antibodies that are measured by the mono test. If the mono spot is inconclusive, additional blood tests may be performed that measure an increase in the overall number of white blood cells or an increase in abnormal-appearing lymphocytes that make antibodies against EBV. Other tests can identify at least six specific types of EBV antibodies that may be present in the blood.

Treatment

The most effective treatment for infectious mononucleosis is rest, followed by a gradual return to normal activities. If the spleen is enlarged, all contact sports, heavy lifting, and jarring activity such as cheerleading, should be avoided until the enlargement has subsided completely. Since mononucleosis can involve the liver, it is important not to consume alcohol.

Although there is no cure for mononucleosis, alternative remedies may help the body to fight the infection and relieve symptoms. Medical practitioners recommend eating four to six small daily meals of unprocessed foods, fresh fruits, and vegetables. It is important to drink plenty of water. Meat, sugar, saturated fats, and caffeinated and decaffeinated drinks should be avoided. Gargling with salt water (one half teaspoon in one cup of warm water) or sucking on lozenges may relieve a **sore throat**.

Vitamins A, B-complex, and C, and **magnesium**, **calcium**, and **potassium** supplements can boost the immune system and increase energy levels.

Herbals

Herbal remedies may help treat mononucleosis, although they are unproven:

- astragalus (*Astragalus membranaceus*) for physical weakness
- cleavers (*Galium* species) to cleanse the lymphatic system

- echinacea (*Echinacea augustifolia*) to boost the immune system
- elder (*Sambucus nigra*) flower to reduce fever
- garlic to fight viral infection
- goldenseal (*Hydrastis canadensis*) to relieve sinus congestion
- slippery elm bark and licorice can be gargled to soothe a sore throat
- St. John's wort (*Hypericum perforatum*) to relieve anxiety and depression
- vervain (*Verbena officinales*) to relieve anxiety and depression and treat jaundice
- wild indigo (*Baptisia tinctoria*) to cleanse the lymphatic system
- yarrow (*Achillea millefolium*) to reduce fever

Other remedies

The following treatments may help relieve symptoms of mononucleosis:

- Acupressure point Lung 6 may boost lung function and the immune system.
- Aromatherapy with bergamot, eucalyptus, and lavender essential oils may relieve fatigue and other symptoms.
- Chinese medicine uses acupuncture and Xiao Chai Hu Wan (Minor Bupleurum pills) in combination with other herbs.
- Homeopathic physicians choose remedies based on a patient's specific symptoms.
- Relaxation techniques such as biofeedback, visualization, meditation, and yoga can reduce fatigue by relieving stress.

Allopathic treatment

Acetaminophen (Tylenol) or ibuprofen (Advil, Motrin) may relieve symptoms of IM. Aspirin should not be given to children or teens because it has been linked to the development of Reye's syndrome, a potentially fatal illness.

Although antibiotics are ineffective for treating EBV, a sore throat from mononucleosis can be complicated by a streptococcal infection, **sinus infection**, or an **abscess** or pocket of infection on the tonsils. Such bacterial infections can be treated with antibiotics. A five-day course of corticosteroid anti-inflammatory medications (Prednisone) occasionally is prescribed for breathing difficulties caused by swollen tonsils or lymph nodes in the neck or throat.

KEY TERMS

Antibody—A specific protein produced by the immune system in response to a specific antigen such as a foreign protein.

Endemic—A disease that is always prevalent in a particular location.

Epstein-Barr virus (EBV)—An endemic DNA-containing herpes virus that causes infectious mononucleosis.

Immune system—The body system that recognizes and eliminates foreign pathogens and materials.

Lymph glands or nodes—The filtering components of the lymphatic system that can swell during infection.

Lymphatic system—The vessels, nodes, and organs that carry the clear lymph fluid, containing lymphocytes and other white blood cells, throughout the body and that filter the blood to remove dead cells and other debris.

Lymphocytes—White blood cells that are involved in the immune response, including antibody-producing cells.

Reye's syndrome—A very rare, often-deadly, childhood condition that can occur after a viral infection.

Spleen—A large lymphatic organ, located just under the left rib cage, that filters the blood.

Prognosis

Most people with IM begin to return to their normal daily routines within two to three weeks, but it may take up to six months for normal energy levels to return.

A large study suggested that EBV infection increases the risk for Hodgkin lymphoma, a highly treatable **cancer** of the lymphatic system. About one-third of Hodgkin tumors contain EBV and about one in 1,000 young adults with mononucleosis develop the cancer, typically about four years after IM.

The development of two other rare types of cancer—Burkitt's lymphoma and nasopharyngeal carcinoma—appears to be associated with EBV. There also is some evidence that people with high levels of antibodies against EBV are at a higher risk of developing **multiple sclerosis**.

Prevention

Even though IM is not highly contagious, there is no way to completely avoid infection with EBV. In the

majority of cases, IM is without symptoms. Furthermore, EBV can be transmitted long after the symptoms of infection are gone and, indeed, periodically throughout the remainder of life. Good hygiene, particularly hand washing and the habit of not sharing toothbrushes or eating utensils may help prevent EBV infection.

Morning sickness

Definition

Morning sickness is the **nausea** and **vomiting** experienced during **pregnancy**, particularly in the first trimester. Although it is called morning sickness, it can and usually does occur at any time of the day or night.

Description

Morning sickness is characterized by extreme nausea and vomiting. It varies widely in intensity; some women experience only minor stomach upset for a very brief time period, while others become so ill that they have difficulty keeping food and fluids down and functioning normally.

In the majority of women, morning sickness symptoms subside toward the end of the first trimester (at 12–14 weeks). However, some women continue to experience nausea well into the second trimester, and some mothers of multiples (twins, triplets, etc.) may have morning sickness throughout their pregnancy.

KEY TERMS

Infusion—Introduction of a substance directly into a vein or tissue by gravity flow.

Ptyalism—Excess salivation.

Causes and symptoms

The exact cause of morning sickness is unknown, but several factors are thought likely to contribute to the illness, including:

- Hormones. The pregnancy hormone hCG enters the bloodstream in high levels in the first trimester of pregnancy. These high hormone levels may trigger activity in the nausea and vomiting center of the brain, which is located in the brainstem.
- Muscle relaxation in the digestive tract. During pregnancy, the muscles of the gastrointestinal tract relax, slowing the digestion somewhat and possibly contributing to nausea.
- Heightened sense of smell. Pregnant women experience a heightened sense of smell during pregnancy that can transform unpleasant odors into unbearable, nausea-producing scents.
- Excessive salivation. The phenomena ptyalism, or excess saliva, is another symptom of pregnancy that can cause nausea in some women.
- Postnasal drip. Many pregnant women experience postnasal drip and/or nasal congestion, triggered by high levels of estrogen in their bloodstream. Estrogen increases the blood flow throughout the body, including the mucous membrane of the nose. This postnasal drip contributes to upset stomach in many pregnant women.

Diagnosis

Because it is such a common occurrence, morning sickness is easily diagnosed in pregnant women. A healthcare practitioner should question the patient about her pregnancy symptoms during each prenatal visit. In women who are visiting their healthcare providers because of unexplained nausea, morning sickness is sometimes the first symptom or sign of pregnancy.

Nausea and vomiting accompanied by abdominal **pain** may indicate a more serious problem than simple

morning sickness, such as gall bladder or pancreatic disease. Women who experience pain symptoms in conjunction with their nausea should contact their healthcare provider or an emergency medical facility immediately.

Treatment

There are a number of remedies for morning sickness. These include:

- Eat small, frequent meals. When the stomach is empty, it produces acid that irritates the stomach lining. In addition, an empty stomach can cause low blood sugar, which can also cause nausea.
- Eat foods high in proteins and complex carbohydrates. Protein foods (e.g., eggs, cheese, and yogurt) and complex carbohydrates (e.g., whole-grain breads and cereals, dried beans and peas, and baked potatoes) discourage stomach upset and are also beneficial to both mother and baby.
- Avoid foods and beverages that do not sound appealing. Pregnant women usually experience at least one food aversion. The more appetizing a food appears to be, the more likely it is to stay down.
- Stay hydrated. Dehydration can worsen nausea, so pregnant women should drink plenty of fluids. If a woman has an aversion to fluids, she can eat foods with a high water content, such as watermelon, grapes, and other fruits.
- Try a vitamin B_6 supplement. Vitamin B_6 reduces nausea in some women, and is not harmful in recommended doses during pregnancy. Women should consult their healthcare practitioner before taking supplements.
- Eat or drink ginger. Ginger (*Zingiber officinale*) settles the stomach for some women. Ginger tea and foods made with ginger (such as ginger snaps) are usually available at grocery or health food stores.
- Try an herbal infusion. An infusion, or tea, of two parts black horehound (*Ballota nigra*), one part meadowsweet (*Filipendula ulmaria*), and one part chamomile (*Chamaemelum nobile*), taken three times a day, can soothe morning sickness for some women. Women should always consult their healthcare practitioner before taking herbal remedies during pregnancy.
- Wear sea bands. Sea bands are elastic bands worn around the wrists which place pressure on the inner wrist, an acupressure point for controlling nausea. They are usually used for controlling carsickness and seasickness.
- Keep the mouth fresh. Mints and regular tooth brushing can decrease excess saliva. Using a mouth rinse and/or brushing the teeth after vomiting is a good idea to control tooth decay and lessen stomach upset.
- Stay well rested. Fatigue and stress can make morning sickness worse.

Allopathic treatment

Some women with extreme cases of morning sickness may develop a condition known as hyperemesis gravidarium (excessive vomiting during pregnancy). These women are at risk for dehydration and insufficient weight gain, and may require bed rest and intravenous **nutrition** and fluids if vomiting cannot be controlled.

Several antiemetic, or antivomiting, medications are available for pregnant women. Antiemetic medication should always be prescribed by a physician familiar with its use and with the patient's medical history. Antiemetics may be contraindicated (or not recommended) for patients with certain medical conditions. They may also interact with other medications.

Expected results

Morning sickness treatments have varying success. Some women will find one or more remedies that can completely cure their nausea, while others may remain sick throughout their pregnancy. In addition, women expecting two or more babies usually experience heightened morning sickness due to the higher level of pregnancy hormones in their bodies, and may suffer from nausea and vomiting for a longer time than women with a single pregnancy. However, for the majority of pregnant women, nausea stops or at least diminishes by the end of the first trimester.

Prevention

The best cure for preventing bouts of nausea is to eat frequently. Many women find that eating six small meals or snacks a day (morning, mid-morning, noon, afternoon, evening, and bedtime) prevents stomach upset. Getting adequate rest can also help to keep morning sickness at bay.

Motherwort

Description

Motherwort (*Leonurus cardiaca*) is a perennial plant native to Europe and temperate parts of central Asia. It has been introduced into North America and now grows wild there. A different species, called Chinese motherwort (*Leonurus heterophyllus*), is used by Chinese herbalists in many of the same ways as *Leonurus cardiaca* is used in the West.

Motherwort grows mainly in poor soil or on wastelands, although it is sometimes cultivated in gardens. The plant grows to about 3 ft (1 m) tall. It has a stem that is often red-violet in color and hairy. The hairy, palm-shaped leaves are a dull green, with the upper surface darker than the under surface. The small flowers range from white to pink to red depending on the plant. flowers and leaves are dried and used medicinally. The leaves are at their most potent when harvested just after the plant flowers. Motherwort is also the source of a dark green dye. The plant has astringent properties and an unpleasant smell. Other names for motherwort include lion's tail, lion's ear, throw-wort, heartwort, and *yi mu cao*.

General use

Motherwort has a long history of traditional uses in many different cultures. The Latin name, *cardiaca* refers to the heart, and motherwort has traditionally been used to treat heart-related conditions. These include nervous heart complaints such as palpitations, cardiac arrhythmia (irregular beat), and fast heartbeat. It has also been used as a general tonic to strengthen the heart and to treat cardiac insufficiency. Modern herbalists continue to prescribe motherwort for these conditions.

Motherwort is also used as a mild general sedative, as a calming agent, and as a treatment for **epilepsy**. Scientists have isolated many different active compounds in motherwort. Leonurine and stachydine, both found in the herb, have been show to lower blood pressure and calm the central nervous system in studies using laboratory animals and animal hearts. Scientific investigation into the central nervous system and cardiac effects of motherwort is ongoing with mixed results. As of 2008, the German Federal Health Agency's Commission E, established in 1978 to independently review and evaluate scientific literature and case studies pertaining to herb and plant medications, had found that there is adequate evidence to suggest that motherwort is effective in the treatment of nervous heart complaints and thyroid dysfunction.

Motherwort. *(© Petra Wegner / Alamy)*

Motherwort is also used to treat female conditions related to **menstruation** and **childbirth**. The herb is often given to stimulate menstruation when it is absent (**amenorrhea**) or irregular and delayed (**dysmenorrhea**). At childbirth it is taken to aid labor, and after childbirth it is given to help the uterus relax and return to normal. There appear to be no scientific studies that specifically relate to the effects of motherwort on the reproductive system, so these traditional uses of the herb can be neither confirmed nor denied. Other Western uses of motherwort include treatment for **asthma**, **hyperthyroidism**, flatulence (**gas**), and **insomnia**. It is also used externally as a douche for **vaginitis**.

Chinese herbalists use Chinese motherwort to treat problems of the heart, liver, and kidneys. In addition to the heart and reproductive uses known to Western herbalists, Chinese practitioners use motherwort to treat

KEY TERMS

Tincture—An alcohol-based extract prepared by soaking plant parts.

water retention, in conjunction with other herbs, such as **hawthorn**, to prevent **stroke** and to treat certain kinds of **eczema**. Some Chinese researchers have reported that Chinese motherwort, *Leonurus heterophyllus*, can prevent **blood clots**. Motherwort is an ingredient in several common Chinese herbal formulas, including leonuris and achyranthes.

Motherwort is also used occasionally in homeopathic medicine for the treatment of heart conditions, flatulence, and overactive thyroid (hyperthyroidism).

Preparations

Motherwort is normally prepared by adding about 1 tsp of leaves to 1 cup (8 oz or 250 ml) of boiling water. The resulting infusion is taken twice a day. This infusion has a bitter and unpleasant taste. Honey, lemon, or other flavorings may be added to make its taste more acceptable. Motherwort is also available as a tincture. The normal dose is 2–6 ml daily.

Precautions

Pregnant women should not take motherwort because of its effects on the uterus. Women who have heavy menstrual flow should also avoid motherwort. Anyone who has a heart disorder or who is taking any medication for a heart condition should consult a doctor before taking motherwort. People who are taking medication for thyroid disorders should also consult a doctor before using this herb.

Side effects

Motherwort has a long history of use without any negative side effects being reported when the herb is taken internally as an infusion or tincture. However, some people break out in a rash when handling motherwort leaves.

Interactions

There has been little scientific study of the interaction of motherwort and pharmaceuticals. As noted above, however, people who are taking medications for heart, thyroid, or other serious medical conditions should consult a doctor before taking motherwort. The herb has been used in herbal mixtures for centuries without any known herbal interactions.

Motion sickness

Definition

Motion sickness is a condition characterized by uncomfortable sensations of **dizziness**, **nausea**, and **vomiting** that people experience when their sense of balance and equilibrium is disturbed by constant motion. Riding in a car, aboard a ship or boat, or riding on a swing all cause stimulation of the vestibular system and visual stimulation that often lead to discomfort. While motion sickness can be bothersome, it is not a serious illness, and can be prevented.

Description

Motion sickness is a common problem, with nearly 80% of the general population suffering from it at one time in their lives. People with migraine

KEY TERMS

Acupressure—Often described as acupuncture without needles, acupressure is a traditional Chinese medical technique based on theory of *qi* (life energy) flowing in energy meridians or channels in the body. Applying pressure with the thumb and fingers to acupressure points can relieve specific conditions and promote overall balance and health. Also known as dian xue.

Acupuncture—Based on the same traditional Chinese medical foundation as acupressure, acupuncture uses sterile needles inserted at specific points to treat certain conditions or relieve pain.

Antiemetic—A medication that helps control nausea; also called an antinausea drug.

Neurological system—The system that initiates and transmits nerve impulses including the brain, spinal cord, and nerves.

Optokinetic—A reflex that causes a person's eyes to move when their field of vision moves.

Vertigo—A feeling of dizziness together with a sensation of movement and a feeling of rotating in space.

Vestibular system—The brain and parts of the inner ear that work together to detect movement and position.

headaches or Ménière's syndrome, however, are more likely than others to have recurrent episodes of motion sickness. Researchers at the Naval Medical Center in San Diego, California, reported in 2003 that 70% of research subjects with severe motion sickness had abnormalities of the vestibular system; these abnormalities are often found in patients diagnosed with migraines or **Ménière's disease**.

While motion sickness may occur at any age, it is more common in children over the age of two, with the majority outgrowing this susceptibility.

When looking at why motion sickness occurs, it is helpful to understand the role of the sensory organs. The sensory organs control a body's sense of balance by telling the brain what direction the body is pointing, the direction it is moving, and if it is standing still or turning. These messages are relayed by the inner ears (or labyrinth), the eyes, the skin pressure receptors, such as in those in the feet, and the muscle and joint sensory receptors (which track what body parts are moving). The central nervous system (the brain and spinal cord), is responsible for processing all incoming sensory information.

Motion sickness and its symptoms surface when conflicting messages are sent to the central nervous system. An example of this is reading a book in the back seat of a moving car. The inner ears and skin receptors sense the motion, but the eyes register only the stationary pages of the book. This conflicting information may cause the usual motion sickness symptoms of dizziness, nausea, and vomiting.

Causes and symptoms

While all five of the body's sensory organs contribute to motion sickness, excess stimulation to the vestibular system within the inner ear (the body's "balance center") has been shown to be one of the primary reasons for this condition. Balance problems, or vertigo, are caused by a conflict between what is seen and how the inner ear perceives it, leading to confusion in the brain. This confusion may result in higher heart rates, rapid breathing, nausea, and sweating, along with dizziness and vomiting. There are people who suffer from constant motion sickness. Names for these conditions vary, such as positional dizziness.

Pure optokinetic motion sickness is caused solely by visual stimuli; that is, by what is seen. The optokinetic system is the reflex that allows the eyes to move when an object moves. Many people suffer when they view rotating or swaying images, even if they are standing still. Optokinetic motion sickness is of particular concern to the civilian aviation industry as well as to military aerospace programs. In the United States, both the Federal Aviation Agency (FAA) and the National Aeronautics and Space Administration (NASA) have research programs for the prevention and treatment of optokinetic motion sickness.

Additional factors that may contribute to the occurrence of motion sickness include:

- Poor ventilation lowers a person's threshold for experiencing motion.
- Anxiety or fear also lowers the threshold.
- Food. Physicians recommend avoiding heavy meals of spicy or greasy foods before and during a trip.
- Alcohol. A drink is often thought to help calm the nerves, but in this case it could upset the stomach further. A hangover for the next morning's trip may also lead to motion sickness.
- Pregnancy. Susceptibility in women to vomiting during pregnancy appears to be related to motion sickness, although the precise connections are not well understood.

- Genetic factors. Research suggests that some people inherit a predisposition to motion sickness. This predisposition is more marked in some ethnic groups than in others; one study published in 2002 found that persons of Chinese or Japanese ancestry are significantly more vulnerable to motion sickness than persons of British ancestry.

Often viewed as a minor annoyance, some travelers are temporarily immobilized by motion sickness, and a few continue to feel its effects for hours and even days after a trip (the "mal d'embarquement" syndrome). For those with constant motion sickness, it may not stop at all.

Diagnosis

Most cases of motion sickness are mild and self-treatable disorders. If symptoms such as dizziness become chronic, a doctor may be able to help alleviate the discomfort by looking further into a patient's general health. Questions regarding medications, head injuries, recent **infections**, and other questions about the ear and neurological system will be asked. An examination of the ears, nose, and throat, as well as tests of nerve and balance function, may also be completed.

Severe cases of motion sickness symptoms, and those that become progressively worse, may require additional specific tests. Diagnosis in these situations deserves the attention and care of a doctor with specialized skills in diseases of the ear, nose, throat, equilibrium, and neurological system.

Treatment

Alternative treatments for motion sickness have become widely accepted as a standard means of care. They include herbal therapy, **acupressure**, and **homeopathy**.

Herbal therapy

Ginger (*Zingiber officinale*) in its various forms is often used to calm the stomach, and it is now known that the oils it contains (gingerols and shogaols) appear to relax the intestinal tract in addition to mildly depressing the central nervous system. Some of the most effective forms of ginger include the powdered, encapsulated form; ginger tea prepared from sliced ginger root; or candied pieces. All forms of ginger should be taken on an empty stomach when treating motion sickness.

Acupressure

Placing manual pressure on the Neiguan or Pericardium-6 **acupuncture** point (located about three finger-widths above the wrist on the inner arm), either by acupuncture, acupressure, or a mild, electrical pulse, has shown to be effective against the symptoms of motion sickness. Elastic wristbands sold at most drugstores are also used as a source of relief due to the pressure they place in this area. Pressing the small intestine 17 (just below the earlobes in the indentations behind the jawbone) may also help in the functioning of the ear's balancing mechanism.

Homeopathy

There are several homeopathic remedies that work specifically for motion sickness. They include *Cocculus*, *Petroleum*, *Ipecacuanha*, and *Tabacum*.

Traditional Chinese medicine

In **traditional Chinese medicine**, cases of chronic motion sickness would be considered a "wind" disorder because it is an abnormality movement as the wind causes. Herbs and acupuncture may treat this.

Allopathic treatment

There are a variety of medications to help ease the symptoms of motion sickness, and most of these are available without a prescription. Known as over-the-counter (OTC) medications, it is recommended that these be taken 30-60 minutes before traveling to prevent motion sickness symptoms, as well as during an extended trip.

Drugs

The following OTC drugs consist of ingredients that have been considered safe and effective for the treatment of motion sickness by the Food and Drug Administration:

- Marezine (and others). Includes the active ingredient cyclizine and is not for use in children under age six years.
- Benadryl (and others). Includes the active ingredient diphenhydramine and is not for use in children under age six years.
- Dramamine (and others). Includes the active ingredient dimenhydrinate and is not for use in children under age two years.
- Bonine (and others). Includes the active ingredient meclizine and is not for use in children under age 12 years.

Each of these active ingredients, including such other antiemetics as cinnarizine, are antihistamines whose main side effect is drowsiness. Caution should be used when driving a vehicle or operating machinery,

and alcohol should be avoided when taking any drug for motion sickness. Medications for motion sickness may also cause **dry mouth** and occasional blurred vision. People with **emphysema**, chronic **bronchitis**, **glaucoma**, or difficulty urinating due to an enlarged prostate should not use these drugs unless directed by their physician.

The side effects of cinnarizine and the other antihistamine antiemetics indicate that they should not be used by members of flight crews responsible for the control of aircraft or for other tasks that require sustained attention and alertness.

Longer trips may require a prescription medication called scopolamine (Transderm Scop). Scopolamine gel is most effective when smeared on the arm or neck and covered with a bandage. In chronic cases, such antiseizure drugs as clonazepam (Klonopin) are used.

Another prescription drug that is sometimes given for motion sickness is ondansetron (Zofran), which was originally developed to treat nausea associated with **cancer** chemotherapy. Unlike cyclizine, ondansetron appears to be safe for use in children under the age of six.

Several newer antiemetic medications are under development. The most promising of these newer drugs is a class of compounds known as neurokinin-1 (substance P) antagonists. The neurokinins are being tested for the control of nausea following cancer chemotherapy as well as nausea related to motion sickness. In March 2003 the Food and Drug Administration (FDA) approved the first of this new class of antiemetic drugs. Known as aprepitant, it is sold under the trade name Emend.

Expected results

While there is no cure for motion sickness, its symptoms can be controlled or even prevented. Most people respond successfully to the variety of treatments, or avoid the unpleasant symptoms through prevention methods.

Prevention

Because motion sickness is easier to prevent than treat once it has begun, the best treatment is prevention. The following steps may help deter the unpleasant symptoms of motion sickness before they occur:

- Avoiding reading while traveling, and choosing a seat that faces forward.
- Always riding where the eyes may see the same motion that the body and inner ears feel. Safe positions include the front seat of the car while looking at distant scenery; the deck of a ship where the horizon can be seen; and sitting by the window of an airplane. The least motion on an airplane is in a seat over the wings and the worst is in the tail section.
- Maintaining a fairly straight-ahead view.
- Eating a light meal before traveling, or avoiding food altogether.
- Avoiding conversation with another traveler who is having motion sickness.
- Taking a motion sickness medication at least 30–60 minutes before travel begins, or as recommended by a physician.
- Learning to live with the condition. Even those who frequently endure motion sickness can learn to travel by anticipating the conditions of their next trip. Research also suggests that increased exposure to the stimulation that causes motion sickness may help decrease its symptoms on future trips.

Movement therapy

Definition

Movement therapy refers to a broad range of Eastern and Western movement approaches used to promote physical, mental, emotional, and spiritual well-being. Some forms of movement therapy that combine deep-tissue manipulation and postural correction with movement education are also known as bodywork therapies.

Origins

Movement is fundamental to human life. In fact movement is life. Contemporary physics tells us that the universe and everything in it is in constant motion. We can move our body and at the most basic level our body is movement. According to the somatic educator Thomas Hanna, "The living body is a moving body—indeed, it is a constantly moving body." The poet and philosopher Alan Watts eloquently states a similar view, "A living body is not a fixed thing but a flowing event, like a flame or a whirlpool." Centuries earlier, the great Western philosopher Socrates understood what modern physics has proven, "The universe is motion and nothing else."

Since the beginning of time, indigenous societies around the world have used movement and dance for individual and community healing. Movement and song were used for personal healing, to create community, to worship, to ensure successful crops, and to promote fertility. Movement is still an essential part of many healing traditions and practices throughout the world.

Western movement therapies generally developed out of the realm of dance. Many of these movement approaches were created by former dancers or choreographers who were searching for a way to prevent injury, attempting to recover from an injury, or who were curious about the effects of new ways of moving. Some movement therapies arose out of the fields of physical therapy, psychology, and bodywork. Other movement therapies were developed as way to treat an incurable disease or condition.

Eastern movement therapies, such as **yoga**, **qigong**, and **t'ai chi** began as a spiritual or self-defense practices and evolved into healing therapies. In China, for example, Taoist monks learned to use specific breathing and movement patterns in order to promote mental clarity, physical strength, and support their practice of **meditation**. These practices, later known as qigong and t'ai chi, eventually became recognized as ways to increase health and prolong life.

Benefits

The physical benefits of movement therapy include greater ease and range of movement, increased balance, strength and flexibility, improved muscle tone and coordination, joint resiliency, cardiovascular conditioning, enhanced athletic performance, stimulation of circulation, prevention of injuries, greater longevity, **pain** relief, and relief of rheumatic, neurological, spinal, **stress**, and respiratory disorders. Movement therapy can also be used as a meditation practice to quiet the mind, foster self-knowledge, and increase awareness. In addition, movement therapy is beneficial in alleviating emotional distress that is expressed through the body. These conditions include eating disorders, excessive clinging, and **anxiety** attacks. Since movements are related to thoughts and feelings, movement therapy can also bring about changes in attitude and emotions.

KEY TERMS

Bodywork—A term that covers a variety of therapies that include massage, realignment of the body, and similar techniques to treat deeply ingrained stresses and traumas carried in the tissues of the body.

Equine-facilitated therapy—Another term for therapeutic riding.

Qigong—A traditional form of Chinese energy therapy that includes physical exercises, breathing techniques, postures, and mental discipline. Internal qigong refers to exercises practiced to maintain one's own health and vitality; external qigong refers to the transfer of energy from a qigong master to another person for healing purposes. External qigong is also known as medical qigong.

T'ai chi—A Chinese system of meditative physical exercise, characterized by slow methodical circular and stretching movements.

Yoga—A method of joining the individual self with the divine, universal spirit, or cosmic consciousness. Physical and mental exercises are designed to help achieve this goal, also called self-transcendence or enlightenment. On the physical level, yoga postures, called asanas, are designed to tone, strengthen, and align the body. On the mental level, yoga uses breathing techniques (pranayama) and meditation (dyana) to quiet, clarify, and discipline the mind.

People report an increase in self-esteem and self-image. Communication skills can be enhanced and tolerance of others increased. The physical openness facilitated by movement therapy leads to greater emotional openness and creativity.

Movement therapy is being studied more intensively as a useful adjunct to rehabilitation programs for victims of **stroke** or spinal cord injuries. Actor Christopher Reeves, who was paralyzed in a 1995 accident just below the two top vertebrae in his neck, recovered feeling throughout most of his body and took small steps in a swimming pool. Reeves credited his improvement, which many doctors considered impossible, to exercising five hours every day. Some neuroscientists studied Reeves and other patients with spinal cord injuries to test the hypothesis that movement itself can cause damaged nerves to regenerate.

Another important benefit of movement therapy that is increasingly recognized by mainstream as well as alternative practitioners is social support. Many people, particularly those suffering from **depression** related to physical illness or other forms of stress, find that taking a yoga class or other group form of movement therapy relieves feelings of loneliness and isolation. People who have taken therapeutic riding have reported that the positive relationship they develop with their horse helps them relate better to other animals and to people.

Description

There are countless approaches to movement therapy. Some approaches emphasize awareness and attention to inner sensations. Other approaches use movement as a form of **psychotherapy**, expressing and working through deep emotional issues. Some approaches emphasize alignment with gravity and specific movement sequences, while other approaches encourage spontaneous movement. Some approaches are primarily concerned with increasing the ease and efficiency of bodily movement. Other approaches address the reality of the body "as movement" instead of the body as only something that runs or walks through space.

The term movement therapy is often associated with **dance therapy**. Some dance therapists work privately with people who are interested in personal growth. Others work in mental health settings with autistic, brain injured and learning disabled children, the elderly, and disabled adults.

Laban movement analysis (LMA), formerly known as Effort-Shape is a comprehensive system for discriminating, describing, analyzing, and categorizing movements. LMA can be applied to dance, athletic coaching, fitness, acting, psychotherapy, and a variety of other professions. Certified movement analysts can "observe recurring patterns, note movement preferences, assess physical blocks and dysfunctional movement patterns, and the suggest new movement patterns." As a student of Rudolf Laban, Irmgard Bartenieff developed his form of movement analysis into a system of body training or reeducation called Bartenieff fundamentals (BF). The basic premise of this work is that once the student experiences a physical foundation, emotional, and intellectual expression become richer. BF uses specific exercises that are practiced on the floor, sitting, or standing to engage the deeper muscles of the body and enable a greater range of movement.

Authentic movement (AM) is based upon Mary Starks Whitehouse's understanding of dance, movement, and depth psychology. There is no movement

instruction in AM, simply a mover and a witness. The mover waits and listens for an impulse to move and then follows or "moves with" the spontaneous movements that arise. These movements may or may not be visible to the witness. The movements may be in response to an emotion, a dream, a thought, pain, joy, or whatever is being experienced in the moment. The witness serves as a compassionate, non judgmental mirror and brings a "special quality of attention or presence." At the end of the session the mover and witness speak about their experiences together. AM is a powerful approach for self development and awareness and provides access to preverbal memories, creative ideas, and unconscious movement patterns that limit growth.

Gabrielle Roth (5 Rhythms movement) and Anna Halprin have both developed dynamic movement practices that emphasize personal growth, awareness, expression, and community. Although fundamentally different forms, each of these movement/dance approaches recognize and encourage our inherent desire for movement.

Several forms of movement therapy grew out of specific bodywork modalities. **Rolfing** movement integration (RMI) and Rolfing rhythms are movement forms which reinforce and help to integrate the structural body changes brought about by the hands-on work of Rolfing (structural integration). RMI uses a combination of touch and verbal directions to help develop greater awareness of one's vertical alignment and habitual movement patterns. RMI teacher Mary Bond says, "The premise of Rolfing Movement Integration . . . is that you can restore your structure to balance by changing the movement habits that perpetuate imbalance." Rolfing rhythms is a series of lively exercises designed to encourage awareness of the Rolfing principles of ease, length, balance, and harmony with gravity.

The movement education component of **Aston-Patterning** bodywork is called neurokinetics. This movement therapy teaches ways of moving with greater ease throughout every day activities. These movement patterns can also be used to release tension in the body. Aston fitness is an **exercise** program which includes warm-up techniques, exercises to increase muscle tone and stability, stretching, and cardiovascular fitness.

Rosen method movement (an adjunct to Rosen method bodywork) consists of simple fun movement exercises done to music in a group setting. Through gentle swinging, bouncing, and stretching every joint in the body experiences a full range of movement. The movements help to increase balance and rhythm and create more space for effortless breathing.

The movement form of **Trager psychophysical Integration** bodywork, Mentastics, consists of fun, easy swinging, shaking, and stretching movements. These movements, developed by Dr. Milton Trager, create an experience of lightness and freedom in the body, allowing for greater ease in movement. Trager also worked successfully with polio patients.

Awareness through movement, the movement therapy form of the **Feldenkrais** method, consists of specific structured movement experiences taught as a group lesson. These lessons reeducate the brain without tiring the muscles. Most lessons are done lying down on the floor or sitting. Moshe Feldenkrais designed the lessons to "improve ability . . . turn the impossible into the possible, the difficult into the easy, and the easy into the pleasant."

Ideokinesis is another movement approach emphasizing neuromuscular reeducation. Lulu Sweigart based her work on the pioneering approach of her teacher Mabel Elsworth Todd. Ideokinesis uses imagery to train the nervous system to stimulate the right muscles for the intended movement. If one continues to give the nervous system a clear mental picture of the movement intended, it will automatically select the best way to perform the movement. For example, to enhance balance in standing, Sweigart taught people to visualize "lines of movement" traveling through their bodies. Sweigart did not train teachers in ideokinesis but some individuals use ideokinetic imagery in the process of teaching movement.

The Mensendieck system of functional movement techniques is both corrective and preventative. Bess Mensendieck, a medical doctor, developed a series of exercises to reshape, rebuild and revitalize the body. A student of this approach learns to use the conscious will to relax muscles and releases tension. There are more than 200 exercises that emphasize correct and graceful body movement through everyday activities. Unlike other movement therapy approaches this work is done undressed or in a bikini bottom, in front of mirrors. This allows the student to observe and feel where a movement originates. Success has been reported with many conditions including **Parkinson's disease**, muscle and joint injuries, and repetitive strain injuries.

The **Alexander technique** is another functional approach to movement therapy. In this approach a teacher gently uses hands and verbal directions to subtly guide the student through movements such as sitting, standing up, bending and walking. The Alexander technique emphasizes balance in the neck-head relationship. A teacher lightly steers the students head

into the proper balance on the tip of the spine while the student is moving in ordinary ways. The student learns to respond to movement demands with the whole body, in a light integrated way. This approach to movement is particularly popular with actors and other performers.

Pilates or physical mind method is also popular with actors, dancers, athletes, and a broad range of other people. Pilates consists of over 500 exercises done on the floor or primarily with customized exercise equipment. The exercises combine sensory awareness and physical training. Students learn to move from a stable, central core. The exercises promote strength, flexibility, and balance. Pilates training is increasingly available in sports medicine clinics, fitness centers, dance schools, spas, and physical therapy offices.

Many approaches to movement therapy emphasize awareness of internal sensations. Charlotte Selver, a student of somatic pioneer Elsa Gindler, calls her style of teaching sensory awareness (SA). This approach has influenced the thinking of many innovators, including Fritz Perls, who developed gestalt therapy. Rather than suggesting a series of structured movements, visualizations, or body positions, in SA the teacher outlines experiments in which one can become aware of the sensations involved in any movement. A teacher might ask the student to feel the movement of her breathing while running, sitting, picking up a book, etc. This close attunement to inner sensory experience encourages an experience of body-mind unity in which breathing becomes less restricted and posture, coordination, flexibility, and balance are improved. There may also be the experience of increased energy and aliveness.

Gerda Alexander Eutony (GAE) is another movement therapy approach that is based upon internal awareness. Through GAE one becomes a master of self-sensing and knowing which includes becoming sensitive to the external environment, as well. For example, while lying on the floor sensing the breath, skin or form of the body, one also senses the connection with the ground. GAE is taught in group classes or private lessons which also include hands-on therapy. In 1987, after two years of observation in clinics throughout the world, GAE became the first mind-body discipline accepted by the World Health Organization (WHO) as an alternative health-care technique.

Kinetic awareness developed by dancer-choreographer Elaine Summers, emphasizes emotional and physical inquiry. Privately or in a group, a teacher sets up situations for the student to explore the possible causes of pain and movement restrictions within the body. Rubber balls of various sizes are used as props to focus attention inward, support the body in a stretched position and massage a specific area of the body. The work helps one to deal with chronic pain, move easily again after injuries and increase energy, flexibility, coordination, and comfort.

Body-mind centering (BMC) was developed by Bonnie Bainbridge Cohen and is a comprehensive educational and therapeutic approach to movement. BMC practitioners use movement, touch, **guided imagery**, developmental repatterning, dialogue, music, large balls, and other props in an individual session to meet the needs of each person. BMC encourages people to develop a sensate awareness and experience of the ligaments, nerves, muscles, skin, fluids, organs, glands, fat, and fascia that make up one's body. It has been effective in preventing and rehabilitating from chronic injuries and in improving neuromuscular response in children with **cerebral palsy** and other neurological disorders.

Continuum movement has also been shown to be effective in treating neurological disorders including spinal chord injury. Developed by Emilie Conrad and Susan Harper, continuum movement is an inquiry into the creative flux of our body and all of life. Sound, breath, subtle and dynamic movements are explored that stimulate the brain and increase resonance with the fluid world of movement. The emphasis is upon unpredictable, spontaneous or spiral movements rather than a linear movement pattern. According to Conrad, "Awareness changes how we physically move. As we become more fluid and resilient so do the mental, emotional, and spiritual movements of our lives."

More recently, a form of movement therapy that involves horses has gained fresh attention. It is variously known as therapeutic riding or equine-assisted therapy. Therapeutic riding originated with a Swedish horsewoman who lost her ability to walk when she contracted polio in 1946, and was determined to recover by returning to horseback riding. She eventually won a silver medal in the 1952 Olympics. Therapeutic riding programs allow persons with physical, psychological, or learning disabilities to gain self-esteem and social growth as well as improved balance, body awareness, and physical strength.

Such Eastern movement therapies as yoga, t'ai chi, and qigong are also effective in healing and preventing a wide range of physical disorders, encouraging emotional stability, and enhancing spiritual awareness. There are a number of different approaches to yoga. Some emphasize the development of physical strength, flexibility, and alignment. Other forms of yoga emphasize inner awareness, opening, and meditation.

Precautions

Persons who are seriously ill, acutely feverish, or suffering from a contagious infection should wait until they have recovered before beginning a course of movement therapy. As a rule, types of movement therapy that involve intensive manipulation or stretching of the deeper layers of body tissue are not suitable for persons who have undergone recent surgery or have recently suffered severe injury. With regard to emotional or psychiatric disturbances, persons who are recovering from abuse or receiving treatment for any post-traumatic syndrome or dissociative disorder should consult their therapist before undertaking a course of movement therapy. While movement therapy is often recommended as part of a treatment plan for these disorders, it can also trigger flashbacks or dissociative episodes if the movement therapist is unaware of the client's history. It is always best to consult with a knowledgeable physician, physical therapist, or mental health therapist before a course of movement therapy.

Research and general acceptance

Although research has documented the effects of dance therapy, qigong, t'ai chi, yoga, Alexander technique, awareness through movement (Feldenkrais), and Rolfing, other forms of movement therapy have not been as thoroughly researched.

Training and certification

Training and certification vary widely with each form of movement therapy. Many approaches require several years of extensive training and experience with the particular movement form. Movement therapies that are also considered forms of bodywork have an umbrella national certification board, listed below under Resources. Therapeutic riding programs are accredited by the North American Riding for the Handicapped Association (NARHA), which also credentials riding instructors.

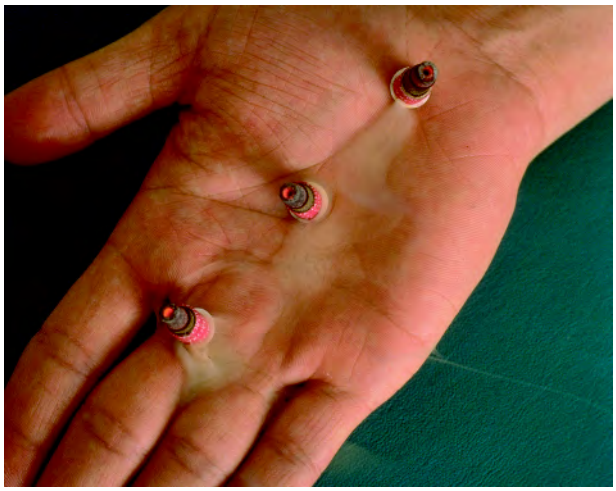
Moxibustion

Definition

Moxibustion is a technique used in traditional Chinese medicine in which a stick or cone of burning mugwort, *Artemesia vulgaris*, is placed over an inflamed or affected area on the body. The cone is placed on an acupuncture point and burned. The cones is removed before burning the skin. The purpose is to stimulate and strengthen the blood and the life energy, or *qi*, of the body.

Origins

The actual Chinese character for **acupuncture** literally translates into "acupuncture-moxibustion." More than 3,000 years ago, during the Shang Dynasty in China, hieroglyphs of acupuncture and moxibustion were found on bones and tortoise shells, meaning the practice precedes that date. The root word, "moxa" is actually derived from the Japanese.



Moxibustion hand acupuncture for stomach, kidneys and chest. *(© PHOTOTAKE Inc. / Alamy)*

Benefits

Moxibustion is used for people who have a cold or stagnant condition. The moxa stick is burned to warm up the blood and qi that are not circulating well. It is particularly known for its ability to turn breech presentation babies into a normal head-down position that is considered safer during **childbirth**. In a 1998 study published in the *Journal of the American Medical Association*, 75% of the pregnant women in the study had breech fetuses that turned in the normal position. Moxibustion significantly increases fetal movements in pregnant women. Moxibustion is also used to treat inflammations. For example, if treating a patient with tendinitis, the moxa stick is burned over the elbow area. It is also highly regarded for menstrual cramps, where the stick is waved over the abdominal area. Often, the cramps disappear immediately.

Moxa on acupuncture points is frequently done with acupuncture treatment for many kinds of ailments. The treatment brings warmth and helps strengthen the activity of the blood.

Description

Moxibustion is the burning of **mugwort** over inflamed and affected areas of the body. The mugwort can come in sticks that closely resemble the circumference and length of a cigar. Moxa cones can also be burned. The mugwort, called *Ai Ye* in **traditional Chinese medicine**, is positioned over acupuncture points to stimulate the qi and blood. In breech presentation babies, the acupoint BL 67, located on the outside of the little toe, is stimulated. For menstrual cramps, the meridian called the Ren Channel, the center line of the lower abdomen, is treated. Moxibustion is almost always used in conjunction with acupuncture, as a complementary technique. In Japan, there are practitioners who are separately licensed to practice as specialists in moxibustion. It is used for a wide variety of ailments, depending on the patient's needs and history. Therefore, it is difficult to cite costs and length of the treatment. For menstrual cramps, moxibustion can be used once. For breech presentation, the turning may occur during the treatment. Similar to acupuncture, it is sometimes covered by insurance and workers' compensation. Patients can be taught how to treat themselves, and moxa sticks are easily purchased.

Preparations

Because patients who undergo moxibustion treatment are also getting acupuncture, it is sometimes

Moxibustion. *(© Photo Researchers, Inc. Reproduced by permission.)*

recommended to consult a physician prior to this therapy.

Precautions

Moxibustion is specifically used for patients with a cold or stagnant constitution. Therefore, if any patient has too much heat, they should not undergo moxibustion treatment. An expert practitioner can advise patients in these matters.

Side effects

Because moxibustion often includes the burning of **smoking** mugwort sticks, patients who have respiratory problems should avoid the use of smoking moxa sticks. Smokeless moxa sticks are available, and patients who have respiratory difficulties may opt for this method. There is also the occasional report of external **burns** if the moxa stick is held too close to the patient, although this is rare.

Research and general acceptance

Moxibustion has been used in traditional Chinese medicine for centuries, and as a result, it is widely accepted in Asia. It is gaining popularity in the west, in particular, for its ability to turn breech presentation babies. Several studies in the *Journal of the American Medical Association* have praised the use of this therapy.

Training and certification

Although moxibustion alone does not require a particular licensing or accreditation process, because it is used with acupuncture, the practitioner must have an acupuncture license in the United States.

MSM

Description

Methylsulfonylmethane, or MSM, is also known as methyl sulfone and dimethylsulfone ($DMSO_2$). It is a sulfur-bearing compound that exists naturally in

many fruits, vegetables, grains, and animals, including humans. Its presence and activity was discovered while working with its parent compound, DMSO, of which it is an oxidized metabolite (hence the O_2 designation). Although 55,000 papers have been written on DMSO, research on MSM has been more limited. A wide range of therapeutic benefits are attributed to it, along with a high degree of safety, and a low degree of toxicity. Actor James Coburn, crippled by **rheumatoid arthritis**, praised MSM's **pain** relieving benefits.

The history of MSM, as derived from DMSO, includes the following highlights:

- DMSO was first synthesized in a nineteenth century Russian lab, and was investigated for its usefulness as a solvent (a dissolver of other substances).
- British scientist Lovelock, working with red blood cells and cryogenics—the science of "alive freezing," reported DMSO as a uniquely helpful agent.
- Stanley Jacob, M.D., an American working in the 1950s to perfect kidney transplants, found Lovelock's report on cryogenic uses of DMSO, and met with DMSO chemist researcher, Robert Herschler, Ph.D.
- Drs. Jacob and Herschler discovered that DMSO, in addition to being useful in transplant surgery, facilitated delivery of other medications through the skin into the body, and that it had significant pain relieving and anti-inflammatory properties. They also discovered an undesirable effect of DMSO—a fishy taste and body odor.
- DMSO was approved for veterinary use (1970) in the treatment of joint and muscle related problems.
- In Russia (1973), prescription DMSO began use for the treatment of pain related to autoimmune disorders, arthritis, and diabetic ulcers. (One source reports as of 1999, more than 125 countries are using DMSO more safely and less expensively than drugs used for the same conditions in the United States.)
- In 1978, DMSO was approved by the United States Food and Drug Administration (FDA) for human use in the treatment of interstitial cystitis only, a painful inflammatory condition affecting many women.
- With lagging FDA approval, Herschler continued research and discovered that approximately 15% of DMSO turns into MSM in the body, and that the MSM metabolite produced the pain-relieving and anti-inflammatory benefits without the unpleasant odor side effect.
- Since that time, Drs. Jacob and Herschler, and others by anecdote, have found MSM to be clinically helpful in treating many more conditions, and that it is extremely safe, and has no known toxicity.

MSM occurs naturally in some foods including cow's milk (its highest source). One source specifies the presence of MSM—in descending order—in unpasteurized cow's milk, coffee, tomatoes, tea, Swiss chard, beer, corn, and **alfalfa**. Some reports say that natural levels of MSM decline with age. Dr. Herschler believes that the average diet is deficient in MSM because of the foods that are eaten or the way in which they are prepared. However, other sources refute the need for supplementing **sulfur** in the form of MSM, claiming that dietary sources of sulfur are sufficient. Sulfur-containing foods include cabbage, Brussels sprouts, broccoli, cauliflower (these are all known as cruciferous vegetables), sunflower seeds, **garlic**, onions, asparagus, avocados, beans, peas, mustard, horseradish, lentils, soybeans, and yogurt. Dietary sources of the three sulfur-containing amino acids—methionine, cystine, and cysteine—include meat, fish, poultry, eggs, milk, cheeses, and nuts, The cruciferous vegetables are reported to contain other sulfur compounds in addition to the sulfur-bearing **amino acids**. Nevertheless, many anecdotes cite the benefit of supplementing the diet with MSM.

General use

Because of its yellow color, the ancients named sulfur "the sun carrier." Sulfur is the fourth most common mineral in the human body. Through the ages, its curative uses have motivated many pilgrimmages to hot springs and sulfur baths around the world. Sulfur's uses within the human body are numerous. In many tissues, it is important in biological processes including nerve signal transmission, facilitative enzymatic processes, insulin production, carbohydrate metabolism regulation, **detoxification**, and waste removal.

MSM, with a 34% bio-availablility of sulfur according to one source, is reported to be useful in treating musculoskeletal, respiratory, circulatory, eliminative, autoimmune, and degenerative disorders. One of the most widely reported benefits is the relief of pain, inflammation, and **muscle spasms**, especially when related, but not limited to, **osteoarthritis** and autoimmune disorders such as lupus, scleroderma, and rheumatoid arthritis. MSM is said to reduce and improve the quality of scar tissue; promote improved healing of joints, tendons, ligaments and collagen support structures; soften, renew and strengthen the skin; and increase blood flow. It is reported to improve mucus membranes, thereby reducing food and airborne allergic reactions, and symptoms related to **asthma** and **emphysema**; improve vascular smooth muscle growth, reducing the risk of coronary artery disease; and improve athletic performance by reducing lactic acid effects, strengthening muscle elasticity and suppleness,

KEY TERMS

Amino acids—Compound molecules from which protein is built. Some are considered essential, meaning the body cannot manufacture them; they must be supplied in the diet.

Cryogenics—A science examining the freezing of living tissue for preservation and use at a later time.

Epsom salts—The common name given to a crystalline compound of magnesium, which, when dissolved in water and taken internally, functions as a laxative. It is also used externally in baths or soaks as an anti-inflammatory and detoxifying remedy.

Interstitial cystitis—An inflammatory, and sometimes scarring, condition of the bladder that affects many women.

Lactic acid—A by-product of muscular work out; slow clearance of lactic acid from tissues is associated with muscular fatigue.

Oxidized metabolite—The result of a process in which one molecule or substance is utilized by the body by first adding oxygen.

Synergistic effect—A compounding effect greater than the effect otherwise expected from adding the involved components.

and enhancing **fatigue** recovery times. It is reported to have an antiparasitic effect, especially against the parasite giardia. Another reported benefit is its tonic effect on the bowels, which increases peristalsis (waves of motion that move food along the digestive tract). This benefit is helpful to the elderly, those with sluggish colons, and those addicted to laxatives. At least one report noted possible anticancer activity.

Preparations

MSM is commonly available in these forms: powder, capsule, lotion, or gel. By itself, the powder is said to have a bitter taste. Users are advised to put the prescribed amount on the forward part of the tongue, followed by a large glass of water. In this way, the powder is dissolved in the stomach, and its bitter taste is not registered by the taste buds, which are located on the back of the tongue. Plenty of water throughout the day is also advised, due to its detoxifying action.

Suggested dosages range widely, from one to three grams daily, and up to 18 grams daily with medical supervision. One report suggests taking from two to six grams daily; the optimal dose depends on body size, age, and the severity of the condition being treated. Dr. Jacob recommends that, "A couple of grams a day would be a good general dosage," and higher doses may be useful to achieve a therapeutic effect. An example of a higher dose is three to four grams, taken for relief of allergy symptoms.

The elderly may benefit with as little as one tenth of a gram (100 mg) daily, up to five grams. Encapsulated preparation dosage recommendations may vary according to how many other ingredients—glucosamine sulfate or **chondroitin**, for example—are included in the preparation. Recommended amounts for topical applications of gel or lotion may also vary. Some sources advise adding an extra amount of powder to a gel or lotion for enhanced effect.

Precautions

MSM has blood thinning effects; therefore caution and consultation with a healthcare professional is especially advised when using medications such as warfarin (commonly known as Coumadin), aspirin, herbals such as ginkgo (**Ginkgo biloba**), and other supplements such as fish and flax oils, which contain Omega-3. An essential fatty acid, Omega-3 also has blood thinning properties.

Product purity is another concern. There are precautions against contamination by other ingredients including bacteria or DMSO, a chemical solvent that is not approved for use by the FDA. One company's product was recalled due to bacterial contamination. However, no related injuries were reported.

Dilution of the more expensive MSM product with less expensive bulk filler ingredients like Epsom salts, is a caution to buyers. ConsumerLab, LLC, lists many of these products on their Web site, with additional ingredients and test findings.

One product reported that it achieved "GRAS" (generally regarded as safe) status. The named product, as others, may derive mainly from pine tree lignan. A plant cell wall constituent, lignan facilitates the transport of nutrients up and down the stem or tree trunk. MSM may therefore facilitate movement and metabolism of other drugs, supplements, or nutrients within the body. Several reports caution that the sulfur of MSM must not be confused with sulfa drugs or with sulfites used as food preservatives. Some persons demonstrate allergic reaction to one or both of these.

Several sources report that few well-designed human studies have been conducted or reported. This factor contributes to the charge that MSM is unproven, while the array of anecdotal testimony points to the contrary.

Side effects

Side effects include gastrointestinal disturbance, such as **diarrhea**; **headache**; decreased ability to fall asleep (may occur if taken at bedtime); skin that is softer; nails that are thicker; and hair that is harder. Some reports have claimed that diarrhea or GI disturbances such as hyperacidity, **nausea**, and inflammation that are part of a **stress** response prior to taking MSM may clear "dramatically" by using MSM.

Interactions

Favorable interactions

Two sources report syngergistic interactions that reduced swelling and scarring in trauma patients, involving combinations of MSM and **vitamin C**. This occurred with additional use of the digestive proteins for starch and cellulose (amylase and cellulase, respectively), fats (**lipase**), sugars (sucrase, maltase and lactase), and **bromelain** (from pineapples). The addition of **glucosamine** HCL is reported to improve MSM effects when used for osteoarthritis.

Unfavorable interactions

Unfavorable interactions may include blood thinning medications such as Coumadin (warfarin), aspirin, and fish or flax (Omega-3) oil. One source reports studies involving prevention, regression, and promotion of tumor growth. Unfavorable interactions between MSM and chemotactic or chemopreventive agents may exist. The counsel of a knowledgeable healthcare professional is advised.

Mugwort

Description

Mugwort (*Artemisia vulgaris*) also known as common artemisia, felon herb, St. John's herb, chrysanthemum weed, sailor's tobacco, and moxa is a perennial member of the Compositae family, and a close relative of **wormwood** (*Artemisia absinthium L.*). Mugwort's generic name is from that of the Greek moon goddess Artemis, a patron of women. Mugwort has long been considered an herbal ally for women with particular benefit in regulating the menstrual cycle and easing the transition to **menopause**. The common name may be from the old English word *moughte* meaning "moth," or *mucgwyrt*, meaning "midgewort," referring to the plant's folk use to repel moths and other insects.

Mugwort has a long history of folk tradition and use. Anglo-Saxon tribes believed that the aromatic mugwort was one of the nine sacred herbs given to the world by the god Woden. It was used as a flavoring additive to beer before **hops** (*Humulus lupulus*) became widely used. Mugwort is considered a magical herb, with special properties to protect road-weary travelers against exhaustion. The Romans planted mugwort by roadsides where it would be available to passersby to put in their shoes to relieve aching feet. St. John the Baptist was said to have worn a girdle of mugwort when he set out into the wilderness. Some of the magic in mugwort is in its reputed ability to induce prophetic and vivid dreams when the herb is placed near the bed or under the sleeper's pillow. In Pagan ceremony, a garland or belt of mugwort is worn while dancing

Mugwort (*Artemisia vulgaris*). *(© blickwinkel / Alamy)*

around the fire during summer solstice celebrations. The herb is then thrown into the fire to ensure continued protection throughout the coming year.

Mugwort is a tall and hardy European native with stout, angular, slightly hairy stems tinged with a purple hue. Leaves, which may be as long as 4 in (10 cm), are deeply divided with numerous lance-shaped, pointed segments, which may be toothed or entire. They are arranged alternately along the erect, grooved stem and are a dark green on top and pale green with downy hairs on the underside. Mugwort has a pungent aroma when the leaves are crushed. In late summer the small reddish-yellow disk flowers cluster in long spikes at the top of the plant. Mugwort may reach to 6 ft (2 m) or more in height. This tenacious herb has naturalized throughout North America and may be found growing wild in rocky soils, along streams and embankments, and in rubble and other waste places, particularly in the eastern United States. In some areas, including North Carolina and Virginia, mugwort is characterized as a noxious, alien weed. Mugwort root is about 8 in (20 cm) long with many thin rootlets. It spreads from stout and persistent rhizomes.

General use

Mugwort leaf and stem are used medicinally. Mugwort acts as a bitter digestive tonic, uterine stimulant, nervine, menstrual regulator, and antirheumatic. The volatile oil of mugwort includes thujone, linalool, borneol, pinene, and other constituents. The herb also contains hydroxycoumarins, lipohilic flavonoids, vulgarin, and triterpenes.

Mugwort acts as an emmenagogue, an agent that increases blood circulation to the pelvic area and uterus and stimulates **menstruation**. It is a useful remedy for painful and irregular menstruation. A compress of the herb has been used to help promote labor and assist with expulsion of the afterbirth. A mild infusion of mugwort is useful as a digestive stimulant. It is helpful in cases of mild **depression** and nervous tension. The herb also may stimulate the appetite. A weak infusion of mugwort has sedative properties that may quiet restlessness and **anxiety**. Its antispasmodic action may relieve persistent **vomiting**, and has been used in the treatment of **epilepsy**. Mugwort added to bath water is an aromatic and soothing treatment for relief of aches in the muscles and joints. In a clinical trial, crushed fresh mugwort leaves applied to the skin were shown to be effective in eradicating **warts**. Taken as an infusion, mugwort is helpful in ridding the system of pinworm infestation. Dried mugwort leaf also acts as a natural tinder, useful in holding a smoldering fire. The dried herb has also been smoked as a nicotine-free tobacco. A species of mugwort (*A. douglasiana*), common in the southwestern United States, was used by some western Native Americans as a prevention for poison **oak** rash. The fresh mugwort leaf was rubbed over areas of exposed skin before walking into poison oak habitat. The two plants often grow near one another.

In Chinese medicine mugwort, known as *Ai ye* or *Hao-shu* is highly valued as the herb used in **moxibustion**, a method of heating specific **acupuncture** points on the body to treat physical conditions. Mugwort is carefully harvested, dried and aged, then it is shaped into a cigar-like roll. This "moxa" is burned close to the skin to heat the specific pressure points. It has been used in this way to alleviate rheumatic pains aggravated by cold and damp circumstances. Mugwort has also been used in various size cones that are places on the skin directly or on top of an herb or some salt and burned. In Japan, some practitioners only use moxa for treatment.

A study published in the *Journal of the American Medical Association* reported on the successful use of moxibustion in reversing breech birth positions. The study found that 75% of 130 fetuses had reversed their

KEY TERMS

Antioxidant—Any substance that reduces the damage caused by oxidation, such as the harm caused by free radicals.

Artemisinin—An antimalarial agent derived from an ancient Chinese herbal remedy. Two of the most popular varieties are artemether and artesunate, used mainly in Southeast Asia in combination with mefloquine.

Emmenagogue—A type of medication that brings on or increases a woman's menstrual flow.

Mugwort-spice syndrome—A type of food allergy that occurs in people who are sensitized to mugwort, celery, carrots, and other spices. It often takes the form of a skin rash.

Tonic—Characterized by tonus, a state of partial contraction that is maintained at least in part by a continuous bombardment of motor impulses.

Volatile oil—The fragrant oil that can be obtained from a plant by distillation. The word "volatile" means that the oil evaporates in the open air.

position after moxibustion treatment of the mother. The technique is said to stimulate the acupuncture point known as BL67, located near the toenail of the fifth toe, stimulating circulation and energy flow and resulting in an increase in fetal movements.

In Chinese medicine, mugwort is ingested to stop excessive or inappropriate menstrual bleeding.

Mugwort has also been used in Brazilian folk medicine as a remedy for stomach ulcers. Researchers have found that the plant contains **antioxidants** which help to explain its protective effects on gastric tissues.

More recently, mugwort has attracted attention as the source of a natural compound, artemisinin, which has been shown to have antimalarial properties. Artemisinin is a promising natural remedy for **malaria** because of its low toxicity and its effectiveness against drug-resistant mutations of the malaria parasite. In addition to its effectiveness in treating malaria, artemisinin is also being tested as a possible anticancer drug. A group of researchers in Mississippi has shown that artemisinin is toxic to several different types of human **cancer** cells.

Preparations

Mugwort is harvested just as the plant comes into flower, before the blossoms are fully open. The leaves are removed from the stalks and dried on paper-lined trays in a light, airy room, away from direct sunlight. The flowerheads should be dried intact and the dried herb stored in clearly-labeled, tightly-sealed, dark glass containers.

For infusion, 1 oz of fresh mugwort leaf, less if dried, is placed in a warmed glass container. One pint of fresh, nonchlorinated boiling water is added to the herb. The mixture is covered to prevent loss of volatile oils. The tea should be infused for five to 10 minutes. A mild infusion is best. After straining, it is recommended to drink two cups of mugwort tea per day. Use should be discontinued after six days.

Four ounces of finely-cut fresh or powdered dry herb can be combined with 1 pt of brandy, gin, or vodka, in a glass container. The alcohol should be enough to cover the plant parts and have a 50/50 ratio of alcohol to water. The mixture should be kept in a dark place for about two weeks, shaking several times each day. It can then be strained and stored in a tightly capped, dark glass bottle. Dosage recommendations vary, with some herbalists cautioning against ingestion of mugwort in medicinal preparations.

In **traditional Chinese medicine**, the herb is burned slightly in a pan before simmering with other herbs to stop menstrual bleeding.

Precautions

Mugwort should be avoided during **pregnancy** and lactation. The herb is a uterine stimulant. Women should avoid its use during lactation as the chemical constituent thujone may be passed to the baby through the mother's milk. Mugwort should no be ingested if uterine inflammation or pelvic infection is present.

Side effects

High doses of mugwort may cause liver damage, **nausea**, and convulsions.

Some people develop a **contact dermatitis**, or allergic skin rash, if they are in contact with mugwort and certain other spices. This food allergy has been called the mugwort-spice syndrome, or sometimes the mugwort-celery-spice syndrome. Other foods and spices that are part of this syndrome include carrots, paprika, curry, cumin, birch, and pepper. In addition, mugwort pollen has been reported to cause **asthma** in susceptible children.

Interactions

People who are allergic to mugwort are also highly likely to be allergic to **chamomile** and should not take preparations made from either herb.

Mullein

Description

Mullein (*Verbascum thapsus*) also known as great mullein, is a dramatic biennial herb of the Scrophular-iaceae or figwort family. The family name of this European native may have derived from the word scrofula, a disease that is now understood to be a form of **tuberculosis**. In Ireland mullein was widely cultivated as a remedy for tuberculosis. The seed is said to have arrived on the North American continent in the dirt used as ballast in old sailing vessels. At least five species of mullein have naturalized in North America. This sturdy and adaptive herb is found on roadsides, rocky and gravely banks, and in marginal areas throughout the world. It thrives in full sun and adapts well to arid conditions. The seeds of this hardy plant, particularly *V. blattaria,* may remain viable as long as 70 years.

Mullein (Verbascum thapsus). *(© Geoffrey Kidd / Alamy)*

Mullein is known by many names reflecting the numerous medicinal and practical uses people have found for this beneficial wayside herb throughout its long association with human communities. Among the common names for mullein are flannel leaf, beggar's blanket, velvet plant, feltwort, tinder plant, candlewick plant, witch's candle, Aaron's rod, lady's **foxglove**, donkey's ears, hag's taper, candlewick plant, torches, and Quaker rouge. This last name was given because the leaves were sometimes used as a natural rouge rubbed vigorously on the cheeks to give a rosy glow, particularly among young women whose cultures have shunned cosmetics. Mullein has been known for centuries as Gordolobo in Mexico, where it was used by the Nahuatl and other indigenous cultures long before the coming of the conquistadors. Gordolobo is still sold in medicinal herbs stands throughout Mexico as a remedy for **hemorrhoids** and **varicose veins** as well as throat ailments.

Like many plants of European origin, mullein was credited with power over witches and evil spirits. It was considered one of 23 important healing herbs in medieval Jewish medical practice. Mullein's large stalk was used as a ceremonial torch as far back as ancient Rome. Stripped of its leaves and dipped in tallow, the cylindrical spike could hold a flame when carried aloft from place to place. One name for mullein is miner's candle. During the 1849 California gold rush, the mine shafts were aglow with mullein torches carried by the prospectors. The leaves were used as tinder to start fires, or as a smudge, burned over the embers of Native American campfires. The smoke was inhaled to relieve pulmonary congestion. Mullein leaf, which some tribes called "big tobacco," was mixed with nicotine leaf and smoked to relieve **asthma**. The leaves were boiled to make a hot poultice to treat **gout** and painful joints. Mullein's thick, soft leaves lined the shoes of many common folk during the winter months to provide extra warmth. The leaves were also warmed over a hot rock and fitted to the foot to relieve **fatigue**. Figs were wrapped in the leaves to ripen and keep, and the flowers were used to add blonde highlights to the hair, or soaked in oil to make ear drops.

Mullein's branching, spindle-shaped root produces a low-lying basal rosette of broadly lance-shaped leaves in the first year of growth. Dense and downy white hairs give mullein's light-green leaves a soft texture somewhat like the fine pile of velvet. These leaves winter over from the first year's growth. They may reach 15-20 in (38-50 cm) in length and 8 in (20 cm) across. In its second season mullein transforms, reaching skyward with a single, pithy and fibrous stem stout enough hold itself erect when in full leaf. Small yellow, five-petaled blossoms each form a golden cup and encircle the upper few feet of the stem, opening randomly. The usually solitary stem, which may grow to 10 ft (3 m) high, is sometimes branched. The leaves clasp the stem, growing alternately, and are increasingly smaller toward the top of the stem, an arrangement that facilitates the flow of rain water to the roots.

General use

The flowers, leaves, and root of mullein have been used as healing remedies for centuries. Mullein leaf and flower were listed as an official medicine in the United States *National Formulary* from 1916 to 1936. The plant contains mucilage, triterpene saponins, volatile oil, flavonoids, and bitter glycosides. The efficacy of these compounds in the quantity found in mullein is questioned by at least one researcher. However, in the realm of folk medicine, practiced for centuries, mullein is valued as a demulcent, emollient, antispasmodic, astringent, diuretic, vulnerary, and expectorant. Mullein is approved by the German Commission E, an advisory panel for herbal medicine, for treatment of respiratory catarrh. Studies have confirmed the anti-inflammatory action of mullein. Mullein tea, made from the flowers and leaf, is a beneficial remedy for **bronchitis**, **sore throat**, **tonsillitis**, dry coughs, and hoarseness. The flowers have bactericidal and sedative properties and are generally considered more medicinally potent than the leaves. Their bactericidal activity was confirmed by researchers at Clemson University, who reported in 2002 that mullein extracts are effective against several species of disease bacteria, including *Staphylococcus aureus*, *Staphylococcus epidermidis*, *Escherichia coli*, and *Klebsiella pneumoniae*.

An oil extract of mullein flowers relieves **earache**, and the blossom tea can ease **headache pain** and promote sleep. The fresh leaves, traditionally boiled in milk and consumed daily, are an Irish folk remedy for tuberculosis. When this mixture is applied externally in poultice form, it is helpful in the treatment of **boils**, carbuncles, skin ulcers, chilblains, and hemorrhoids.

Preparations

Mullein leaves should be harvested before the herb is in blossom, leaving at least two thirds of the foliage on the plant. The flowers should be harvested just as they open. Blossoms are short-lived and drop easily from the plant. Roots are best harvested in the fall of the year. Leaves and blossoms should be dried in a single layer on paper-lined trays in a light, warm, and airy room out of direct sunlight. The medicinal

KEY TERMS

Antispasmodic—A drug or other substance that relieves mild cramping or muscle spasms.

Catarrh—Inflammation of a mucous membrane, especially of the nose and air passages.

Chilblains—Redness and swelling of the skin often accompanied by burning, itching, and blisters. A condition caused by excessive exposure to the cold.

Demulcent—A gelatinous or oily substance that has a protective or soothing influence on irritated mucous membranes.

Diuretic—An herbal preparation or medication given to increase urinary output.

Expectorant—A drug that promotes the discharge of mucus from respiratory system.

Mucilage—A gummy, gelatinous substance found in the stems of borage that is useful for treating throat irritations.

properties of the flowers are diminished if they lose their color, so care should be taken in the drying process.

Oil extraction: Combine one cup of mullein blossoms in one-half cup of olive oil in a glass double boiler over low flame. Heat slowly for about three hours. Strain with cheesecloth to remove all plant parts. Pour the oil into small, dark glass bottles, tightly sealed and clearly labeled for storage. A cold extraction can also be prepared. Cover flowers in olive oil in a glass container with a lid and set aside on a sunny windowsill to steep for seven to 10 days. Strain before storing in dark glass bottles.

Infusion: Place 2 oz of finely cut fresh (less if dried) mullein leaf and blossom in a warmed glass container. Bring 2.5 cups of fresh, nonchlorinated water to the boiling point, add it to the herbs. Cover. Infuse the tea for about 10 minutes. Strain carefully, as mullein's fine hairs are an irritant. The blossoms are sweeter to the taste than the leaf. The prepared tea will store for about two days in the refrigerator. Drink three cups a day.

Syrup: Using fresh blossoms and leaves, prepare a strong infusion of mullein. Combine the infusion with a 50/50 mixture of honey and brown sugar. Use 24 oz of sweetener for each 2.5 cups of the herbal infusion. Heat mixture in a glass or enamel pot; stir frequently as the mixture thickens. Cool and pour into a clearly labeled glass bottles. Refrigerate for storage. Take 1 tsp of syrup three times a day, or every two hours if needed for chronic coughs.

Precautions

The seeds of some species of mullein are considered toxic. The seeds of the species *N. phlomoides* contains a type of poisonous saponin and are slightly narcotic. They have been used to intoxicate fish to make them easier to catch. The Clemson researchers, however, found that mullein extract has this effect on fish only at high concentrations.

Although mullein is safe to use by itself, it is sometimes mixed with such other herbs as **comfrey**, **echinacea**, Irish moss, **yarrow**, **garlic**, or ginseng in a variety of commercial herbal preparations. The Food and Drug Administration (FDA) has issued consumer warnings about thirteen different herbal syrups, powders, capsules, or other dietary supplements containing mullein since 1999. Because the FDA classifies herbal preparations as dietary supplements and does not subject them to the approval process that prescription drugs must pass, consumers should purchase herbs and herbal products only from established manufacturers. People who would like to try mullein as an alternative remedy for sore throats might want to use the herb by itself first before trying herbal mixtures.

Side effects

There have been isolated case reports of people developing **contact dermatitis** (allergic skin rash) from mullein plants.

Interactions

Mullein has been reported to inhibit the effectiveness of antidiabetic drugs. It intensifies the effects of muscle relaxants and lithium. Persons taking prescription diuretics should consult a physician before taking mullein, as it may interact with the prescription drugs to cause a loss of **potassium** from the body.

Multiple chemical sensitivity

Definition

Multiple chemical sensitivity—also known as MCS syndrome, environmental illness, idiopathic environmental intolerance, chemical **AIDS**, total allergy syndrome, or simply MCS—is a disorder in which a person develops symptoms from exposure to chemicals in the environment. With each incidence of exposure, lower levels of the chemical will trigger a reaction and the person becomes increasingly vulnerable to reactions triggered by other chemicals.

Medical experts disagree on the cause of the syndrome, and as to whether MCS is a clinically recognized illness. In a 1992 position statement that remained unchanged as of early 2000, the American Medical Association's Council on Scientific Affairs did not recognize MCS as a clinical condition due to a lack of accepted diagnostic criteria and controlled studies on the disorder. A more recent discussion of methodological problems in published studies of MCS, as well as recommendations for patient care, may be found in the 1999 position paper on MCS drafted by the American College of Occupational and Environmental Medicine (ACOEM). As of 2003, however, many researchers in Europe as well as the United States regard MCS as a contemporary version of neurasthenia, a concept first introduced by a physician named George Miller Beard in 1869.

Description

Multiple chemical sensitivity typically begins with one high-dose exposure to a chemical, but it may also develop from long-term exposure to a low level of a chemical. Chemicals most often connected with MCS include: formaldehyde; pesticides; solvents; petrochemical fuels such as diesel, gasoline, and kerosene; waxes, detergents, and cleaning products; latex; tobacco smoke; perfumes and fragrances; and artificial colors, flavors, and preservatives. People who develop MCS are commonly exposed in one of the following situations: on the job as an industrial worker; residing or working in a poorly ventilated building; or living in conditions of high air or water pollution. Others may be exposed in unique incidents.

Because MCS is difficult to diagnose, estimates vary as to what percentage of the population develops MCS. However, most MCS patients are female. The median age of MCS patients is 40 years old, and most experienced symptoms before they were 30 years old. There is also a large percentage of Persian Gulf War veterans who have reported symptoms of chemical sensitivity since their return from the Gulf in the early 1990s.

Causes and symptoms

Chemical exposure is often a result of indoor air pollution. Buildings that are tightly sealed for energy conservation may cause a related illness called **sick building syndrome**, in which people are thought to develop symptoms from chronic exposure to airborne environmental chemicals such as formaldehyde from the furniture, carpet glues, and latex caulking. A person moving into a newly constructed building, which has not had time to degas (or air out), may experience the initial high-dose exposure that leads to MCS.

The specific biochemical and physiological mechanisms in humans that lead to MCS are not well understood. A recent hypothesis, however, suggests that MCS is the end result of four different mechanisms of sensitization acting to reinforce one

KEY TERMS

Capsaicin—A colorless, bitter compound that is present in cayenne and gives it its heat.

De-gas—To release and vent gases. New building materials often give off gases and odors and the air should be well circulated to remove them.

Neurasthenia—Nervous exhaustion; a disorder with symptoms of irritability and weakness, commonly diagnosed in the late 1800s.

Sick building syndrome—An illness related to multiple chemical sensitivity in which a person develops symptoms in response to chronic exposure to airborne environmental chemicals found in a tightly sealed building.

another. Further research is required to test this hypothesis.

The symptoms of MCS vary from person to person and are not chemical-specific. Symptoms are not limited to one physiological system, but primarily affect the respiratory and nervous systems. Symptoms commonly reported are **headache**, **fatigue**, weakness, difficulty concentrating, short-term **memory loss**, **dizziness**, irritability and **depression**, **itching**, numbness, burning sensation, congestion, **sore throat**, hoarseness, shortness of breath, **cough**, and stomach pains.

One commonly reported symptom of MCS is a heightened sensitivity to odors, including a stronger emotional reaction to them. A Japanese study published in late 2002 reported that patients diagnosed with MCS can identify common odors as accurately as most people, but regard a greater number of them as unpleasant.

One test that has been devised to evaluate patients with MCS is the capsaicin inhalation test. Capsaicin is an alkaloid found in hot peppers that is sometimes used in topical creams and rubs for the treatment of arthritis. When inhaled, capsaicin causes coughing in healthy persons as well as those with **allergies** that affect the airway; however, persons with MCS cough more deeply and frequently than control subjects when given a dose of capsaicin. Although the test is not diagnostic in the strict sense, it has been shown to be an effective way of identifying patients with MCS.

Diagnosis

Multiple chemical sensitivity is a twentieth-century disorder, becoming more prevalent as more human-made chemicals are introduced into the environment in greater quantities. It is especially difficult to diagnose because it presents no consistent or measurable set of symptoms and has no single diagnostic test or marker. For example, a 2002 study of PET scans of MCS patients found no significant functional changes in the patients' brain tissues. Physicians are often either unaware of MCS as a condition, or refuse to accept that MCS exists. They may be unable to diagnose it, or may misdiagnose it as another degenerative disease, or may label it as a psychosomatic illness (a physical illness that is caused by emotional problems). Their lack of understanding generates frustration, **anxiety**, and distrust in patients already struggling with MCS. However, a new specialty of medicine is evolving to address MCS and related illnesses: occupational and environmental medicine. A physician looking for MCS will take a complete patient history and try to identify chemical exposures.

Some MCS patients may be helped by a psychologic evaluation, particularly if they show signs of panic attacks or other anxiety disorders. It is known that many patients with MCS suffer from comorbid depression and anxiety. In addition, MCS patients appear to have high rates of mood disorders compared to **asthma** patients as well as normal test subjects.

A 1999 consensus statement signed by 34 physicians and MCS researchers and published in the *Archives of Environmental Health* lists six criteria for MCS diagnosis:

- The MCS symptoms are chronic.
- The symptoms are reproducible with repeated chemical exposure.
- Low levels of chemical exposure trigger symptoms.
- Symptoms occur with multiple, unrelated chemicals.
- Symptoms improve when the chemicals are removed.
- Symptoms involve multiple organ systems.

Treatment

The most effective treatment for MCS is to avoid the chemicals that trigger the symptoms. Avoidance becomes increasingly difficult as the number of offending chemicals increases; things as seemingly harmless as air freshener devices, scented soaps, and perfume can trigger serious reactions in MCS patients. Individuals with MCS often remain at home where they are able to control the chemicals in their environment. In many cases, it may be recommended that an individual turn one room in his or her home, usually the bedroom, into an environmentally safe haven by

removing all known chemical irritants and furnishing it with 100% natural materials. The isolation that is a necessary part of treatment for MCS patients limits their abilities to work and socialize, so supportive counseling is often appropriate.

Many MCS patients undergo food-allergy testing and testing for accumulated pesticides in the body to learn more about their condition and what chemicals to avoid. Eliminating foods with artificial colors and flavors, preservatives, monosodium glutamate, and other additives can help to lessen MCS symptoms, as can choosing pesticide-free, organically grown fruits and vegetables.

Some MCS patients find relief with **detoxification** programs of **exercise** and sweating, and chelation of heavy metals. **Acupuncture** can give added support to any treatment program for MCS patients. **Yoga**, massage, and **aromatherapy** may be helpful in relieving **stress** symptoms associated with MCS. However, great care should be taken when selecting aromatherapy oils for MCS patients, and the practice is best left to a trained aromatherapist familiar with MCS. **Essential oils** should be verified as 100% unadulterated and nonchemically extracted. If a negative reaction results from the use of a particular oil, the MCS patient should stop using it immediately and consult his or her healthcare professional.

A number of herbs may be prescribed to treat the symptoms of MCS. They should also be prescribed and selected with great care, especially in those patients who suffer from known food allergies. Herbs should be recommended by a trained herbalist or naturopathic healthcare professional, and small sample doses may be administered before trying full dosage strength in order to check for an allergic reaction. **Milk thistle** (*Silybum marianum*) can be useful for cleansing the liver after chemical damage.

Allopathic treatment

Some doctors may recommend antihistamines, analgesics, and other medications to combat the symptoms of MCS. Care must be taken in prescribing these substances, as they may provoke a reaction in some MCS patients.

Expected results

Once MCS sets in, sensitivity continues to increase and a person's health continues to deteriorate. Strictly avoiding exposure to triggering chemicals for a year or more may improve health.

Prevention

Multiple chemical sensitivity is difficult to prevent because even at high-dose exposures, different people react differently. Ensuring adequate ventilation in situations with potential for acute high-dose or chronic low-dose chemical exposure, as well as wearing the proper protective equipment in industrial situations, will minimize the risk.

Symptoms of multiple sclerosis

Symptoms

Numbness in one or more limbs, typically occurring on one side of the body at a time, or on the bottom half of the body.

Tingling in one or more limbs and chest

Tremors, or unsteady gait

Lack of muscular coordination

Blurred vision, double vision, or loss of vision (often in one eye at a time, with pain during eye movement

Incontinence

Exhaustion and weakness in limbs/Fatigue

Dizziness

Electric-shock sensations that occur with certain head movements

Multiple sclerosis

Definition

Multiple sclerosis is a chronic, degenerative disease of the central nervous system (CNS). The CNS is comprised of the brain and the spinal cord. In the CNS, the nerves are covered by a protective layer called the myelin sheath. Myelin helps keep the nerve healthy. It also improves nerve conduction. In multiple sclerosis, inflammation causes the nerves to gradually lose this myelin cover. This repeated inflammation and erosion leads to scarring (sclerosis), which impairs the nerve's ability to conduct impulses. Eventually, even the nerves themselves are affected. Because the nervous system controls and coordinates a number of body functions, patients with MS gradually lose a variety of functions, including memory and the ability to see, speak or walk.

Description

Multiple sclerosis is a chronic debilitating disease that affects as many at 350,000 in the United States alone (2.5 million worldwide). Most patients are first diagnosed of the disease at age 20-40. However, the disease may appear as early as age 12 or as late as age 50. MS strikes women earlier in life. Women are also affected more frequently than men and whites more often than other races.

Causes and symptoms

The causes of multiple sclerosis are still unknown, although many factors are suspected. In the United States, whites are diagnosed with MS twice as often as blacks or Hispanics. Asians are the least affected. There is some consensus, however, that the following factors may contribute to the development of multiple sclerosis:

- *Genetic heredity*. Family members of multiple sclerosis patients have a 1 in 50 chance of having MS; the odds for people without an affected family member are 1 in 1,000. If an identical twin is diagnosed with MS, the remaining twin has a 1 in 3 chance of becoming affected as well. Recent research has shown that several autoimmune diseases, including MS, share a common genetic link. In other words, patients with MS might share common genes with family members that have other autoimmune diseases like systemic lupus, rheumatoid arthritis, and others.
- *Viral infection*. Most MS patients have high levels of antibodies to measles and other viruses. Therefore,

multiple sclerosis may be the body's delayed immune reaction to viruses such as measles, *Herpes simplex*, rubella, and parainfluenza. A 2001 study also suggested that Epstein-Barr virus, the virus that causes mononucleosis, probably increases risk of MS.

- *Autoimmune reaction*. Scientists know that MS is an autoimmune disorder, an illness in which the body attacks its own myelin as if it were a foreign substance. Although research has identified which immune cells are responsible and how they are activated, no one knows what causes the immune system to begin this attack.
- *Geography*. Countries in the temperate zones (above 40°) such as Northern Europe, North America, Australia, and New Zealand have significantly higher incidence of multiple sclerosis than countries in the tropics. In the United States, people who live below the 37th parallel develop MS at a rate of 57–78 cases per 100,000 people. Those who live above the line have a prevalence rate of 110–140 cases per 100,000 people.
- *Diet*. Studies have shown that populations at high risk of developing multiple sclerosis tend to consume a lot of dairy products and animal fats. On the contrary, in countries such as Japan, people eat few dairy products but consume lots of fish, soy-rich foods, and seeds, which are good sources of essential fatty acids. The incidence rates in these countries are very low. Thus, essential fatty acid deficiency due to excessive consumption of saturated fats may contribute to the development of multiple sclerosis.

Diagnosis

In order to determine whether or not a patient has multiple sclerosis, doctors often rely on the Schumacher criteria:

- Patient's symptoms indicate neurological damage in more than one areas.
- Patient's symptoms have worsened for more than six months.
- There are at least two events (each lasting for more than one day) separated by at least one month.
- Neurological exam of the patient shows abnormal central nervous system function.
- Symptoms reflect damage in the white matter of the CNS only.
- Patient is older than 10 but less than 50 years old.
- Patient does not have stroke, lupus, or any disease that may have similar symptoms.

A diagnosis of multiple sclerosis is made when patient's symptoms fit Schumacher's criteria and neurological exams, MRI, and laboratory results also show corresponding abnormalities. In 2001, a panel convened by the National Multiple Sclerosis Society wrote new diagnostic criteria for MS, the first update in about 20 years. The new criteria formally recommend MRI and outline how doctors should use the results of tests like cerebral spinal fluid analysis.

KEY TERMS

Exacerbations—Increase in severity of a disease or condition.

Myelin—A fatty sheath surrounding nerves throughout the body that helps them conduct impulses more quickly.

Relapse—A return to a disease state, after recovery appeared to be occurring. In alcoholism, relapse refers to a patient beginning to drink alcohol again after a period of avoiding alcohol.

Remission—A disappearance of a disease and its symptoms. Complete remission means that all disease is gone. Partial remission means that the disease is significantly improved, but residual traces of the disease are still present. A remission may be due to treatment or may be spontaneous.

MS symptoms vary significantly in terms of severity, intensity and duration. Sensory symptoms are the first warning signs. Many patients notice color distortion, blurred or double vision, and temporary blindness. Their senses of smell, hearing, touch, and taste are also affected. They experience muscle weakness and difficulty walking, as well as **muscle spasms** and numbness, tingling, or prickling ("pins and needles") sensations called *paresthesias*. As the disease progresses, sudden partial or complete paralysis of the arms or legs is common, as are an inability to speak clearly, move without tremors, or hear clearly. Mental functions are also affected. Patients can not concentrate or remember as clearly as before. They often become depressed. They may laugh or cry uncontrollably. As conditions worsen, they lose control of bodily functions. Some patients find that hot weather exacerbates their symptoms. Cold baths or air conditioning may help during these periods. There are also periods, called remissions, in which patients are free of symptoms; remission can be complete or partial.

While there is a rare, rapidly progressing form of MS that can be fatal in as little as a few days or weeks,

MS generally affects the quality of life more than it diminishes life expectancy. Most patients can look forward to decades of life after diagnosis. Many are able to continue to live a relatively normal life for at least 20 years after onset, although some patients become disabled within a few months of being diagnosed. In addition, because MS patients are frequently forced into immobility and spend a lot of time sitting in wheelchairs, they are susceptible to such common complications of the disabled as urinary tract **infections**, skin ulcers, pneumonia, or pulmonary embolism (blood clot in the lung) in addition to side effects from prescribed drugs.

Treatment

Nutritional therapy

Many multiple sclerosis patients follow a low-fat diet developed by Dr. Roy Swank, who recommends his diet to slow down disease progression. The following are his recommendations:

- Consume no more than 10 g of saturated fat per day.
- Limit polyunsaturated fat consumption to 50 g or less per day.
- Take 1 tbsp of cod liver oil per day to supplement essential fatty-acid intake. Cod liver oil is a good source of omega-3 fatty acid, one of the two essential fatty acids.
- Consume adequate amount of protein in the diet, preferably plant protein such as soy, beans, seeds, and nuts.
- Eat more fish, a good source of omega-3 fatty acid. Swank recommends having fish three or more times per week. Omega-3 fatty acid is believed to support myelin production and improve nerve function.

In addition to following the Swank diet, Dr. Michael Murray and Dr. Joseph Pizzorno, the authors of the book *Encyclopedia of Natural Medicine* also recommend the following nutritional supplements:

- *Flaxseed oil*. Murray and Pizzorno recommend replacing the fish oil in Swank's diet with flaxseed oil because the latter can provide both omega-3 and omega-6 fatty acids. Omega-6 fats, studies have shown, also help alleviate MS symptoms.
- *Antioxidants* such as selenium , vitamin C, and vitamin E. Patients with multiple sclerosis often have antioxidant deficiency.
- *Vitamin B_{12}*. MS patients often lack Vitamin B_{12}, and correcting this deficiency is believed to help decrease myelin destruction.

Exercise and physical therapy

Almost any form of **exercise** or **movement therapy** is beneficial for MS patients. For patients too weak to exercise alone, a massage or assisted physical therapy should be helpful to improve circulation to the limbs and promote well-being. Those that are less restricted may find **t'ai chi**, **qigong**, **yoga**, martial arts, conventional cardiovascular exercise, and/or water aerobics helpful.

Other treatments

Other alternative treatments such as aromatherapy (body massage with **rosemary** or juniper **essential oils**) and **hydrotherapy** (hot or cold baths used to treat affected areas, also a program of exercise performed in water) may also improve muscle strength in MS patients. Chinese herbs, especially ginseng, are also helpful in managing the disease. Wearing a cooling vest may also help, according to a 2001 study. The vest cools patients (without affecting their temperatures) and also appears to promote production of white cell nitrous oxide, which may play a role in MS.

Allopathic treatment

Standard treatment consists of an exercise program, diet modification, and medication. Three relatively new drugs may be prescribed: beta-interferon A (Avonex), which can limit the progressions of disability; beta-interferon-B (Betaseron), which reduces the number and severity of relapses; and Glatiramer acetate (Copaxone), which helps prevent relapse in patients with the relapsing-remitting (RR) type of MS. (These are patients who have a period of time with no or few symptoms [remission] following acute exacerbations [relapse] of disease.) All are administered by injection. These drugs have significant side effects including **fever**, tiredness, weakness, chills, muscle aches and inflammation at injection sites. Avonex may be better tolerated than Betaseron.

For symptomatic treatment of muscle spasm, Baclofen is most effective; its dosage must be carefully tailored to specific patient's needs. An implantable infusion pump that delivers the drug directly into the spinal cord can be used for patients with severe spasticity. Diazepam (valium) is sometimes given together with baclofen to increase its effectiveness. Alternative antispastic drugs are tizanidine and dantrolene. Steroids such as methylprednisolone and prednisone are also sometimes used to treat flare-ups.

Expected results

Patients whose symptoms worsen quickly right after diagnosis, those who have significant impairment in muscle movement or brain functions at onset and who have very abnormal magnetic resonance imaging (MRI) results at the beginning have poor prognosis. On the other hand, patients who recover quickly after the initial symptoms or those who experience only sensory impairment for five years or more after diagnosis often are able to maintain work longer and live longer than those with chronic progressive multiple sclerosis.

Prevention

There is no way to prevent the onset of multiple sclerosis, though a diet low in saturated fat may be helpful.

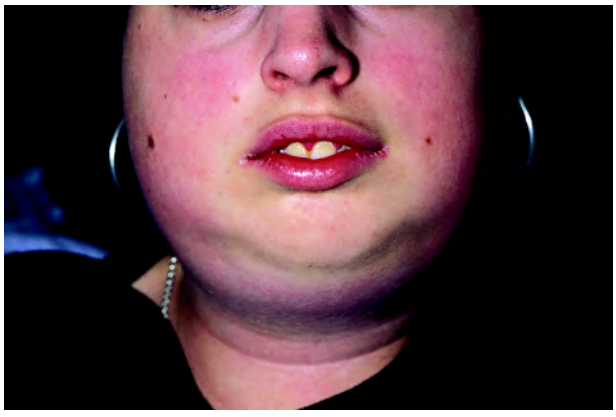
Mumps

Definition

Mumps is a relatively mild short-term viral infection of the salivary glands that usually occurs during childhood. Typically, mumps is characterized by a painful swelling of both cheek areas, although the person could have swelling on one side or no perceivable swelling at all. The salivary glands are also called the parotid glands; therefore, mumps is sometimes referred to as an inflammation of the parotid glands (epidemic parotitis). The word mumps comes from an old English dialect word that means lumps or bumps within the cheeks.

Description

Mumps is a very contagious infection that spreads easily in such highly populated areas as day care centers and schools. Although not as contagious as **measles** or **chickenpox**, mumps was once quite common.



Mumps is an acute generalized virus infection, commonly causing enlargement of the salivary glands, especially the parotid gland. *(© Hercules Robinson / Alamy)*

Prior to the release of a mumps vaccine in the United States in 1967, approximately 92% of all children had been exposed to mumps by the age of 15. In these pre-vaccine years, most children contracted mumps between the ages of four and seven. Mumps epidemics came in two to five year cycles. The greatest mumps epidemic was in 1941 when approximately 250 cases were reported for every 100,000 people. In 1968, the year after the live mumps vaccine was released, only 76 cases were reported for every 100,000 people. By 1985, less than 3,000 cases of mumps were reported throughout the entire United States, which works out to about 1 case per 100,000 people. The reason for the decline in mumps was the increased usage of the mumps vaccine. However, 1987 noted a five-fold increase in the incidence of the disease because of the reluctance of some states to adopt comprehensive school immunization laws. Since then, state-enforced school entry requirements have achieved student immunization rates of nearly 100% in kindergarten and first grade. In 1996, the Centers for Disease Control and Prevention (CDC) reported only 751 cases of mumps nationwide, or, in other words, about one case for every five million people.

KEY TERMS

Autism—A developmental disability that appears early in life, in which normal brain development is disrupted and social and communication skills are retarded, sometimes severely.

Encephalitis—Inflammation of the brain, usually caused by a virus. The inflammation may interfere with normal brain function and may cause seizures, sleepiness, confusion, personality changes, weakness in one or more parts of the body, and even coma.

Epidemic parotitis—The medical name for mumps.

Immunoglobulin G (IgG)—Immunoglobulin type gamma, the most common type found in the blood and tissue fluids.

Meningitis—An infection or inflammation of the membranes that cover the brain and spinal cord. It is usually caused by bacteria or a virus.

Orchitis—Inflammation of one or both testes, accompanied by swelling, pain, fever, and a sensation of heaviness in the affected area.

Paramyxovirus—A genus of viruses that includes the causative agent of mumps.

Parotitis—Inflammation and swelling of one or both of the parotid salivary glands.

Causes and symptoms

The paramyxovirus that causes mumps is harbored in the saliva and is spread through **sneezing**, coughing, and other direct contact with another person's infected saliva. Once the person is exposed to the virus, symptoms generally become noticeable in 14–24 days. Initial symptoms include **chills**, **headache**, loss of appetite, and a lack of energy. However, an infected person may not experience these initial symptoms. Swelling of the salivary glands in the face (parotitis) generally occurs within 12–24 hours of the above symptoms. Accompanying the swollen glands is **pain** on chewing or swallowing, especially with acidic beverages, such as lemonade. A **fever** as high as 104°F (40°C) is also common. Swelling of the glands reaches a maximum on about the second day and usually disappears by the seventh day. Once a person has contracted mumps, he or she becomes immune to the disease, despite how mild or severe symptoms may have been.

While the majority of cases of mumps are uncomplicated and pass without incident, some complications can occur. Complications are, however, more noticeable in adults who get the infection. In 15% of cases, the covering of the brain and spinal cord becomes inflamed (**meningitis**). Symptoms of meningitis usually develop within four or five days after the first signs of mumps. These symptoms include a stiff neck, headache, **vomiting**, pain with bending or flexing the head, and a lack of energy. Mumps meningitis is usually resolved within seven days, and damage to the brain is exceedingly rare.

Mumps infection can spread into the brain causing inflammation of the brain (encephalitis). Symptoms of mumps encephalitis include the inability to feel pain, seizures, and high fever. Encephalitis can occur during the parotitis stage or one to two weeks later. Recovery from mumps encephalitis is usually complete, although complications, such as seizure disorders, have been noted. Only about 1 in 100 patients with mumps encephalitis dies from the complication.

About one-quarter of all post-pubertal males who contract mumps can develop a swelling of the scrotum (orchitis) about seven days after the parotitis stage. Symptoms include marked swelling of one or both testicles, severe pain, fever, **nausea**, and headache. Pain and swelling usually subside after 5–7 days, although the testicles can remain tender for weeks.

Girls occasionally suffer an inflammation of the ovaries, or oophoritis, as a complication of mumps, but this condition is far less painful than orchitis in boys.

As of late 2002, some researchers in Europe are studying the possibility that mumps increases a person's risk of developing **inflammatory bowel disease** (IBD) in later life. This hypothesis will require further research, as present findings are inconclusive.

Diagnosis

When mumps reaches epidemic proportions, diagnosis is relatively easy on the basis of the physical symptoms. The doctor will take the child's temperature, gently palpate (touch) the skin over the parotid glands, and look inside the child's mouth. If the child has mumps, the openings to the ducts inside the mouth will be slightly inflamed and have a "pouty" appearance. With so many people vaccinated today, a case of mumps must be properly diagnosed in the event the salivary glands are swollen for reasons other than viral infection. For example, in persons with poor oral hygiene, the salivary glands can be infected with bacteria. In these cases, antibiotics are necessary. Also in rare cases, the salivary glands can become blocked, develop tumors, or swell due to the use of certain drugs, such as **iodine**. A test can be performed to determine whether the person with swelling of the salivary glands actually has the mumps virus.

Researchers in London have reported the development of a bioassay for measuring mumps-specific IgG. This test allows a doctor to check whether an individual patient is immune to mumps, and allow researchers to measure the susceptibility of a local population to mumps in areas with low rates of vaccination.

Treatment

Nutritional therapy

Nutritional therapy may alleviate pain and aid healing. A nutritionist or naturopath may recommend the following:

- drinking lots of fluids to replace fluid loss
- eating only such easy-to-digest foods as soups, broth or bland foods
- taking multivitamin/mineral supplement to help boost the immune function

Homeopathy

A number of homeopathic remedies can be used in the treatment of mumps. For example, **belladonna** may be useful for flushing, redness, and swelling. **Bryonia** (wild **hops**) may be useful for irritability, lack of energy, or thirst. **Phytolacca** (poke root) may be prescribed for extremely swollen glands. A homeopathic physician should always be consulted for appropriate doses for children, and remedies that do not work within one day should be stopped. A homeopathic preparation of the mumps virus can also be used prophylactically or as a treatment for the disease.

Herbal therapy

Several herbal remedies may be useful in helping the body recover from the infection or may help alleviate the discomfort associated with the disease. **Echinacea** (*Echinacea* spp.) can be used to boost the immune system and help the body fight the infection. Other herbs taken internally, such as cleavers (*Galium aparine*), **calendula** (*Calendula officinalis*), and phytolacca (poke root), target the lymphatic system and may help to enhance the activity of the body's internal filtration system. Since phytolacca can be toxic, it should only be used by patients under the care of a skilled practitioner. Topical applications are also useful in relieving the discomfort of mumps. A cloth dipped in a heated mixture of vinegar and **cayenne** (*Capsicum frutescens*) can be wrapped around the neck several times a day. Cleavers or calendula can also be combined with vinegar, heated, and applied in a similar manner.

Acupressure

Acupressure can be used effectively to relieve pain caused by swollen glands. The patient can, by using the middle fingers, gently press the area between the jawbone and the ear for two minutes while breathing deeply.

Allopathic treatment

When mumps occurs, the illness is usually allowed to run its course. The symptoms, however, are treatable. Because of difficulty swallowing, the most important challenge is to keep the patient fed and hydrated. The individual should be provided a soft diet, consisting of cooked cereals, mashed potatoes, broth-based soups, prepared baby foods, or foods put through a home food processor. Aspirin, acetaminophen, or ibuprofen can relieve some of the pain due to swelling, headache, and fever. Avoiding fruit juices and other acidic foods or beverages that can irritate the salivary glands is recommended, as is avoiding dairy products that can be hard to digest. In the event of complications, a physician should be contacted at once. For example, if orchitis occurs, a physician should be

called. Also, supporting the scrotum in a cotton bed on an adhesive-tape bridge between the thighs can minimize tension. Ice packs are also helpful.

Expected results

When mumps is uncomplicated, the prognosis for full recovery is excellent. In rare cases, however, a relapse occurs after about two weeks. Complications can also delay complete recovery.

Prevention

A vaccine exists to protect against mumps. The vaccine preparation (MMR) is usually given as part of a combination injection that helps protect against measles, mumps, and **rubella**. MMR is a live vaccine administered in one dose between the ages of 12-15 months, 4-6 years, or 11-12 years. Persons who are unsure of their mumps history and/or mumps vaccination history should be vaccinated. Susceptible health care workers, especially those who work in hospitals, should be vaccinated. Because mumps is still prevalent throughout the world, susceptible persons over age one who are traveling abroad would benefit from receiving the mumps vaccine.

The mumps vaccine is extremely effective, and virtually everyone should be vaccinated against this disease. There are, however, a few reasons why people should *not* be vaccinated against mumps:

- Pregnant women who contract mumps during pregnancy have an increased rate of miscarriage, but not birth defects. As a result, pregnant women should not receive the mumps vaccine because of the possibility of damage to the fetus. Women who have had the vaccine should postpone becoming pregnant for three months following vaccination.
- Unvaccinated persons who have been exposed to mumps should not get the vaccine, as it may not provide protection. The person should, however, be vaccinated if no symptoms result from exposure to mumps.
- Persons with minor fever-producing illnesses, such as an upper respiratory infection, should not get the vaccine until the illness has subsided.
- Because mumps vaccine is produced using eggs, individuals who develop hives, swelling of the mouth or throat, dizziness, or breathing difficulties after eating eggs should not receive the mumps vaccine.
- Persons with immune deficiency diseases and/or those whose immunity has been suppressed with anti-cancer drugs, corticosteroids, or radiation should not receive the vaccine. Family members of immunocompromised people, however, should get vaccinated to reduce the risk of mumps.
- The CDC recommends that all children infected with human immunodeficiency disease (HIV) who are asymptomatic should receive an MMR vaccine at 15 months of age.

The mumps vaccine has been controversial in recent years because of concern that its use was linked to a rise in the rate of childhood **autism**. The negative publicity given to the vaccine in the mass media led some parents to refuse to immunize their children with the MMR vaccine. One result has been an increase in the number of mumps outbreaks in several European countries, including Italy and the United Kingdom.

In the fall of 2002, the *New England Journal of Medicine* published a major Danish study disproving the hypothesis of a connection between the MMR vaccine and autism. A second study in Finland showed that the vaccine is not associated with aseptic meningitis or encephalitis as well as autism. Since these studies were published, American primary care physicians have once again reminded parents of the importance of immunizing their children against mumps and other childhood diseases.

Muscle spasms & cramps

Definition

Muscle spasms and cramps are spontaneous, often painful muscle contractions.

Description

Most people are familiar with the sudden **pain** of a muscle cramp. The rapid, uncontrolled contraction, or spasm, happens unexpectedly. Sometimes it can happen during or following athletic activity or a workout. It can also happen with either no stimulation or some trivially small one. The muscle contraction and pain last for several minutes, and then slowly ease. Cramps may affect any muscle, but are most common in the calves, thighs, feet, and hands. While painful, they are harmless, and in most cases, not related to any underlying disorder. Nonetheless, cramps and spasms can be manifestations of many neurological or muscular diseases.

The terms cramp and spasm are often used interchangeably. They can be somewhat vague because they are sometimes used to also include types of abnormal muscle activity other than sudden painful contraction. These include stiffness at rest, slow muscle **relaxation**, and spontaneous contractions of a muscle at rest (fasciculation or clonism). Fasciculation is a type of painless muscle spasm, marked by rapid, uncoordinated contraction of many small muscle fibers that people often describe as a sort of "muscle fluttering." For a physician, a critical part of diagnosis is to distinguish these different meanings and to allow the patient to describe the problem as precisely as possible.

Causes and symptoms

Normal voluntary muscle contraction begins when electrical signals are sent from the brain through the spinal cord along nerve cells called motor neurons. These include both the upper motor neurons within the brain and the lower motor neurons within the spinal cord and leading out to the muscle. At the muscle, chemicals released by the motor neuron stimulate the internal release of **calcium** ions from stores within the muscle cell. These calcium ions then interact with proteins within the muscle cell, causing chains of the proteins actin and myosin to slide past one another with a ratchet-like motion. This motion pulls their fixed ends closer, thereby shortening the cell and, ultimately, contracting the muscle itself. Recapture of calcium and unlinking of actin and myosin allows the muscle fiber to return to its resting length (i.e., relax).

Abnormal contraction may be caused by abnormal activity at any stage in this process. Certain mechanisms within the brain and the rest of the central nervous system monitor the length of the muscles and help regulate contraction. Interruption of these mechanisms can cause spasm. Motor neurons that are overly sensitive may fire below their normal thresholds. The muscle membrane itself may be hypersensitive, causing contraction without stimulation. Calcium ions may not be recaptured quickly enough, causing prolonged contraction.

Interruption of brain mechanisms and overly sensitive motor neurons may result from damage to the nerve pathways. Possible causes include **stroke**, **multiple sclerosis**, **cerebral palsy**, neurodegenerative diseases, trauma, spinal cord injury, and such nervous system poisons as strychnine, **tetanus** toxin, and certain insecticides. Nerve damage may lead to a prolonged or permanent muscle shortening called contracture. However, most muscle spasms are not caused by disease, but more commonly by physical activity or **stress**.

KEY TERMS

Actin—A protein that functions in muscular contraction by combining with myosin.

Fasciculation—Small involuntary muscle contractions visible under the skin.

Motor neuron—A nerve cell that specifically controls and stimulates voluntary muscles.

Myosin—A protein found in muscle tissue that interacts with another protein called actin during muscle contraction.

Myotonia—The inability to normally relax a muscle after contracting or tightening it.

Changes in muscle responsiveness may be due to or associated with:

- Prolonged exercise. Relaxation of a muscle actually requires energy to be expended. The energy is used to recapture calcium and to unlink the actin and myosin. This causes the muscles fibers to lengthen because the unlinked chains slide back to their resting positions. Normally, sensations of pain and fatigue signal that it is time to slow down or stop. Resting allows the muscles to restore their supplies of energy. Ignoring or overriding those warning signals can lead to such severe energy depletion that the muscle cannot be relaxed, causing a cramp. For example, this is why long distance runners may cramp up after a run. The lack of blood flow deprives the muscles of their source of energizing oxygen and nutrients and removal of fatigue causing waste. Rigor mortis, the stiffness of a corpse within the first 24 hours after death, is also due to this phenomenon.
- Using a muscle inappropriately. Muscle cramps in such sports as golf or tennis are sometimes caused by an incorrect grip on the club or racket, or an incorrect swing.
- Anemia adversely effects blood flow to the muscles and can cause cramping and spasms.
- Dehydration and salt depletion. This may be brought on by protracted vomiting or diarrhea, or by copious sweating during prolonged exercise, especially in high temperatures. Loss of fluids and salts—especially sodium, potassium, magnesium, and calcium—can disrupt ion balances in both muscle and nerves. This can prevent them from responding and recovering normally, and can lead to a cramp.
- Metabolic disorders that affect the energy supply in muscle. These are inherited diseases in which particular muscle enzymes are deficient. They include deficiencies of myophosphorylase (McArdle's disease), phosphorylase b kinase, phosphofructokinase, phosphoglycerate kinase, and lactate dehydrogenase.
- Myotonia. Myotonia is a condition that causes stiffness due to delayed relaxation of the muscle, but does not cause the spontaneous contraction usually associated with cramps. However, many patients with myotonia do experience cramping from exercise. Symptoms of myotonia are often worse in the cold. Myotonias include myotonic dystrophy, myotonia congenita, paramyotonia congenita, and neuromyotonia.
- Vascular disease, such as arteriosclerosis, Reynaud's disease, and diabetic vasculopathy, decreases blood flow to muscles, which can cause cramping.
- Exposure to cold can also decrease blood flow, resulting in cramping and muscle spasms.

Fasciculations may be due to **fatigue**, cold, medications, metabolic disorders, nerve damage, or neurodegenerative disease, including amyotrophic lateral sclerosis. Most people experience brief, mild fasciculations from time to time, usually in the calves.

The pain of a muscle cramp is intense, localized, and often debilitating. Coming on quickly, it may last for minutes and fade gradually. Contractures develop more slowly, over days or weeks, and may be permanent if untreated. Fasciculations may occur at rest or after muscle contraction, and may last several minutes.

Diagnosis

Abnormal contractions are diagnosed through a careful medical history, physical and neurological examination, and electromyography of the affected muscles. Electromyography records electrical activity in the muscle during rest and movement.

Treatment

Most cases of simple cramps require no medical treatment. However, because cramps hurt, a person suffering a cramp will want to stop the cramp. An effective method for stopping a cramp involves contracting the muscle that causes the opposite action of the cramping muscle. This technique requires some training and knowledge of muscular anatomy, so it may be more effective if done by a therapist. Gently and gradually stretching and massaging the affected muscle may ease the pain and hasten recovery.

A massage technique that can work is applying broad pressure on the cramping muscle. Applying ice can help if cramps persist. Fluid and salt replacement, by drinking water or properly prepared "sports drinks," and/or eating fruits and salads bearing **sodium**, **potassium**, **magnesium**, and calcium (bananas are a good source) can also help.

Cramps may be treated or prevented with gingko (*Ginkgo biloba*) or Japanese quince (*Chaenomeles speciosa*). Supplements of **vitamin B_{12}**, folate, **vitamin E**, **niacin**, calcium, and magnesium may also help. Taken at bedtime, they may help to reduce the likelihood of night cramps.

Guided imagery, relaxation, and **meditation** may all help lessen the pain associated with muscle cramps and spasms and may also dissipate the cramp or spasm.

Allopathic treatment

More prolonged or regular cramps may be treated with drugs such as carbamazepine, phenytoin, or quinine. Treatment of underlying metabolic or neurologic disease, where possible, may help relieve symptoms. Identified **anemia** can be treated with **iron** supplementation.

Prevention

The likelihood of developing cramps may be reduced by eating a healthy diet with appropriate levels of minerals, and getting regular **exercise** and adequate rest to build up energy reserves in muscle. Exercise should be accompanied by a proper stretching program. Avoiding exercising in extreme heat helps prevent heat cramps. Heat cramps can also be avoided by drinking ample amounts of water before prolonged exercise in hot weather. For intense activity over one hour, drinking fluid containing some sodium plus 4–8% carbohydrate in the form of sugars (glucose or sucrose) or starch (maltodextrin) is useful. Fluid temperature should be cool (45–55°F or 7.2–12.8°C). Taking a warm bath before bedtime may increase circulation to the legs and reduce the incidence of nighttime leg cramps.

Music therapy

Definition

Music therapy is a technique of complementary medicine that uses music prescribed in a skilled manner by trained therapists. Programs are designed to help patients overcome physical, emotional, intellectual, and social challenges. Applications range from improving the well being of geriatric patients in nursing homes to lowering the **stress** level and **pain** of women in labor. Music therapy is used in many settings, including schools, rehabilitation centers, hospitals, hospices, nursing homes, community centers, and sometimes even in the home.

Origins

Music has been used throughout human history to express and affect human emotion. In biblical accounts, King Saul was reportedly soothed by David's harp music, and the ancient Greeks expressed thoughts

A music therapist with a disabled child. *(Abraham Menashe / Photo Researchers, Inc.)*

about music having healing effects as well. Many cultures are steeped in musical traditions. It can change mood, have stimulant or sedative effects, and alter physiologic processes such as heart rate and breathing. The apparent health benefits of music to patients in Veterans Administration hospitals following World War II lead to it being studied and formalized as a complementary healing practice. Musicians were hired to continue working in the hospitals. Degrees in music therapy became available in the late 1940s, and in 1950, the first professional association of music therapists was formed in the United States. The National Association of Music Therapy merged with the American Association of Music Therapy in 1998 to become the American Music Therapy Association.

Benefits

Music can be beneficial for anyone. Although it can be used therapeutically for people who have physical, emotional, social, or cognitive deficits, even those who are healthy can use music to relax, reduce stress, improve mood, or to accompany **exercise**. There are no potentially harmful or toxic effects other than the risk that listening to loud music poses by contributing to hearing loss. Music therapists help their patients achieve a number of goals through music, including improvement of communication, academic strengths, attention span, and motor skills. They may also assist with **behavioral therapy** and pain management.

Physical effects

Brain function physically changes in response to music. The rhythm can guide the body into breathing in slower, deeper patterns that have a calming effect. Heart rate and blood pressure are also responsive to the types of music that are listened to. The speed of the heartbeat tends to speed or slow depending on the volume and speed of the auditory stimulus. Louder and faster noises tend to raise both heart rate and blood pressure; slower, softer, and more regular tones produce the opposite result. Music can also relieve muscle tension and improve motor skills. It is often used to help rebuild physical patterning skills in rehabilitation clinics. Levels of endorphins, natural pain relievers, are increased while listening to music, and levels of stress hormones are decreased. This latter effect may partially explain the ability of music to improve immune function. A 1993 study at Michigan State University showed that even 15 minutes of exposure to music could increase interleukin-1 levels, a consequence which also heightens immunity.

KEY TERMS

Adjunctive—Refers to a form of treatment that is not strictly necessary to a therapy regimen but is helpful. Music therapy is an example of an adjunctive form of treatment.

Entrainment—The patterning of body processes and movements to the rhythm of music.

Physiologic—Refers to physiology, particularly normal, healthy, physical functioning.

Mental effects

Depending on the type and style of sound, music can either sharpen mental acuity or assist in **relaxation**. Memory and learning can be enhanced, and this used with good results in children with learning disabilities. This effect may also be partially due to increased concentration that many people have while listening to music. Better productivity is another outcome of an improved ability to concentrate. The term "Mozart effect" was coined after a study showed that college students performed better on math problems when listening to classical music.

Emotional effects

The ability of music to influence human emotion is well known, and is used extensively by moviemakers. A variety of musical moods may be used to create feelings of calmness, tension, excitement, or romance. Lullabies have long been popular for soothing babies to sleep. Music can also be used to express emotion nonverbally, which can be a very valuable therapeutic tool in some settings.

Description

Goals

Music is used to form a relationship between the therapist and the patient. The music therapist sets goals on an individual basis, depending on the reasons for treatment, and selects specific activities and exercises to help the patient progress. Objectives may include development of communication, cognitive, motor, emotional, and social skills. Some of the techniques used to achieve this are singing, listening, instrumental music, composition, creative movement, **guided imagery**, and other methods as appropriate. Other disciplines may be integrated as well, such as dance, art, and psychology. Patients may develop musical abilities as a result of therapy, but this is not

a major concern. The primary aim is to improve the patient's ability to function.

Techniques

Learning to play an instrument is an excellent musical activity to develop motor skills in individuals with developmental delays, brain injuries, or other motor impairment. It is also an exercise in impulse control and group cooperation. Creative movement is another activity that can help to improve coordination, as well as strength, balance, and gait. Improvisation facilitates the nonverbal expression of emotion. It encourages socialization and communication about feelings as well. Singing develops articulation, rhythm, and breath control. Remembering lyrics and melody is an exercise in sequencing for **stroke** victims and others who may be intellectually impaired. Composition of words and music is one avenue available to assist the patient in working through fears and negative feelings. Listening is an excellent way to practice attending and remembering. It may also make the patient aware of memories and emotions that need to be acknowledged and perhaps talked about. Singing and discussion is a similar method, which is used with some patient populations to encourage dialogue. Guided Imagery and Music (GIM) is a very popular technique developed by music therapist Helen Bonny. Listening to music is used as a path to invoke emotions, picture, and symbols from the patient. This is a bridge to the exploration and expression of feelings.

Music and children

The sensory stimulation and playful nature of music can help to develop a child's ability to express emotion, communicate, and develop rhythmic movement. There is also some evidence to show that speech and language skills can be improved through the stimulation of both hemispheres of the brain. Just as with adults, appropriately selected music can decrease stress, **anxiety**, and pain. Music therapy in a hospital environment with those who are sick, preparing for surgery, or recovering postoperatively is appropriate and beneficial. Children can also experience improved self-esteem through musical activities that allow them to succeed.

Newborns may enjoy even greater benefits from music. Premature infants experience more rapid weight gain and an earlier discharge from the hospital than their peers who are not exposed to music. There is also anecdotal evidence of improved cognitive function in premature infants from listening to music.

Music and rehabilitation

Patients with brain damage from stroke, traumatic brain injury, or other neurologic conditions have been shown to exhibit significant improvement as a result of music therapy. This is theorized to be partially the result of entrainment, which is the synchronization of movement with the rhythm of the music. Consistent practice leads to gains in motor skill ability and efficiency. Cognitive processes and language skills often benefit from appropriate musical intervention.

Music and the elderly

The geriatric population can be particularly prone to anxiety and **depression**, particularly in nursing home residents. Chronic diseases causing pain are also not uncommon in this setting. Music is an excellent outlet to provide enjoyment, relaxation, relief from pain, and an opportunity to socialize and reminisce about music that has had special importance to the individual. It can have a striking effect on patients with **Alzheimer's disease**, even sometimes allowing them to focus and become more responsive for a time. Music has also been observed to decrease the agitation that is so common with this disease. One study shows that elderly people who play a musical instrument are more physically and emotionally fit as they age than their nonmusical peers.

Music and psychiatric disorders

Music can be an effective tool for treating the mentally or emotionally ill. **Autism** is one disorder that has been particularly researched. Music therapy has enabled some autistic children to relate to others and have improved learning skills. **Substance abuse**, **schizophrenia**, paranoia, and disorders of personality, anxiety, and affect are all conditions that may be benefited by music therapy. In these groups, participation and social interaction are promoted through music. Reality orientation is improved. Patients are helped to develop coping skills, reduce stress, and express their feelings.

In the treatment of psychotic disorders, however, the benefits of music therapy appear to be limited. One study of patients diagnosed with schizophrenia or schizoaffective psychosis found that while music therapy improved the patients' social relationships, these benefits were relatively short-lived.

Music and hospice care

Pain, anxiety, and depression are major concerns with patients who are terminally ill, whether they are

in hospice or not. Music can provide some relief from pain, through release of endorphins and promotion of relaxation. It can also provide an opportunity for the patient to reminisce and talk about the fears that are associated with death and dying. Music may help regulate the rapid breathing of a patient who is anxious, and soothe the mind. The Chalice of Repose project, headquartered at St. Patrick Hospital in Missoula, Montana, is one organization that attends and nurtures dying patients through the use of music, in a practice they called music-thanatology by developer Therese Schroeder-Sheker. Practitioners in this program work to relieve suffering through music prescribed for the individual patient.

Music and gynecologic procedures

Research has proven that women require less pharmaceutical pain relief during labor if they make use of music. Listening to music that is familiar and associated with positive imagery is the most helpful. During early labor, music will promote relaxation. Maternal movement is helpful to get the baby into a proper birthing position and dilate the cervix. Enjoying some "music to move by" can encourage the mother to stay active for as long as possible during labor. The rhythmic auditory stimulation may also prompt the body to release endorphins, which are a natural form of pain relief. Many women select different styles of music for each stage of labor, with a more intense, or faster-moving piece feeling like a natural accompaniment to the more difficult parts of labor. Instrumental music is often preferred.

The benefits of music therapy during **childbirth** have also been shown to apply to other surgical procedures. Women who have listened to music tapes during gynecologic surgery have more restful sleep following the procedure and less postoperative soreness.

Precautions

Patients making use of music therapy should not discontinue medications or therapies prescribed by other health providers without prior consultation.

Research and general acceptance

There is little disagreement among physicians that music can be of some benefit for patients, although the extent of its effects on physical well-being is not as well acknowledged in the medical community. Acceptance of music therapy as an adjunctive treatment modality is increasing, however, due to the growing diversity of patient populations receiving music therapy. Research has shown that listening to music can decrease anxiety, pain, and recovery time. There are also good data for the specific subpopulations discussed. A therapist referral can be made through the AMTA.

Training and certification

Music therapists are themselves talented musicians; they also study the ways in which music can be applied to specific groups and circumstances. Coursework includes classes regarding music history and performance, behavioral science, and education. The American Music Therapy Association dictates what classes must be included in order for a music therapy program to be certified. There are approximately 70 colleges with approved curricula. A six-month internship follows the completion of the formal music therapy program, and the graduate is then able to take a national board exam to gain certification.

Myopia

Definition

Myopia is the medical term for nearsightedness. People with myopia see objects more clearly when they are close to the eye, while distant objects appear blurred or fuzzy. Reading and close-up work may be clear, but distance vision is blurry.

Description

Myopia affects about 30% of the population in the United States. To understand myopia it is necessary to have a basic knowledge of the main components involved in the eye's focusing system: the cornea, lens, and retina. The cornea is a tough, transparent, dome-shaped tissue that covers the front of the eye (not to be confused with the white, opaque sclera). The cornea lies in front of the iris (the colored part of the eye). The lens is a transparent, double-convex structure located behind the iris. The retina is a thin membrane that lines the rear of the eyeball. Light-sensitive retinal cells convert incoming light rays into electrical signals that are sent along the optic nerve to the brain, which then interprets the images. In people with normal vision, parallel light rays enter the eye and are bent by the cornea and lens (a process called refraction) to focus precisely on the retina, providing a crisp, clear image. In the myopic eye, the focusing power of the cornea (the major refracting structure of the eye) and the lens is too great with respect to the length of the eyeball. Light rays are bent too much, and they converge in front of the retina. This results in what is called a refractive error. In other words, an overly focused, fuzzy image is sent to the brain.

There are many types of myopia. Some common types include:

- physiologic
- pathologic
- acquired

By far the most common, physiologic myopia develops sometime between the ages of five to 10 years and gradually progresses until the eye is fully grown. This may include refractive myopia (cornea and lens-bending properties are too strong) and axial myopia (the eyeball is too long). Pathologic myopia is a far less common abnormality. This condition begins as physiologic myopia, but rather than stabilizing, the eye continues to enlarge at an abnormal rate (progressive myopia). This more advanced type of myopia may lead to degenerative changes in the eye, or degenerative myopia. Acquired myopia occurs after infancy. This condition may be seen in association with uncontrolled diabetes and certain types of **cataracts**. Antihypertensive drugs and other medications can also affect the refractive power of the lens.

Causes and symptoms

Myopia is said to be caused by an elongation of the eyeball. This means that the oblong (as opposed to normal spherical) shape of the myopic eye causes the cornea and lens to focus at a point in front of the retina. A more precise explanation is that there is an inadequate correlation between the focusing power of the cornea and lens and the length of the eye.

Myopia is considered to be primarily a hereditary disorder, meaning that it runs in families. People are generally born with a small amount of **hyperopia** (farsightedness), but as the eye grows this decreases and myopia does not become evident until later. Because of this, it is sometimes argued that myopia is not inherited, but acquired. Some eyecare professionals believe that a tendency toward myopia may be inherited, but the actual disorder results from a combination of environmental and genetic factors. Environmental factors include close work, **stress**, and eye strain.

The symptoms of myopia are blurred distance vision, eye discomfort, squinting, and eye strain.

Diagnosis

The diagnosis of myopia is typically made during the first several years of elementary school when a teacher notices a child having difficulty seeing the chalkboard, reading, or concentrating. The teacher or school nurse often recommends an eye exam by an ophthalmologist or optometrist. An ophthalmologist—M.D. or D.O. (Doctor of Osteopathy)—is a medical doctor trained in the diagnosis and treatment of eye problems. Ophthalmologists also perform eye surgery. An optometrist (O.D.) diagnoses and manages and/or treats eye and visual disorders. In many states,

KEY TERMS

Accommodation—The ability of the lens to change its focus from distant to near objects and vice versa. It is achieved through the action of the ciliary muscles that change the shape of the lens.

Cornea—The clear, dome-shaped outer covering of the eye that lies in front of the iris and pupil. The cornea lets light into the eye.

Diopter (D)—A unit of measure for describing the refractive power of a lens.

Laser-assisted in-situ keratomileusis (LASIK)—A procedure that uses a cutting tool and a laser to modify the cornea and correct moderate to high levels of myopia (nearsightedness).

Lens—The transparent, elastic, curved structure behind the iris (colored part of the eye) that helps focus light on the retina. Also refers to any device that bends light waves.

Ophthalmologist—A physician who specializes in the anatomy and physiology of the eyes and in the diagnosis and treatment of eye diseases and disorders.

Optic nerve—A bundle of nerve fibers that carries visual messages from the retina in the form of electrical signals to the brain.

Optometrist—A health care professional who examines and tests the eyes for disease and treats visual disorders by prescribing corrective lenses and/or vision therapy. In many states, optometrists are licensed to use diagnostic and therapeutic drugs to treat certain ocular diseases.

Orthokeratology—A method of reshaping the cornea using a contact lens. It is not considered a permanent method to reduce myopia.

Peripheral vision—The ability to see objects that are not located directly in front of the eye. Peripheral vision allows people to see objects located on the side or edge of their field of vision.

Photorefractive keratectomy (PRK)—A procedure that uses an excimer laser to reshape the cornea and permanently correct nearsightedness (myopia).

Radial keratotomy (RK)—A surgical procedure involving the use of a diamond-tipped blade to make several spoke-like slits in the peripheral (non-viewing) portion of the cornea to improve the focus of the eye and correct myopia by flattening the cornea.

Refraction—The turning or bending of light waves as the light passes from one medium or layer to another. In the eye it means the ability of the eye to bend light so that an image is focused onto the retina. Also used to describe the determination and measurement of the eye's focusing system by an optometrist or ophthalmologist.

Refractive eye surgery—A general term for surgical procedures that can improve or correct refractive errors of the eye by permanently changing the shape of the cornea.

Retina—The inner, light-sensitive layer of the eye containing rods and cones. The retina transforms the image it receives into electrical signals that are sent to the brain via the optic nerve.

Visual acuity—Sharpness or clearness of vision.

optometrists are licensed to use diagnostic and therapeutic drugs.

A patient's distance vision is tested by reading letters or numbers on a chart posted a set distance away (usually 20 ft, or 6 m). The doctor has the patient view images through a variety of lenses to obtain the best correction. The doctor also examines the inside of the eye and the retina. An instrument called a slit lamp is used to examine the cornea and lens. The eyeglass prescription is written in terms of diopters (D), which measure the degree of refractive error. Mild to moderate myopia usually falls between -1.00D and -6.00D. Normal vision is commonly referred to as 20/20 to describe the eye's focusing ability 20 ft away from an object. For example, 20/50 means that a myopic person must be 20 ft away from an eye chart to see what a normal person can see at 50 ft (15 m). The larger the bottom number, the greater the myopia.

Treatment

Nutritional therapy

The following nutritional supplements may help improve vision:

- Vitamin A: essential vitamin for healthy eyes.
- Bioflavonoids. These plant chemicals can help myopic people see better, especially at night.
- Zinc: may improve night vision.
- Ginkgo extract: increases blood supply to the eye. It may help prevent deterioration in vision.

Eye exercises

Some eye care professionals recommend exercises to help improve circulation, reduce eye strain, and relax the eye muscles. The **Bates method** is a common set of exercises. It is possible that by combining exercises with changes in behavior, the progression of myopia may be slowed or prevented. Alternative treatments include: visual therapy (also referred to as vision training or eye exercises); discontinuing close work; reducing eye strain (taking a rest break during periods of prolonged near vision tasks); and wearing bifocals to decrease the need to accommodate when doing close-up work.

Acupuncture

Acupuncture, by acting on eye muscles, causes changes in the shape of the eyeball and thus, may be able to correct nearsightedness. Approximately 10 sessions followed by daily eye exercises are needed to see significant and prolonged results.

Allopathic treatment

People with myopia have three main options for treatment: eyeglasses, contact lenses, and for those who meet certain criteria, refractive eye surgery.

Eyeglasses

Eyeglasses are the most common method used to correct myopia. Concave glass or plastic lenses are placed in frames in front of the eyes. The lenses diverge the light rays so they focus further back, directly upon the retina, producing clear distance vision.

Contact lenses

Contact lenses are a second option for treatment. Contact lenses are extremely thin round discs of plastic that are worn on the eye in front of the cornea. Contact lenses offer several benefits over glasses, including: better vision, less distortion, clear peripheral vision, and cosmetic appeal. In addition, contacts don't steam up from changes in temperature or perspiration.

Refractive eye surgery

Recommended for people who find glasses and contact lenses inconvenient and uncomfortable, refractive eye surgery improves myopic vision by permanently changing the shape of the cornea so light rays focus properly on the retina. These procedures are performed on an outpatient basis and generally take 10-30 minutes. There are three types of corrective surgeries available as of 1998: (1) radial keratotomy, (2) photorefractive keratectomy, and (3) laser-assisted in-situ keratomileusis (LASIK). Each of these surgery techniques changes rapidly in price and effectiveness. Patients should investigate the procedures and ask many questions of their doctors or others who have had the procedures before having them done.

RADIAL KERATOTOMY. Radial keratotomy (RK), the first of these procedures made available, is considered the riskiest. The surgeon uses a delicate diamond-tipped blade, a microscope, and microscopic instruments to make several spoke-like, "radial" incisions in the non-viewing (peripheral) portion of the cornea. The slits surgically alter the curve of the cornea, making it flatter, which may improve the focus of images onto the retina.

PHOTOREFRACTIVE KERATECTOMY. Photorefractive keratectomy (PRK) involves the use of a computer to measure the shape of the cornea. Using these measurements, the surgeon applies a computer-controlled laser to make modifications to the cornea. The PRK procedure flattens the cornea by vaporizing small amounts of tissue from the cornea's surface. Photorefractive keratectomy can be used to treat mild to moderate forms of myopia. The cost is approximately $2,000 per eye.

LASER-ASSISTED IN-SITU KERATOMILEUSIS. Laser-assisted in-situ keratomileusis (LASIK) is the newest of these procedures. It is recommended for moderate to severe cases of myopia. A variation on the PRK method, LASIK uses lasers and a cutting tool called a microkeratome to form a circular flap on the cornea. The flap is flipped back to expose the inner layers of the cornea. The cornea is treated with a laser to change the shape and focusing properties, then the flap is replaced.

Myopia treatments under research include corneal implants and permanent, surgically placed contact lenses.

Expected results

Glasses and contact lenses can (but not always) bring vision to 20/20. Refractive surgery can make permanent improvements for the right myopic candidate. Ophthalmologists continue to improve upon and develop new techniques to correct myopia. Alternative treatments have not been widely studied.

Prevention

Myopia is generally considered a hereditary condition, which means that it runs in families. From this perspective there is nothing that can be done to prevent

this disorder. However, because the percentage of people with myopia in the United States has steadily increased over the last 50 years, some believe that the condition results from a combination of genetic and environmental factors. If this is true, then it may be possible to prevent or control myopia by reducing close work, reading and working in good light, maintaining good **nutrition**, and practicing visual therapy (when recommended). In fact, a 2002 study showed that children's **diets** high in starches may be adding to the high prevalence of myopia. Diets high in refined starches from breads and cereals increase insulin levels, which in turn affect development of the eyeball. Increasing protein consumption has been shown to slow the progression of myopia in children.

Eye strain can be prevented by using sufficient light for reading and close work, and by wearing corrective lenses as prescribed. Everyone should have regular eye exams to see if the prescription has changed or if any other problems have developed. This is particularly important for people with high (degenerative) myopia who may be at a greater risk of developing retinal detachments or other problems.

Myotherapy

Definition

Myotherapy is a method intended to relieve **pain**, and is based on the application of pressure at trigger points throughout the body. Trigger points are defined as hypersensitive locations in the muscles that cause pain in response to undue **stress**. They may be caused by occupational or other injuries as well as by disease, physical stress, and emotional stress. Trigger points rarely occur in the same location where the pain is felt. Myotherapy is founded on the notion that relief of tension in the muscle followed by revitalization of the relieved muscle through stretching, promotes healing and reduces the disposition of the muscle and the nerve to cause further pain.

Origins

Myotherapy developed out of trigger-point therapy, a method of pain relief developed by Dr. Janet Travell. Fitness expert Bonnie Prudden built on Travell's method to investigate certain parallels that she perceived between the injection of pain relievers into nerve locations in trigger-point therapy and the potential to relieve pain similarly through external physical pressure on the nerve points. She spent approximately

four years investigating and experimenting with the idea. During that time, she studied anatomy and developed a new pain-relief therapy that she named myotherapy. Its name is derived from the Greek prefix "myo," meaning muscle. Within 10 years, she had established a certified training program for myotherapy technicians.

Benefits

Myotherapy is claimed to be effective in eliminating 95 percent of all physical pain associated with muscular discomfort and to be successful in patients suffering from many types of head, back, and **neck pain**. It is also used to relieve the discomfort of **carpal tunnel syndrome**, **fibromyalgia**, and arthritis, and to reduce swelling in patients who have **multiple sclerosis**.

In addition, some athletes seek myotherapy to experience enhanced physical performance.

Description

Myotherapy is used to eliminate pain and swelling through the application of pressure at strategically located nerve sites called trigger points. Unlike many other techniques to alleviate **muscle spasms**, myotherapy is not based on topical or internal medication.

Myotherapy treatment is a two-step process. The therapist first locates and diffuses the trigger points of pain by applying pressure to those locations. This process is designed to relieve the pain and also to relax the muscles associated with the specific discomfort. Secondly, the patient undergoes a series of exercises during the therapy session to progressively stretch the muscles that have been relaxed by the pressure therapy. Therapy generally continues for fewer than 10 sessions.

The age of the patient who undergoes myotherapy is significant only in determining the number of trigger points that might cause muscle pain. Because practitioners believe trigger points accumulate over time, they expect older patients to usually have developed more trigger points.

Preparations

As with most treatments, patients should have a physical examination done by a qualified doctor or technician before undergoing this pain-relief technique. Patients should seek clearance for treatment from a general practitioner (M.D.), osteopath (D.O.), doctor of podiatric medicine (D.P.M.), doctor of **chiropractic** (D.C.), doctor of **naturopathic medicine** (N.M.D.), registered nurse practitioner (R.N.P.), or physical therapist (P.T.) before myotherapy treatment. Patients who undergo myotherapy to relieve the discomfort of **temporomandibular joint syndrome** (TMJ) or other facial pain should consult a dentist (D.D.S.) for a clearance examination. Preparatory examination is necessary to determine that no structural anatomical problem is causing the pain, because problems of this nature require medical treatment that cannot be replaced by myotherapy.

KEY TERMS

Trigger points—Hypersensitive muscle locations that cause pain in response to undue stress.

To benefit fully from myotherapy, adherents note that the patient should have a positive attitude and willingness to give up any emotional investment in the pain syndrome. They assert that myotherapy requires full commitment to the therapy sessions and an attitude of self-healing to bring about relief.

Precautions

To facilitate recuperation from pain relief, myotherapy patients are advised to involve a relative, friend, or other trusted acquaintance who can learn the technique as well as the patient's personal pressure points. This buddy system allows the patient to renew the effects of the myotherapy sessions in the event of a relapse.

Side effects

Myotherapy has no known side effects. For anatomical pathology patients, however, medical attention is necessary before seeking myotherapy treatment. This examination is crucial in order to eliminate any physical abnormalities that may be the source of the patient's discomfort.

Athletes who gain enhanced performance following myotherapy may consider the improvement a positive side effect.

Research and general acceptance

Many myotherapists operate as self-employed practitioners in private clinics. In addition, certified myotherapists hold positions in hospitals, doctors' offices, dental offices, and clinics.

Training and certification

Certified myotherapists undergo a two-year program of education and training in preparation for certification. After the completion of the training

BONNIE PRUDDEN (1914-)

(AP/Wide World Photos. Reproduced by permission.)

Fitness expert Bonnie Prudden was born on January 29, 1914, in New York City. She attended Columbia University Extension School, Grand Central School of Art, and Weidman Humphrey School of Dance. Prudden served as the director of both the ski patrol and Red Cross disaster units in New York State from 1939 1949. She founded and directed the Institute for Physical Fitness in White Plains, New York in 1950.

Prudden came to the attention of the American public in 1955 after she used the Kraus Weber test to assess the physical fitness levels of children worldwide. Prudden's test results revealed that 58% of American children were unfit and scored worse than the children of underdeveloped nations. She presented her test results to President Dwight Eisenhower, and her actions ultimately inspired what has come to be called the President's Council on Physical Fitness and Sport.

During the era before videotape, Prudden released six exercise recordings and authored 19 books on fitness. She hosted the first nationally televised exercise show and established physical fitness programs at schools, hospitals, and other institutions. Prudden, the mother of two daughters, was credited with inventing the first pre and post natal exercise programs for women. Additionally, over 500,000 babies learned rudimentary water skills as a result of her mother and baby, swim and gym classes.

Prudden altered her focus in 1976 when she discovered the theory of myotherapy, the use of applying pressure to trigger points in the body to lessen muscle spasms and pain and to improve circulation. In 1979, after some investigation, she established the Bonnie Prudden Two year School of Physical Fitness and Myotherapy. She explained the basics of myotherapy in her 1980 book, *Pain Erasure,* and later published *Bonnie Prudden's Complete Guide to Pain Free Living,* followed by *Fitness Guide for the After 50 Crowd.* Additionally she presented seminars on the topic.

Bonnie Prudden has received many honors, including a Safety Award from Eastern Amateur Ski Association and a Service to Youth Award from Young Men's Christian Association.

regimen, the candidate must pass a board examination in order to receive official recognition as a Certified Bonnie Prudden Myotherapist. The training sessions total 1,300 hours prior to the board-certification examination. To retain myotherapist credentials, a program of continuing education involving 45 hours of enrichment and update training on a bi-annual basis is required.

Myrrh

Description

Myrrh (*Commiphora molmol,C. abyssinica*, or *C. myrrha*) is a close relative and member of the Burseraceae family, native to the eastern Mediterranean, Ethiopia, the Arabian peninsula, and Somalia. Myrrh

Myrrh. *(©PlantaPhile, Germany. Reproduced by permission.)*

is a shrubby desert tree known variously as gum, myrrh tree, guggal gum, guggal resin, didin, and didthin. Myrrh is an Arabic word meaning bitter. The highly valued aromatic gum resin of myrrh has a bitter, pungent taste and a sweet, pleasing aroma. A particularly treasured variety of myrrh is known as *karam* or Turkish myrrh.

Myrrh grows to a height of about 9 ft (2.7 m). The light gray trunk is thick and the main branches are knotted with smaller branches protruding at a right angle and ending in sharp spines. The hairless, roughly toothed leaves are divided into one pair of small, oval leaflets with a larger, terminal leaflet. The yellow-red flowers grow on stalks in an elongated and branching cluster. The small brown fruit is oval, tapering to a point.

During the time of the Egyptian pharaoh Thutmose III, around the fifteenth century B.C., the pharaoh's aunt, Queen Hatshepsut, sent an expedition to Africa and the "Land of Punt" where myrrh trees were abundant. The Queen wanted to please the god Amon by surrounding his temple with living myrrh trees. The mission was successful and the story of the expedition was depicted on the walls of the temple built to enclose the Queen's tomb. According to legend Queen Hatshepsut was promised "life, stability and satisfaction . . . forever" by the well-pleased god, and the revered myrrh tree was introduced to the Egyptian people.

Myrrh has been used since ancient times in incense, perfumes, and holy ointments. The Egyptians used myrrh in embalming compounds and burned pellets of myrrh to repel fleas. Archeological evidence indicates that myrrh was carried in small pouches that wealthy persons hung around the neck for fragrance. The Ebers Papyrus, believed to have been found in the necropolis outside Thebes, provides evidence of Egyptian medicinal use of myrrh. This ancient document contains as many as 800 medicinal recipes using such plants as myrrh, **peppermint**, **aloe**, **castor oil**, and numerous other herbs in common use today. Myrrh was mentioned in the bible as a component of the bitter solution offered to the crucified Jesus during Roman times. The herb was traditionally mixed with wine and offered to prisoners prior to execution to ease **pain**.

The use of myrrh medicinally was recorded in China in A.D. 600 during the Tang Dynasty. Myrrh is used today in Chinese medicine to treat **wounds**, relieve painful swelling, and to treat menstrual pain due to blood stagnation. Myrrh is called *mo yao* in China.

Myrrh was a highly valued commodity for commerce on ancient spice routes, and is woven into legend and myth. In Syrian legend the myrrh tree is named for the daughter of Thesis, a Syrian king. She was transformed by the gods into a myrrh tree to escape her father's murderous wrath.

General use

Myrrh is the sweet-smelling oleo-gum resin that naturally exudes from wounds or **cuts** in the stems and bark of several species of this shrubby desert tree. This sap forms a thick, pale yellow paste as it seeps out. It then hardens into a mass about the size of a walnut, taking on a reddish-brown color. The volatile oil contained in the resin consists of sesquiterpenes, triterpenes, and mucilage. The tannin content gives myrrh its astringent action. Powdered myrrh has been endorsed by the German advisory Commission E as a beneficial treatment for mild inflammations in the throat and mouth. Myrrh acts as a broad-spectrum antiseptic and can be applied directly to sores and wounds.

Taken internally in tincture or capsule form, myrrh is a beneficial treatment for loose teeth, gingivitis, and bad breath. The tincture may also be applied directly to a tooth to relieve tooth ache. It is antifungal, and has been used to treat **athlete's foot** and candida. Some research indicates that myrrh is effective in reducing **cholesterol** levels. It is a tonic remedy said to relax smooth muscles, increase peristaltic action, and stimulate gastric secretions. The myrrh resin has antimicrobial properties and acts to stimulate macrophage activity in the blood stream. The herb is being studied for its potential as an anticancer medication. Taken internally in tincture or capsule form, myrrh is useful for relieving gastric distress and as an expectorant, though this folk application has not been confirmed by experimental evidence. Myrrh is burned as incense and used to repel mosquitoes. It is also a component in healing salves used in veterinary medicine. In Chinese medicine, it is used for wounds, **bruises**, and bleeding.

Preparations

Myrrh is available in capsule, powder, and tincture form. It is pulverized into powder, and prepared as a tincture. It is found combined with other ingredients in dental powders, mouthwash preparations, and toothpaste. Myrrh is used as fragrance in cosmetics, perfumes, and soaps, and as flavoring in foods.

Tincture: Four ounces of powdered myrrh are combined with 1 pt of brandy, gin, or vodka in a glass container, with enough alcohol to cover the herb. A 50/50 ratio of alcohol to water is generally recommended. The mixture should be placed away from light for about two weeks, and shaken several times each day. Strain and store in a tightly capped, dark glass bottle. A standard dose is 1 or 2 ml of the tincture three times a day.

Essential oil: Myrrh's essential oil is pale yellow to amber in color. It is obtained by steam distillation. The essential oil is commercially available from numerous sources. It is said to be beneficial when used as a chest rub to treat **bronchitis**, and externally in diluted form on ulcers and wounds.

Gargle: One teaspoon of dry, powdered myrrh should be combined with 1 tsp of boric acid. One pint of boiling water is poured over the mixture and steeped for 30 minutes, then strained. This mixture is a good gargle preparation, according to herbalist John Lust.

Precautions

Myrrh should be avoided during **pregnancy** and should not be administered to children. It should be kept away from the eyes and mucous membranes and out of children's reach.

Side effects

According to the *PDR For Herbal Medicine*, "No health hazards or side effects are known in conjunction with the proper administration of designated therapeutic dosages."

Interactions

No interactions are reported.

Narcolepsy

Definition

Narcolepsy is a neurological disorder characterized by uncontrollable episodes of sleepiness during the day. Episodes can last from a few seconds to more than an hour and can significantly interfere with daily activities.

Description

People with narcolepsy often fall asleep suddenly, anywhere at any time, even in the middle of a conversation. They may sleep for just a few seconds or for up to a half hour, and then reawaken feeling alert until they fall asleep again. The condition affects 135,000 Americans. **Sleep apnea** (difficulty in breathing while sleeping) is the leading cause of excessive daytime sleepiness. Narcolepsy is the second leading cause.

The attacks of sleepiness that are the hallmark of this condition may be mildly inconvenient or deeply disturbing. Some people continue to function during the sleep episodes, even talking and putting things away, but will reawaken with no memory of what they had been doing while briefly asleep.

Narcolepsy is related to the dreaming part of sleep known as rapid eye movement (REM) sleep. Normally, people fall asleep for about 90 minutes of non-REM sleep followed by REM sleep. However, people with narcolepsy enter REM sleep immediately; then, after reawakening, REM sleep recurs inappropriately throughout the day.

Causes and symptoms

Scientists believe narcolepsy is caused by a deficiency of the brain cells that make a substance called hypocretin; genetics are a factor in the condition, as well. Hypocretin, which is secreted by the hypothalamus, is responsible for enhancing wakefulness. Researchers are unsure why the hypocretin-secreting neurons are destroyed in some individuals; one possibility is that a person's immune system is a factor.

Cross-ethnic studies indicate significant variations in the prevalence of narcolepsy in different countries, with the Japanese having a very high rate and Israeli Jews one of the lowest in the world. One study of five European countries found that the prevalence of narcolepsy is higher in the United Kingdom and Germany than in Italy, Portugal, and Spain.

In the late 1990s, three independent research groups discovered a neuropeptide system in the hypothalamus, a gland in the brain that regulates body temperature and appetite. The discovered system, which was called the hypocretinergic system, regulates sleep and wakefulness. The nerve cells, or neurons, in this part of the hypothalamus secrete substances known as hypocretins or orexins, which regulate the sleep/wake cycle in humans. There are two of these compounds, known as orexin-A and orexin-B, or as hypocretin-1 and hypocretin-2. As of 2002, narcolepsy was thought to be an orexin deficiency syndrome; that is, it develops when a person's hypothalamus does not secrete enough orexins to keep the person from falling asleep at inappropriate times. Samples of cerebrospinal fluid taken from patients with narcolepsy contain little or no orexins. MRI scans of these patients indicate that there is some loss of brain tissue in the hypothalamus itself, suggesting that the neurons responsible for secreting orexins have died.

Symptoms of narcolepsy typically appear during adolescence; however, studies have shown that they may also begin in childhood. The disorder itself may not be diagnosed for many years after the first appearance of symptoms. The primary symptom is an overwhelming feeling of **fatigue**, together with sleep attacks that may occur with or without warning. About 75% of patients also experience cataplexy, a sudden loss of

muscle control lasting a few seconds to 30 minutes resulting in physical collapse without any loss of consciousness. Episodes of narcolepsy can be triggered by emotions such as laughter, fear, or anger. Other symptoms include sleep paralysis and hypnogogic (vivid) hallucinations as the person wakes up or falls asleep. Some patients may also have trouble staying asleep at night.

Diagnosis

If a person has both excessive daytime sleepiness and cataplexy, narcolepsy can be diagnosed on the basis of patient history alone. Lab tests, however, can confirm a diagnosis. Tests at a **sleep disorders** clinic include an overnight polysomnogram (sleep monitored with electrocardiography, video, and respiratory parameters) followed by a multiple sleep latency test, which measures sleep onset and how quickly REM sleep occurs. In narcolepsy, sleep latency is usually less than five minutes. First REM period latency is also abnormally short.

A genetic blood test can reveal certain antigens in people who have a tendency to develop narcolepsy. Positive blood test results suggest, but do not prove, the existence of narcolepsy.

As of 2002, the diagnosis of narcolepsy could be confirmed by taking a sample of the patient's cerebrospinal fluid by a spinal tap and testing it for the presence of hypocretin-1. Patients with narcolepsy have no hypocretin-1 in their spinal fluid.

Treatment

Several short naps scheduled throughout the day may help relieve some of the sleepiness associated with narcolepsy. The botanical remedy **yohimbe** (*Pausinystalia yohimbe*) may also be useful in promoting alertness. As with any herbal preparation or medication, individuals should check with their healthcare professional before taking the remedy to treat narcolepsy.

Allopathic treatment

Patients can be treated with amphetamine-like stimulant drugs (Dexedrine) to control drowsiness and sleep attacks. The symptoms of abnormal REM sleep (cataplexy, sleep paralysis, and hypnogogic hallucinations) are treated with antidepressants.

In the 2000s nonamphetamine wake-promoting drugs were available to treat narcolepsy. These medications lack the unpleasant side effects of amphetamines, particularly jitteriness and **anxiety**. Modafinil (Provigil) is the most commonly prescribed of the psychostimulants. Modafinil is believed to stimulate the neurons in the brain that are responsible for a person's wakefulness.

Patients who do not like taking high doses of stimulants may choose to nap every couple of hours to relieve daytime sleepiness and take smaller doses of stimulants.

KEY TERMS

Cataplexy—A symptom of narcolepsy in which there is a sudden episode of muscle weakness triggered by emotions. The muscle weakness may cause the person's knees to buckle or the head to drop. In severe cases, the patient may become paralyzed for a few seconds to minutes.

Hypnogogic hallucinations—Dream-like auditory or visual hallucinations that occur while falling asleep.

Hypocretins—Chemicals secreted in the hypothalamus that regulate the sleep/wake cycle.

Hypothalamus—A gland in the forebrain that controls heartbeat, body temperature, thirst, hunger, body temperature and pressure, blood sugar levels, and other functions.

Orexin—Another name for hypocretin, a chemical secreted in the hypothalamus that regulates the sleep/wake cycle. Narcolepsy is sometimes described as an orexin deficiency syndrome.

Sleep paralysis—An abnormal episode of sleep in which the patient cannot move for a few minutes, usually occurring on falling asleep or waking up. Often found in patients with narcolepsy.

Expected results

Narcolepsy can be a devastating disease that impairs a person's ability to work, play, and engage in meaningful activities. In severe cases, an inability to work and drive can interfere with daily life, leading to **depression** and a loss of independence. Drug treatments can ease symptoms but will not cure the disease. Narcolepsy is not a degenerative disease, and patients are not expected to develop new neurologic symptoms. Lifespan is normal if common sense is exercised regarding such hazards as automobile accidents.

KEY TERMS

Medicine bundle—A leather bag or animal skin in which a Native American healer carries herbs, stones, and various ritual objects as a sign of his or her healing powers.

Peyote—One of the dried tops of the mescal cactus. Peyote contains mescaline, a hallucinogen that is sometimes used in Native American healing ceremonies.

Shaman—In certain indigenous tribes or groups, a person who acts as an intermediary between the natural and supernatural worlds. Shamans are regarded as having the power or ability to cure illnesses.

Native American medicine

Definition

According to Ken "Bear Hawk" Cohen, "Native American medicine is based on widely held beliefs about healthy living, the repercussions of disease-producing behavior, and the spiritual principles that restore balance." These beliefs are shared by all tribes; however, the methods of diagnosis and treatment vary greatly from tribe to tribe and healer to healer.

Origins

The healing traditions of Native Americans have been practiced in North America since at least 12,000 years ago and possibly as early as 40,000 years ago. Although the term Native American medicine implies that there is a standard system of healing, there are approximately 500 nations of indigenous people in North America, each representing a diverse wealth of healing knowledge, rituals, and ceremonies.

Many aspects of Native American healing have been kept secret and are not written down. The traditions are passed down by word of mouth from elders, from the spirits in vision quests, and through initiation. It is believed that sharing healing knowledge too readily or casually will weaken the spiritual power of the medicine.

There are, however, many Native American healers who recognize that writing down their healing practices is a way to preserve these traditions for future generations. Many also believe that sharing their healing ways and values may help all people to come into a healthier balance with nature and all forms of life.

Benefits

Native American medicine can benefit anyone who sincerely wishes to live a life of wholeness and balance. These benefits may be physical, emotional, or spiritual. There is, however, the understanding that "the diseases of civilization," or white man's diseases, often need white man's medicine. In those cases, Native American medicine can be an important part of an integrative approach to healing. For example, the most successful programs for treating alcohol addiction in Native communities have combined Western approaches to psychological counseling, social work, and traditional Native American healing practices.

Such inherited conditions as birth defects or retardation are not easily treatable with Native American medicine. Native healers also believe that some illnesses are the result of a patient's behavior. Sometimes they will not treat a person because they do not want to interfere with the life lessons the patient needs to learn. Other illnesses are not treated because they are "callings" or initiation diseases. Native healer Medicine Grizzly Bear Lake explains, "The calling comes in the form of a dream, accident, sickness, injury, disease, near-death experience, or even actual death."

Description

Native American medicine is based upon a spiritual view of life. A healthy person is someone who has a sense of purpose and follows the guidance of the Great Spirit. This guidance is written upon the heart of every person. To be healthy, a person must be committed to a path of beauty, harmony, and balance. Gratitude, respect, and generosity are also considered

to be essential for a healthy life. Ken Cohen writes, "Health means restoring the body, mind, and spirit to balance and wholeness: the balance of life energy in the body; the balance of ethical, reasonable, and just behavior; balanced relations within family and community; and harmonious relationships with nature."

Theories of disease causation and even the names of diseases vary from tribe to tribe. Diseases may be thought to have internal or external causes or sometimes both. According to Cherokee medicine man Rolling Thunder, negative thinking is the most important internal cause of disease. Negative thinking includes not only negative thoughts about oneself but also feelings of shame, blame, low self-esteem, greed, despair, worry, **depression**, anger, jealousy, and self-centeredness. Johnny Moses, a Nootka healer, says "No evil sorcerer can do as much harm to you as you can do to yourself."

Diseases have external causes too. "Germs are also spirits," according to Shabari Bird of the Lakota Nation. A person is particularly susceptible to harmful germs if they live an imbalanced life, have a weak constitution, engage in negative thinking, or are under a lot of **stress**. Other people or spirits may also be responsible for an illness. Another external source of disease is environmental poisons. These poisons include alcohol, impure air, water, and some types of food.

Native American healers believe that disease can also be caused by physical, emotional, or spiritual trauma. These traumas can lead to mental and emotional distress, loss of soul, or loss of spiritual power. In these cases the healer must use ritual and other ways to physically return the soul and power to the patient. Some diseases are caused when people break the "rules for living." These rules may include ways of showing respect for animals, people, places, ritual objects, events, or spirits.

Native American healers have several different techniques for diagnosing an illness. These may include a discussion of one's symptoms, personal and family history, observation of non-verbal cues like posture or tone of voice, and medical divination. More important than the particular technique is the healer's intuition, sensitivity, and spiritual power.

There is no typical Native American healing session. Methods of healing include **prayer**, chanting, music, smudging (burning **sage** or aromatic woods), herbs, laying-on of hands, massage, counseling, imagery, **fasting**, harmonizing with nature, dreaming, sweat lodges, taking hallucinogens (e.g., peyote), developing inner silence, going on a shamanic journey, and ceremony. Family and community are also important in many healing sessions. Sometimes healing happens quickly. Sometimes a long period of time is needed for healing. The intensity of the therapy is considered to be more important than the length of time required. Even if the healing happens quickly, however, a change in life style is usually required in order to make the healing last.

A medicine bundle may also be used in Native American healing. The medicine bundle is a bag made of leather or an animal pelt in which the healer carries an assortment of ritual objects, charms, herbs, stones, and other healing paraphernalia. The bundle is a concrete token of the medicine power that the spirits have given the healer, either for healing in general or for healing a particular illness. The bundles vary according to clan, tribe, and individual.

Native American medicine is not covered by insurance unless perhaps the practitioner is a licensed health care provider. Most Native healers do not charge a set fee for their services. Healing is considered to be "a gift from the Great Spirit." Gifts to the healer are welcomed, however. The offering of a gift "ensures success of treatment because healing spirits appreciate generosity." Gifts may include groceries, cloth, money, or another personal expression of respect and appreciation. Frequently the only gift that is required is a pouch of tobacco.

Preparations

The medicine person tells the patient what preparations are necessary before the healing ceremony.

Precautions

A medicine person is essential to ensure safe healing through Native American medicine. People with **hypertension** should watch themselves during a sweat lodge ceremony for a possible increase in blood pressure. People with **asthma** may have difficulty when sage or cedar is used in a ceremony. People who are claustrophobic may find the close, hot, dark environment of a sweat lodge overwhelming.

Side effects

Some herbs may cause **vomiting**, **nausea**, or **diarrhea**. From the Native American point of view these reactions are usually welcomed and considered a form of purging or cleansing of the physical body.

Research and general acceptance

There has been no formal scientific research conducted on Native American healing practices. Medicine people do not write down their practices out of

fear that they might be misused by people who are not trained in their sacred ways. The most prominent users of this form of medicine are Native Americans or others who want a spiritually based approach to medicine.

Training and certification

Native American medicine has been passed down by word of mouth for thousands of years. Healing power can come from one's ancestors, another healer, or through training and initiation. Generally, healers train under one primary mentor. Today, however, with the ease of long-distance travel and communication, many healers have several mentors. Training as a medicine person is a long process that requires strength, sacrifice and patience. Denet Tsosi, a Navajo medicine man, said that it took him six years to learn one of the chants.

Natrum muriaticum

Description

Natrum muriaticum is the homeopathic remedy commonly known as table salt or **sodium** chloride. Salt is the second most common substance in nature, water being the first. Salt is an important component in regulating the balance of body fluids. Salt is a constituent in both body fluids and tissues. Excessive salt intake inhibits proper absorption of nutrients and weakens the nervous system, while a lack of salt creates a lack of fluid, resulting in an emaciated and withered appearance.

Salt was not extensively used for medicinal purposes until the time of Samuel Hahnemann, the father of **homeopathy**. While ancient physicians did employ salt in the treatment of liver enlargement and other swellings,

Natrum muriaticum, also known as sodium chloride, seen here as crystallized salt deposits beside China's Dead Sea, Xinjiang. *(© Natural Visions / Alamy)*

KEY TERMS

Polychrest—A homeopathic remedy that is used in the treatment of many ailments.

Succussion—The act of shaking diluted homeopathic remedies as part of the process of potentization.

salt had little medicinal value until Hahnemann's studies of the remedy in the early nineteenth century.

Natrum muriaticum (*Nat. mur.*) is a slow acting remedy that responds well to chronic ailments. It is seldom prescribed for acute conditions, and then only when symptoms specific to the remedy are present. This polychrest is a very powerful and deep acting remedy and makes long lasting changes, often continuing to bring about results for several years.

Nat. mur. increases production of red blood cells and albumin, a protein found in animal and vegetable tissues. It does not cure by supplying the amount of salt that the body needs, but acts to alter and restore the tissues of the body so they can assimilate the body's needs for salt from food. By bringing the body into a state of health, *Nat. mur.* reduces the patient's susceptibility to colds, fevers, and other ailments.

General use

Nat. mur. ailments typically come about as a result of emotional excitement, trauma, bad news, grief, disappointed love, fright, suppression of emotions, sexual excess, and head injuries. Exposure to the sun and intake of alcohol or salt may also cause *Nat. mur.* ailments. These conditions may weaken the immune system and create illness.

This remedy is frequently indicated in emaciated persons, teething children, persons who are congested and catch cold easily, the elderly, or awkward, pubescent girls who suffer from headaches and menstrual irregularities. *Nat. mur.* children are frequently serious. They dislike excessive physical contact and hate to be teased. These children often have frightening dreams about being robbed.

Nat. mur. is indicated when the following remedy picture is present. The patient's face is pale and waxy and her body has an emaciated appearance. Her face and hair may be oily, while the lips and corners of the mouth are dry and cracked. She is weak, both in body and mind, and is absent-minded and forgetful. The mucous from bodily discharges has the constituency of egg whites. A craving for salty, sour, or bitter foods is present, as is an aversion to bread, fats, or rich foods. The patient is thirsty for cold drinks even though she is constantly chilly and suffers from a lack of vital heat. She is sensitive to light touch and pressure. Cold sores on the lips or mouth may appear frequently, often as a result of suppressed emotions or as a companion to **fever**. The body may exude a sour smell. Hangnails are prevalent. Complaints are better from open air, but worse from warmth or heat.

Mentally she is depressed, sad, easily startled, sensitive, anxious, irritable, restless, angry, moody, nervous, easily offended, and indifferent. She dwells on past occurrences and is fearful of crowds, of an impending situation or calamity, thunderstorms, or being robbed. The patient wishes to be alone and demonstrates introverted behavior. To avoid being hurt she may avoid intimacy. She is very emotional but does not like to express her emotions in public and retires to the safety of her own home to cry. Her emotions are exaggerated and her moods often alternate radically. She may appear to desire consolation, but when it is offered she becomes angry or rejects it. She acts in a hasty or rushed manner and cannot urinate in public.

Symptoms are generally worse in the morning around 10 A.M., at night, from the cold, the heat of summer, sun exposure, open air, consolation, suppression of sweat, physical and mental exertion, lying on the left side, after eating, from noise, from pressure or touch, and before, after, and during **menstruation**. Symptoms are better from bathing in cold water, lying down, from sweating, or through rest.

Specific indications

Nat. mur. patients frequently suffer from digestive ailments, oftentimes from the suppression of emotions. The stomach is distended with **gas**, there is a slowness of bowel function, and digestion takes a long time. Other indications include stomach **pain**, **heartburn**, liver pain two or three hours after eating, excessive hunger and thirst, a constant need to urinate, an aversion to bread, and a craving for salty, sour, and bitter foods. An empty feeling in the stomach may occur at 10 A.M. Symptoms are often relieved upon eating. The patient is frequently constipated. When stools do occur, they are dry and hard and often difficult to expel. They may be preceded by rumbling in the abdomen and flatulence. *Nat. mur.* is a good remedy for **indigestion** caused by the consumption of rich food, which often causes green, watery **diarrhea**. Symptoms are worse from eating starchy food.

The *Nat. mur.* woman is greatly affected by her menstrual cycle. Her mental symptoms are increased

before menstruation, and she may suffer from headaches, **nausea**, skin eruptions, weakness, back pains, heart palpitations, and pains in her abdomen and loins. She is discontented and lacks enjoyment of any kind. Her cycle is either early or late. After the menstrual flow has stopped, the woman may still suffer from **depression**, **headache**, or cramps.

The headaches typical of *Nat. mur.* are centered in the forehead and temples, although they may occur at the back of the head. Headaches are often caused by emotional excitement, grief, anger, head injuries, eye strain, **anemia**, or malnutrition. The pain is of a bursting or throbbing nature. The headache is accompanied by nausea, **vomiting**, **dry mouth**, and extreme thirst. The eyes are sore and watery. The headache is worse from 10 A.M. to 3 P.M., after eating, light, noise, motion, mental strain, lying down, and during menstruation. It is often relieved by sweating.

The **cough** is dry, hacking, and irritating. It is worse during fever, and may be accompanied by a bursting headache. Involuntary urination may occur while coughing or **sneezing**.

The cold is accompanied by watery eyes, postnasal drip, thirst, stuffy nose, dry lips, sneezing, and white mucus. The patient may lose his sense of smell and taste. The same symptoms occur in **hay fever**.

The fever is hot and burning. The patient is chilled and may be nauseous, sleepy, restless, and dazed. His face is flushed and he may talk without stopping. He is also excessively thirsty.

The **sore throat** is dry and burning. The voice is hoarse and the patient can only swallow liquids. There may be a sensation described as a lump in the throat.

Preparations

The homeopathic remedy is created by dissolving sodium chloride in hot, boiling water. The mixture is then filtered and crystallized through evaporation. The resulting substance is then dissolved in water and succussed to create the final preparation.

Natrum muriaticum is available at health food and drug stores in various potencies in the form of tinctures, tablets, and pellets.

Precautions

If symptoms do not improve after the recommended time period, a homeopath or healthcare practitioner should be consulted.

The recommended dose of *Nat. mur.* should not be exceeded.

Side effects

There are no known side effects, although individual aggravations may occur.

Interactions

When taking any homeopathic remedy, use of **peppermint** products, coffee, or alcohol should be avoided. These products may cause the remedy to be ineffective.

Natural hormone replacement therapy

Definition

Natural hormone replacement therapy (NHRT) is the use of non-synthetic, bio-identical hormones (estrogens, progesterone, and/or testosterone), derived from plants), to treat hormone imbalances and deficiencies. The first oral contraceptive pill was originally derived from Dioscorea species, wild yam; later soy was used as the precursor for oral contraceptive hormones.

Origins

Chinese medicine has made use of phytohormones for thousands of years. Natural progesterone was first crystallized from plants in 1938. NHRT was developed in the late 1970s and became available commercially in the early 1980s. By 1989 micronized (very finely ground) progesterone was developed for better absorption into the bloodstream. The use of NHRT has increased as women have become increasingly dissatisfied with conventional hormone replacement therapy (HRT) because of ineffectiveness, side effects, and/or growing concerns about risks, especially breast and **uterine cancer** risk.

KEY TERMS

Androgen—Sex hormones that are predominant in males.

Andropause—Midlife hormonal changes in men.

Bioavailability—The amount of a substance that can enter the bloodstream and be utilized effectively by the body.

Bioidentical—Molecules that are identical in chemical formulae and similar or identical in chemical structures, actions, and effects to naturally occurring biological molecules.

Compounding pharmacy—A pharmacy that uses bulk materials to fill prescriptions according to a physician's formulation; a formulating pharmacy.

Dehydroepiandrosterone (DHEA)—A hormone precursor to testosterone, estrogen, and other hormones.

Diosgenin—A phytohormone extracted from Mexican yams that is used to make natural progesterone.

Estrogen—A class of steroid hormones that are predominant in females. The term often refers to the three major estrogens: estriol, estradiol, and estrone.

Follicle-stimulating hormone (FSH)—A hormone that stimulates the development of egg follicles in the ovaries, egg maturation, and the production of estrogen.

Isoflavone—A phytoestrogen found in soybeans and other plants that sometimes is used as an estrogen supplement.

Menopause—The permanent cessation of menstruation; also called the change of life or climacteric.

Micronized—A crystal that is ground to a very fine powder.

Osteoporosis—A disease in which bone is lost and new bone formation is slowed. It usually occurs in older people, particularly postmenopausal women.

Phytohormones—Steroid hormones found in plants, including phytoestrogens and phytoandrogens.

Premenstrual syndrome (PMS)—Symptoms including lower back and abdominal pain, nervous irritability, and/or breast tenderness, occurring during the week prior to the onset of menstruation.

Progesterone—An important hormone, particularly in women, that declines sharply during menopause.

Receptor—A cell-surface molecule that binds a specific hormone to produce a specific biological effect.

Stigmasterol—A plant steroid that is extracted from soybeans and used to produce natural human hormones.

Testosterone—A steroid hormone that is predominant in males.

Benefits

NHRT often alleviates symptoms of hormone imbalances and deficiencies that may occur at any stage of life after puberty. In particular, NHRT is used to support hormone balance in the body during and after **menopause**, when estrogens, progesterone and testerone decline. It also is used in men to treat andropause that often affects middle-aged men as testosterone levels fall. Menopausal and andropausal symptoms often subside within months to years without any treatment. The symptoms also often improve after one to three months of NHRT use.

Low levels of estrogen, progesterone, and testosterone may be associated with chronic diseases of **aging**.

- heart disease
- bone loss and osteoporosis
- cancer
- digestive problems
- high cholesterol levels
- Alzheimer's disease

Some researchers claim that NHRT may slow the aging process and help prevent:

- fibroblastic or lumpy breasts
- heart disease
- osteoporosis
- cancer

Reported benefits of testosterone NHRT therapy in men include:

- increased muscle mass and lower body fat
- increased sex drive
- increased energy levels
- improved concentration and productivity

Description

Human sex hormones

The major steroid sex hormones—estrogen, progesterone, and testosterone—control gender and the aging process. They help maintain health and have profound effects on emotions and behavior. Cells throughout the body have receptor molecules on their surfaces that bind specific hormones. Receptor-binding causes a series of reactions within the cell that are specific for the hormone and cell type.

In the human body **cholesterol** is converted into pregnenolone, which is converted into both progesterone and dehydroepiandrosterone (**DHEA**). These hormones, in turn, can be converted into estrogens, testosterone, and other hormones.

High levels of sex hormones are produced in the developing fetus and then almost disappear until puberty. Estrogen and progesterone are at high levels during the reproductive years and are extremely high during **pregnancy**. With aging, the levels of sex hormones decline. When ovulation ceases at menopause, progesterone production drops to very low levels. Estrogen and progesterone have opposing effects in the body, balancing each other. At various times in their lives, many women experience hormone imbalances or sudden changes in hormone levels. During menopause the ratio of estrogen to progesterone may increase. During andropause the ratio of testosterone to estrogen may decline.

Although the body produces many forms of estrogen, the term usually refers to the three major types:

- Estriol is the weakest estrogen.
- Estradiol is the most active estrogen. Nearly every cell in the body has estradiol receptors, making it extremely important for cell and organ function.
- Estrone is made from testosterone derivatives in fat cells of postmenopausal women.

The body also produces several different types of testosterone.

NHRT hormones

The hormones used in NHRT are considered to be "bioidentical" to human sex hormones. The chemical formulae of NHRT hormones are identical to the corresponding hormones produced in the human body. They are very similar or identical to human hormones in their chemical structures, modes of action, and interactions with cell-surface receptors and other hormones. Receptors do not distinguish between the body's own hormones and natural hormones. Therefore natural hormones do not compete with endogenous hormones for receptor sites; rather they supplement and balance the endogenous hormones. In contrast, the synthetic hormones used in conventional HRT are processed and synthesized from chemicals or animal products and are not chemically or biologically identical to human hormones. Synthetic hormones can compete with or replace the body's own hormones because some receptors mistake them for endogenous hormones.

Prescription-strength natural hormones usually are produced from stigmasterol extracted from soybeans. They are chemically altered so as to be bioidentical to human forms such as progesterone or the human estrogens. Progesterone and testosterone may be micronized for NHRT. Over-the-counter (OTC) natural progesterone creams usually are derived from diosgenin extracted from the giant **Mexican yam**. NHRT hormones are manufactured for pharmaceutical companies that make standard-dosage medications and for compounding or formulating pharmacies that make up individualized medications.

Testosterone is often supplied as DHEA. Pharmaceutical-grade DHEA is available without a prescription.

NHRT delivery

Natural estriol, estradiol, estrone, and progesterone are available as:

- oral capsules
- oral tablets
- gel caps
- lozenges, drops, or sprays that are absorbed through the mucous membranes under the tongue
- transdermal creams and gels applied to the skin
- injectable solutions
- suppositories
- implants

Estradiols are available as skin patches (Estraderm, Vivelle, Climera) that slowly and continuously release estrogen through the skin into the bloodstream, bypassing the liver. The patches are worn at all times and changed once or twice per week.

Oil-based micronized oral progesterone appears to be most-readily utilized by the body, since the oil protects the progesterone from stomach acids. Some research suggests that a natural vitamin-E base (tocopherol) is more effective and least toxic. Mineral-oil-based preparations may not be effectively absorbed and/or metabolized.

Testosterone as DHEA is available as:

- oral tablets
- lozenges
- transdermal or vaginal creams
- patches

NHRT creams and gels are absorbed rapidly through the skin in areas with high blood flow, such as the lower neck, upper chest, inner wrists, or hands. Lower dosages are used for NHRT creams and gels because they are absorbed into the bloodstream more efficiently than oral NHRT. Transdermal preparations bypass the gastrointestinal tract and the liver where side effects are more likely to occur. With creams and gels, individual dosages can be adjusted easily, according to symptom relief. Low-dosage natural progesterone creams are available without a prescription. However, absorption of transdermals is highly variable between patients. Those with dry skin, poor circulation, etc. absorb less transdermally. Studies also show that transdermal delivery of hormones may result if very high blood levels over time. More research is need in this area, but for this reason some physicians do not prefer transdermal delivery forms.

Some NHRTs mix highly concentrated estrogen, progesterone, and sometimes testosterone in a propylene glycol base for rapid absorption through the skin. Only one to four drops are required daily, costing as little as $70 per year.

Forms of NHRT

Typical NHRTs include:

- estradiol gel applied daily
- micronized ethinyl estradiol (Estrace) as 0.3–2.5-mg daily tablets
- estriol (80%) and estradiol (20%) as 1.25- or 2.3-mg twice-daily tablets (Biestrogen)
- estriol (80%), estradiol (10%), and estrone (10%), as a 2.5–5% gel applied daily (Triest), or as 1.25- or 2.5-mg, twice-daily tablets (Triestrogen)
- micronized progesterone as 50-, 100-, or 200-mg peanut-oil-based tablets or capsules (oral micronized progesterone, Prometrium)
- micronized progesterone as a 5% cream (percutaneous progesterone cream) or gel
- combined NHRT as 1.25-mg Triestrogen tablets and oral micronized progesterone (50–100 mg), twice daily
- oral micronized testosterone as 1.25–5-mg tablets
- micronized testosterone as a 1% cream or gel (Androgel), applied to the inner thigh or scrotum once or twice daily

Vaginal creams, tablets, and rings are not significantly absorbed into the bloodstream. However they can be useful for treating menopausal symptoms such as urinary problems, vaginal dryness, and thinning of the vaginal wall, which can cause painful intercourse. Vaginal NHRTs include:

- micronized estriol cream, 0.5 mg per g of base (Estriol)
- micronized estradiol cream, 1 mg per g of base (Estrace)
- estradiol as a silicone ring with a 2-mg reservoir, changed every 90 days (Estring)
- progesterone gel, 4 or 8% (Crinone)

Most effective NHRTs require a prescription and may be covered by insurance.

Women's symptoms & NHRT

The dosages and duration of NHRT vary according to response, as determined by symptom relief. Dosages in women may be cycled to correspond to the menstrual cycle.

Symptoms of hormone imbalance in teenagers and young women with normal menstrual cycles include:

- acne
- mood swings
- stress syndromes
- night sweats
- sleep disturbances
- premenstrual syndrome (PMS)

A typical NHRT is micronized progesterone cream, 4–6 mg per kg (2.2 lb) body weight, rubbed daily on the neck, upper chest, and inner wrists, for the entire month or for two weeks prior to **menstruation**, depending on symptoms. It is not used on the face in the presence of **acne**.

Symptoms of hormone imbalances in women in their twenties and thirties with normal menstrual cycles, in addition to the above, may include:

- occasional or postpartum (after giving birth) depression
- infertility
- bloating from salt and fluid retention
- migraine headaches
- breast tenderness
- decreased attention span
- weight gain
- food cravings

Typical NHRTs for three months to one year:

- micronized progesterone cream, 4-6 mg per kg (2.2 lb) body weight, daily
- estradiol, 6–8 µg per kg body weight.

In addition to the above symptoms, hormone imbalances in premenopausal women (aged 35 to over 40), with regular or irregular menstruation, may cause:

- sleep disorders
- hair loss
- hot flashes
- depression
- loss of libido
- digestive problems
- anxiety

Typical NHRTs for three months to one year:

- Micronized progesterone, 4–6 mg per kg (2.2 lb) body weight, daily
- Estradiol, 7–9 micro;g per kg (2.2 lb) body weight, daily

NHRT may be particularly appropriate for perimenopausal symptoms in women aged 40–55. Their symptoms can be similar to those listed above, but may be more pronounced. Menstruation may have ceased or cycles may be irregular. Typical NHRTs:

- micronized progesterone cream, 5–7 mg per kg (2.2 lb) body weight
- estradiol, 6–9 µg. per kg (2.2 lb) body weight
- testosterone cream, 10 µg per kg (2.2 lb) body weight, applied to the labia and around the clitoris

Daily NHRT is continued for two to four months, followed by a five-day break.

Menopausal and postmenopausal women (usually aged 55 or older) may have, in addition to any of the above symptoms:

- bone loss
- cardiac disease
- urinary incontinence

Typical NHRTs:

- micronized progesterone cream, 5–7 mg per kg (2.2 lb) body weight, daily
- estradiol, 6–9 µg per kg (2.2 lb) body weight, daily.

Men's symptoms and NHRT

Symptoms of low testosterone levels or hormone imbalances in andropausal men are very similar to those in women. Additional symptoms may include:

- fatigue
- nighttime urination
- impotence or decreased ability to maintain an erection
- decrease in muscle-building ability
- inability to lose weight

A natural androgen replacement protocol, lasting 3–14 months, might consist of:

- pine pollen, 0.5–5 gm, once or twice daily; a one-quarter-teaspoon tincture, three times daily; 5–10 gm daily in warm milk, in Chinese and Korean medicine
- David's lily flower, one-quarter-teaspoon tincture, twice daily
- Panax/tienchi ginseng tincture, one-third teaspoon daily
- nettle root (*Urtica dioica*), 300–1,200 mg daily
- tribulus (*Tribulus terrestris*), 250–500 mg standardized extract as pills or tablets, three times per day
- pregnenolone, a primary steroid hormone (prohormone) in men and women, 5–50 mg daily
- androstenedione (andro), 50–100 mg, one to three times per day, as a pill dissolved under the tongue
- androstenediol (andiol, 4-andiol, androdiol), 100 mg once or twice daily
- DHEA, 25–50 mg daily
- zinc, 20–40 mg daily
- celery juice, daily from three fresh stalks
- a diet high in oatmeal, corn, and pine nuts

Zinc is required for the transformation of **androstenedione** to testosterone. Zinc preparations usually include **copper** to prevent copper depletion.

Ginseng as an androgen replacement:

- Asian ginseng as 1–9 gm daily tablets
- Asian white (20–40 drops) and Kirin or dark red (5–20 drops) as a daily tincture
- Asian ginseng combined with tienchi (*Panax pseudoginseng*), one to one, one-third teaspoon daily in water
- Siberian ginseng

Foods & supplements

Most researchers believe that the human body cannot utilize the phytoestrogens in soy or the progesterone in yams; nor can the body transform these phytohormones into biologically available hormones. However some researchers believe that phytoestrogens called isoflavones (genistein and daidzein) found in soy can serve as short-term estrogen supplements. **Soy protein** in a low-fat diet reduces the risk of **heart disease** and isoflavones may help prevent bone

loss. Isoflavones are found in tofu, tempeh, and soy drinks but not in soy oil.

Wild Mexican yam creams may contain phytoestrogens; however they are ineffective as progesterone supplements because they contain only a progesterone precursor which is inactive in the human body.

Phytoandrogens have been reported to increase androgen levels and the androgen-to-estrogen ratio in men. Foods containing high levels of phytoandrogens:

- celery
- parsnips
- corn
- oats (*Avena sativa*)
- garlic (*Allium sativum*)
- onions
- pine nuts

Foods that lower androgen levels and suppress androgenic activity in men include:

- licorice
- black cohosh (*Cimicifuga racemosa*), which is very high in estrogen and sometimes used to treat hot flashes in menopausal women
- hops, one of the most powerful estrogenic foods
- grapefruit, which interferes with removal of estrogen from the body

Preparations

Blood hormone levels may be measured before and/or during NHRT:

- Follicle-stimulating hormone (FSH): high FSH levels indicate low sex hormone production and menopause.
- Estrogen blood tests measure how much of one type of estrogen is circulating in the blood and the total amount present in the bloodstream. However most estrogen in the body is bound to other molecules or cell receptors and cannot be measured.

Other tests include:

- Saliva hormone testing: inexpensive as performed by mail-order laboratories or with home test kits
- Urine testing reveals how much hormone is excreted through the kidneys over a 24-hour period. It is expensive and may be difficult to interpret.
- Yearly bone mineral density tests for those using NHRT to improve bone density
- Annual pelvic ultrasounds can be used to monitor the effectiveness of NHRT. These tests are inexpensive and enable the physician to view the thickness of the uterine lining and the shape of the ovaries, both of which are affected directly by estrogen and progesterone. Pelvic ultrasound also can detect and monitor ovarian cysts that may develop with hormone therapies.

Testosterone and/or DHEA levels in the blood or saliva are monitored regularly when DHEA is used in NHRT. However hormone levels are constantly changing and most tests reflect only the measurable hormone present at a single point in time.

Precautions

Although they are approved by the U. S. Food and Drug Administration, natural hormones are not regulated as drugs. Most large manufacturers use standardized labeling and dosages of active ingredients. Nevertheless, the bioavailability—the amount of active ingredient that enters the bloodstream and can be utilized effectively—is not known for most NHRTs. The results of oral NHRT may be inconsistent since many factors can affect their bioavailability. Although many OTC products are labeled as natural hormones, they contain very low concentrations and their bioavailability is unknown. They may be useful if only a small amount of hormone supplementation is required.

NHRTs, especially androgen replacement, have not been well-studied. There have been no clinical safety trials. It is not known whether NHRT carries risks similar to some HRTs, including increased risk for **breast cancer**, coronary heart disease, **stroke**, and pulmonary embolism (a blood clot in an artery of the lung). Androgen replacement therapies should not be used by adolescent males.

Some synthetic hormone products may be labeled as "natural" because they are synthesized from naturally occurring substances. For example, synthetic estrogen is manufactured from the urine of pregnant horses. Some prescription hormones contain bioidentical estrogen but synthetic progesterone.

Side effects

There have been very few reports of side effects from NHRT in women. Since the estrogens used in NHRT are bioidentical to human estrogens and tend to be weaker than the synthetic estrogens used in HRT, they are expected to have fewer side effects. Furthermore, NHRT can be halted and resumed at any time without side effects.

Natural androgen replacement therapy may cause irritability and other side effects in men, particularly in coffee-drinkers. Ginseng has many side effects and should be used with caution. Very high zinc intake also can have numerous side effects.

Research and general acceptance

The few research studies that have included NHRT have had positive results. NHRT practitioners claim that it is safer and more effective than HRT.

Training and certification

Most NHRTs are available only as prescriptions from a medical or naturopathic physician or nurse practitioner. Most doctors who use NHRT rely on personal research and the experiences of their patients.

Natural hygiene diet

Definition

The natural hygiene diet is a system of healthy living whereby moral, physical, and environmental pollution is strictly avoided, and natural healthy food is chosen in preference over processed food. The principle is to provide everything the body needs to be healthy, and to avoid anything that may hinder health and well being.

Origins

Actually, early in the twentieth century, there were similar "natural hygiene" movements or health culture societies advocating exercise, the consumption of healthy foods, and massage. The American Natural Hygiene Society was founded in 1948, and as such is the oldest and largest natural hygiene organization in the world. The Society publishes the *Health Science* magazine. The British Natural Hygiene Society was founded in 1959 by Keki Sidhwa and two other natural hygienists. Their magazine, *Hygienist,* which is published quarterly, was started in 1959, making it the oldest natural hygiene publication. Both organizations aim to educate and inform, and they can also recommend practitioners and clinics.

Benefits

This regime is designed to cleanse the body of all toxic matter, so that it is free to work, instead of being hampered by stored wastes that reduce the efficiency of the human organism. Together with improved nutrition, this should bring about a complete transformation for most people. Less sleep may be needed, and there should be a general feeling of increased well being and energy, which will almost certainly help the individual to make better and more productive use of his or her time.

It is possible that an improvement may be noticed in powers of recall; many people complain of loss of memory in our time, and this may be due to a combination of **stress** and a toxic body system.

Proponents say improvement in symptoms of conditions such as arthritis, migraine, hypoglycemia, diabetes, and more can be expected. In addition, the principles of natural hygiene often lead to unexpected benefits, such as improvements in the appearance and texture of skin, and the condition of hair and fingernails, the disappearance of eye bags, and less body odor.

KEY TERMS

Denatured—Changed from its natural state and robbed of nutrients.

Hypoglycemia—A condition characterized by abnormally low levels of glucose in the blood.

Description

The term "natural hygiene" refers more to a way of life than merely to a diet. For some time, proponents have asserted that their recommendations can provide the foundation for a healthy, fulfilling life that is disease-free and emotional ennui that have become commonplace in so-called modern society. These, and many other diseases of modern life, are due to the multi-faceted pollution of ourselves and our planet, and a denatured diet. Together, it is considered that they cause poisoning and the stifling of the body's natural strength and vitality. Natural hygienists reason that since the body "constructs itself" after the fertilization of the ovum, it must also have powers of repair and renewal in order to maintain the organism, if given the right conditions.

Natural hygiene concerns every aspect of a human being's life, because everything—the physical, the spiritual, and the moral—affects the well being of the individual and society. The theory is that people should obey their natural instincts, and that only when they have achieved perfect health, will they be able to achieve their full potential as human beings.

Natural hygienists believe that mankind is naturally good and virtuous, but will not display these traits unless they are following all the principles of healthy lifestyle. The theories of natural hygiene, they claim, if properly adhered to will allow mankind to achieve supreme heights of achievement at all levels of his being.

If given the right circumstances and facilities, the human body, believed to be perfect in its creation, will be able to preserve itself in an optimum state, and efficiently perform repairs when needed, quickly returning to a state of total well being. The prerequisites for total well being are pure air, pure water, sufficient rest and sleep, and uncontaminated food of a high quality that will provide all the necessary nutrients in a readily available form. In addition to these, satisfactory human companionship should be sought, as well as protection from extreme cold and extreme heat, sunshine, sufficient exercise, a purpose in life, and in general, an atmosphere conducive to all that is good concerning human life.

An essential concept of natural hygiene is that to be healthy is normal, and healing is a biological process that cannot be bought. The same natural laws apply whether one is sick or well, and that which makes a well person sick can never make a sick person well. Allopathic medicine, in treating merely the symptoms of disease, in many instances actually worsens the condition in the long run.

A simple example of this would be the administering of laxatives to a patient suffering from **constipation**, as opposed to finding the underlying cause of the constipation. With time, laxatives cause the bowels to become even more sluggish, and so the cycle continues. Natural hygiene aims to correct the cause.

The first step, when embarking on a regime of natural hygiene, is to rid the body of accumulated toxins. There are many aspects to be taken into account for this procedure. Usually, the first to be considered is the gastrointestinal tract, but in addition, the skin, liver, gallbladder, lymphatic system, lungs, kidneys, and bladder all need to be detoxified in order to facilitate perfect functioning of the human organism. Although cleansing is of major concern, natural hygiene therapists caution that it is also very important to ensure that the body has access to fresh, clean air, clean water, and good food while the **detoxification** is in process, so that the body can rebuild itself. They warn that cleansing without rebuilding will weaken a body and its immune system.

There are many variations on this, but basically this consists of **fasting** the body at some time, and feeding it mainly fruits and vegetables that will have a dual effect of cleansing and rebuilding. Usually, food combining is an important aspect of the **nutrition** of natural hygiene, and requires that a protein food is never eaten with a starch food. They should be taken at different meals with a minimum of four hours between each meal. Fruit is recommended to be eaten by itself, but since it digests quickly only half an hour need pass before other food can be consumed.

To follow the natural hygiene way of living at home, the only expenses that will be incurred are the cost of **organic food**, which can be more expensive than ordinary food. However, if patients feel that they would benefit from a trip to a natural hygiene clinic, information can be obtained from some natural hygiene organizations.

Preparations

Those wishing to treat themselves in accordance with natural hygiene principles are required to follow a mainly raw diet that includes all the nutrients and enzymes that

will help to flush toxins from the body, while at the same time building health. However, it is wise to consult a natural hygienist before beginning treatment.

There are special formulas for speeding the elimination of toxins, which can be obtained from practitioners who specialize in natural hygiene. Information regarding these treatments can be obtained from various national organizations.

Precautions

When undertaking a cleansing diet, it is important not to impose anything too harsh on the body. If an individual is suffering from acute toxicity, it may be better advised to proceed slowly and cautiously with the process of detoxification, particularly if the patient is continuing as normal with his/her everyday life.

Side effects

There are few side affects associated with the practice of natural hygiene. Some may experience what is known as a "healing crisis" while the body is throwing off toxins. Symptoms may include headaches, **nausea**, or sensitivity. These symptoms are transient, and may normally be relieved with herbal teas, a walk in the fresh air, or by simply lying in a darkened room for a while.

Under very rare circumstances, an individual may have such a toxic condition that it would be dangerous for him/her to undertake cleansing without assistance. When the body is subjected to poisons, whether in their food, in the air, or from the water they drink, the body attempts to deal with them in such a way that they will cause the least harm to the body. Thus, they may be stored in the liver, or in fatty deposits under the skin.

When a person who has poisons stored in such a way undergoes a fast, or undertakes some other method to flush poisons from the body, sometimes the flushing causes large amounts of toxins to enter the blood system at the same time. Without proper supervision or consultation, and without the correct step being taken, the results could possibly be fatal.

Research and general acceptance

There is a large body of research to support the theories of natural hygienists, although most of it is not accepted by allopathic practitioners. General belief exists that detoxification can improve the effectiveness of many healing therapies. Though many nutritionists see numerous health benefits in eating natural foods and greater amounts of fruits and vegetables, they may warn against eating large amounts of any particular kind of food. For example, eating too many fruits and vegetables at one time can cause **diarrhea**. Fasting may be dangerous for some individuals—those with weakened immune systems, the elderly, or pregnant women. It may also cause muscle weakness and **dizziness** in healthy individuals.

However, many people continue to seek assistance from clinics dispensing some form of natural hygiene and are satisfied with the results. Keki Sidhwa, the president of the British Natural Hygiene Society, has records covering many years of successful treatment of his patients, where many leave from his clinic days or weeks later in a better state of health.

Training and certification

The American College of Health Science awards degrees up to PH.D. standard, but these are not yet accredited by mainstream education in the United States. Practitioners must be members of one of the national associations.

Naturopathic medicine

Definition

Naturopathic medicine is a branch of medicine in which a variety of natural medicines and treatments are used to heal illness. It uses a system of medical diagnosis

and therapeutics based on the patterns of chaos and organization in nature. Naturopathy is founded on the premise that people are naturally healthy, and that healing can occur through removing obstacles to a cure and by stimulating the body's natural healing abilities. The foundations of health in natural medicine are diet, **nutrition**, **homeopathy**, physical manipulation, **stress** management, and **exercise**.

Naturopaths are general practitioners who treat a wide variety of illnesses. They believe in treating the "whole person"—the spirit as well as the physical body—and emphasize preventive care. They often recommend changes in diet and lifestyle to enhance the health of their patients.

KEY TERMS

Clinical nutrition—The use of diet and nutritional supplements as a way to enhance health and prevent disease.

Cryosurgery—Freezing and destroying abnormal cells.

Herb—In naturopathy, a plant or plant derivative or extract prescribed for health or healing.

Homeopathy—A holistic system of treatment developed in the eighteenth century. It is based on the idea that substances that produce symptoms of sickness in healthy people will have a curative effect when given in very dilute quantities to sick people who exhibit those same symptoms. Homeopathic remedies are believed to stimulate the body's own healing processes.

Hydrotherapy—The use of water (hot, cold, steam, or ice) to relieve discomfort and promote physical well-being. Also called water therapy.

Physical manipulation—The use of deep massage, spinal alignment, and joint manipulation to stimulate tissues.

Ultrasound—A painless and non-invasive procedure in which sound waves are bounced off the kidneys. These sound waves produce a pattern of echoes that are then used by a computer to create pictures of areas inside the kidney (sonograms).

Origins

People have always seen connections between diet and disease; many therapies are built around special **diets**. Naturopathy began in the eighteenth and nineteenth centuries, as the industrial revolution forced many people into unhealthy lifestyles, and the European custom of "taking the cure" at natural spas became popular. Benedict Lust, who believed deeply in natural medicine, organized naturopathy as a formal system of healthcare in the 1890s. By the early 1900s, it was flourishing.

The first naturopaths in the United States emphasized the healing properties of a nutritious diet, as did a number of their contemporaries. In the early twentieth century, for instance, John Kellogg, a physician and vegetarian, opened a sanitarium that used such healing methods as **hydrotherapy**, often prescribed by today's naturopaths. His brother Will produced such health foods as corn flakes and shredded wheat. The Post brothers helped make naturopathic ideas popular and emphasized the value of whole grains over highly refined ones. Together with one of their employees, C. W. Post, they eventually went on to start the cereal companies that bear their names.

In the early 1900s, most states licensed naturopaths as physicians. There were 20 medical schools of naturopathic medicine. From early on, naturopathic physicians were considered "eclectic," since they drew on a variety of natural therapies and traditions for treating their patients.

In the 1930s, naturopathy dramatically declined for several reasons. Allopathic medicine finally stopped using such therapies as bloodletting and heavy metal poisons as curative compounds. New therapies were more effective and less toxic. Allopathic medical schools became increasingly well-funded by foundations with links to the emerging drug industry. In addition, allopathic physicians became much more organized and came to wield considerable political clout. Naturopathy has experienced a resurgence over the last 20 years, however. The lay public is aware of the connections between a healthful diet and lifestyle and avoiding chronic disease. In addition, conventional medicine is often unable to treat these chronic diseases. Patients are now health care consumers, and will seek their own resolution to health problems that cannot be resolved by conventional physicians. As a result, even medical groups that once considered naturopathy ineffective are now beginning to accept it.

Benefits

Naturopathic medicine is useful for treating chronic as well as acute diseases. It is sometimes used in conjunction with allopathic care to enhance wellness and relieve chronic symptoms, such as **fatigue** and **pain**. A naturopath treats a wide range of health problems, ranging from back pain to **depression**.

A naturopathic physician will spend extra time interviewing and examining the patient to find the underlying cause for a medical problem. Emotional and spiritual symptoms and patterns are included in the assessment. The naturopath often spends more time educating patients in preventive health, lifestyle, and nutrition than most M.D.s.

Description

Naturopathic medicine modalities include a variety of healing treatments, such as diet and clinical nutrition, homeopathy, **botanical medicine**, soft tissue and spinal manipulation, ultrasound, and therapeutic exercise. A naturopath provides complete diagnostic and treatment services in such specialties as obstetrics and pediatrics. Some are also licensed midwives.

Naturopaths consider health to be not just the absence of disease, but complete physical, mental and social well being. Naturopathic physicians often say that diseases must be healed not just by suppressing symptoms, but by rooting out the true cause. Symptoms are actually viewed as the body's natural efforts to heal itself and restore balance.

A typical office visit to a naturopath takes about an hour. During the first visit, the doctor will ask detailed questions about the patient's symptoms, lifestyle, history of illness, and state of his or her emotions. The naturopath will take a complete medical history, and may order lab tests such as urine and blood tests. A naturopath may talk with the patient about the possible causes for an illness—poor diet, life stresses, occupational dangers, and mental, emotional, and spiritual problems. Naturopaths believe that even widely varying symptoms can sometimes be traced to one underlying cause. Often environmental or metabolic toxins or serious stress bring on an illness.

As with most doctors, treatment by a naturopath can range from one office visit to many. Some acute illnesses can be alleviated with one or two visits. Other chronic diseases need regular weekly or monthly attention. Clinical care provided by naturopathic physicians are covered by insurance in a number of states in the United States.

Preparations

There are about 1,500 naturopathic physicians in the United States practicing as of 2004; nearly 80% of these practitioners entered the profession following the revival of interest in naturopathy in the late 1970s. Consumers can find naturopaths by contacting the American Association of Naturopathic Physicians (AANP) or logging on to their web site. Naturopaths recommended by the AANP have met requirements for state licensure and have taken a national exam that qualifies them to practice. Qualified naturopaths can also be found through the local branch of the national or state association of naturopathic physicians. It is sometimes useful to request names from another health care provider who knows naturopathic practitioners in the community.

Precautions

A good naturopath is always willing to work with the patient's other physicians or health care providers. To avoid drug interactions and to coordinate care, it is important for a patient to inform his or her allopathic doctor about supplements prescribed by a naturopath.

Many naturopaths give childhood vaccinations, but some do not. If a parent is concerned about immunizations, it is best to go to an allopathic doctor for vaccinations.

Naturopaths are not licensed to perform major surgery, or prescribe narcotics and antidepressant drugs. They must also consult an oncologist when treating a **cancer** patient.

Side effects

Although naturopathic remedies are derived from natural sources and pose much less risk than allopathic drugs do, there are certain side effects associated with the use of some herbal preparations. One problem they can pose is through interactions with prescription medicines. It is important for a patient to inform his or her allopathic physician about any natural remedies or herbs prescribed by a naturopath.

It is also important to note that the U.S. Food and Drug Administration (FDA) considers medicinal herbs to be dietary supplements, not drugs; as a result, they are not subject to the same regulations as prescription medications. Because herbal remedies come from natural sources, the active ingredients may not always be in the same concentration from bottle to bottle, since plants naturally vary. To guard against using too little or too much of a natural remedy, patients should use herbs and supplements recommended by a naturopath or those produced by well-respected companies.

Research and general acceptance

Medical research in naturopathy has increased dramatically in the United States within the last 10 years. Naturopathic research often employs case histories,

BENEDICT LUST (1872–1945)

German healer, Benedict Lust, is credited with nam ing the natural medical technique of naturopathy. He was married to Louisa Lust who was a student of another natur opathy pioneer, Arnold Rikli.

Benedict, who was born in Germany in 1872, immi grated to the United States in 1892 but returned to his native Germany when he contracted tuberculosis. In Germany he met Father Sebastian Kneipp who treated and cured Lust using hydrotherapy. Lust subsequently returned to the United States as Kneipp's representative to publicize the cure. He founded the Water Cure Institute in New York City and established Kneipp Societies throughout the United States.

Lust acquired degrees in osteopathy and medicine and drew from his combined knowledge to devise the healing art of naturopathy. In 1901 he organized the Naturopathic Society of America, and he founded the American School of Naturopathy. He purchased the rights to the term naturopathy from John H. Scheel in 1902 and publicized himself as a naturopath. Lust's school initially offered a two year, post graduate curric ulum and later expanded into a four year residential pro gram. The school received a charter in 1905 and, thereafter, awarded degrees in naturopathy and chiro practic. Lust established a second school devoted to teaching the principles of massage and physiotherapy. Additionally he offered home study courses in naturop athy and started a magazine about naturopathy.

Lust later reorganized the Naturopathic Society of America at the national level, calling the group the Amer ican Institute of Naturopathy. Likewise in 1919, he com bined the independent Kneipp Societies into a unified group, called the American Naturopathic Association (ANA). In 1921 the ANA elected Lust to a lifetime term as president of the society. Benedict Lust, a staunch propo nent of natural healing and natural food remedies, champ ioned the cause of the naturopath and spent much of his lifetime battling the American Medical Association for legitimacy.

summaries of practitioners' clinical observations, and medical records. Some studies by naturopaths in the United States have also met today's scientific gold standard; they were double-blind and placebo-controlled. Much naturopathic research has also been done in Germany, France, England, India, and China.

Some mainstream medical practitioners remain distrustful of naturopathy, however. Such problems as health-food store employees without naturopathic credentials giving health-related advice to customers, or occasional rare cases of **infections** caused by naturopathic injections, continue to damage the reputation of this form of alternative medicine.

Single-treatment studies

Research in naturopathy tends to focus on single treatments used by naturopaths, rather than naturopathy as a whole. In 1998, an extensive review of such single-treatment studies found that naturopathic healing methods were effective for 15 different medical conditions, including **osteoarthritis**, **asthma**, and middle ear infections. A study of 8,341 men in with damaged heart muscles in 1996 revealed that supplementation with **niacin**, a B vitamin, was associated with an 11% reduced risk of mortality over 15 years. In 1996, a study showed **St. John's wort** was effective as prescription antidepressants in relieving depression, and had fewer side effects.

Women's health

Naturopathic studies have also demonstrated benefits in the arena of women's health issues. In recent years, more women than men have been drawn to naturopathy because of its holistic emphasis, its tradition of relative equality between practitioner and patient, and its philosophy of eclecticism and freedom of choice in healing methods. In one classic 1993 study, women with **cervical dysplasia** or abnormal Pap smears were treated by naturopaths with topical applications of herbs and dietary supplements. These medications included Bromelian, an enzyme from the pineapple; **bloodroot**; marigold; **zinc** chloride; and suppositories made from herbal and nutritional ingredients, such as **echinacea**, **vitamin A**, and **vitamin E**. Thirty-eight of the 43 women in the study had normal Pap smears and normal tissue biopsies after treatment. The study concluded that these protocols might benefit the health of patients undergoing more traditional treatments for cervical dysplasia, such as cryosurgery.

Other more recent research has documented the benefits of such nutritional foods as soy in relieving **hot flashes** and vaginal dryness. Nutritional supplements prescribed by naturopaths to enhance women's health during **menopause** have also proven effective; in general, naturopathy appears to be as useful as conventional medicine for treating menopausal symptoms. Research shows vitamin E supplements are helpful for

50% of postmenopausal women with thinning vaginal tissue. Studies also reveal that **bioflavonoids** with **vitamin C** and gamma-oryzanol, a substance taken from rice bran oil, can relieve hot flashes.

Another area of women's health concerns that naturopathy has taken seriously is a growing preference for skin care and beauty products derived from natural sources rather than from chemical laboratories. Such products are often more beneficial to the skin and less likely to cause **rashes** or other allergic reactions.

Training and certification

Naturopathic medical students attend a four-year medical school and are educated in many of the same basic sciences as MDs, including anatomy and pathology. In the last two years, they also study such holistic therapies as nutrition, homeopathic medicine, botanical medicine, psychology, hydrotherapy, and counseling. The naturopathic curriculum places a strong emphasis on disease prevention and optimizing wellness.

After his or her education, a naturopath takes a national qualifying examination known as the Naturopathic Physicians Licensing Examination or NPLEX. A doctor should have graduated from a school that qualifies him or her to take these examinations. As of 2003, these schools include the National College of Naturopathic Medicine in Portland, Oregon; Bastyr University in Seattle, Washington; Southwest College of Naturopathic Medicine in Tempe, Arizona; Canadian College of Naturopathic Medicine in Toronto, Canada; and the University of Bridgeport College of Naturopathic Medicine in Bridgeport, Connecticut.

Some states license naturopathic physicians. As of late 2003, those states included Hawaii, Alaska, Washington, Oregon, Utah, Montana, Arizona, Connecticut, New Hampshire, Vermont, Maine, and Kansas, in addition to the territories of Puerto Rico and the Virgin Islands. Training via a correspondence school does not qualify a naturopath for licensure or to take the national qualifying examination.

Nausea

Definition

Nausea is the sensation of having a queasy stomach or being about to vomit. **Vomiting**, or emesis, is the expelling of undigested food through the mouth.

Description

Nausea is a reaction to a number of causes that include overeating, infection, or irritation of the throat or stomach lining. Persistent or recurrent nausea and vomiting should be checked by a doctor.

A doctor should be called if nausea and vomiting occur:

KEY TERMS

Acupuncture—Based on the same traditional Chinese medical foundation as acupressure, acupuncture uses sterile needles inserted at specific points to treat certain conditions or relieve pain.

Antiemetic—A medication that helps control nausea; also called an antinausea drug.

Dehydration—An excessive loss of water from the body. It may follow vomiting, prolonged diarrhea, or excessive sweating.

Diabetic coma—A life-threatening, reduced level of consciousness that occurs in persons with uncontrolled diabetes mellitus.

Emesis—An act or episode of vomiting.

- after eating rich or spoiled food or taking a new medication
- repeatedly or for 48 hours or longer
- following intense dizziness

It is important to see a doctor if nausea and vomiting are accompanied by:

- yellowing of the skin and whites of the eyes
- pain in the chest or lower abdomen
- trouble with swallowing or urination
- dehydration or extreme thirst
- drowsiness or confusion
- constant, severe abdominal pain
- a fruity breath odor

A doctor should be notified if vomiting is heavy and/or bloody; if the vomitus looks like coffee grounds or feces; or if the patient has been unable to keep food down for 24 hours.

An ambulance or emergency response number should be called immediately if:

- Diabetic shock is suspected.
- Nausea and vomiting continue after other symptoms of viral infection have subsided.
- The patient has a severe headache.
- The patient is sweating and having chest pain and trouble breathing.
- The patient is known or suspected to have swallowed a drug overdose or poisonous substance.
- The patient has a high body temperature, muscle cramps, and other signs of heat exhaustion or heat stroke.
- Nausea, vomiting, and breathing problems occur after exposure to a known allergen.

Causes and symptoms

Persistent, unexplained, or recurring nausea and vomiting can be symptoms of a variety of serious illnesses. It can be caused by simply overeating or drinking too much alcohol. It can be due to **stress**, certain medications, or illness. For example, people who are given morphine or other opioid medications for **pain** relief after surgery sometimes feel nauseated by the drug. Such poisonous substances as arsenic and other heavy metals cause nausea and vomiting. **Morning sickness** is a consequence of pregnancy-related hormone changes. **Motion sickness** can be induced by traveling in a vehicle, plane, or on a boat. Many patients experience nausea after eating spoiled food or foods to which they are allergic. Patients who suffer **migraine headache** often experience nausea. **Cancer** patients on chemotherapy are often nauseated. **Gallstones**, **gastroenteritis**, and stomach ulcer may cause nausea and vomiting. Such infectious illnesses as dengue **fever** and severe acute respiratory syndrome (SARS) may be accompanied by nausea and vomiting. These symptoms should be evaluated by a physician.

Diagnosis

Diagnosis is based on the severity, frequency, and duration of symptoms, and other factors that could indicate the presence of a serious illness.

Treatment

Getting a breath of fresh air or getting away from whatever is causing the nausea can solve the problem. Eating olives or crackers or sucking on a lemon can calm the stomach by absorbing acid and excess fluid. Coke syrup is another proven antiemetic remedy.

Vomiting relieves nausea immediately but can cause dehydration. Sipping clear juices, weak tea, and some sports drinks help replace lost fluid and minerals without irritating the stomach. Food should be reintroduced gradually, beginning with small amounts of dry, bland food like crackers and toast.

Biofeedback

Biofeedback uses **exercise** and deep **relaxation** to control nausea.

Acupuncture

Acupuncture is increasingly regarded as a useful adjunct to treating nausea. A growing body of literature

shows that acupuncture is effective in treating nausea associated with **pregnancy**, surgery, and chemotherapy for cancer. The most effective acupuncture point for nausea appears to be PC-6.

A few patients, however, may experience temporary nausea as a side effect of acupuncture. It is not considered a serious side effect.

Acupressure

Acupressure (applying pressure to specific areas of the body) may be helpful in reducing nausea and vomiting and relaxes the gastrointestinal tract. Acupressure can be applied by wearing a special wristband or by applying firm pressures to the:

- back of the jawbone
- webbing between the thumb and index finger
- top of the foot
- inside of the wrist
- base of the rib cage

Nutritional therapy

- Rehydration. It is very important to replace fluid loss through prolonged vomiting. However, patients should take fluid in slowly to prevent shock to the body. Fruit juice or soup are even better than plain water because they also contain glucose and salt, which may also be deficient.
- Avoid eating solids right away. Patients should wait until the body has enough rests and the stomach has a chance to settle down before starting on solid foods.
- Bland foods. To avoid overworking the digestive system too soon, patients should resume eating with bland food such as toast or yogurt. In addition, they should not try to eat too much right away, as this also stresses out the digestive system.
- Lactaid. Lactaid helps prevent upset stomach in persons allergic to milk.

Herbal treatments

There are several herbal remedies that can help alleviate short bouts of nausea and vomiting.

- Chamomile (*Matricaria recutita*) or lemon balm (*Melissa officinalis*) tea may relieve symptoms.
- Ginger (*Zingiber officinale*), a very effective herbal remedy for nausea, can be drunk as tea or taken as candy or powered capsules. Ginger has been shown in several studies to relieve morning sickness associated with pregnancy.
- Peppermint tea is effective in alleviating nausea and vomiting associated with indigestion.
- Stomach tea, a combination of anise seed, fennel, peppermint and thyme, is a good herbal treatment for gas.
- Strong green tea can stop nausea especially if it is caused by eating spoiled foods.

Homeopathy

Depending on a patient's specific condition, a homeopathic practitioner may prescribe one of the following remedies: *Arsenicum album*, *Carbo vegetabilis*, *Ignatia*, homeopathic **ipecac**, and *Nux vomica*.

Aromatherapy

Peppermint or **lavender** oil when inhaled, calms the body and reduces nausea and vomiting.

Allopathic treatment

Meclizine (Bonine), a medication for motion sickness, also diminishes the feeling of queasiness in the stomach. Dimenhydrinate (Dramamine), another motion-sickness drug, is not effective on other types of nausea and may cause drowsiness.

Newer drugs that have been developed to treat postoperative or postchemotherapy nausea and vomiting include ondansetron (Zofran) and granisetron (Kytril). Another treatment that has been found to lower the risk of nausea after surgery is intravenous administration of supplemental fluid before the operation.

Prevention

Massage, **meditation**, **yoga**, and other relaxation techniques can help prevent stress-induced nausea. Antinausea medication taken before traveling can prevent motion sickness. Sitting in the front seat, focusing on the horizon, and traveling after dark can also minimize symptoms.

Food should be fresh, properly prepared, and eaten slowly. Overeating, tight-fitting clothes, and strenuous activity immediately after a meal should be avoided.

Neck pain

Definition

Neck **pain** is a nonspecific symptom of discomfort in the neck.

Description

Neck pain has a number of possible causes. Depending on the cause, neck pain may be experienced as limited to the neck itself (localized) or as radiating to the shoulders and upper arm. An individual may experience the pain as a dull ache, a sharp stabbing or burning sensation, or a feeling resembling a muscle cramp. Neck pain is often accompanied by stiffness or difficulty moving the neck.

Causes and symptoms

Possible causes of neck pain include:

- Trauma. Whiplash injuries from car accidents and fractures or sprains from rough contact sports or fights are examples of traumatic causes of neck pain.
- Chronic strain on the muscles and tendons of the neck. This stress is often related to the individual's occupation, as some jobs require workers to hold their neck and shoulders in one position for long periods. Computer programmers, dentists and dental hygienists, professional musicians (especially string and woodwind players), dancers, and long-distance truck drivers are especially vulnerable to this type of neck pain. In addition, teenagers who work are at higher risk of chronic neck pain than teenagers who participate in sports. Poor posture can also contribute to chronic strain on the neck.
- Degenerative disorders that affect the neck and spine. These include osteoarthritis, ankylosing spondylitis, and osteoporosis.
- A herniated disk in one of the cervical (neck) vertebrae. In a herniated disk, the disk projects outward between the vertebrae and can put pressure on a nerve.
- Congenital abnormalities. People who are born with abnormally shaped vertebrae or loose joints in the neck region may develop neck pain when the vertebrae begin to put pressure on the spinal cord.
- Rheumatoid arthritis (RA).
- Fibromyalgia.
- Infectious diseases. One of the earliest signs of mumps, meningitis, encephalitis, and poliomyelitis is stiffness and soreness in the neck.

- Cancer. Malignant tumors in the neck cause pain when they grow large enough to press on nerve endings and the spinal cord.
- Climatic factors. People whose jobs require them to work in drafty areas or outdoors in cold weather are at higher risk of developing neck pain.

Diagnosis

Diagnosis of neck pain is complicated not only by the number of possible causes but also by the fact that many patients suffer from two or more conditions at the same time. In most cases, the physician will begin by trying to determine if the neck pain is caused by a primary disorder in the neck and shoulder region or if the pain is the result of a systemic disease that is affecting the neck.

Patient history

Taking a careful patient medical and lifestyle history is particularly important in cases of neck pain because of the number of possible causes. A thorough history will include questions about the patient's occupation and sports or hobbies as well as a medical history.

Physical examination

The physician begins by touching, or palpating, the patient's neck and shoulder girdle. Because the underlying bones and muscles in the neck are close to the surface, an experienced examiner can feel swollen glands, tumorous swellings, **muscle spasms**, or abnormal protrusions between the vertebrae. The doctor then turns the patient's head gently from side to side to determine the neck's range of motion and whether movement worsens the pain. Examination of the inside of the patient's mouth and throat allows the doctor to check the salivary glands, which are swollen and inflamed if the patient has **mumps**.

Diagnostic imaging

An x ray of the neck may be ordered if the doctor suspects traumatic injury, **osteoarthritis**, **osteoporosis**, **rheumatoid arthritis**, a **herniated disk**, or congenital deformities. Chronic strain disorders of the neck do not always appear on a plain x ray. If **cancer** is suspected, the patient may be given a computed tomography (CT) scan of the head, neck, and chest, as well as a gallium scan and a bronchoscopy, laryngoscopy, and esophagoscopy. The patient's lungs and upper gastrointestinal tract are examined because most cancerous tumors in the neck are secondary tumors (metastases) from primary cancers located elsewhere in the body. The doctor may also order a CT scan before scheduling a lumbar puncture if the patient appears to have **meningitis** or another infection of the central nervous system.

Laboratory tests

The doctor may order a blood test to distinguish rheumatoid arthritis (RA) from **systemic lupus erythematosus** (SLE) or other inflammatory diseases. Abnormal values for the proteins in blood serum are often present in RA. In addition, a sample of the patient's joint fluid may be taken. Laboratory tests are most important, however, if the doctor suspects that neck pain is due to a central nervous system infection. *Central nervous system infections are medical emergencies and require rapid treatment with intravenous antibiotics*. Following a CT scan, a sample of the patient's spinal fluid is withdrawn through a lumbar puncture and cultured in order to identify the specific organism causing the infection.

Treatment

Most forms of alternative treatment for neck pain are directed at the milder forms of chronic pain caused by occupational or emotional **stress**. Many of them can be performed as self-help or self-treatment.

Lifestyle modification

Neck pain caused by chronic stress on the muscles of the neck can interfere significantly with overall quality of life as well as efficiency at work. Work-related neck pain may require a change in occupation or a modification of the equipment that the individual uses (e.g., an ergonomic chair for people who work long hours at the computer). People who have poor posture may benefit from various types of **exercise** or **movement therapy**. In some cases, **psychotherapy** may help to lower stress or relieve the painful feelings that are often associated with poor posture.

Acupressure and acupuncture

Acupressure and **shiatsu** are traditional Chinese and Japanese therapies that make use of pressure points (sometimes called acupoints) on the body to release muscular pain and tension. For most types of neck pain, the therapist makes use of acupoints on the neck and upper shoulders. **Acupuncture** as an alternative treatment for neck pain has become increasingly popular in the West since the early 1990s. While some studies indicate that acupuncture is effective in relieving pain in the neck and upper shoulders, other researchers as of 2008 were not convinced.

Chiropractic

Neck pain is a common reason for seeking **chiropractic** treatment. A chiropractor treats neck pain by checking the cervical vertebrae for misalignment, which is called subluxation in chiropractic terminology. The misaligned vertebra is then moved back into proper position with manual pressure. A chiropractic adjustment is thought to restore normal functioning by reducing the stress on the joints, by lowering muscle tension resulting from subluxation, and by minimizing pressure on the spinal nerves. Some health insurance policies pay for chiropractic treatment.

Movement therapies

Both traditional **hatha yoga** and **breema**, a newer form of movement therapy, claim to treat neck pain by reducing or eliminating some of the underlying causes. Teachers of **yoga** maintain that the postures improve the flexibility of the spine and keep the disks between the vertebrae well nourished by spinal fluid. In breema, instructors individualize the exercises, so that persons with neck pain can be given a set of exercises for that specific problem. In addition, both yoga and breema emphasize the importance of cultivating healthy spiritual and emotional attitudes toward the body, thus lowering the level of psychological stress that often contributes to neck pain. Other systems that help to re-educate patients in body movement include **Feldenkrais**, the **Alexander technique**, and Hanna **somatics**.

Reiki, reflexology, and polarity balancing

These methods of treatment rely on light or indirect contact with the affected area rather than on touching it with the techniques used in traditional massage. All three systems of treatment regard neck pain as a symptom of energy imbalance in the body. **Reiki** and **polarity therapy** practitioners seek to realign the energy flow by placing the hands lightly on or over parts of the body that are thought to redirect the energy. In **reflexology**, the feet are regarded as a map of the entire body. Neck pain would be treated by massaging the base of the large toes, which represent the neck area.

Traditional Chinese medicine

In **traditional Chinese medicine**, neck pain is treated by *Tui na* massage, followed by a herbal poultice on the neck; by suction cups, a traditional remedy for arthritis; or by skin scraping, a technique often used for ailments in the neck area. To perform **cupping**, the practitioner flames the inside of a glass suction cup with a cotton ball dipped in alcohol and lighted. The heat from the fire reduces air pressure inside the cup, which is then pressed on the sore area and removed after 15 to 20 minutes. This treatment withdraws excess moisture from the tissues. In skin scraping, the skin on the back and sides of the neck is scraped with a coin dipped in salt water or by pinching a fold of skin, pulling sharply, and letting it fall back. These motions are performed rapidly until bright red stripes appear. Skin scraping is done to release excess heat and energy from the treated area.

Magnetic field therapy

Magnetic field therapy, which involves the application of a pulsed magnetic field to an injured area of the body, gained in popularity in the early 2000s as a treatment for chronic muscular and joint pain. It is thought that magnetic treatments relieve pain by increasing the flow of oxygenated blood to injured tissue. Some studies indicate that magnetic field therapy is useful in relieving chronic neck pain, particularly pain associated with whiplash injuries.

Allopathic treatment

Medications

Some forms of neck pain can be treated by medication. Osteoporosis is often treated with such compounds as alendronate (Fosamax) or etidronate (Didronel). These medications are intended to prevent further weakening of the bone. Pain caused by osteoarthritis, **fibromyalgia**, rheumatoid arthritis, or **ankylosing spondylitis** is usually treated with aspirin or nonsteroidal anti-inflammatory drugs (NSAIDs, e.g., Advil, Motrin). Patients with RA may also be given injections of gold salts or methotrexate (MTX, Rheumatrex). Pain from severe fibromyalgia may be treated with local anesthetics or muscle relaxants.

Appliances

Patients with neck pain caused by traumatic injury, chronic muscular strain, a herniated disk, some forms of osteoarthritis, or congenital deformity may need to have the neck temporarily kept from moving (immobilized) in order to heal. A cervical collar may be used in milder cases. Chronic or severe pain may require more extensive bracing or traction and a period of bed rest.

Surgery

Surgical treatment may be needed to replace damaged joints in severe cases of osteoarthritis or rheumatoid arthritis. Herniated disks occasionally require surgery to fuse the vertebrae around the disk. Some patients with severe cases of ankylosing spondylitis

KEY TERMS

Ankylosing spondylitis—A type of arthritis that causes gradual loss of flexibility in the spinal column. It occurs most commonly in males between the ages of 16 and 35 and may be initiated by a food allergy component, such as an allergy to wheat.

Bronchoscopy—A procedure in which a thin, flexible, lighted tube that is threaded through the airways to view the air passages in the lungs.

Cervical—Relating to the top part of the spine that is composed of the seven vertebrae of the neck and the disks that separate them.

Chiropractic—A method of treatment based on the interactions of the spine and the nervous system. Chiropractors adjust or manipulate segments of the patient's spinal column in order to relieve pain and increase the healthy flow of nerve energy.

Fibromyalgia—A chronic disorder causing pain in the bones and muscles along with severe fatigue.

Herniated—Characterized by an abnormal protrusion of a body part. In a herniated disk, the disk protrudes into the spinal canal between the vertebrae.

Nonsteroidal anti-inflammatory drugs (NSAIDs)—These compounds, which include aspirin, ibuprofen, and indomethacin, are first-choice drugs for treating pain associated with arthritis and autoimmune disorders.

Osteoporosis—A condition found in older individuals in which bones decrease in density and become fragile and more likely to break. It can be caused by lack of vitamin D and/or calcium in the diet.

Palpation—The examination of the body using the sense of touch.

Rheumatoid arthritis—A disease characterized by inflammation and degeneration of connective tissue in multiple joints at a young age.

Subluxation—A partial or incomplete dislocation of the bones that form a joint.

Systemic lupus erythematosus (SLE)—A chronic, inflammatory, autoimmune disorder in which the individual's immune system attacks, injures, and destroys the body's own organs and tissues. It may affect many organ systems, including the skin, joints, lungs, heart, and kidneys.

may need to have the cervical spine stabilized by surgery. Most cancers of the neck are removed surgically after a course of radiation treatment.

Expected results

The results of treatment for neck pain vary widely because of the number of possible causes. While mild arthritis and minor stress injuries in the neck respond well to treatment, cancers in the neck have low survival rates because they are often stage III or stage IV metastases of cancers elsewhere in the body.

Prevention

Some potential causes of neck pain are difficult to prevent because they involve a genetic predisposition or component. These include ankylosing spondylitis, osteoarthritis, and RA. Others are easier to prevent by lifestyle choices. Attention to proper posture; the choice of office chairs and other furniture proportioned to the person's height and size; and exercise breaks from office work, study, or musical practice can help to lower the risk of neck pain from chronic muscular stress. Diet as well as exercise is a prominent factor in the prevention of osteoporosis. Observing safety guidelines and wearing protective equipment during contact sports can lower the risk of trauma to the neck. The use of certain types of shoulder harness while driving appears to lower the risk of whiplash injuries. Lastly, **meditation** and other spiritual practices are effective in lowering the level of emotional stress that often underlies chronic neck pain.

Neem

Description

Neem is a compound that has a long history of use in both traditional Indian medicine and Ayurveda. Many of the popular herbal treatments in these two systems are still derived from it. Neem is a large evergreen tree, *Azadirachta indica*, in the mahogany family. It grows naturally in India and Sri Lanka, and has been successfully transplanted to other regions including West Africa, Indonesia, and Australia. The tree has small white flowers and produces a smooth, yellow-green fruit. All parts of the tree have medical uses. In India, neem is sometimes called "the village pharmacy." Over 100 pharmacologically active substances have been identified in this plant, and it has many traditional applications.

General use

Neem's wide variety of reported benefits include use in the treatment of **fever**, gastrointestinal disease, dermatologic (skin) disorders, immune dysfunction, respiratory disease, parasites, inflammatory conditions, and **infections** by some bacteria, fungi, and viruses. Some components have been shown to have antimalarial properties. The seeds contain an insecticidal substance that is EPA approved for use on non-food crops.

Some viral diseases have been treated by components of neem. It may inhibit the multiplication of viruses and prevent them from entering and infecting cells. Some of the diseases that have reportedly been relieved include colds, flu, and conditions caused by herpes, such as **chickenpox** and **shingles**.

Neem appears to be an appropriate treatment for numerous dermatologic indications. Its anti-inflammatory and **pain** relieving activity make it potentially useful against **psoriasis**, **eczema**, **acne**, **dermatitis**, and an assortment of fungal conditions. The neem leaf has been shown to have activity that suppresses the fungi that cause **athlete's foot**, ringworm, and *Candida*. Seed oil and aqueous leaf extracts have been used to treat **jock itch**, another fungal infection. The oil and leaf extract may be applied externally in the form of lotions and soaps. Leaf preparations may also be used internally for the **detoxification** properties. Poultices made from the leaf have antiseptic and astringent properties that treat **wounds** and **boils**.

Both internal and external parasites may be sensitive to the effects of neem. External parasites, such as lice and mites, are often treated in India with aqueous extracts of neem leaves. A medical research center in Nagercoil, India, found that a combination of neem and **turmeric** cured 97% of patients with **scabies** within 3–15 days of treatment. Teas are used against internal parasites, including intestinal **worms**. Perhaps one of the most interesting claims for neem is for the prevention and treatment of **malaria**. Leaf extracts are said to have the same effectiveness as quinine and chloroquine, the conventional medications that are used. Some studies show that even chloroquine-resistant **strains** of malaria are sensitive to neem, particularly a component called Irodin A. The recommended preventative measure is to chew and consume the leaves on a daily basis.

Twigs and leaves of the neem tree may be used for oral hygiene, and neem bark extracts used in toothpastes and mouthwashes are active against gingivitis. Ayurveda holds that neem has healthful properties for teeth and gum tissue.

Ayurvedic tradition holds that neem bark improves resistance to disease. It appears that certain carbohydrates contained in the bark do indeed stimulate the production of antibodies. One source recommends a cyclical use of neem to strengthen the immune system in order to lower the incidence of infections, particularly in people who have conditions that compromise the immune system.

Some studies show that neem can lower blood sugar levels. It has traditionally been used in Indian medicine for diabetes, and research with animals confirms this potential. Neem is an approved medication for the treatment of diabetes in India. Several forms of the supplement, including leaf extracts and teas, have been shown to have beneficial effects on reducing blood sugar.

There are several components of neem that may make it valuable in the treatment of both **osteoarthritis** and **rheumatoid arthritis**. It is a proven anti-inflammatory that decreases histamine and other

Neem plant. *(©PlantaPhile, Germany. Reproduced by permission.)*

mediators of inflammation in the body. Some of the important chemicals in neem that contribute to this effect are nimbidin, limonoids, and catechin. Warmed neem oil is also recommended for external use to reduce pain and inflammation in affected joints.

Neem has documented spermicidal properties when used intravaginally in women, and is sometimes used as a contraceptive. It is also being studied as a birth control measure for use by males.

Other claims for neem are extensive. They include treatment of high blood pressure, **cholesterol**, heart arrhythmia, kidney disorders, **indigestion**, **anxiety**, **epilepsy**, and many more. Some cancers may possibly be affected by the use of neem products. Consult a practitioner of Ayurveda or other expert in the use of botanicals for guidance in appropriate indications and products.

In addition to the treatment of human diseases and disorders, neem is being intensively studied as a natural insect repellent and pesticide. Studies in India and Pakistan have shown that it is an effective mosquito repellent. In 2002, the United States Department of Agriculture (USDA) reported that neem seed extract is toxic to the larvae of the Florida root weevil and other pests that attack citrus trees. As of 2000, 70 different patents had been granted for neem products intended for agricultural use.

Researchers in the textile industry are also finding uses for neem in the production of natural compounds for treating fabric. Neem seed hulls can be used to support the growth of fungi that produce an enzyme that will remove dye from cloth.

Preparations

There are many forms and routes of use for neem. Some of the preparations include seed oil, aqueous extracts of the leaf, powder from the leaf, smoke from burning dried leaves, and leaf pastes. Topically, neem oil and leaf extracts are incorporated into some soaps and lotions for the treatment of skin conditions. These act to relieve inflammation and kill some of the infectious causes of conditions including acne and many fungi. A decoction of the bark is used externally for **hemorrhoids**. Some bark extracts are also especially bactericidal.

KEY TERMS

Ayurveda—In Sanskrit, *Ayur,* means life, and *veda* means knowledge. Ayurveda is a system of holistic medicine from India that aims to bring the individual into harmony with nature. It provides guidance regarding food and lifestyle, so that healthy people can stay healthy and people with health challenges can improve their health.

Decoction—An herbal extract produced by mixing an herb in cold water, bringing the mixture to a boil, and letting it simmer to evaporate the excess water. The decoction is then strained and drank hot or cold. Decoctions are usually chosen over infusion when the botanical or herb in question is a root, seed, or berry.

Gingivitis—Inflammation of the gums in which the margins of the gums near the teeth are red, puffy, and bleeding. It is most often due to poor dental hygiene.

Scabies—A contagious parasitic skin disease caused by a tiny mite and characterized by intense itching.

Sequela (plural, sequelae)—An abnormal condition resulting from a previous disease or disorder.

The directions for use and application of products vary depending on the formulation. Refer to the label information or consult a health care provider.

Precautions

Due to a lack of sufficient study data and possible toxicity, it is inadvisable for children and pregnant or nursing women to use neem. Those who have impaired liver or kidney function should also use great caution. Large doses of seed or seed components may be toxic.

Traditional Ayurvedic practitioners advise against the use of neem if the patient suffers from obvious wasting or **fatigue**.

Side effects

The long history of the use of neem in India appears to show that there is a low incidence of side effects when used appropriately. Infants have suffered severe sequelae, and even death as a result of internal use of neem. Avoid using neem products on children.

Interactions

No clinically significant interactions between neem and other supplements or medications have been reported as of 2002.

Nerve pain *see* **Neuralgia**

Nettle

Description

Nettle is a member of the Urticaceae family, which includes as many as 500 species worldwide. Many species are tropical. The stinging nettle (*Urtica dioica*)

Nettle plant. *(©PlantaPhile, Germany. Reproduced by permission.)*

grows wild in nitrogen-rich soil on the edges of fields, stream banks, waste places, and close to stables and human habitations throughout the United States and Europe. This fibrous perennial is found throughout the world in temperate regions from Japan to the Andes Mountains. The plant seeds itself, and, in favorable conditions, nettle spreads freely from its tough, creeping yellow root. The hairy, erect, single stalks grow in dense clusters giving the plant a bushy look. The square stems produce heart-shaped, alternate leaves with pointed tips and deeply serrated edges. Leaves are dark green on the top and are a paler green and downy on the underside. The plant grows as tall as 4 ft (1.2 m). Leaves and stems are covered with needlelike hairs that pierce the skin on contact. The plant delivers a sharp sting and a lingering irritation caused by a combination of formic acid, serotonin, acetylcholine, and 5-hydroxytryptamine injected through the tiny needlelike hairs.

The common name nettle is taken from the Anglo-Saxon word *noedl* meaning "needle." Nettle's tiny green flowers grow in dangling clusters in the angles formed by the stalk and stem of the leaf. Flowers bloom from July to September. Each small fruit contains just one seed. Male and female flowers usually grow on separate plants of the stinging nettle, hence the species name *dioica*, meaning "separate," or "two houses." The genus name, *Urtica*, is taken from the Latin *uro*, "to burn." Small nettle (*U. urens*), an annual, usually has both male and female flowers on the same branched cluster. Its properties and uses are similar to those of the stinging nettle.

Older herbals cite the planet Mars with dominion over this common wayside plant. Nettle was certainly used in many battles. Roman nettle (*U. pilulifera*) is said to have been brought to Britain by Caesar's troops, who used the plant to flail themselves in an effort to keep warm in the cool, damp climate. Nettle's fibrous characteristics rival those of hemp and flax. Nettle fibers were woven into fabric for sails and ropes, and for German army uniforms as recently as World War I.

General use

Despite its piercing defense, the stinging nettle has long been valued as a medicinal and nutritional treasure. Nettle has astringent, expectorant, galactagogue (milk producing), tonic, anti-inflammatory, hemostatic, and diuretic properties. The plant is rich in chlorophyll, and a good source of **beta carotene**; vitamins A, C, and E; tannins; **iron**; **calcium**; phosphates; and various other minerals, especially **silica**. The active ingredients include water-soluble polysaccharides that stimulate the immune system, and large protein-sugar molecules known as lectins. The entire plant may be used in various medicinal preparations.

Nettle leaf is used in a simple infusion as a tonic decoction to cleanse the blood. Nettle can also be combined with **yellow dock** (*Rumex crispis*), **dandelion** (*Taraxacum officinale*), cleavers (*Galium aparine*), and **burdock root** (*Arctium lappa*). In folk medicine, the plant was used in a practice known as urtication. The fresh herb was thrashed across the skin to induce a stinging, burning sensation used to relieve the deeper **pain** of rheumatism. A leaf infusion, or a homeopathic tincture of nettle, may also be helpful as supportive therapy for rheumatism. With sufficient water intake, nettle acts as a diuretic and is helpful in treating arthritis and rheumatism. A team of German researchers has reported that the anti-inflammatory effect of nettle is related to its suppression of a type of cell that stimulates the inflammatory response.

An early twentieth-century herbalist reported that the juice of the fresh leaves and root (or the dried leaf when burned and inhaled) was useful to treat **asthma**. Nettle seeds, when ingested, were once thought to be beneficial in the treatment of **bites** from "mad dogs" or the stinging of "venomous creatures," according to Nicolas Culpeper, a seventeenth century doctor. Seeds were also used as an antidote to poisonous herbs such as nightshade (*Solanum dulcamara*) and henbane (*Hyoscyamus niger*), though no recent studies support this use.

Nettle is thought to be particularly helpful for treating urinary tract problems. An infusion of the leaves may be used for inflammatory diseases of the lower urinary tract. The infusion is thought to flush the system and to help expel kidney gravel. It has also been used internally to stop bleeding. An ointment preparation of the aerial parts, or a strong infusion, can be applied externally to relieve **hemorrhoids**. Nettle can increase and enrich the flow of milk in breast-feeding mothers.

Clinical studies have confirmed stinging nettle's benefit to men in reducing symptoms of benign prostatic hyperplasia (a noncancerous enlargement of the prostate gland). A concentrated root extract of nettle is sometimes combined with **saw palmetto** (*Serenoa repens*) and the bark of the pygeum evergreen tree (*Pygeum africanum*) to treat the early stages of the disease. The herbal combination helps to increase the urinary volume and maximize the rate of urine flow. German research suggests that active ingredients in the nettle root may reduce prostate swelling.

During allergy season, a tincture of the fresh herb, or an infusion as a tea, may reduce symptoms of **hay fever**, such as itchy eyes and **sneezing**. However, a study published in 2002 indicates that the antiallergic effects attributed to nettle require further study. Nettle's expectorant properties have been beneficial for coughs and have been used to expel phlegm from the lungs and stomach. The freshly gathered and cooked herb was used as a nutritive potherb in folk medicine to treat consumption. Nettle continues to be valued by wild-food foragers as an early spring potherb, rich in minerals. Nettle juice may be used as a vegetarian substitute for rennet to curdle milk when making cheese.

When boiled with equal parts vinegar and water, a decoction of the plant (particularly the root) is a beneficial and conditioning hair and scalp rinse useful in cases of **dandruff** and thinning hair. A nettle rinse won't restore hair to a bald head. However, it will lend a shine and enhance the color of the hair one does have. A small piece of cotton soaked in a nettle decoction and placed in the nostril can be used to stop a nosebleed. The root, when boiled, will produce a yellow dye, and the leaves produce a permanent, light green dye for wool.

Preparations

Numerous commercial preparations of the herb are available in the form of capsules, dried leaf for tea, homeopathic tinctures, or ointments. The medicinal potency of the herb will vary depending on the growing conditions and the manner and care with which the herb is harvested and prepared.

The fresh leaves and stems should be gathered from young plants on a dry day, just before the plant flowers. Caution should be used when harvesting to avoid the sting. Nettle's aerial parts may be used fresh or dried. To dry, the bunches are hung upside down out of direct sun in an airy room. The root is harvested in the fall when the plant has died back. It is washed thoroughly. Large roots may be chopped into slices while fresh and spread on a tray in a warm, sunny room for several days. Dried plant parts are stored in sealed containers in a dark place.

To make an infusion, 2 oz of fresh, finely chopped nettle leaves are combined with 2.5 cups of fresh, non-chlorinated water (2 tbsp of the dried herb may be used). This mixture is brought to a boil, removed from the heat, and covered. The tea is steeped for about 10 minutes. It is then strained and can be drunk warm or cold. The prepared tea can be stored for about two days in the refrigerator. Dosage for a general tonic is 3 or 4 cups per day. Ample fresh water should be drunk when using nettle as a diuretic tea.

To make a decoction, 2 oz of fresh or 1 tbsp of dried root is combined in a nonmetallic pan with 2.5 cups of water. The mixture is simmered for two minutes, then steeped for 10 minutes. The mixture is then strained.

To extract the juice, an abundance of nettle leaves and stems are gathered. A household food processor or juicer may be used to pulp the plant parts. The resulting pulp is then squeezed through a sieve. The juice is then sealed in dark glass containers and refrigerated.

To make an essential oil, the fresh nettle leaves and stems are packed in a large glass container. They are then covered completely with olive oil. A lid is placed on the container and the mixture is left on a sunny windowsill for two to three weeks. It is stirred daily. After this time period, the mixture is strained through cheesecloth and the oil is stored in a dark glass container.

To make an ointment, beeswax or petroleum jelly is melted in the top of a glass or ceramic double boiler. Finely chopped nettle leaf and stems are stirred in. The mixture is heated on low for about two hours. The mixture is strained through cheesecloth and, with gloved hands, the liquid is squeezed from the cloth. The liquid is then poured into clean, dark glass storage containers while still warm. The containers should be sealed with tight-fitting lids and stored away from direct sunlight.

Precautions

Gloves should always be worn when nettle is harvested to avoid the sharp sting. According to folk tradition, fresh yellow dock leaves may alleviate the burning when rubbed on nettle **stings**. When using stinging nettle preparations to irrigate and flush out the urinary tract, or as a treatment of kidney gravel, abundant fluid intake is required. Stinging nettle preparations are not to be used in the treatment of fluid retention brought on by reduced heart or kidney function. This plant should never be harvested after flowers appear because if harvested at this time, the plant can cause urinary tract damage.

Side effects

Aside from the distinctive sting when touching the fresh plant, there are few side effects from use of the herb in properly prepared therapeutic doses. Mild gastrointestinal distress may occasionally occur. Some people are allergic to nettle.

This plant should not be consumed raw because it can irritate mucous membranes. Leaves of the young plant can be safely consumed when cooked as a nutritional potherb. Boiling the young leaves and stems disarms the stinging hairs. Drying the herb also disarms the stinging hairs. The uncooked, mature nettles should not be eaten.

Interactions

Nettle appears to intensify the effects of nonsteroidal anti-inflammatory drugs, or NSAIDs, which are commonly given for arthritis and similar conditions. While this increased effect may be beneficial to patients with arthritis, they should nonetheless consult a healthcare provider before taking nettle.

Neural therapy

Definition

Neural therapy is a comprehensive healing system that focuses on the relief of chronic **pain** and long-term illness. These symptoms, practitioners say, can be stopped by injecting local anesthetics into scars, **acupuncture** points peripheral nerves, and glands. Other, less-invasive methods may also be used to correct "short circuits" and restore electrical conductivity in the body.

Origins

The earliest known use of neural therapy was in 1925, when two German doctors treated migraine headaches by injecting a local anesthetic (Novocain)

A patient is injected with a local anesthetic as part of neural therapy. *(Horacio Sormani / Photo Researchers, Inc.)*

into the veins. The injections immediately aborted not only the headaches but also a number of other symptoms (**dizziness**, **nausea**, a visual "flashing" sensation) also associated with migraine. In 1940, Dr. Ferdinand Huneke, a German physician, found that injecting procaine (Novocain) into an osteomyelitis scar on a patient's leg seemed to instantly cure chronic pain in her shoulder. Now called the lightning reaction or Huneke phenomenon, it showed that injuries in one part of the body may cause symptoms elsewhere in the body. Although it is still not fully understood, neural therapy has been widely practiced since the 1940s in both Europe and South America. More recently, some neural therapists have employed less-invasive procedures involving electricity, lasers, and other light sources.

Benefits

Neural therapy has been used in the treatment of hundreds of conditions. These include **depression**, hormonal imbalances, dizziness, **allergies**, **asthma**, skin diseases, **hemorrhoids**, ulcers, chronic bowel problems, prostrate and bladder problems, **headache** (including migraine), kidney disease, arthritis, back pain, as well as whiplash and other soft-tissue injuries.

Description

The most common procedures used by practitioners of neural therapy involve injections of procaine (Novocain), lidocaine, other local anesthetics, or saline solution into scars, glands, ganglia, peripheral nerves, acupuncture points, and other tissues. These injections are intended to correct abnormal electrical signaling caused by injuries, or to detoxify tissues or

KEY TERMS

Anesthetics—Drugs that cause a loss of feeling, especially of pain. Some anesthetics also cause a loss of consciousness.

enhance the effectiveness of drugs or nutrients. Other substances that may be injected include nutrients, isopathic dilutions of toxic substances, or diluted traditional medicines such as Benadryl or Demerol. It is argued that all scars cause problems and must be injected at least once. A typical course of treatment may involve between one and six sessions at a frequency of twice a week.

Precautions

Neural therapy involves invasive procedures that should be done only by properly licensed practitioners. It is not advisable for patients with allergies to local anesthetics. Anyone with serious illness should avoid using neural therapy as a sole method of treatment. In such cases, advice should also be sought from a medical practitioner. Neural therapy is thought, in some cases, to activate repressed psychological trauma. Patients may wish to consider whether their practitioner is competent to deal with the resurrection of these subconscious memories. Neural therapy is considered ineffective against **cancer** and metabolic disorders.

Side effects

When carried out by a competent, experienced therapist, neural therapy is considered generally free of adverse side effects. However, in one case reported in a German medical journal, serious internal bleeding resulted from an attempt to inject the adenoids. This indicates that life-threatening side effects are possible when neural therapists inject deeply into internal structures and organs, the article warned.

Research and general acceptance

Neural therapy has gained considerable acceptance among medical doctors and other practitioners in Germany, but is not widely known outside of Europe and South America. Its effectiveness as a pain-management tool is generally accepted, but there has been little scientific research into other claimed therapeutic benefits.

Training and certification

In Germany, neural therapy is available from many orthodox medical practitioners. Elsewhere in the world, a variety of medical doctors, osteopaths, dentists, naturopaths, chiropractors, and acupuncturists have undergone training in the discipline. The American Academy of Neural Therapy offers workshops, videos, and course manuals. Early in 2000, this group was moving toward board certification of neural therapists.

Neuralgia

Definition

Neuralgia describes a variety of rare and painful conditions in which shooting, stabbing, burning, **pain**; electric-like shocks; or tingling, pins and needles, or numbness occur along the course of a nerve, usually in the head or neck.

Description

Neuralgia attacks tend to by cyclic, often coming and going without warning. They can last for minutes, hours, days, or longer, depending on the patient, and range from mild to debilitating. Often, no physical cause can be found, although some forms of neuralgia may be triggered when nerves are compressed by injuries, arteries, tumors, or, in rare cases, as the result of nerve damage from **multiple sclerosis**. Neuralgia is an uncommon condition, with trigeminal neuralgia occuring most often. Other types are occipital neuralgia, glossopharyngeal neuralgia, and postherpetic neuralgia. Most neuralgia patients are 50 or older, although younger patients can be affected as well.

Causes and symptoms

Most neuralgias appear suddenly, with no apparent physical basis for the pain, which can be severe. Other neuralgias may follow an injury, with pain, burning, tingling, or numbness in whatever part of the body the affected nerve supplies.

Trigeminal neuralgia (TN) also called *tic douloureux*, from the French for "painful spasm," is a disorder of the fifth cranial nerve, whose three branches supply the face. (There are 12 pairs of cranial nerves that supply the human head.) Most TN patients are 50 or older, with more women affected than men. Early attacks are short—one to two minutes long—but excruciating, with stabbing, shooting, pain on one side of the face. The location depends on which branch of the nerve is affected. At first, weeks or months separate incidents, but as the condition progresses the time between attacks shortens. Eventually, the area becomes hypersensitive, and painful bouts can even be triggered by eating, drinking, talking, cold, or even touching the face.

Glossopharyngeal is a relatively rare neuralgia, marked by recurring attacks of severe pain that occur for no apparent reason in the throat, ears, and neck. Glossopharyngeal neuralgia patients also tend to be middle-aged, but are more often male than female. The attacks can occur without warning, but, like other facial neuralgias, can also be triggered by **sneezing**, swallowing, talking, yawning, or clearing the throat.

Occipital neuralgia is caused by pain from one of the two occipital nerves that supply the back of the head. Unlike TN or glossopharyngeal neuralgia, occipital neuralgia may occur in conjunction with muscle tension or migraine headaches, with the spasms of nerve pain on top of nearly continual aching.

Although most neuralgias have no known cause, one type, postherpetic neuralgia (PHN) is only seen following an outbreak of **shingles**, a painful, blistering rash caused by the Herpes zoster virus, the same virus that causes chicken pox. Herpes zoster lives in nerve tissue, and never goes away, even after the initial outbreak of chicken pox has disappeared. Older people, especially those with weak immune systems, can suffer a relapse, with the rash appearing along the course of the nerve that is affected. This produces the searing pain of neuralgia, which can be made even worse by the touch of clothing, bedclothes, or another person. PHN and TN are the most common types of neuralgia.

Diagnosis

Physicians begin with a thorough examination, and often include a CT scan or MRI. These will sometimes uncover an artery or tumor that is compressing the nerve and creating the symptoms, but very often no obvious medical problem is found.

KEY TERMS

Desensitization—A treatment for phobias which involves exposing the phobic person to the feared situation. It is often used in conjunction with relaxation techniques. Also used to describe a technique of pain reduction in which the painful area is stimulated with whatever is causing the pain.

Dorsal root entry zone (DREZ)—A type of nerve surgery for postherpetic neuralgia that is occasionally used when the patient can get no other pain relief. The surgery destroys the area where damaged nerves join the central nervous system, thereby interfering with inappropriate pain messages from nerves to the brain.

Glossopharyngeal neuralgia—Sharp recurrent pain deep in the throat that extends to the area around the tonsils and possibly the ear. It is triggered by swallowing or chewing.

Occipital neuralgia—Pain on one side of the back of the head caused by entrapment or pinching of an occipital nerve.

Postherpetic neuralgia—Persistent pain that occurs as a complication of a herpes zoster infection. Although the pain can be treated, the response is variable.

Shingles—An disease caused by an infection with the *Herpes zoster* virus, the same virus that causes chickenpox. Symptoms of shingles include pain and blisters along one nerve, usually on the face, chest, stomach, or back.

Transcutaneous electrical nerve stimulation (TENS)—A technique used to control chronic pain. Electrodes placed over the painful area deliver a mild electrical impulse to nearby nerve pathways, thereby blocking transmission of pain signals to the brain.

Trigeminal neuralgia or tic douloureux—An affliction of the trigeminal or fifth cranial nerve. The condition is characterized by attacks of shooting, stabbing pain on one side of the face. These episodes are triggered by touching the affected area.

In addition, trigeminal neuralgia can be identified by several distinctive traits, many of which apply to other neuralgias as well:

- The patient has attacks of pain in the face that last less than two minutes.
- The pain follows the path of the trigeminal (or another) nerve.
- The pain is described as sudden, sharp, stabbing or burning, and severe.
- The pain may be triggered by certain activities.
- There are no symptoms between attacks.
- In many patients, TN can be positively diagnosed if the drug carbamazepine (Tegretol) diminishes the pain of an attack.

Glossopharyngeal neuralgia is identified in the same way as TN, that is, the patient complains of stabbing, spasmodic pain that follows the Glossopharyngeal nerve. A positive diagnosis is usually achieved if the pain stops when the nerve is blocked with a local anesthesia.

Occipital neuralgia is caused by pain from one of the two occipital nerves that supply the back of the head. Unlike TN or glossopharyngeal neuralgia, occipital neuralgia may occur in conjunction with muscle tension or migraine headaches, with the spasms of nerve pain on top of nearly continual aching. X rays and CT scans can help indicate if the nerve is compressed; numbing the nerve with anesthetics can pinpoint the cause.

Treatment

Trigeminal neuralgia was identified almost 2,000 years ago. Early treatments, like most medicine in those days, were mostly topical (applied to the skin) and ineffective. Today, the most effective treatments for neuralgia are allopathic, but alternative therapies may help support the patient's general well being and improve overall health.

Nutritional therapy

B-complex vitamins, taken orally or given by intramuscular injection, are important for a healthy nervous system, and may supplement medical treatment. A whole foods diet with adequate protein, carbohydrates, and fats that also includes yeast, liver, **wheat germ**, and foods that are high in B vitamins is important. **Essential fatty acids**, such as flax or **fish oil**, may also help reduce inflammation.

Herbal therapy

Capsaicin cream, made from capsicum, a substance found in hot peppers, has sometimes been helpful in desensitizing painful areas in postherpetic neuralgia. Capsaicin may diminish the amount of "substance P," a chemical used by nerves to send pain signals to the brain. **St. John's wort**, an antidepressant, may help the other forms of neuralgia, which

are often treated allopathically with tricyclic antidepressants (TCAs)

Acupuncture

Some patients found that **acupuncture** was helpful in treating their neuralgia pain, especially that of postherpetic neuralgia. Others were unable to obtain relief from the procedure.

Chiropractic

Chiropractors can manipulate the jawbone, neck or spine to treat neuralgia pain. Like most alternative treatments for neuralgia, this is effective for some patients and not for others.

Homeopathy

Homeopathic treatment can also be tried. An experienced homeopathic practitioner will prescribe remedies to bolster the paitient's general health, tailoring remedies to the patient's overall personality profile as well as specific symptoms.

Other alternative therapies

The pain of neuralgia may also be relieved by **hydrotherapy** (hot shower or bath), deep massage, **reflexology** (massaging reflex points in the feet relating affected painful areas in the body) or **yoga** exercises. In addition, **guided imagery**, **biofeedback** therapy, and hypnosis may be beneficial. Patients should also consider **t'ai chi**, **qigong**, and other **movement therapy**.

Patients may also be helped by transcutaneous electrical nerve stimulation (TENS), in which a weak electrical current applied to the skin interferes with the nerve's ability to send pain signals to the brain. Although somewhat controversial, initial results, especially for postherpetic neuralgia, are promising.

Allopathic treatment

Once a diagnosis of neuralgia has been established, physicians prescribe drugs to alleviate the pain. The anticonvulsant drug carbamazepine (Tegretol) is often an effective treatment for TN, relieving or reducing the pain within a day or two. Unfortunately, it can also cause **dizziness**, drowsiness, **nausea**, and double vision, as well as other side effects. If Tegretol is not well tolerated, doctors can try another anitconvulsant, like gabapentin (Neurontin), antispasmodics like baclofen (Lioresal), or anti-anxiety drugs like clonazepam (Klonopin). These drugs are also frequently prescribed for other forms of neuralgia as well.

Injecting local anesthetics into the nerve can stop the pain for a few hours, and for some patients this is effective for a much longer time. Lidocaine cream may be somewhat helpful in treating PHN, probably by temporarily desensitizing nerves just under the skin. Lidocaine may also help atypical forms of TN. Alcohol and glycerin injections that destroy part of the nerve (and thereby its ability to transmit pain) may also be an option.

One particularly unpleasant, but evidently successful, method of treating neuralgia seems to be desensitization. This means that if a patient is bothered by the touch of clothing on the skin, the therapist may rub a towel briskly over the area for a few minutes. If the patient has trouble tolerating heat or cold, warm or cold water may be applied. Although initially quite painful, this method gradually diminishes the frequency and intensity of the patient's pain, apparently by overwhelming (and eventually reducing) the nerve's ability to send messages to the brain.

For PHN, the best treatment seems to be prevention. People with shingles should see a doctor as soon as the rash develops so they can receive treatment to ease the severity of the outbreak and minimize the risk of developing postherpetic neuralgia. It is not clear, however, whether treatment can prevent subsequent neuralgia. If PHN does develop, TCAs—especially amitriptyline—are often helpful. It's important to **stress**, though, that early attention to either a shingles outbreak or PHN episode will reduce the incidence and severity of future attacks. Some patients receive complete pain relief after treatment. Others are able only to reduce the pain (to greater or lesser degrees), while for a very few treatment is completely ineffective. For these patients PHN becomes a lifelong, chronic condition; most cases, however, moderate on their own and disappear within five years. In 2002, clinical trials showed that gabapentin (Neurontin) was effective in treating patients with PHN with relatively low adverse effects.

As a last resort, surgery may bring relief for those neuralgia patients not helped by pharmaceuticals. Most procedures try to reduce the nerve's ability to send pain signals to the brain. One of the most promising is dorsal root entry zone (DREZ) lesioning, which uses radio frequency to disrupt the nerves that are causing pain. Some studies showed that as many as 80% of DREZ patients were helped.

Expected results

Only a few neuralgia patients will not be helped by some combination of drugs and surgery. PHN, in

particular, tends to fade away on its own, and only 2–3% of patients have pain that lasts a year or longer. For those unfortunate few, however, PHN can become a lifelong, debilitating condition.

Neurolinguisitic programming

Definition

Neurolinguistic programming (NLP) is aimed at enhancing the healing process by changing the conscious and subconscious beliefs of patients about themselves, their illnesses, and the world. These limiting beliefs are "reprogrammed" using a variety of techniques drawn from other disciplines including **hypnotherapy** and **psychotherapy**.

Origins

NLP was originally developed during the early 1970s by linguistics professor John Grinder and psychology and mathematics student Richard Bandler, both of the University of California at Santa Cruz.

Studying the well-known psychotherapist Virginia Satir, the hypnotherapist Milton Erickson, the anthropologist Gregory Bateson, and others whom they considered "charismatic superstars" in their fields, Grinder and Bandler identified psychological, linguistic and behavioral characteristics that they said contributed to the greatness of these individuals. On the other hand, they found that persons experiencing emotional difficulties could be similarly identified by posture, breathing pattern, choice of words, voice tone, eye movements, body language, and other characteristics.

Grinder and Bandler then focused on using these indicators to analyze and alter patterns of thought and behavior. After publishing their findings in two books in 1975, Grinder and Bandler parted company with themselves, with a number of other collaborators, and with the University of California, continuing their work on NLP outside the formal world of academia. As a result, NLP split into a number of competing schools.

Popularized by television "infomercial" personality Anthony Robbins and others, NLP was quickly adopted in management and self-improvement circles. During the 1990s, there was growing interest in NLP's healing potential.

Benefits

Neurolinguistic programming has been used to change the limiting beliefs of patients about their prospects of recovery from a wide variety of medical conditions including **Parkinson's disease**, **AIDS**, migraines, arthritis, and **cancer**. Practitioners claim to be able to cure most **phobias** in less than one hour, and to help in making lifestyle changes regarding **exercise**, diet, **smoking**, etc. NLP has also been used to treat **allergies**. In other fields, claimed benefits include improved relationships, communication, motivation, and business performance.

Description

In a health-care context, practitioners of neurolinguistic programming first seek to identify the negative attitudes and beliefs with which a client has been "programmed" since birth. This is accomplished by asking questions and observing physical responses such as changes in skin color, muscle tension, etc. Then, a wide variety of techniques is employed to "reprogram" limiting beliefs. For example, clients with chronic illness such as AIDS or cancer might be asked to displace the despair and loss of identity caused by the disease by visualizing themselves in

vigorous health. Treatment by NLP practitioners is often of shorter duration than that of other alternative practitioners, but NLP self-help seminars and courses can be quite expensive.

For those who wish to try self-treatment with NLP, a wide variety of books, audio tapes, and videos are available.

Precautions

NLP is particularly popular in the self-improvement and career-development fields, and some trainers and practitioners have little experience in its use for healing. Practitioners should be specifically asked about this.

Because NLP is intended to enhance the healing process, it should not be used independently of other healing methods. In all cases of serious illness, a physician should be consulted.

Side effects

NLP is believed to be generally free of harmful side effects.

Research and general acceptance

Although some physicians and mental health practitioners employ principles of neurolinguistic programming, the field is generally considered outside of mainstream medical practice and academic thinking.

Training and certification

Since the originators of NLP parted company more than 20 years ago, a number of schools have been established to offer training and certification. Consumers should be aware that, in some cases, there has been considerable competition and even litigation among individuals and institutions involved in NLP. At the time of publication, there was no umbrella organization covering these institutions or offering uniform standards of training and certification.

Niacin

Description

Niacin, also known as vitamin B_3 or nicotinic acid, is important for the normal function of many bodily processes. Like other B vitamins, it is water-soluble and plays a role in turning food into energy and in the metabolism of fats and carbohydrates. Niacin can also act as an antioxidant within cells, which means it can destroy cell-damaging free radicals. In conjunction with **riboflavin** and **pyridoxine**, it helps to keep the skin, intestinal tract, and nervous system

Recommended dietary allowance of niacin

Age	mg/day
Children 0-6 mos.	2 (AI)
Children 7-12 mos.	4 (AI)
Children 1-3 yrs.	6
Children 4-8 yrs.	8
Children 9-13 yrs.	12
Boys 14-18 yrs.	16
Girls 14-18 yrs.	14
Men ≥ 19 yrs.	16
Women ≥ 19 yrs.	14
Pregnant women	18
Breastfeeding women	17

Foods that contain niacin	mg
Cereal, fortified, 1 cup	20-27
Tuna, light packed in water, 3 oz.	11.3
Chicken, light meat, 3 oz.	10.6
Salmon, 3 oz.	8.5
Cereal, unfortified, 1 cup	5-7
Turkey, light meat, 3 oz.	5.8
Beef, lean, 3 oz.	3.1
Pasta, enriched, 1 cup cooked	2.3
Bread, whole wheat, 1 slice	1.1
Asparagus, cooked, 1/2 cup	1
Carrots, raw, 1/2 cup	0.6
Coffee, brewed, 1 cup	0.5

AI = Adequate Intake
mcg = milligram

(Illustration by GGS Information Services. Cengage Learning, Gale)

functioning smoothly. The term *vitamin B_3* may also include the amide form of nicotinic acid, known as nicotinamide or niacinamide.

General use

The recommended daily allowance (RDA) of niacin for children from one to three years of age is 6 mg. It is 8 mg at four to eight years, and 12 mg at nine to 13 years. For males from age 14 to 18, the RDA is 16 mg; for females of that age range, 14 mg. Males 19 years and older require 16 mg, while females in that age range should have 14 mg per day. The RDA for pregnant females is 18 mg, and for lactating females, 17 mg. As of 2008, no RDA had been set for children under the age of one year, although an adequate intake (AI) is thought to be 2 mg for the first six months of life, and 4 mg for the next six months.

Niacin can be taken in very large doses to decrease blood **cholesterol** levels and reduce the risk of **heart attack**. Niacin is an important part of the treatment of familial hyperlipidemia, an inherited disorder characterized by high blood cholesterol levels and increased risk of heart disorders. The amount of niacin required is between 2 and 3 g per day. Although treatment with niacin is considered one of the best strategies for normalizing blood cholesterol levels, it should not be undertaken without professional medical advice and supervision. Niacin has been singled out as a dietary supplement for which people frequently exceed the upper limits of safe intake. One Canadian study found that 47% of adults who were taking dietary supplements were taking niacin above recommended levels.

Certain conditions preclude the use of high doses of niacin. These disorders include **gout**, diabetes, peptic ulcer, liver or kidney disease, and high blood pressure requiring medication. Even in the absence of these conditions, a patient on high doses of niacin should be closely monitored to be sure the therapy is both effective and without complications. A frequent, harmless but unpleasant side effect of this therapy is extreme flushing of the face and neck. An alternative form of nicotinic acid that does not cause flushing is **inositol** hexaniacinate. Slow-release niacin also causes less flushing, but it should not be taken as there is higher risk of liver inflammation.

There is some evidence that niacin used on a long-term basis can prevent the onset of juvenile diabetes in many susceptible children. Those who have been newly diagnosed with juvenile diabetes may also benefit by extending the time that the pancreas continues to produce a small amount of insulin. The advice of a healthcare provider should be sought for these uses.

Inositol hexaniacinate can be helpful for people suffering from intermittent claudication. This condition causes leg **pain** with **exercise** due to poor blood flow to the legs. Dilation of the blood vessels caused by the inositol hexaniacinate relieves this condition to some extent, allowing the patient to walk farther with less pain.

Other conditions that may be benefited by supplemental niacin include vertigo, **tinnitus**, **premenstrual syndrome** (PMS) headaches, and **osteoarthritis**. Raynaud's phenomenon reportedly may be improved by large doses of inositol hexaniacinate. A healthcare provider should be consulted for these uses. Niacin is not effective for the treatment of **schizophrenia**.

Preparations

Natural sources

Tuna is one of the best sources of niacin, but many other foods contain the vitamin. Most processed grain products are fortified with niacin, as well as other B vitamins. Although niacin is not destroyed by cooking, it does leach into water, so cooking with minimal liquid best preserves it. The amino acid tryptophan is widely found in foods high in protein, and about half of the tryptophan consumed is used to make niacin. Cottage cheese, milk, fowl, and tuna are some of the foods that are high in tryptophan.

Supplemental sources

Niacin can be purchased as an oral single vitamin product. A balanced B complex supplement is preferred over high doses of an individual vitamin unless there is a specific contraindication. Supplements should be stored in a cool, dry place, away from light, and out of the reach of children.

Deficiency

A serious deficiency of niacin causes a condition called pellagra. Once quite common in all countries, it has become rare outside areas in which poor **nutrition** is still the norm. Affected groups include refugees displaced by war as well as populations affected by such emergency situations as famine. The symptoms of pellagra include **dermatitis**, **dementia**, and **diarrhea**.

Milder deficiencies of niacin can cause similar, but less severe symptoms. Dermatitis, especially around the mouth, and other **rashes** may occur, along with **fatigue**, irritability, poor appetite, **indigestion**, diarrhea, **headache**, and possibly delirium.

Risk factors for deficiency

Severe niacin deficiency is uncommon in most parts of the world, but some people may need more than the RDA in order to maintain good health. Vegans, and other individuals who do not eat animal protein, should consider taking a balanced B vitamin supplement. Others who may need extra niacin and other B vitamins are people under high **stress**, including those experiencing chronic illnesses, liver disease, sprue, or poor nutritional status. People over 55 years old are more likely to have a poor dietary intake. Certain metabolic diseases also increase the requirement for niacin. Those who abuse nicotine, alcohol, or other drugs are very frequently deficient in B vitamins, but use of niacin with alcohol can cause seriously low blood pressure. A healthcare professional can determine if supplementation is appropriate.

Precautions

Niacin should not be taken by anyone with a B vitamin allergy, kidney or liver impairment, severe hypotension, unstable **angina**, arterial hemorrhage, or coronary artery disease. Supplemental niacin can exacerbate peptic ulcers. Diabetics should use caution as supplements of either niacin or niacinamide can alter medication requirements to control blood glucose. Supplements can raise uric acid levels and aggravate gout in people with this condition. Pregnant women should not take high doses of niacin, or any supplement, except on the advice of a healthcare provider.

Health care should be sought immediately if certain symptoms occur following niacin supplementation. These include abdominal pain, diarrhea, **nausea**, **vomiting**, yellowing of the skin, faintness, or headache. Such symptoms may indicate excessively low blood pressure or liver problems. Heart palpitations and elevated blood sugar are also potential effects.

Side effects

High doses of niacin can cause a harmless but unpleasant flushing sensation as well as darkening of the urine. The no-flush form can lessen this complication.

Interactions

Niacin supplements should not be taken by anyone on medication for high blood pressure, due to the vitamin's potential to reduce blood pressure. Isoniazid, a drug used to treat **tuberculosis**, inhibits the body's ability to make niacin from tryptophan. Extra niacin may be required. Supplements may also be needed by women taking oral contraceptives. Concomitant use of niacin with statin class drugs to lower cholesterol can cause myopathy. Cholestyramine and cholestipol, older medications to lower cholesterol, should be taken at a different time than niacin or they will reduce its absorption. Transdermal nicotine used with niacin is likely to cause flushing and **dizziness**. Carbamazepine, an antiseizure medication, is more likely to cause toxicity in combination with niacin.

KEY TERMS

Antioxidant—Any substance that reduces the damage caused by oxidation, such as the harm caused by free radicals.

Gout—A metabolic disorder characterized by sudden recurring attacks of arthritis caused by deposits of crystals that build up in the joints due to abnormally high uric acid blood levels. In gout, uric acid may be overproduced, underexcreted, or both.

Myopathy—Any abnormal condition or disease of muscle tissue, characterized by muscle weakness and wasting.

Pellagra—A condition caused by a dietary deficiency of niacin, one of the B vitamins. Symptoms include dementia, diarrhea, and dermatitis.

Sprue—A disorder in which the absorption of nutrients from the diet by the small intestine (malabsorption) is impaired, resulting in malnutrition. Two forms of sprue exist: tropical sprue, which occurs mainly in tropical regions; and celiac sprue, which occurs more widely and is due to sensitivity to wheat protein gluten.

Night blindness

Definition

Night blindness is the inability or reduced ability to see in dim light or darkness. It also refers to the condition in which the time it takes for the eyes to adapt to darkness is prolonged.

Description

Night blindness, also called nyctalopia, is a symptom of several different diseases or conditions. All of the possible causes of night blindness are associated with the way in which the eye receives light rays. Light travels through the cornea and lens and lands on the retina at the back of the eye. The retina is composed of photoreceptors. Photoreceptors are specialized nerve cells that receive light rays and convert them into electrical signals, which are then transmitted to the brain, creating an image.

There are two types of photoreceptors, rods and cones. There are three million cones and 100 million rods in each eye. The two different photoreceptors are similar in structure, however, rods have a larger outer segment than cones. The outer segments of photoreceptors contain light-sensitive photopigments which change shape whenever light rays strike them. Rods contain the photopigments retinal and rhodopsin, whereas cones contain retinal and three different opsins. Rhodopsin is only able to discriminate between different degrees of light intensity, whereas the opsins of cones distinguish between light wavelengths in the red, blue, and green ranges. Hence, rods see only black and white, but cones see colors. Also, rods enable the eyes to detect motion and provide peripheral vision.

KEY TERMS

Cones—Receptor cells, located in the retina of the eye, that allow the perception of colors.

Photoreceptors—Specialized nerve cells (rods and cones) in the retina that are responsible for vision.

Retina—The inner, light-sensitive layer of the eye containing rods and cones. The retina transforms the image it receives into electrical signals that are sent to the brain via the optic nerve.

Retinitis pigmentosa—A group of inherited degenerative eye disorders characterized by deterioration of the retina. This deterioration of the retina causes vision impairment and ultimately blindness, usually by the time the individual reaches middle age.

Rhodopsin—The light-sensitive photopigment contained in rods which discriminates between different levels of light intensity.

Rods—Photoreceptors, located in the retina of the eye, that are highly sensitive to low levels of light.

Rods are responsible for vision in dim light, and cones are responsible for vision in bright light. The rods are spread throughout the retina, but the cones are only in the center of the retina. Vision in dim light or darkness is blurry because of the connections between the photoreceptors and the nerve cells which are linked to the brain. Each rod must share this connection to the brain with several other rods so the brain does not know exactly which rod produced the signal. Alternatively, vision in bright light is sharp because each cone has its own connection to the brain so the brain can determine exactly where on the retina the signal originated.

Another feature of rods is that they must adapt to darkness. This is best exemplified by walking into a dark movie theater. At first, one can see very little. With time, vision improves and one is able to discern objects. Ultimately, one can see moderately well. This dark adaptation process occurs because of the chemical nature of rhodopsin. Rhodopsin is decomposed in bright light making the rods nonfunctional. In darkness, rhodopsin is regenerated faster than it can be decomposed. Dark adaptation takes about 15–30 minutes and, when complete, increases light sensitivity by about 100,000 times.

Causes and symptoms

Several different conditions and diseases can cause night blindness.

These include:

- Cataracts. This condition is characterized by a cloudiness of the lens.
- Congenital night blindness. This is an inherited, stable disease in which persons suffer from night blindness. Recent advances in gene mapping have identified several mutations responsible for this form of night blindness.
- Liver conditions. Reduced night vision can be linked to poor liver functioning, due to a variety of conditions, which impairs vitamin A metabolism.
- Macular degeneration. Degeneration of the macula retinae, a specialized region of the retina, can cause night blindness.
- Retinitis pigmentosa. This is an inherited eye disease in which there is progressive deterioration of the photopigments of the photoreceptors, eventually resulting in blindness. The rods are destroyed early in the course of disease resulting in night blindness. Night blindness in children may be an early indicator of retinitis pigmentosa. Recent genetic studies have identified mutations related to retinitis pigmentosa on human chromosome 19.
- Vitamin A deficiency. Night blindness is commonly caused by a deficiency in vitamin A, in fact, it is one of the first indicators of vitamin A deficiency.
- Xerophthalmia. This condition is characterized by dryness of the conjunctiva (the membrane that covers the eyelids and exposed surface of the eye) and cornea, light sensitivity, and night blindness. It is caused by vitamin A deficiency. Xerophthalmia rarely occurs in countries with adequate supplies of milk products.
- Zinc deficiency. Zinc is a mineral that is necessary for vitamin A to improve vision.

Diagnosis

Night blindness can be diagnosed and treated by an ophthalmologist, a physician who specializes in eye disorders. Opticians can only dispense eye glasses but optometrists may be able to diagnose and treat vision problems.

Diagnosis begins with a detailed medical history regarding the night blindness. Questions include: severity of night blindness, when night blindness began, did it occur gradually or suddenly, etc. An eye examination is performed. A slit lamp examination, in which a narrow beam of intense light is used to examine the internal components of the eye, may also be performed. Additional testing may be performed based upon the results of these standard tests.

Treatment

Changes in vision should never be taken lightly. Because night blindness can be a symptom of a serious disease, an ophthalmologist should be consulted before a person embarks on self treatment.

Persons who experience night blindness should not drive during the evening or at night. Additional safety precautions should be taken. Alternative remedies may be effective at reducing night blindness, particularly when caused by a **vitamin A** deficiency.

Food remedies and supplements

Because night blindness can be caused by a vitamin A deficiency, supplementation with vitamin A, or eating foods rich in vitamin A, may help reduce symptoms. Vitamin A was found to slow the progression of retinitis pigmentosa. Foods rich in vitamin A include dairy products, egg yolks, fish liver oil, and liver. Pregnant women should consult a physician before taking vitamin A supplements because of the link between this vitamin and birth defects.

Vitamin A in humans is primarily obtained by conversion of beta-carotene, a pigment found in fruits and vegetables. Food sources for beta-carotene include apricots, asparagus, broccoli, brussel sprouts, cantaloupe, carrots, cherries, kale, lettuce, mango, mustard greens, papaya, peaches, pumpkin, red cabbage, seaweed, spinach, sweet potatoes, watermelon, winter squash, and yams.

Zinc is necessary to transport vitamin A from the liver to the retina, so zinc supplementation (up to 25 mg daily) may help improve night vision. Docosahexaenoic acid (DHA) helps to increase rhodopsin levels and lines the photoreceptor cells of the retina. DHA is converted from **omega-3 fatty acids**, both of which are found in certain fish oils. The suggested daily dose of DHA (from fish oils) is 500–1000 mg.

Herbal remedies

Herbals which may improve night vision include:

- bilberry (*Vaccinium myrtillus*)
- blueberry (*Vaccinium*) juice
- dandelion (*Taraxacum officinale*)
- eyebright (*Euphrasia officinalis*)
- matrimony vine (*Lycii fructus*, kou chi tza) berries
- passionflower (*Passiflora incarnata*)
- Queen Anne's lace (*Daucus carota sativas*)
- rose (*Rosa* species) flower eye wash
- yellow dock (*Rumex crispus*) leaves

Colored light therapy

One researcher found that some persons have reduced levels of photocurrent transmission (transmission of light signals from the eye to the brain) which can cause, among other things, night blindness. Colored **light therapy**, in which colored light stimulates the brain, can reduce night blindness caused by this photocurrent deficit. In colored light therapy, patients look at a device that cycles through 11 wave bands of color. Treatment involves 25–30 sessions over a period of four to six weeks.

Allopathic treatment

Night blindness caused by vitamin A deficiency will be treated with vitamin A supplements. Night vision devices are available which collect and magnify tiny amounts of light to help persons with night blindness see as well as they can during daylight.

Vitamin A supplementation may slow the progress of retinitis pigmentosa. There is no cure for retinitis pigmentosa or **macular degeneration**, but there are treatments, including laser surgery and the drug thalidomide, which slow down the growth of blood vessels. **Cataracts** require surgery.

Expected results

Vitamin A can effectively treat night blindness in persons who have a deficiency of this nutrient.

Prevention

Vitamin A may prevent night blindness and slow the progression of eye conditions, such as macular degeneration, which cause night blindness. Wearing sunglasses during the day can prevent eye damage.

Noni

Description

Noni, the common name for *Morinda citrifolia,* is a medicinal herbal substance derived from the noni tree, which is found in various areas of the South Pacific. Other names for the herb include morinda, Indian mulberry, nona, nonu, Polynesian bush fruit, Tahitian noni juice, and cheesefruit.

The noni tree is an evergreen shrub, up to 20 ft (6 m) tall, that grows in tropical areas of the South Pacific, including Australia, Malaysia, the West Indies, India, Vietnam, the Philippines, Taiwan, and Hawaii. Its branches and trunk are coarse, tough wood, and the leaves are glossy, oval, and dark green. Year-round, the tree yields a small fruit, which is cream-colored and about the size of a small potato. The noni fruit is noted for its bitter taste, unpleasant smell, and reportedly strong healing properties. Other parts of the plant also are used medicinally, including the leaves, bark, flowers, and roots.

Noni was first found in India, and migrating peoples may have carried it around regions in the Pacific. In Polynesia, the plant is considered a sacred healing herb with many uses. American soldiers stationed there during World War II were reportedly given noni as a health tonic. Other peoples of the South Pacific, including in Hawaii and Tahiti, use noni as a medicinal herb. Traditional uses of all parts of the plant for various conditions are numerous. Noni has been commercially grown for hundreds of years in the South Pacific region. The fruit is also a food source used by South Pacific peoples. The principal regions for commercial cultivation of noni are Hawaii, French Polynesia, and Tahiti.

Noni juice became an increasingly popular health drink during the 1990s, when a group of Hawaiians began internationally marketing the juice as an herbal remedy. Since then, many claims have been made

Noni (Morinda citrifolia) is a medicinal herbal substance derived from the noni tree, which is found in various areas of the South Pacific. *(inga spence / Alamy)*

about its healing powers, a few of which have been somewhat validated by controlled studies. However, there is a lack of research to conclusively back up the optimistic claims regarding the herb's healing powers, and most evidence of the herb's success exists in testimonial accounts.

General use

Traditionally, the fruit has been used for **aging**, diabetes, **halitosis**, **hemorrhoids**, tumors, **tuberculosis**, high blood pressure, and as a tonic for overall health and energy. The leaves have been ingested in remedies for arthritis, digestive problems, parasites, and dysentery (severe infection of the lower digestive tract characterized by acute **diarrhea** and dehydration). Topically, the leaves, fruit, and roots are used in poultices for arthritis and joint **pain**, headaches, for **burns** and lesions, poisonous **bites**, and to improve signs of aging.

Noni is used by some **cancer** patients for its anti-cancer and tumor-reducing possibilities. Some sufferers from immune-compromised diseases such as **AIDS** and **chronic fatigue syndrome** use noni to boost immune system function. People with diabetes and **hypoglycemia** have reported that noni helps stabilize blood sugar levels in the body. People with arthritis, joint pain, and inflammatory conditions have used noni. It is also used as a sedative, painkiller, and sleeping aid. Noni juice is recommended to remove parasites, to cleanse the digestive tract and improve digestion, and to control weight. It is used as a general health tonic to improve energy and resistance and to slow the effects of aging. It is also used for **asthma**; digestive disorders including ulcers; **irritable bowel syndrome**; **constipation** and diarrhea; and **fibromyalgia**, a condition characterized by **fatigue** and chronic pain.

Scientific studies

A substance called ursolic acid found in the leaves of the noni plant has been shown to have anti-cancer properties in the body. A Japanese study found that noni fruit contains another substance (damnacanthal) that has some effectiveness against pre-cancerous cells. Some evidence points to noni's ability to increase

immune system activity, due to substances found in the fruit (including a chemical called proxeronine). The leaves of the plant contain chemicals that may lower blood sugar levels, as well as reduce pain and inflammation. One study showed that laboratory mice with **lung cancer** had much longer survival times when given noni juice daily. A French study determined that the roots of the noni plant contain natural sedatives, while another study pointed to a compound that noni leaves may contain that is anti-malarial and anti-parasitic in its effects. Finally, surveys of noni users have indicated testimonial success with the use of noni for cancer, strokes, diabetes, and as a general health and energy improver. Noni has been shown to contain vitamins, minerals, and **antioxidants**.

Preparations

Noni is available in several forms, including bottled juice from the fruit; essential oil; capsules containing dried fruit, leaves, roots, or combinations thereof; tablets; teas; and topical sprays. Organically grown sources of the supplement are recommended. Noni is best taken on an empty stomach, and can be taken daily. Between one quarter of an ounce and one ounce of the juice is a recommended daily dosage for adults. Up to ten ounces of the juice may be taken by those seeking therapeutic use of the herb and who are under the supervision of a health professional. Consumers should follow manufacturers' recommendations for capsules, tablets, and teas. In capsule form, it is estimated that 1,200 mg equals roughly one ounce of the juice.

Precautions

Although few allergic reactions to noni have been observed, consumers should ingest small amounts of the herb (one tablespoon of the juice) at first to test for adverse reactions. Noni should not be used by pregnant or nursing women, as there is insufficient evidence of its safety during **pregnancy** or for infants.

Side Effects

Reported side effects from the use of noni include **indigestion**; allergic reactions including **rashes**, swelling, and difficulty swallowing; diarrhea; and constipation.

Interactions

The use of noni with potassium-sparing drugs is not recommended, due to the high **potassium** content in the herb. It is recommended that noni not be taken with food, as stomach acid may render one of its active ingredients ineffective. Noni can cause discoloration of the urine and may interfere with diagnostic urine tests. Noni juice may increase the risk of hyperkalemia (higher than normal blood potassium levels) in people with kidney problems by elevating potassium levels in the body.

Nosebleeds

Definition

A nosebleed is characterized by bleeding from the interior of the nasal cavity. It can be caused by heat, dry air, trauma to the nose, certain medications, or a medical condition.

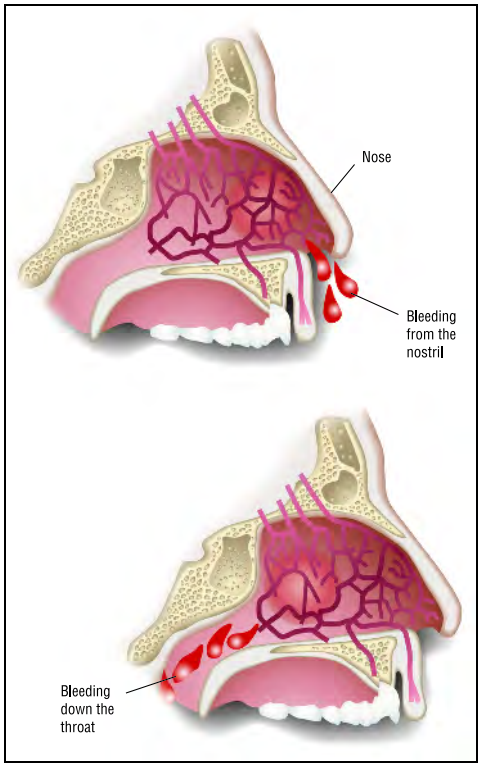
Description

Anterior nosebleeds, or bleeding of the nose that comes from near the nose opening, are the most common nosebleeds in children. Children are twice as likely to experience nosebleeds as adults are. Bleeding that originates from deep within the nasal cavity is known as a posterior nosebleed, the type usually experienced by adults.

Causes and symptoms

The most common causes of nosebleeds are:

- Low humidity. Hot and dry climates can dry out the nasal cavities.
- Nasal trauma. Injuries to the nose can cause bleeding. Excessive nose picking can also injure the interior of the nose.
- Cold, allergies, and sinus infections. Excessive nose blowing and irritation to the mucous membrane can cause bleeding.



Two types of nosebleeds. *(Illustration by GGS Information Services, Inc. Cengage Learning, Gale)*

- Medications. Bleeding can be triggered by certain medications, particularly those with anticoagulant (or blood thinning) properties.

Nosebleeds can also be symptomatic of less common, but more serious, medical conditions. These include:

- nasal polyps
- high blood pressure
- blood clotting disorders (i.e., thrombocytopenia, liver disease)
- leukemia
- malaria

Diagnosis

A nosebleed is easily diagnosed by sight. Further examination of the nasal cavity may be necessary to determine the source of the bleeding, and a medical history should be taken if the cause of the nosebleed is not readily apparent.

Treatment

The first step in treating a nosebleed is to stop the bleeding. An individual experiencing a nosebleed should lightly blow his or her nose, and then pinch both nostrils to encourage clotting of the blood flow. The nose should be pinched close for five to 10 minutes, or until bleeding has stopped. In most cases, this will resolve the nosebleed.

If pinching does not stop blood flow completely, an astringent can also be used to dry up the blood flow. A piece of cotton soaked in **witch hazel** (*Hamamelis virginiana*) can be inserted into the bleeding nostril(s) to tighten and seal the blood vessels. Sniffing a small pinch of powdered **yarrow** (*Achillea millefolium*) can also stop bleeding.

KEY TERMS

Astringent—A substance or compound that causes contraction or constriction of soft tissue.

Cauterization—Sealing tissue or blood vessels by burning with a heat source or electrical current.

Allopathic treatment

Use of a spray decongestant is sometimes recommended to shrink blood vessels and stop bleeding. In severe cases where bleeding from the nose does not stop after 20 minutes, professional emergency care should be sought. Surgery to remove nasal polyps may be required in patients with this problem. In some cases of repeated, serious nosebleeds, cauterization of the blood vessels in the nasal passages is necessary.

Expected results

Most nosebleeds will resolve by themselves in 10–15 minutes. Nutritional and environmental measures can prevent further occurrences in many cases.

Prevention

The following precautions can prevent or lessen the frequency of nosebleeds:

- Vitamin C. An adequate supply of vitamin C is necessary to form collagen, the connective tissue that strengthens blood vessel walls.
- Humidify the air. Using a humidifier in the home and office can prevent nosebleeds caused by a dry environment.
- Vitamin E. Rubbing liquid vitamin E in the nose keeps the mucous membrane moist.

Notoginseng root

Description

Notoginseng root is a frequently prescribed herb in Chinese medicine. The scientific names for the plant are *Panax notoginseng* and *Panax pseudoginseng*. The herb is also referred to as pseudoginseng, and in Chinese it is called Tien qi ginseng, San qi, three-seven root, and Mountain paint. Notoginseng belongs to the same scientific genus, *Panax*, as Asian ginseng. In Latin, the word *panax* means "cure-all," and the family of ginseng plants is one of the most famous and frequently used of all families of herbs.

Notoginseng grows naturally in China and Japan. The herb is a perennial with dark green, compound leaves and red clusters of berries. It is both cultivated and gathered from forests, with wild plants being the most expensive. The root of the plant is used medicinally, and tea is sometimes made from the leaves. At the top of the root is a section called the "age root," which has notches that indicate the age of the particular root. Chinese herbalists consider roots older than three years to be the most effective medicinally. Notoginseng root has a very bitter flavor.

Notoginseng plant. *(© Arco Images / Alamy)*

Notoginseng root has been used in Chinese medicine for thousands of years. One of China's most famous herbalists once said that the root was "more valuable than gold." The herb is used as a general tonic, or a medicine to tone and strengthen the entire system. In particular, notoginseng is considered a blood and heart tonic. Chinese herbalists regard it as having a neutral to warm energy. In **traditional Chinese medicine**, notoginseng is believed to act on the heart and kidney meridians, which are the channels that contain the flow of qi (life energy) in the body. The herb was given the name "mountain paint" because herbalists sometimes recommend a liquid solution of it to reduce swelling and **boils** on the body.

General use

Notoginseng is used to treat external and internal bleeding, including **nosebleeds** as well as bloody stools and urine. Notoginseng has been used in the United States for some years to control postpartum bleeding in women and heavy bleeding associated with **menopause**. Some herbalists recommend notoginseng as an alternative to hormone replacement therapy.

Notoginseng is also used as a general tonic for the heart and circulatory system, and for such specific problems as coronary **heart disease** and high **cholesterol**. Chinese herbalists prescribe notoginseng to relieve the **pain** of **angina** pectoris, a condition that results in sharp pain in the chest region. Notoginseng is also used for painful **menstruation**, and for swelling and boils on the skin.

Research and general acceptance

Considerable research has been performed on notoginseng root in China and Japan over the years, but many of these findings have not been translated into English. Researchers from Western institutions have also taken a more recent interest in herbal treatments and have conducted their own notoginseng-related studies, many of which have been published since 2000.

From notoginseng, researchers have isolated chemicals called saponins and flavonoids, substances that are active biologically in the body. Some of the saponins in notoginseng are believed to provide the raw materials for the creation of important hormones that regulate energy levels and sexual function.

Ginsenoside compounds are a group of saponins of special interest to biologists because they are found only among species in the Panax genus, and they are believed to be the primary source of these plants' pharmacological activity. Notoginseng has especially high concentrations of these compounds.

Notoginseng possesses anti-inflammatory properties, and research published in 2007 suggested that it may be helpful in treating arthritis, which is a chronic inflammatory condition that affects the joints. According to the study, notoginseng inhibits the secretion of a certain arthritis-related regulatory protein, known as a cytokine, and this contributes to notoginseng's anti-inflammatory effects.

In addition, notoginseng has been reported to stimulate the immune system. Other research has pointed to notoginseng's benefits for the heart and circulatory system, and the results of a preliminary study suggest that it may be useful in treating coma patients by decreasing pressure on brain tissue inside the skull.

Notoginseng also has been reported to have positive effects on the blood. It lowers low density lipoprotein (bad cholesterol), and is believed to help dissolve clots. At the same time, it is reputed to stop bleeding both internally and externally. Notoginseng root is one of the main herbs prescribed in Chinese medicine for traumatic injuries. In fact, the root has been distributed to members of armed forces in Asian countries to be used in case of traumatic injury and bleeding.

Possible newer uses for notoginseng root include treatment of HIV, or human immunodeficiency virus, infection. In 2002, researchers reported that they had isolated a compound known as a xylanase, which is a type of enzyme found in plant roots, from the roots of *Panax notoginseng*. According to their study, the new xylanase appeared to inhibit HIV-1 reverse transcriptase, which is an enzyme that allows HIV to integrate itself into the chromosomes inside a cell.

Researchers have also reported that an herbal product that combined extracts of **American ginseng**, *Panax quinquefolium*, and *Ginkgo biloba* showed promise as a treatment for **attention-deficit hyperactivity disorder**. They studied the treatment over a four-week span in three dozen children who were 3–17 years old and had been diagnosed with ADHD, and saw positive results.

Preparations

Notoginseng is available in Asian markets and some health food stores. It comes as dried root, powder, and in capsules. The root is sometimes steamed and then powdered, which is believed to increase its healing effects for the blood. The powdered root can also be applied topically to **wounds** and swelling on the skin.

Notoginseng users sometimes decoct the dried root into a tea by briefly boiling and then simmering it for more than an hour. A daily dosage of the root by this method may be between 3–9 g. Some users instead stir 1–3 g of the powder into tea or juice as a daily serving. The dried root can be used in cooking as well. A common method of taking the herb in China is to prepare it with chicken or soups.

KEY TERMS

Meridian—In traditional Chinese medicine, meridians are the invisible channels that run beneath the skin and through which the body's energy (chi) flows. Meridian also refers to a section of a sphere, such as the line connecting the North and South Poles on the face of the Earth.

Qi—Universal life energy, according to Traditional Chinese Medicine, that is found in the body, air, food, water, and sunlight.

Traditional Chinese medicine—Ancient Chinese healing system involving acupuncture, herbal remedies, dietary therapies, and other healing techniques.

Precautions

Herbalists note that notoginseng root can usually be safely taken in normal doses, but advise that women avoid it during **pregnancy**. Some also recommend that persons who have heart or blood-vessel problems use caution when taking some notoginseng preparations.

Interactions

Notoginseng has been reported to interact with warfarin and heparin, which are medications to thin the blood, or anticoagulants; and with ticlopidine, a drug given to prevent blood platelets from clumping and to prolong bleeding time. Patients taking any of these medications may wish to avoid preparations containing notoginseng.

Nutmeg

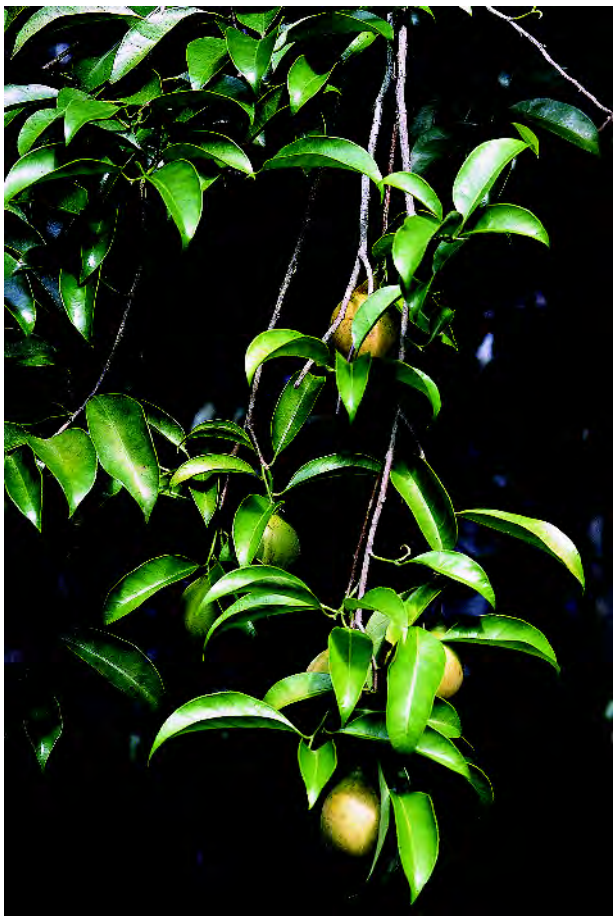
Description

Nutmeg is known by many names, such *Myristica fragrans*, mace, magic, muscdier, muskatbaum, myristica, noz moscada, nuez moscada, and nux moschata. Nutmeg is most commonly used as a cooking spice, comes from the fruit of a 50 ft (15 m) tall tropical evergreen tree. This tree grows in Indonesia, New Guinea, and the West Indies. The bark is smooth and grayish brown with green young branches and leaves. The oblong, fleshy fruit, called the nutmeg apple, contains a nut from which nutmeg is made. The dried nut and essential oil are both used as medicine.

Nutmeg is used in both Western and Chinese herbal medicine. It is most popular as a spice in food and drinks, and is also used in cosmetics and soaps. In ancient Greece and Rome, where nutmeg was rare and expensive, people thought it stimulated the brain. The Arabs have used nutmeg since the seventh century.

General use

Nutmeg relaxes the muscles, sedates the body, and helps remove **gas** from the digestive track. It is most commonly used for stomach problems such as **indigestion**. It is also used for chronic nervous disorders, kidney disorders, and to prevent **nausea** and **vomiting**. In Chinese medicine, nutmeg is used to treat abdominal **pain**, **diarrhea**, inflammation, **impotence**, liver disease, and vomiting. In the Middle East, some cultures are said to use nutmeg in love potions as an aphrodisiac. The essential oil of nutmeg is used for rheumatic pain, toothaches, and bad breath. In Germany, it is used for problems related to the stomach and intestines, but this use is controversial. In **homeopathy**, nutmeg is used to treat **anxiety** or **depression**. Although nutmeg has been used to treat many ailments, it hasn't been proven to be useful or effective for any and it can be harmful. Nutmeg is used in medicines such as Vicks Vaporub, Agua del Carmen, Aluminum Free Indigestion, Incontinurina, Klosterfrau Magentoniuum, Melisana, and Nervospur.



Nutmeg tree branch. *(©PlantaPhile, Germany. Reproduced by permission.)*

Preparation

Nutmeg is made from the nut of the nutmeg apple. It is removed from the fruit and slowly dried. As an herbal medicine, nutmeg is commonly used in capsules (200 mg), powders, and essential oil. As a cooking

KEY TERMS

Anxiogenic—Tending to produce anxiety.

Homeopathy—A holistic system of treatment developed in the eighteenth century. It is based on the idea that substances that produce symptoms of sickness in healthy people will have a curative effect when given in very dilute quantities to sick people who exhibit those same symptoms. Homeopathic remedies are believed to stimulate the body's own healing processes.

Rheumatic—Refers to any of a variety of disorders marked by inflammation, deterioration, or metabolic damage of the body's connective tissues, especially the joints.

Trimyristin—A chemical found in nutmeg that causes anxiety.

spice, the nut is ground and cooked in food. The skin of the nuts is ground to produce another spice, called mace. Nutmeg butter, a mixture of fatty and essential oil, is made by chopping and steaming the nuts until they form a paste.

Some of the suggested doses of nutmeg can be harmful. For nausea, other stomach problems, and chronic diarrhea, one or two capsules or nutmeg kernel as a single dose or three to five drops of essential oil on a lump of sugar or on a teaspoon of honey is suggested. For diarrhea, 4-6 tbsp of powder could be taken every day. For a **toothache**, one or two drops of essential oil can be applied to the gum around the toothache to relieve pain; a visit to the dentist care is still necessary.

In Chinese medicine, 250–500 mg of nutmeg mixed with other herbs is recommended, once or twice a day. It can be taken in powder plain, capsules, pills, or infusion, and should be taken on an empty stomach. When used as a digestive stimulant in Chinese medicine, it is said to work best when ground and cooked in food.

Precautions

Nutmeg is not recommended for use as a medicine because it is too risky. An overdose of nutmeg is harmful and sometimes deadly. There are more effective treatments for all of the ailments that nutmeg could be used for.

Pregnant women should not use nutmeg because it can cause a miscarriage. Women who are breastfeeding should not use nutmeg either. Nutmeg should be used with caution in patients with psychiatric illnesses, as it can cause feelings of anxiety. Touching the nuts can cause an allergic skin reaction. In the home, nutmeg should be kept out of the reach of children and pets.

Side effects

There are no known side effects from using nutmeg properly. Too much nutmeg, however, can cause serious health problems and even death. Early symptoms of an overdose of nutmeg (one to three nuts) are thirst, nausea, and feelings of urgency. There may also be experiences of altered consciousness; this can range from mild to intensive hallucinations, and results in a stupor that lasts from two to three days. Sometimes shock and seizures occur. Immediate medical attention is necessary when someone has taken too much nutmeg.

Interactions

Recent studies of the anxiogenic, or anxiety-causing, effects of nutmeg indicate that it counteracts such tranquilizers as diazepam (Valium), ondansetron (Zofran), and buspirone (BuSpar). The specific substance in nutmeg that is responsible for this effect is a compound called trimyristin. There are, however, no known medical conditions that contraindicate the use of nutmeg in small quantities.

Nutrition

Definition

Good nutrition can help prevent disease and promote health. There are six categories of nutrients that the body needs to acquire from food: protein, carbohydrates, fat, fibers, vitamins and minerals, and water.

Proteins

Protein supplies **amino acids** to build and maintain healthy body tissue. There are 20 amino acids considered essential because the body must have all of them in the right amounts to function properly. Twelve of these are manufactured in the body but the other eight amino acids must be provided by the diet. Foods from animal sources such as milk or eggs often contain all these essential amino acids while a variety of plant products must be taken together to provide all these necessary protein components.

Fat

Fat supplies energy and transports nutrients. There are two families of fatty acids considered essential for the body: the omega-3 and **omega-6 fatty acids**. **Essential fatty acids** are required by the body to function normally. They can be obtained from canola oil, **flaxseed** oil, cold-water fish, or **fish oil**, all of which contain **omega-3 fatty acids**, and primrose or **black currant seed oil**, which contain omega-6 fatty acids. The American diet often contains an excess of omega-6 fatty acids and insufficient amounts of omega-3 fats. Increased consumption of omega-3 oils is recommended to help reduce risk of cardiovascular diseases and **cancer** and alleviate symptoms of **rheumatoid arthritis**, **premenstrual syndrome**, **dermatitis**, and **inflammatory bowel disease**.

Foods high in sugar

- Chewing gum
- Chocolate bar
- Chocolate milk
- Fruit yogurt
- Jelly beans
- Ice cream
- Liqueurs
- Peanut butter and jelly sandwich
- Pork and beans
- Soda

(Illustration by Corey Light. Cengage Learning, Gale)

Carbohydrates

Carbohydrates are the body's main source of energy and should be a major part of total daily caloric intake. There are two types of carbohydrates: simple carbohydrates (such as sugar or honey) or complex carbohydrates (such as grains, beans, peas, or potatoes). Complex carbohydrates are preferred because these foods are more nutritious yet have fewer calories per gram compared to fat and cause fewer problems with overeating than fat or sugar. Complex carbohydrates also are preferred over simple carbohydrates for diabetics because they allow better blood glucose control.

Fiber

Fiber is the material that gives plant texture and support. Although it is primarily made up of carbohydrates, it does not have a lot of calories and usually is not broken down by the body for energy. Dietary fiber is found in plant foods such as fruits, vegetables, legumes, nuts, and whole grains.

There are two types of fiber: soluble and insoluble. Insoluble fiber, as the name implies, does not dissolve in water because it contains a high amount of cellulose. Insoluble fiber can be found in the bran of grains, the pulp of fruit and the skin of vegetables. Soluble fiber is the type of fiber that dissolves in water. It can be found in a variety of fruits and vegetables such as apples, oatmeal and oat bran, rye flour, and dried beans.

Although they share some common characteristics such as being partially digested in the stomach and intestines and have few calories, each type of fiber has its own specific health benefits. Insoluble fiber speeds up the transit of foods through the digestive system and adds bulk to the stools, therefore, it is the type of fiber that helps treat **constipation** or **diarrhea** and helps prevent colon cancer. On the other hand, only soluble fiber can lower blood **cholesterol** levels. This type of fiber works by attaching itself to the cholesterol so that it can be eliminated from the body, preventing cholesterol from re-circulating and being reabsorbed into the bloodstream.

Vitamins and minerals

Vitamins are organic substances present in food and required by the body in a minute amount for regulation of metabolism and maintenance of normal growth and functioning. The most commonly known vitamins are A, B_1 (**thiamine**), B_2 (**riboflavin**), B_3 (**niacin**), B_5 (**pantothenic acid**), B_6 (**pyridoxine**), B_7 (**biotin**), B_9 (**folic acid**), B_{12} (cobalamin), C (ascorbic acid), D, E, and K. The B and C vitamins are water-soluble, excess amounts of which are excreted in the urine. The A, D, E, and K vitamins are fat-soluble and will be stored in the body fat.

Minerals are vital to our existence because they are the building blocks that make up muscles, tissues, and bones. They also are important components of many life-supporting systems, such as hormones, oxygen transport, and enzyme systems.

There are two kinds of minerals: the major (or macro) minerals and the trace minerals. Major minerals are the minerals that the body needs in large amounts. The following minerals are classified as major: **calcium**, **phosphorus**, **magnesium**, **sodium**, **potassium**, **sulfur**, and chloride. They are needed to build muscles, blood, nerve cells, teeth, and bones. They also are essential electrolytes that the body requires to regulate blood volume and acid-base balance.

Unlike the major minerals, trace minerals are needed only in tiny amounts. Even though they can be found in the body in exceedingly small amounts, they are also very important to the human body. These minerals participate in most chemical reactions in the body. They also are needed to manufacture important hormones. The following are classified as trace minerals: **iron**, **zinc**, **iodine**, **copper**, **manganese**, fluoride, **chromium**, **selenium**, molybdenum, and **boron**.

Many vitamins (such as vitamins A, C, and E) and minerals (such as zinc, copper, selenium, or manganese) act as **antioxidants**. They protect the body against the damaging effects of free radicals. They scavenge or mop up these highly reactive radicals and change them into inactive, less harmful compounds. In so doing, these essential nutrients have been claimed to help prevent cancer and many degenerative diseases, such as premature **aging**, **heart disease**, autoimmune diseases, arthritis, **cataracts**, **Alzheimer's disease**, and **diabetes mellitus**.

Water

Water helps to regulate body temperature, transport nutrients to cells, and rid the body of waste materials.

Origins

Unlike plants, human beings cannot manufacture most of the nutrients they need to function. They must eat plants and/or other animals. Although nutritional therapy came to the forefront of the public's awareness in the late Twentieth century, the notion that food affects health is not new. John Harvey Kellogg was an early health food pioneer and an advocate of a **high-fiber diet**. An avowed vegetarian, he believed that meat products were particularly detrimental to the colon. In the 1870s, Kellogg founded the Battle Creek Sanitarium, where he developed a diet based on nut and vegetable products.

Benefits

Good nutrition helps individuals achieve general health and well-being. In addition, dietary modifications might be prescribed for a variety of complaints including **allergies**, **anemia**, arthritis, colds, **depression**, **fatigue**, gastrointestinal disorders, high or low blood pressure, **insomnia**, headaches, **obesity**, **pregnancy**, premenstrual syndrome (PMS), respiratory conditions, and **stress**.

Nutritional therapy also may be involved as a complement to the allopathic treatments of cancer, diabetes, and **Parkinson's disease**. Other specific dietary measures include the elimination of food additives for attention deficit hyperactivity disorder (ADHD), gluten-free **diets** for **schizophrenia**, and dairy-free diets for chronic respiratory diseases.

A high-fiber diet helps prevent or treat the following health conditions:

- High cholesterol levels. Fiber effectively lowers blood cholesterol levels. It appears that soluble fiber binds to cholesterol and moves it down the digestive tract so that it can be excreted from the body. This prevents the cholesterol from being reabsorbed into the bloodstream.
- Constipation. A high-fiber diet is the preferred non-drug treatment for constipation. Fiber in the diet adds more bulk to the stools, making them softer and shortening the time foods stay in the digestive tract.
- Hemorrhoids. Fiber in the diet adds more bulk and softens the stool, thus reducing painful hemorrhoidal symptoms.
- Diabetes. Soluble fiber in the diet slows down the rise of blood sugar levels following a meal and helps control diabetes.
- Obesity. Dietary fiber makes a person feel full faster.

- Cancer. Insoluble fiber in the diet speeds up the movement of the stools through the gastrointestinal tract. The faster food travels through the digestive tract, the less time there is for potential cancer-causing substances to work. Therefore, diets high in insoluble fiber help prevent the accumulation of toxic substances that cause cancer of the colon. New studies released in 2003 seemed to confirm these findings. Because fiber reduces fat absorption in the digestive tract, it also may prevent breast cancer.

A diet low in fat also promotes good health and prevents many diseases. Low-fat diets can help treat or control the following conditions:

- Obesity. High fat consumption often leads to excess caloric and fat intake, which increases body fat.
- Coronary artery disease. High consumption of saturated fats is associated with coronary artery disease.
- Diabetes. People who are overweight tend to develop or worsen existing diabetic conditions due to decreased insulin sensitivity.
- Breast cancer. A high dietary consumption of fat is associated with an increased risk of breast cancer.

Description

The four basic food groups, as outlined by the United States Department of Agriculture (USDA) are:

- dairy products (such as milk and cheese)
- meat and eggs (such as fish, poultry, pork, beef, and eggs)
- grains (such as bread, cereals, rice, and pasta)
- fruits and vegetables

The USDA recommendation for adults is that consumption of meat, eggs, and dairy products should not exceed 20% of total daily caloric intake. The rest (80%) should be devoted to vegetables, fruits, and grains. For children age two or older, 55% of their caloric intake should be in the form of carbohydrates, 30% from fat, and 15% from proteins. In addition, saturated fat intake should not exceed 10% of total caloric intake. This low-fat, high-fiber diet is believed to promote health and help prevent many diseases, including heart disease, obesity, and cancer.

Allergenic and highly processed foods should be avoided. Highly processed foods do not contain significant amounts of essential trace minerals. Furthermore, they contain lots of fat and sugar as well as preservatives, artificial sweeteners and other additives. High consumption of these foods causes buildup of these unwanted chemicals in the body and should be avoided. Food allergy causes a variety of symptoms including food cravings, weight gain, bloating, and water retention. It also may worsen chronic inflammatory conditions such as arthritis.

Preparations

An enormous body of research exists in the field of nutrition. Mainstream Western medical practitioners point to studies that show that a balanced diet, based on the USDA Food Guide Pyramid, provides all of the necessary nutrients. However, the USDA is working to revise the pyramid for the first time in a decade. Other pyramids are suggested by various research agencies, many of which emphasize different nutrition areas. A Harvard University researcher emphasizes whole grains and plant oils over meat, dairy and refined carbohydrates. Some nutritionists believe that the USDA will modify the Food Pyramid to reflect similar modifications. The basic pyramid will likely not change, but explanations about the types of fats, grains and carbohydrates that are best to choose are likely.

In the first revision of the Food Guide Pyramid in 2003, the USDA proposed new patterns about how much Americans eat. Calorie recommendations and vitamin intake will be based on a person's age, sex, and activity level. The complete revision was proposed for final publishing in the winter of 2005. As of early 2004, the Food Guide Pyramid recommends the following daily servings in six categories:

- Grains: Six or more servings
- Vegetables: Five servings
- Fruits: Two to four servings
- Meat: Two to three servings
- Dairy: Two to three servings
- Fats and oils: Use sparingly

A new food guide pyramid for various vegetarian diets has been released by the American Dietetic Association (ADA). The guide helps vegetarians obtain the vitamins and minerals they need from whole grains, vegetables, fruits, legumes, nuts and other protein-rich foods.

Precautions

Individuals should not change their diets without the advice of nutritional experts or health care professionals. Certain individuals, especially children, pregnant and lactating women, and chronically ill patients should only change their diets under professional supervision.

Side effects

It is best to obtain vitamins and minerals through food sources. Excessive intake of vitamins and mineral supplements can cause serious physiological problems. 2001 guidelines to help nutritionists counsel cancer patients in use of complementary and alternative medicine reported that 73% of cancer patients used these therapies in addition to their allopathic treatment. Of those, only about 38% discussed the alternative therapies with their physicians. Patients using dietary supplements should document their use, discuss them with their doctor or nutritionist, and watch standard cautions like possible interactions with prescribed drugs, cumulative effects of several supplements containing the same vitamin or mineral, and to stop taking the supplements if adverse reactions occur.

The following is a list of possible side effects resulting from excessive doses of vitamins and minerals:

- vitamin A: Birth defects, irreversible bone and liver damage
- vitamin B_1: Deficiencies in B_2 and B_6
- vitamin B_6: Damage to the nervous system
- vitamin C: affects the absorption of copper; diarrhea
- vitamin D: Hypercalcemia (abnormally high concentration of calcium in the blood)
- phosphorus: affects the absorption of calcium
- zinc: affects absorption of copper and iron; suppression of the immune system

Research and general acceptance

Due to a large volume of scientific evidence demonstrating the benefits of the low-fat, high-fiber diet in disease prevention and treatment, this diet has been accepted and advocated by both complementary and allopathic practitioners.

Nux vomica

Description

Nux vomica is the homeopathic remedy that is created from the seeds of the strychnos *Nux vomica* tree. Also known as poison nut or **vomiting** nut, this tree is an evergreen tree that is native to East India, Burma, Thailand, China, and Northern Australia.

The tree belongs to the *Loganiaceae* family and has small flowers and orange colored fruits that are the size of an apple or orange. Inside the fruit are five seeds surrounded by a jelly-like pulp. The ash gray seeds are round and measure 1 in (2.5 cm) in diameter and are

The main alkaloids in the seeds of nux vomica are strychnine and brucine. Strychnine by itself is extremely poisonous, but when given in small doses to humans it promotes appetite, aids digestion, and increases the frequency of urination. *(Bon Appetit / Alamy)*

.25 in (0.6 cm) thick. The seeds are coated with downy hairs that give them a satiny appearance.

The main alkaloids in the seeds are strychnine and brucine. These alkaloids give the seeds their bitter taste. Strychnine by itself is extremely poisonous, but when given in small doses to humans it promotes appetite, aids digestion, and increases the frequency of urination. In the nineteenth century it was used as a central nervous stimulant. In larger doses, however, strychnine produces a loss of appetite, hypersensitivity, **depression**, **anxiety**, and rigidity and stiffness of arms and legs. Toxic doses may cause convulsions and death. Some historians think that Alexander the Great died from drinking wine poisoned by strychnine.

Medicinal use of the nut dates back to the middle of the sixteenth century, where it was written about extensively by Valerius Cordus. Germans used the nut as a treatment for **worms**, **rabies**, hysteria, rheumatism, **gout**, and as an antidote for the plague.

General use

Nux vomica is one of the most frequently used homeopathic remedies, especially for acute conditions. Homeopaths prescribe this polychrest for hangovers, back **pain**, digestive problems, headaches, **allergies**, colds, flu, emotional **stress**, **constipation**, menstrual problems, and **hemorrhoids**.

Nux vomica affects the nervous system. When taken by a healthy person the remedy causes **muscle spasms and cramps**, and even convulsions. It affects all five senses and bodily reflexes and causes extreme sensitivity to light, touch, noise, and smells.

KEY TERMS

Gastritis—Inflammation of the lining of the stomach.

Placebo—An inactive substance with no pharmacological action that is administered to some patients in clinical trials to determine the relative effectiveness of another drug administered to a second group of patients.

Polychrest—A homeopathic remedy that is used in the treatment of many ailments.

Strychnine—A colorless, crystalline poison obtained from the seeds of *Nux vomica*.

Succussion—The act of shaking diluted homeopathic remedies as part of the process of potentization.

The remedy is primarily indicated in ailments that are caused by abuse of narcotic drugs, alcohol, coffee, or tobacco, overindulgence in rich food and drink, and mental strain brought about by too much work. *Nux vomica* patients are typically thin and dark-complected workaholics who wear themselves down by working late, eating heavily, neglecting **exercise**, and overindulging in mood-altering foods such as coffee or alcohol. They are hurried and have an overactive mind, even at night, which is why they often suffer from **insomnia**. Their digestive systems are weakened by the rich, spicy, stimulating food and drink they crave and consume. As such, they suffer from **diarrhea**, constipation, hemorrhoids, digestive problems, and an overall weakened vitality. *Nux vomica* patients catch colds easily and are hypersensitive to light, touch, noise, smells, and the effect of medicines. They are also sensitive to the cold and dislike cold weather immensely. Patients may be tidy and fastidious.

Children who require *Nux vomica* are mischievous, stubborn, sensitive, and easily offended. They like to get their own way and become difficult if they do not.

Mentally, *Nux vomica* patients are irritable, impatient, jealous, suspicious, malicious, never satisfied or content, anxious, argumentative, critical, stubborn, and rude. They have a violent temper and are often suicidal. They also have a difficult time concentrating and their memory often fails them.

Physically they may suffer from **muscle spasms** and twitching of muscles, emaciation, **anemia**, internal muscle tension, numbness of the affected part, an ineffectual urge to urinate, cramping pains, and heat in the stomach, chest, uterus, head, face, and palms of

the hands. The complaints are generally right-sided, especially in conditions of **tonsillitis**, hernias, and renal **colic**.

Symptoms are generally worse in the morning, at night (particularly after midnight or from 3:00 to 4:00 A.M.), in cold or open air, in dry weather, after eating, from cold food and drinks, from lying down or lying on the painful side, during the menstrual cycle, from mental strain, loss of sleep, and from use of alcohol, coffee, and tobacco. Symptoms are better with warmth, warm food and drinks, wet weather, and sleep.

Specific indications

The headaches indicative of *Nux vomica* are concentrated in the forehead (over the eyes) or back of the head. The pains are sharp, bursting pains and the scalp may feel sore and bruised. Constipation and other gastric symptoms are often present. This **headache** is typical of a **hangover** headache. It may be caused by alcohol, cold wind, damp weather, insomnia, mental strain, or overeating. The headache is aggravated by eating, cold air, moving the eyes, or shaking the head. Stillness and quiet relieves the headache, as does pressure, rising in the morning, or lying in bed at night.

The *Nux vomica* cold occurs as a result of exposure to cold, dry wind or from **indigestion**. Colds generally settle in the nose, throat, chest, and ears. Colds are accompanied by a hoarse voice, headache, **sore throat**, **sneezing**, **chills**, a tickling **cough**, **fever**, and bone pains. The voice sounds nasal from the stuffy nose, which is plugged in open air and at night. The nose emits a watery discharge during the day and in a warm room. The patient has a desire for cold water and the eyes are watery. Colds are better from fresh air and worse upon rising in the morning and after eating. The **earache** that accompanies the cold is made worse by swallowing. The ear is itchy and painful.

Flus and **hay fever** both exhibit the *Nux vomica* cold symptoms. The flu may be accompanied by an aching, sore sensation. The hay fever may last throughout the year.

The cough is a dry, tickling cough that comes about in violent fits. It is accompanied by headaches, a sore throat, and pain in the abdomen. Coughs are worse after midnight, from mental exertion, in cold air, and after eating. They are relieved by hot drinks and from fresh air.

Sore throat pains spread to the ears. The throat is raw and the patient may feel as though there is "a lump in his throat." The sore throat is worse from swallowing and cold air.

Fever is accompanied by chills, shivering, and an aching of the back, arms and legs. The fever begins early in the morning around 6:00 or 7:00 A.M. The fever is hot and dry and is often one-sided. The patient becomes chilled when he moves around in bed or when a limb becomes uncovered. He is thirsty and may perspire. The gastric symptoms typical of this remedy may occur with the fever.

Digestive complaints are brought about by overindulging in rich, spicy foods, alcohol, tobacco, or coffee. Disturbances include diarrhea, constipation, and abdominal pains and may be accompanied by **nausea**, vomiting, and indigestion. The patient feels bloated and full. The abdomen is painful and cramped and the patient may be doubled over. He may strain to urinate, defecate, or vomit. The pains are relieved by passing **gas** or passing a stool, from hot drinks, loose clothing, and warmth.

Menstrual difficulties occur throughout the cycle. The period is early, late, or too long. The menses may be heavy and clotted and accompanied by back pain and violent cramps that are aggravated by air or the cold and relieved by warmth and pressure.

Insomnia is caused by excitement, mental exertion, or the effects of alcohol. The patient is sleepy but as soon as her head hits the pillow she is awake. She often wakes up early in the morning, around 3:00 A.M., and cannot get back to sleep.

Recent research

Because *Nux vomica* is prescribed so frequently in homeopathic treatment, it has figured in several different areas of research into homeopathic remedies:

- Gastritis. Studies were done as early as 1966 comparing patients who received *Nux vomica* 4X for gastritis compared with a group that received a placebo. While one study showed that twice as many patients responded to the homeopathic remedy as responded to the placebo, other studies found no difference in the rate of response.
- Alcoholism. A study published in 2001 reported that *Nux vomica* reduced alcohol intake in rats that had been conditioned to crave alcohol. The rise in the number of animal studies using *Nux vomica*, however, has led to some debate among homeopaths regarding the morality of experimentation on animals.
- Abnormal psychology. The compilation of the Constitutional Type Questionnaire, or CTQ, as a homeopathic psychological research instrument has led to studies comparing its findings to those of mainstream psychological measures. One group of researchers reported that subjects who fit the *Nux*

vomica profile on the CTQ scored high in neurotic traits as well as high in chemical intolerance.

Preparations

The seeds of the tree are ground until powdered then mixed with milk sugar. This solution is then diluted and succussed to create the final preparation.

Nux vomica is available at health food and drug stores in various potencies in the form of tinctures, tablets, and pellets.

Precautions

If symptoms do not improve after the recommended time period, a homeopath or healthcare practitioner should be consulted.

The recommended dose should not be exceeded, as the strychnine in *Nux vomica* is poisonous. People should be careful to use only preparations made by established manufacturers, as cases of accidental strychnine poisoning from non-homeopathic herbal preparations containing *Nux vomica* have been reported.

Side effects

There are no known side effects at recommended dosages, but individual aggravations may occur.

Interactions

When taking any homeopathic remedy, use of **peppermint** products, coffee, or alcohol should be avoided. These products may cause the remedy to be ineffective.

O

Oak

Description

Oak is the common name for many acorn-producing trees and shrubs that are members of the beech, or Fagaceae, family. Oak trees are classified as members of the genus *Quercus*, a Latin word said to be derived from a Celtic word meaning "fine tree." Worldwide there are more than 600 different species of oak. They thrive across the Northern Hemisphere in China, Japan, Europe, the British Isles, and in all of the continental United States except for Alaska. More than half of the 600 species are native to North America. Yet only about 60 varieties grow north of Mexico. In the forests of northern areas that have short summer growing seasons and long winters, such as Canada, northern Europe, and Siberia, varieties of oak are very scarce.

The oak family is a diverse group of trees and shrubs, influenced by climatic and environmental changes. Recent studies indicate that global warming contributes to oak dieback by speeding up the reproduction of beetles and fungi that attack oak trees. There are oaks that grow to heights of about 100 ft (30.5 m), while other types never grow larger than a small shrub. In warmer climates, oaks are evergreens, keep their leaves all year long, and are often used as ornamental trees in parks. In colder climates, they usually drop their leaves in autumn.

Many of these deciduous oaks have leaves that turn brilliant gold or scarlet in the autumn. In spring small, yellow green flowers appear. The male flowers hang in clusters called catkins and have profuse amounts of pollen. This oak pollen is carried by the wind to fertilize female flowers that produce acorns. Oak trees grow very slowly. In 80 years, it's estimated that one will grow to no more than 2 ft (0.6 m) in diameter. Oaks do not even produce acorns for their first 20 years, but they live a very long time. Average life expectancy for most oaks is between 200 and 400 years, and there are oak trees over 800 years old that are still alive.

Oaks are divided into two basic categories: white and red. The leaves of most of these are characteristically lobed, and depending upon the variety, can have anywhere from five to 11 lobes. Historically, the oak has been considered sacred by many civilizations. Abraham's Oak, the Oak of Mamre, is thought to be on the spot where the bible states Abraham pitched his tent. Legend states that anyone defacing this tree will lose their firstborn son. Both the ancient Greeks and Romans revered the oak, but its longest association has been with the British Isles. The Druids considered it to have both medicinal and mystical significance. For centuries, an oak sprig was inscribed on English coins. Legend states that King Arthur's round table was made from one gigantic slice of a very ancient oak tree. Oak has been used as a medicine since the ancient Greek and Roman times. The famous Roman doctor Galen first used oak leaves to heal **wounds**.

The American white oak, *Quercus alba*, and the English oak, *Quercus robur*, have bark with similar healing qualities. Oak bark contains saponins, tannins, calcium oxalate, starch, glycosides, oak-red, resin, pectin, levulin, and quercitol.

General use

Oak wood as timber is prized for its strength, elasticity, and durability. It is ideal for making furniture, barrels, railroad ties, and in the past, ships. Oak acorns are a source of food for wildlife and have been used as fodder for farm animals in the past. A flour made from ground acorns was also a part of the diet of Native Americans. The tannin in oak bark is used in leather preparation. Cork is made from the bark of some species that grow only in Spain and Portugal.

Recent advances in molecular genetics have shown that DNA from samples of oak can be isolated and analyzed. This type of analysis has a variety of potential applications in archaeology and forensic investigations.

KEY TERMS

Bowel astringent—A substance that causes bowel tissue to dry and shrink by reducing its ability to absorb water.

Dermatitis—Inflammation of the skin.

Diuretic—A group of medications that increase the amount of urine produced and relieve excess fluid buildup in body tissues. Diuretics may be used in treating high blood pressure, lung disease, premenstrual syndrome, and other conditions.

Forensic—Pertaining to courtroom procedure or evidence used in courts of law.

Leukorrhea—White discharge from the vagina, normally occurring during the menstrual cycle, pregnancy, lactation, and menopause. A change in color, amount, or odor is a symptom of a reproductive tract disorder.

Staphylococcus—Any of several species of spherical bacteria that occur in groups of four or in irregular clusters. They can infect various parts of the body, especially the skin and mucous membranes.

Tannin—An astringent compound found in chamomile, oak bark, and certain other plants. Tannin in large quantities can interfere with iron absorption.

Oak used to make wine barrels has been found to increase the antioxidant activity of wines aged in the barrels as well as adding a distinctive aroma to the wine. The increase in antioxidant activity can be measured by a new technique known as electron paramagnetic resonance, or EPR.

Oak bark is used in medicine as a bowel astringent to treat **diarrhea** and as an anti-inflammatory gargle for soothing sore throats. It can be used topically for such skin inflammations as **dermatitis**, as an enema for hemorrhoids, or as a douche for vaginal **infections** and leukorrhea. A study in 1980 showed some evidence that oak bark may prevent kidney stone formation and act as a diuretic. A 1990 Russian study demonstrated that oak bark had antibacterial activity against *Staphylococcus*. One study in 1994 showed that oak bark could reduce serum cholesterol levels in animals.

Preparations

One teaspoonful of pulverized oak bark powder can be added to 1 cup of water, boiled, and then simmered at a reduced heat for 15 minutes to make an oak bark tea. This tea can be taken internally as an intestinal astringent up to three times per day. Oak bark is also available in both an extract and a tincture. For rinses, compresses, and gargles, 20 g of pulverized bark should be dissolved in 1 qt (1 L) of water, and prepared in the same manner as the tea. Oak bark is also available as snuff, tablets, and capsules.

Precautions

Oak bark should not be used externally over large areas of skin damage or used as a full bath. Oak bark for gargles, enemas, or douches should not be used for more than two weeks before consulting a doctor. A doctor should also be consulted for any episode of diarrhea that lasts longer than three days despite treatment with oak bark.

Side effects

No side effects have been reported when oak preparations are used at recommended dosage levels. Patients occasionally experience mild stomach upset or **constipation** if the dosage is exceeded.

Interactions

Oak bark preparations are believed to inhibit or reduce the absorption of such alkaline drugs as antacids. In addition, oak bark has been found to reduce the effectiveness of codeine and atropine.

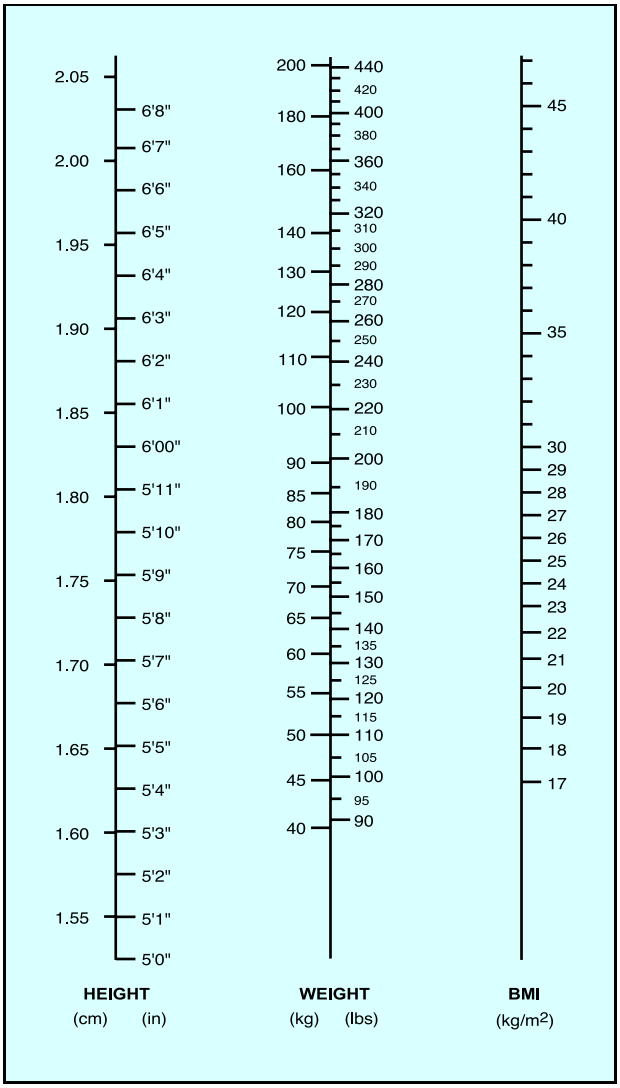
Obesity

Definition

Obesity is an abnormal accumulation of body fat, usually 20% or more over an individual's ideal body weight. Obesity is associated with increased risk of illness, disability, and death.



(Illustration by Argosy Inc. Cengage Learning, Gale)

The branch of medicine that deals with the study and treatment of obesity is known as bariatrics. As obesity has become a major health problem in the United States, bariatrics has become a separate medical and surgical specialty.

Description

Obesity traditionally has been defined as body weight at least 20% above the weight corresponding to the lowest death rate for individuals of a specific height, sex, and age (designated as the ideal weight). Twenty to forty percent over ideal weight is considered mildly obese; 40–100% over ideal weight is considered moderately obese; and 100% over ideal weight is considered severely, or morbidly, obese. According to some estimates, approximately 25% of the United

Percentage of healthy, overweight, and obese adults in the United States

Age ≥20 yrs.	Healthy weight BMI 18.5 to 24.9	Overweight BMI 25.0—29.9	Obese BMI 30 and above
All Adults	32.9%	34.1%	32.2%
Women	35.4%	28.6%	34.6%
Men	30.4%	39.7%	31.1%

(Illustration by GGS Information Services. Cengage Learning, Gale)

States population can be considered obese, 4 million of whom are morbidly obese. Other studies state that over 50% of American adults are obese, based on body mass index (BMI) measurements. Excessive weight can result in many serious, and potentially deadly, health problems, including **hypertension**, Type II **diabetes mellitus** (non-insulin dependent diabetes), increased risk for coronary disease, increased unexplained **heart attack**, hyperlipidemia, **infertility**, and a higher prevalence of colon, prostate, endometrial, and possibly, **breast cancer**. Approximately 300,000 deaths a year are attributed to obesity, prompting leaders in public health, such as former Surgeon General C. Everett Koop to label obesity "the second leading cause of preventable deaths in the United States."

Causes and symptoms

The mechanism for excessive weight gain is clear—more calories are consumed than the body **burns**, and the excess calories are stored as fat (adipose) tissue. However, the exact cause is not as clear and likely arises from a complex combination of factors. Genetic factors significantly influence how the body regulates appetite and the rate at which it turns food into energy (metabolic rate). Studies of adoptees confirm this relationship. The majority of adoptees followed a pattern of weight gain that more closely resembled that of their birth parents than their adoptive parents. A genetic predisposition to weight gain, however, does not automatically mean that a person will be obese. Eating habits and patterns of physical activity also play a significant role in the amount of weight a person gains.

Some recent studies have indicated that the amount of fat in a person's diet may have a greater impact on weight than the number of calories the food contains. Carbohydrates like cereals, breads, fruits and vegetables, and protein (fish, lean meat, turkey breast, skim milk) are converted to fuel almost as soon as they are consumed. Most fat calories are immediately stored in fat cells, which add to the body's weight and girth as they expand and multiply. There is continuing research on the theory that fat is metabolized as fuel and energy and that only excess carbohydrates are converted to stored fat. Current evidence shows that weight gain comes mostly from total calories consumed, rather than from the amount of carbohydrates. A study published in 2002 found that low-fat **diets** are no more effective in weight reduction programs than low-calorie diets. At any rate, a sedentary life-style, particularly prevalent in affluent societies like the United States, can contribute to weight gain. Psychological factors, such as **depression** and low self-esteem may, in some cases, also play a role in weight gain.

KEY TERMS

Adipose tissue—Fat tissue.

Appetite suppressant— A drug that decreases feelings of hunger. Most work by increasing levels of serotonin or catecholamine, chemicals in the brain that control appetite.

Bariatrics—The branch of medicine that deals with the prevention and treatment of obesity and related disorders.

Ghrelin—A recently discovered peptide hormone secreted by cells in the lining of the stomach. Ghrelin is important in appetite regulation and maintaining the body's energy balance.

Hyperlipidemia—A condition characterized by abnormally high levels of lipids in blood plasma.

Hyperplastic obesity—Excessive weight gain in childhood, characterized by an increase in the number of new fat cells.

Hypertension—Abnormally high arterial blood pressure, which if left untreated can lead to heart disease and stroke.

Hypertrophic obesity—Excessive weight gain in adulthood, characterized by expansion of already existing fat cells.

Ideal weight—Weight corresponding to the lowest death rate for individuals of a specific height, gender, and age.

Leptin—A protein hormone that affects feeding behavior and hunger in humans. At present it is thought that obesity in humans may result in part from insensitivity to leptin.

At what stage of life a person becomes obese can effect his or her ability to lose weight. In childhood, excess calories are converted into new fat cells (hyperplastic obesity), while excess calories consumed in adulthood only serve to expand existing fat cells (hypertrophic obesity). Since dieting and **exercise** can only reduce the size of fat cells, not eliminate them, persons who were obese as children can have great difficulty losing weight, since they may have up to five times as many fat cells as someone who became overweight as an adult.

Obesity can also be a side effect of certain disorders and conditions, including:

- Cushing's syndrome, a disorder involving the excessive release of the hormone cortisol
- hypothyroidism, a condition caused by an underactive thyroid gland
- neurologic disturbances, such as damage to the hypothalamus, a structure located deep within the brain that helps regulate appetite
- consumption of certain drugs, such as steroids, antipsychotic medications, or antidepressants

The major symptoms of obesity are excessive weight gain and the presence of large amounts of fatty tissue. Obesity can also give rise to several secondary conditions, including:

- arthritis and other orthopedic problems, such as lower back pain
- heartburn
- high cholesterol levels
- high blood pressure
- menstrual irregularities or cessation of menstruation (amenorhhea)
- shortness of breath that can be incapacitating
- skin disorders, arising from the bacterial breakdown of sweat and cellular material in thick folds of skin or from increased friction between folds

Diagnosis

Dignosis of obesity is made by observation and by comparing the patient's weight to ideal weight charts. Many doctors and obesity researchers refer to the body mass index (BMI), which uses a height-weight relationship to calculate an individual's ideal weight and personal risk of developing obesity-related health problems. Physicians may also obtain direct measurements of an individual's body fat content by using calipers to measure skin-fold thickness at the back of the upper arm and other sites. The most accurate means of measuring body fat content involves immersing a person in water and measuring relative displacement; however, this method is very impractical and is usually only used in scientific studies requiring very specific assessments. Women whose body fat exceeds 30% and men whose body fat exceeds 25% are generally considered obese.

Doctors may also note how a person carries excess weight on his or her body. Studies have shown that this factor may indicate whether or not an individual has a predisposition to develop certain diseases or conditions that may accompany obesity. "Apple-shaped" individuals who store most of their weight around the waist and abdomen are at greater risk for **cancer**, **heart disease**, **stroke**, and diabetes than "pear-shaped" people whose extra pounds settle primarily in their hips and thighs.

Treatment

Treatment of obesity depends primarily on the degree of a person's overweight and his or her overall health. However, to be successful, any treatment must affect life-long behavioral changes rather than short-term weight loss. "Yo-yo" dieting, in which weight is repeatedly lost and regained, has been shown to increase a person's likelihood of developing fatal health problems than if the weight had been lost gradually or not lost at all. Behavior-focused treatment should concentrate on:

- What a person eats and how much. This aspect may involve keeping a food diary and developing a better understanding of the nutritional value and fat content of foods. It may also involve changing grocery shopping habits (e.g. buying only what is on a prepared list and going only on a certain day), timing of meals (to prevent feelings of hunger, a person may plan frequent small meals), and actually slowing down the rate at which a person eats.
- How a person responds to food. This may involve understanding what psychological issues underlie a person's eating habits. For example, one person may binge eat when under stress, while another may always use food as a reward. In recognizing these psychological triggers, an individual can develop alternate coping mechanisms that do not focus on food.
- How people spend their time. Making activity and exercise an integral part of everyday life is a key to achieving and maintaining weight loss. Starting slowly and building endurance keeps individuals from becoming discouraged. Varying routines and trying new activities also keeps interest high.

For most who are mildly obese, these behavior modifications entail lifestyle changes they can make

independently while being supervised by a family physician. Other mildly obese persons may seek the help of a commercial weight loss program (e.g. Weight Watchers). The effectiveness of these programs is difficult to assess, since programs vary widely, dropout rates are high, and few employ members of the medical community. However, programs that emphasize realistic goals, gradual progress, sensible eating, and exercise can be very helpful and are recommended by many doctors. Programs that promise instant weight loss or feature severely restricted diets are not effective and, in some cases, can be dangerous.

For individuals who are moderately obese, medically supervised behavior modification and weight loss are required. While doctors will put most moderately obese patients on a balanced low-calorie diet (1200–1500 calories a day), they may recommend that certain individuals follow a very low-calorie liquid protein diet (400–700 calories) for as long as three months. This therapy, however, should not be confused with commercial liquid-protein diets or commercial weight-loss shakes and drinks. Doctors tailor these diets to specific patients, monitor patients carefully, and use them for only a short period of time. In addition to reducing the amount and type of calories consumed by the patient, doctors will recommend professional therapists or psychiatrists who can help the individual effectively change his or her behavior in regard to eating.

The Chinese herb **ephedra** (*Ephedra sinica*, or ma huang), combined with exercise and a low-fat diet in physician-supervised weight-loss programs, can cause at least a temporary increase in weight loss. However, the large doses of ephedra required to achieve the desired result can also cause:

- anxiety
- heart arrhythmias
- heart attack
- high blood pressure
- insomnia
- irritability
- nervousness
- seizures
- strokes
- death

Ephedra should not be used by anyone with a history of diabetes, heart disease, or thyroid problems. It is not recommended for long-term use, and can cause serious medical or psychiatric problems if used too long. An article that appeared in the *Journal of the American Medical Association* in early 2003 advised against the use of ephedra.

Diuretic herbs, which increase urine production, can cause short-term weight loss but cannot help patients achieve lasting weight control. The body responds to heightened urine output by increasing thirst to replace lost fluids, and patients who use diuretics for an extended period of time eventually start retaining water again anyway. In moderate doses, **psyllium**, a mucilaginous herb available in bulk-forming laxatives like Metamucil, absorbs fluid and makes patients feel as if they have eaten enough. Red peppers and mustard help patients lose weight more quickly by accelerating the metabolic rate. They also make people more thirsty, so they crave water instead of food. Walnuts contain serotonin, the brain chemical that tells the body it has eaten enough. **Dandelion** (*Taraxacum officinale*) can raise metabolism and counter a desire for sugary foods.

The amino acid 5-hydroxytryptophan, or **5-HTP**, which is extracted from the seeds of the *Griffonia simplicifolia* plant, is thought to increase serotonin levels in the brain. Serotonin is a neurotransmitter, or brain chemical, that regulates mood and thus can be linked to mood-related eating behaviors. When physical and mental **stress** reduces serotonin levels in the body, 5-HTP may be helpful in regulating mood by boosting serotonin levels. Individuals should consult with their healthcare professional before taking 5-HTP, as the amino acid may interact with other medications and can have potentially serious side effects.

Acupressure and **acupuncture** can also suppress food cravings. Visualization and **meditation** can create and reinforce a positive self-image that enhances the patient's determination to lose weight. By improving physical strength, mental concentration, and emotional serenity, **yoga** can provide the same benefits. Also, patients who play soft, slow music during meals often find that they eat less food but enjoy it more.

Eating the correct ratio of protein, carbohydrates, and good-quality fats can help in weight loss via enhancement of metabolism. Support groups and self-help groups such as Overeaters Anonymous and TOPS (Taking Off Pounds Sensibly) that are informed about healthy, nutritious, and balanced diets can offer an individual the support he or she needs to maintain this type of eating regimen.

Allopathic treatment

For individuals who are severely obese, dietary changes and behavior modification may be accompanied by surgery to reduce or bypass portions of the stomach or small intestine. The risks of obesity surgery have declined in recent years, but it is still only

performed on patients for whom other strategies have failed and whose obesity seriously threatens their health. Other surgical procedures are not recommended, including liposuction, a purely cosmetic procedure in which a suction device is used to remove fat from beneath the skin, and jaw wiring, which can damage gums and teeth and cause painful **muscle spasms**.

A newer approach to weight loss is the development of functional foods, which are food products that incorporate natural compounds shown to help in weight loss programs. These compounds include carbohydrates with a low glycemic index, which help to suppress appetite; **green tea** extract, which increases the body's energy expenditure; and **chromium**, which encourages the body to burn stored fat rather than lean muscle tissue. Functional food products are currently undergoing clinical testing.

Appetite suppressant drugs are sometimes prescribed to aid in weight loss. These drugs work by increasing levels of serotonin or catecholamine, which are brain chemicals that control moods and feelings of fullness. Appetite suppressants, though, are not considered truly effective, since most of the weight lost while taking them is usually regained after stopping. Also, suppressants containing amphetamines can be potentially abused by patients. While most of the immediate side effects of these drugs are harmless, the long-term effects in many cases, are unknown. Two drugs, dexfenfluramine hydrochloride (Redux) and fenfluramine (Pondimin) as well as a combination fenfluramine-phentermine (Fen/Phen) drug, were taken off the market when they were shown to cause potentially fatal heart defects. In 1999, the United States Food and Drug Administration (FDA) approved a new prescription weight loss drug, Orlistat. Unlike other anti-obesity drugs that act as appetite suppressants, Orlistat encourages weight loss by inhibiting the body's ability to absorb dietary fat. The drug can cause side effects of abdominal cramping, **gas**, and **diarrhea**.

Other weight-loss medications available with a doctor's prescription include:

- Sibutramine (Meridia)
- Diethylpropion (Tenuate, Tenuate Dospan)
- Mazindol (Mazanor, Sanorex)
- Phendimetrazine (Bontril, Prelu-2)
- Phentermine (Adipex-P, Fastin, Ionamin, Oby-Cap)

Phenylpropanolamine (Acutrim, Dextarim) is the only nonprescription weight-loss drug approved by the FDA. These over-the-counter diet aids can boost weight loss by 5%. Combined with diet and exercise and used only with a doctor's approval, prescription anti-obesity medications enable some patients to lose 10% more weight than they otherwise would. Most patients regain lost weight after discontinuing use of either prescription medications or nonprescription weight-loss products.

Prescription medications or over-the-counter weight loss products can cause:

- constipation
- dry mouth
- headache
- irritability
- nausea
- nervousness
- sweating

None of the weight loss drugs should be used by patients taking monoamine oxidate inhibitors (MAO inhibitors).

Doctors sometimes prescribe fluoxetine (Prozac), an antidepressant that can increase weight loss by about 10%. Weight loss may be temporary and side effects of this medication include diarrhea, **fatigue**, **insomnia**, **nausea**, and thirst. Weight loss drugs currently being developed or tested include ones that can prevent fat absorption or digestion, reduce the desire for food and prompt the body to burn calories more quickly, and regulate the activity of substances that control eating habits and stimulate overeating.

Expected results

As many as 85% of dieters who do not exercise on a regular basis regain their lost weight within two years. In five years, the figure rises to 90%. Repeatedly losing and regaining weight (yo-yo dieting) encourages the body to store fat and may increase a patient's risk of developing heart disease. The primary factor in achieving and maintaining weight loss is a lifelong commitment to regular exercise and sensible eating habits.

Prevention

Obesity experts suggest that a key to preventing excess weight gain is monitoring fat consumption rather than counting calories, and the National **Cholesterol** Education Program maintains that only 30% of calories should be derived from fat. Only one-third of those calories should be contained in saturated fats (the kind of fat found in high concentrations in meat, poultry, and dairy products). Because most people eat more than they think they do, keeping a detailed food

diary is a useful way to assess eating habits. Eating three balanced, moderate-portion meals a day—with the main meal at mid-day—is a more effective way to prevent obesity than **fasting** or crash diets. Exercise increases the metabolic rate by creating muscle, which burns more calories than fat. When regular exercise is combined with regular, healthful meals, calories continue to burn at an accelerated rate for several hours. Finally, encouraging healthful habits in children is a key to preventing childhood obesity and the health problems that follow in adulthood.

New directions in obesity treatment

The rapid rise in the incidence of obesity in the United States since 1990 has prompted researchers to look for new treatments. One approach involves the application of antidiabetes drugs to the treatment of obesity. Metformin (Glucophage), a drug that was approved by the Food and Dug Administration (FDA) in 1994 for the treatment of type 2 diabetes, shows promise in treating obesity associated with **insulin resistance**.

Another field of obesity research is the study of hormones, particularly leptin, which is produced by fat cells in the body, and ghrelin, which is secreted by cells in the lining of the stomach. Both hormones are known to affect appetite and the body's energy balance. Leptin is also related to reproductive function, while ghrelin stimulates the pituitary gland to release growth hormone. Further studies of these two hormones may lead to the development of new medications to control appetite and food intake.

A third approach to obesity treatment involves research into the social factors that encourage or reinforce weight gain in humans. Researchers are looking at such issues as the advertising and marketing of food products; media stereotypes of obesity; the development of eating disorders in adolescents and adults; and similar questions.

Obsessive-compulsive disorder

Definition

Obsessive-compulsive disorder (OCD) is a type of **anxiety** disorder characterized by distressing repetitive thoughts, impulses, or images that are intense, frightening, absurd, or unusual. These thoughts are followed by ritualized actions that are usually bizarre and irrational. These ritual actions, known as compulsions, help reduce anxiety caused by the individual's obsessive thoughts. Often described as the "disease of doubt," the sufferer usually knows the obsessive thoughts and compulsions are irrational but, on another level, fears they may be true.

Description

Almost one out of every 40 people will suffer from obsessive-compulsive disorder at some time in their lives. The condition is two to three times more common than either **schizophrenia** or manic **depression**, and strikes men and women of every ethnic group, age, and social level. Because the symptoms are so distressing, sufferers often hide their fears and rituals but cannot avoid acting on them. OCD sufferers are often unable to decide if their fears are realistic and need to be acted upon.

Most people with obsessive-compulsive disorder have both obsessions and compulsions, but occasionally a person will have just one or the other. The degree to which this condition can interfere with daily living also varies. Some people are barely bothered, while others find the obsessions and compulsions to be profoundly traumatic and spend a great deal of time each day in compulsive actions.

Obsessions are intrusive, irrational thoughts that keep popping up in a person's mind, such as, "My hands are dirty, I must wash them again." Typical obsessions include fears of dirt, germs, contamination, and violent or aggressive impulses. Other obsessions include feeling responsible for others' safety, or an irrational fear of hitting a pedestrian with a car. Additional obsessions may involve intrusive sexual thoughts. The patient may fear acting out the strong sexual thoughts in a hostile way. People with obsessive-compulsive disorder may have an intense preoccupation with order and symmetry, or be unable to throw anything out.

Compulsions usually involve repetitive rituals such as excessive washing (especially handwashing or bathing), cleaning, checking and touching, counting, arranging, or hoarding. As the person performs these acts, he may feel temporarily better, but there is no long lasting sense of satisfaction or completion after the act is performed. Often, a person with obsessive-compulsive disorder believes that if the ritual isn't performed, something dreadful will happen. While these compulsions may temporarily ease **stress**, short-term comfort is purchased at a heavy price–time spent repeating compulsive actions and a long-term interference with life.

The difference between OCD and other compulsive behavior is that while people who have problems with gambling, overeating, or **substance abuse** may appear to be compulsive, these activities also provide pleasure to some degree. The compulsions of OCD, on the other hand, are never pleasurable.

KEY TERMS

Anxiety disorder—This is the experience of prolonged, excessive worry about circumstances in one's life. It disrupts daily life.

Cognitive-behavior therapy—A form of psychotherapy that seeks to modify behavior by manipulating the environment to change the patient's response.

Compulsion—A rigid behavior that is repeated over and over each day.

Obsession—A recurring, distressing idea, thought, or impulse that feels "foreign" or alien to the individual.

Scrupulosity—A spiritual disorder characterized by perfectionism and obsessive fears of God's punishment. Some patients with OCD also develop religious scrupulosity.

Selective serotonin reuptake inhibitors (SSRIs)—A class of antidepressants that work by blocking the reabsorption of serotonin in brain cells, raising the level of the chemical in the brain. SSRIs include Prozac, Zoloft, Luvex, and Paxil.

Serotonin—One of three major neurotransmitters found in the brain that is related to emotion, and is linked to the development of depression and obsessive-compulsive disorder.

OCD may be related to some other conditions, such as the continual urge to pull out body hair (trichotillomania); fear of having a serious disease (hypochondriasis), or preoccupation with imagined defects in personal appearance disorder (body dysmorphic disorder). Some people with OCD also have **Tourette syndrome**, a condition featuring tics and unwanted vocalizations (such as swearing). OCD is often linked with depression and other anxiety disorders.

Causes and symptoms

The tendency to develop obsessive-compulsive disorder appears to be inherited. In the summer of 2002, researchers at the University of Michigan identified a segment of human chromosome 9p as containing genes for susceptibility to OCD. Other chromosomes that may also be linked to OCD are 19q and 6p.

There are several theories behind the cause of OCD. Some experts believe that OCD is related to a chemical imbalance within the brain that causes a communication problem between the front part of the brain (frontal lobe) and deeper parts of the brain responsible for the repetitive behavior. Research has shown that the orbital cortex located on the underside of the brain's frontal lobe is overactive in OCD patients. This may be one reason for the feeling of alarm that pushes the patient into compulsive, repetitive actions. The higher-than-average rate of concurrent eating disorders in patients diagnosed with OCD has been attributed to the fact that hyperactivity in the orbital cortex is associated with both disorders. It is possible that people with OCD experience overactivity deep within the brain that causes the cells to get "stuck," much like a jammed transmission in a car damages the gears. This could lead to the development of rigid thinking and repetitive movements common to the disorder. The fact that drugs which boost the levels of serotonin (a brain chemical linked to emotion) in the brain can reduce OCD symptoms may indicate that to some degree OCD is related to brain serotonin levels.

Recently, scientists have identified an intriguing link between childhood episodes of **strep throat** and the development of OCD. It appears that in some vulnerable children, strep antibodies attack a certain part of the brain. Antibodies are cells that the body produces to fight specific diseases. That attack results in the development of excessive washing or germ **phobias**. A phobia is a strong but irrational fear. In this instance the phobia is fear of disease germs present on commonly handled objects. These symptoms would normally disappear over time, but some children who have repeated **infections** may develop full-blown OCD. Treatment with antibiotics has resulted in lessening of the OCD symptoms in some of these children.

If one person in a family has obsessive-compulsive disorder, there is a 25% chance that another immediate family member has the condition. It also appears that stress and psychological factors may worsen symptoms, which usually begin during adolescence or early adulthood.

Some studies indicate that the nature of parent-child interactions is an important factor in the development of OCD. Observers have often remarked that parents and children in OCD families can be differentiated from members of other types of families on the basis of behavior. One Australian study described the parents of children with OCD as "...less confident in their child's ability, less rewarding of independence, and less likely to use positive problem solving."

OCD has also sometimes been linked to religion, in that the symptoms of some persons diagnosed with OCD reflect religious beliefs or practices. Christian clergy have been trained since the Middle Ages to recognize a specific spiritual problem known as scrupulosity, in which a person is troubled by excessive fears of God's punishment or fears of having sinned and offended God. A new inventory for measuring scrupulosity in devout Jews as well as Protestants and Catholics has been tested at the University of Pennsylvania and appears to be a reliable instrument for evaluating OCD symptoms that take religious forms. Scrupulosity has been traditionally treated in both Judaism and Christianity by consultation with a rabbi, priest, or pastor who is able to correct the distorted beliefs that underlie the obsessions or compulsions. In some cases the clergyperson may also use an appropriate religious ritual in treating scrupulosity.

Diagnosis

People with obsessive-compulsive disorder feel ashamed of their problem and often try to hide their symptoms. They may avoid seeking treatment. Because they can be very good at keeping their problem from friends and family, many sufferers do not get the help they need until the behaviors are deeply ingrained habits and harder to change. As a result, the condition is often misdiagnosed or underdiagnosed. All too often, it can take more than a decade between the onset of symptoms and proper diagnosis and treatment.

While scientists seem to agree that OCD is related to a disruption in serotonin levels, there is no blood test for the condition. Instead, doctors diagnose OCD after evaluating a person's symptoms and history.

Treatment

Because OCD sometimes responds to selective serotonin reuptake inhibitors (SSRI) antidepressants, herbalists believe a **botanical medicine** called **St. John's wort** (*Hypericum perforatum*) might have some beneficial effect as well. Known popularly as "Nature's Prozac," St. John's wort is prescribed by herbalists for the treatment of anxiety and depression. They believe that this herb affects brain levels of serotonin in the same way that SSRI antidepressants do. Herbalists recommend a dose of 300 mg, three times per day. In about one out of 400 people, St. John's wort (like Prozac) may initially increase the level of anxiety. Homeopathic constitutional therapy can help rebalance the patient's mental, emotional, and physical well-being, allowing the behaviors of OCD to abate over time.

Other alternative treatments for OCD are intended to lower the patient's anxiety level; some are thought to diminish the compulsions themselves. Alternative recommendations include the following:

- Bach flower remedies: White chestnut, for obsessive thoughts and repetitive thinking.
- Traditional Chinese medicine: a mixture of bupleurum and dong quai, to strengthen the spleen and regulate the liver. In Chinese medicine, obsessive-compulsive disorder is due to liver stagnation and a weak spleen.
- Aromatherapy: a mixture of lavender, rosemary, and valerian for relaxation.
- Yoga: Yogis in India developed a special technique of yogic breathing specifically for OCD. The specific yogic technique for treating OCD requires blocking the right nostril with the tip of the thumb; slow deep inspiration through the left nostril; holding the breath; and slow complete expiration through the left nostril. This is followed by a long breath-holding out period.
- Schuessler tissue salts: for OCD, 10 tablets of *Ferrum phosphorica* 30X and 10 tablets of *Kali phosphorica* 200X, twice daily.
- Massage therapy: with special emphasis on loosening the muscles in the neck, back, and shoulders.

Cognitive-behavioral therapy (CBT) teaches patients how to confront their fears and obsessive thoughts by making the effort to endure or wait out the activities that usually cause anxiety without compulsively performing the calming rituals. Eventually their anxiety decreases. People who are able to alter their thought patterns in this way can lessen their preoccupation with the compulsive rituals. At the same time, the patient is encouraged to refocus attention elsewhere, such as on a hobby.

Allopathic treatment

Obsessive-compulsive disorder can be effectively treated by a combination of cognitive-behavioral therapy and medication that regulates the brain's serotonin levels. Drugs that are approved to treat obsessive-compulsive disorder include fluoxetine (Prozac), fluvoxamine (Luvox), paroxetine (Paxil), and sertraline (Zoloft), all SSRIs that affect the level of serotonin in the brain. Drugs should be taken for at least 12 weeks before deciding whether or not they are effective.

In a few severe cases where patients have not responded to medication or **behavioral therapy**, brain surgery may be attempted to relieve symptoms. Surgery can help up to a third of patients with the most severe form of OCD. The most common operation involves removing a section of the brain called the cingulate cortex. The serious side effects of this surgery for some patients include seizures, personality changes, and decreased ability to plan.

Expected results

Obsessive-compulsive disorder is a chronic disease that, if untreated, can last for decades, fluctuating from mild to severe and worsening with age. When treated by a combination of drugs and behavioral therapy, some patients go into complete remission. Unfortunately, not all patients have such a good response. About 20% of people cannot find relief with either drugs or behavioral therapy. Hospitalization may be required in some cases.

Omega–3 fatty acids

Description

Omega-3 fatty acids are one of two groups of fatty acids—the omega-3s and the omega-6s—that are vital to human life. The omega-3 fatty acids get their name from the fact that the molecules of which they are made contain a double bond attached to the number 3 carbon atom, counting from the end of the molecule opposite the carboxyl group, the so-called omega end of the molecule. (This system of nomenclature is just the reverse of the one used by chemists.) The omega-3 fatty acids are called **essential fatty acids** (EFAs) because the body is unable to make them, but they are essential for normal growth and development. These fats must be supplied by diet. People living in industrialized western countries eat up to 30 times more omega-6 than omega-3 fatty acids, resulting in a relative deficiency of omega-3 fats. Omega-6 metabolic products (inflammatory prostaglandins, thromboxanes, and leukotrienes) are formed in excessive amounts causing allergic and inflammatory disorders

Sources of omega 3 fatty acids

- Beans, navy or kidney
- Canola oil
- Fish, fatty
  - Albacore tuna
  - Anchovies
  - Herring
  - Lake trout
  - Mackerel
  - Salmon
  - Sardines
- Flaxseed (ground) and flaxseed oil
- Hemp seed/hemp nut (ground) and hemp oil
- Olive oil
- Soybeans and soybean oil
- Tofu
- Walnuts
- Winter squash

(Illustration by Corey Light. Cengage Learning, Gale)

and making the body more prone to heart attacks, strokes, and **cancer**. Eating foods rich in omega-3 acids or taking **fish oil** supplements can restore the balance between the two fatty acids and can possibly reverse these disease processes.

General use

Heart disease and stroke

The American Heart Association (AHA) has endorsed omega-3 fatty acids as good for the heart. The omega-3 oils increase the concentrations of good **cholesterol** (high density lipoproteins, HDL) while decreasing the concentrations of bad cholesterol (low-density lipoproteins, LDL) and triglycerides. In addition, eating omega-3-rich food results in a moderate decrease in total cholesterol level. In one study of 38 women, **flaxseed** flour, which contains high amounts of omega-3 fatty acids, decreased total cholesterol level by 6.9% and LDL cholesterol by 14.7%. In addition, lipoprotein(a), which is associated with heart attacks in older women, decreased by almost 10%. Thus, omega-3 fatty acids are natural alternatives to estrogen in prevention of heart attacks in postmenopausal women.

Furthermore, omega-3 oils protect the heart by preventing **blood clots** or keeping other fats from injuring the arterial walls. They relax arteries and help to decrease constriction of arteries and thickening of blood.

Hundreds of studies have shown that **diets** rich in omega-3 fatty acids decrease risk of heart attacks, strokes, and abnormal heart rhythms. Eskimos, who eat a lot of cold-water fish, have low rates of heart attacks and strokes perhaps because they have thinner blood, high HDL to LDL cholesterol ratio, and less buildup of fatty deposits (plaques) in the arteries. A number of clinical trials have shown that regular consumption of fish or fish-oil supplements can prevent sudden deaths due to abnormal heart rhythms. In the Diet and Reinfarction Trial (DART) of 2,033 men who previously suffered a **heart attack**, men who ate two to three servings of fatty fish a week had their risk of sudden cardiac death lowered by 29% compared to those who had a low fat or high fiber diet. In the Physician's Health Study of 20,551 doctors, a 52% reduction in risk of heart attacks was observed in those who ate at least one fish meal per week compared with those who ate fish once a month or less.

Mild hypertension

Several studies have shown that eating 200 g of fatty fish or taking six to 10 capsules of fish oil daily will lower blood pressure (BP). Therefore, omega-3 can benefit patients with borderline high blood pressure. Omega-3 oils also effectively prevent **hypertension** in cardiac patients after transplantation.

Supplement for newborns and babies

Omega-3 fatty acids are essential for normal development of vision and brain function, especially in newborns and children. Very low birth weight preterm infants often have poor vision and motor skills, possibly because they receive less than one-third of the amount of omega-3 fatty acids outside the mother's womb that they would have received as a fetus. Human breast milk contains the appropriate amount of omega-3 and -6 fats and is believed best for babies. If mother's milk is unavailable, formulas with soybean oil that provide higher amounts of omega-3 fatty acids are more beneficial than those made from cow's milk. Even full-term babies benefit from the addition of essential fatty acids to cow-milk formulas. Studies have shown that babies given formulas supplemented with EFAs have better vision and score higher in skills and problem-solving tests compared to babies on formulas that do not contain additional EFAs.

Rheumatoid arthritis

Because omega-3 fatty acids inhibit the action of inflammatory prostaglandins and leukotrienes, they can help control arthritis symptoms. Significant reduction in the number of tender joints and morning stiffness, as well as an increase in grip strength, have been observed in patients taking fish oil capsules. Studies have shown that patients taking fish oil supplements for **rheumatoid arthritis** require fewer **pain** medications; some are able to discontinue their nonsteroidal anti-inflammatory treatment. Despite the beneficial effects of omega-3 fats, regular antirheumatic drugs and nonsteroidal anti-inflammatory medications most likely still are required to control this chronic condition.

Diabetes

Some studies in laboratories have indicated that omega-3 fatty acids in fish oils might prolong life in people with autoimmune disorders such as diabetes. One study looked at substituting fish oil for corn oil in diets and found a tendency to suppress immune system dysfunction and prolong life. As of 2008, more studies were required to prove the diet's benefits in humans.

Inflammatory bowel disease

High-dose fish-oil supplements have been shown to decrease abdominal cramping, **diarrhea**, and pain associated with **Crohn's disease**. In one study of 96

patients, patients who received 4.5 g of omega-3 fatty acids (15 fish oil capsules) required significantly less steroids to control symptoms. In another study of 78 Crohn's disease patients, 59% of patients who received nine fish oil capsules (2.7 g of omega-3 fatty acids) daily did not have any disease flare-ups for at least one year compared to 26% recurrence rate in patients who were not given fish oil. Omega-3 fatty acids also are effective in preventing reappearance of Crohn's disease after surgery to remove sections of diseased bowel. In a clinical trial involving 50 patients, patients who received 2.7 grams of omega-3 fats as fish oil cut their rate of disease reappearance in half compared to patients receiving placebo. However, the effectiveness of omega-3 oils varies depending on the type of omega-3 oils being used, length of use, and the patient's diet.

Asthma

Taking high dose omega-3 fatty acids can reduce inflammation of the airways and reduce **asthma** attacks. According to Donald Rudin, the author of *Omega-3 Oils*, allergic disorders such as asthma may be triggered by too much omega-6 and too little omega-3 fats in the body. Excessive amounts of omega-6 prostaglandins cause the body to produce antibodies that cause allergic reactions. Flaxseed or fish oil supplements can keep the omega-6 fats in check and decrease the inflammatory reactions associated with asthma.

Berger's disease (Immunoglobulin A (IgA) nephropathy)

Omega-3 fats may be effective in treating this autoimmune disease in which kidney function fails over time with few treatment options available. In a large, randomized study of 150 patients, those who received 3 g of omega-3 fatty acids daily for two years had significantly less reduction in renal function than those treated with placebo. Therefore, omega-3 fatty acids appear to have protective effects and may stabilize renal function in these patients.

Raynaud's disease

There have been few studies evaluating the effects of omega-3 fatty acids in treating Raynaud's disease; however, it appears that fish oil supplements may alleviate some blood clotting disorders.

Mental disorders

According to some studies, many common mental disorders, such as **depression**, **bipolar disorder** (manic-depression), attention-deficit hyperactive disorder (ADHD), **anxiety**, or **schizophrenia**, may be triggered by deficiencies of omega-3 fatty acids and/or B vitamins. The rates of depression are low in countries where people eat a lot of fish, while the rate of depression steadily rises in the United States as Americans eat increasingly more processed food and less fresh fish and vegetables containing omega-3 fats. In one study, 53% of bipolar patients on placebo (olive oil) became ill again within four months, while none of the patients who were given 9.6 g daily of omega-3 fatty acids (as fish oil) did. Supplements containing omega-3 fats also reportedly have been effective in children with ADHD precipitated by essential fatty acid deficiencies. Furthermore, a 25% decrease in schizophrenic symptoms was observed in patients receiving eicosapentanoic acid (EPA), one of the omega-3 fatty acids contained in fish oil.

A report in 2001 revealed that omega-3 fatty acids may have effects on stabilizing mood and relieving depression. As studies continued in the early 2000s, researchers found it more and more evident that omega-3 fatty acids can be effective for treating depression, though they remained uncertain about exactly how they work. A 2003 report linked depression to increased risk of sudden cardiac death.

Acquired immunodeficiency syndrome (AIDS)

In a small study of 20 **AIDS** patients, those who received fish oil supplements at dosage of 10 g of omega-3 fatty acids per day for 30 days gained more weight (2.4 kg) and significantly lowered their concentrations of tumor necrosis factor, which is believed to cause wasting in AIDS patients, compared to those who did not.

Cancer prevention

Omega-3 fatty acids inhibit tumor growth when injected into animals. Flaxseed oil, which is a plant source of omega-3 fatty acids, has been shown to prevent cancer of the breast, colon, and prostate. The **Mediterranean diet**, which is heart healthy, also can decrease risk of getting cancer. Omega-3 fats, it seems, strengthen the immune systems and inhibit the inflammation and blood circulation of the tumors.

Preparations

As of 2008, the U.S. Food and **Nutrition** Board had not issued recommended daily allowance (RDA) for omega-3 fatty acids. However, it has established adequate intake (IA) levels for some of the more common omega-3 fatty acids, including alpha linolenic acid (ALA), eicosapentaenoic acid (EPA), and

docosahexaenoic acid (DHA). Those recommendations differ according to age and sex and for women who are pregnant or lactating. For men over the age of 14, the AI for ALA (the only omega-3 fatty acid for which an AI exists) is 1.6 grams per day; for women in the same age range, the AI for ALA is 1.1 grams per day.

The best way to achieve this dietary requirement is by eating fatty fish two or three times a week and/or eating vegetables and oils containing omega-3 fatty acids. Omega-3 fatty acids can be found naturally in the oil of cold-water fish, such as mackerel, salmon, sardines, anchovies, and tuna, or as extracted oils from plants, such as flaxseed, canola (rapeseed), or soybean. If fish oil supplement is preferred, then one to two capsules a day is sufficient. Each 1 g fish oil capsule typically contains 180 mg of EPA and 120 mg of DHA. **Vitamin E** is often contained in fish oil supplements to prevent spoilage and vitamin-E deficiency, which may occur with high dose fish-oil consumption. Patients should take supplements containing omega-3 fatty acids only under professional supervision to prevent an overdose, adverse reactions, or interactions with other medications. For treatment of diseases, flaxseed oil should be the first choice because it is the richest source of omega-3 fatty acids, relatively safe, and inexpensive.

Precautions

The safest and most effective way to get omega-3 fatty acids is through diets of at least three fish meals a week. Fish oil or flaxseed oil supplements should be taken only under a physician's supervision.

Although fish oils can be helpful in relieving arthritic symptoms, patients still may need anti-inflammatory medications to adequately control the disease.

Taking any medication during **pregnancy** is not recommended. Women who are pregnant or breast-feeding should talk to their doctor before taking fish oil supplements or any other medications.

Because of their blood thinning activity, aspirin, nonsteroidal anti-inflammatory drugs (NSAIDS), warfarin, or other anti-clotting medications should be used in conjunction with fish oil supplements only after consultation with a physician.

Side effects

Consuming excessive amounts of fish oil capsules can result in excessive bleeding, gastrointestinal distress, **anemia**, or strokes.

KEY TERMS

Essential fatty acid (EFA)—A fatty acid that the body requires but cannot make. It must be obtained from the diet. EFAs include omega-6 fatty acids found in primrose and safflower oils, and omega-3 fatty acids oils found in fatty fish and flaxseed, canola, soybean, and walnuts.

Prostaglandins—A group of hormone-like molecules that exert local effects on a variety of processes including fluid balance, blood flow, and gastrointestinal function. They may be responsible for the production of some types of pain and inflammation.

Interactions

Because of its blood-thinning activity, fish oil supplements may interact with aspirin, nonsteroidal anti-inflammatory drugs (NSAIDS), warfarin, or other anti-clotting medications to cause excessive bleeding.

Omega-6 fatty acids

Description

Omega-6 fatty acids are one of two groups of **essential fatty acids** (EFAs) that are required in human **nutrition**. The other EFA is the omega-3 fatty acid group. The omega-6 fatty acids get their name from the fact that the molecules of which they are made contain a double bond attached to the number 6 carbon atom, counting from the end of the molecule opposite the carboxyl group, the so-called omega end of the molecule. (This system of nomenclature is just the reverse of the one used by chemists.) Omega-6 fatty acids include **linoleic acid** and its derivatives. Chemically, linoleic acid is *cis*, *cis*-9,12-octadecadienoic acid. The term *essential* means that these fatty acids must be consumed in the diet because humans cannot manufacture them from other dietary fats or nutrients, nor can they be stored in the body. They must be consumed daily to meet the body's requirements. They are macronutrients, required in amounts of grams per day (compared to micronutrients such as vitamins, which are required in milligrams per day). EFAs provide energy, are components of nerve cells and cellular membranes, and are converted to hormone-like substances known as prostaglandins.

Sources of Omega 6-Fatty Acids

- Baked goods
- Brazil nuts
- Cereals
- Corn oil
- Cottonseed oil
- Eggs
- Hemp oil
- Meats from grass-fed animals
- Pecans
- Pine nuts
- Pumpkin oil
- Safflower oil
- Sesame oil
- Soybean oil
- Sunflower oil
- Sunflower seeds
- Wheat germ oil
- Whole grains

(Illustration by GGS Information Services. Cengage Learning, Gale)

In the body, prostaglandins and EFAs are necessary for normal physiology, including the following:

- producing steroids and synthesizing hormones
- regulating pressure in the eye, joints, and blood vessels
- mediating immune response
- regulating bodily secretions and their viscosity
- dilating or constricting blood vessels
- regulating collateral circulation
- directing endocrine hormones to their target cells
- regulating smooth muscles and autonomic reflexes
- being primary constituents of cell membranes
- regulating the rate of cell division
- maintaining the fluidity and rigidity of cellular membranes
- regulating the inflow and out-flux of substances into and out of cells
- transporting oxygen from red blood cells to the tissues
- maintaining proper kidney function and fluid balance
- keeping saturated fats mobile in the blood stream
- preventing blood cells from clumping together (conglomeration, which is the cause of atherosclerotic plaque and blood clots which can cause a stroke)
- mediating the release of inflammatory substances from cells that may trigger allergic conditions

- regulating nerve transmission and communication
- being the primary energy source for the heart muscle

Clinical trials have shown that EFAs protect against such conditions as **heart disease**; **cancer**; autoimmune diseases, including **rheumatoid arthritis** and **multiple sclerosis**; skin diseases, including **acne**, atopic **eczema**, and **psoriasis**; and may protect against **stroke**. The prevalence of heart disease in populations has been shown to be inversely proportional to the relative concentration of linoleic acid in the diet.

Both linoleic acid and its derivatives are obtained from plant and animal sources. Plant sources include unprocessed, unheated vegetable oils such as corn, sunflower seed, safflower, soy, sesame, and cottonseed oils. They are also found in plant materials such as evening primrose, black currant seeds, and gooseberry oils as well as in raw nuts and seeds, legumes, and leafy greens. Animal sources of omega-6 fatty acids (although in smaller amounts than in plants) are lean meats, organ meats, and breast milk.

Linoleic acid is an 18-carbon long polyunsaturated fatty acid containing two double bonds. Its first double bond occurs at the sixth carbon from the omega end, classifying it as omega-6 oil. As linoleic acid is absorbed and metabolized in the human body, it is converted into a derivative fatty acid, gamma linoleic acid (GLA), which is converted into dihomo-gamma linoleic acid (DGLA) and arachidonic acid (AA). The DGLA and AA are then converted into two types of prostaglandins by adding two carbon molecules and removing hydrogen molecules. There are three families of prostaglandins, PGE1, PGE2, and PGE3. DGLA is converted to PGE1, while AA is converted into PGE2. PGE3 is made by the conversion of **omega-3 fatty acids**. Both PGE1 and PGE3, anti-inflammatory agents, protect against coronary disease by keeping blood platelets slippery and flowing, thus preventing blood clotting. PGE2 has inflammatory effects and increases platelet stickiness and blood clotting. All three forms of prostaglandin must be present to ensure a functioning clotting system. There must be enough PGE2 to ensure healthy clotting, but enough PGE1 and PGE3 to protect against too much clotting, which can lead to hardening of the arteries, **heart attack**, and stroke. Likewise, PGE1 appears to act as a diuretic, whereas PGE2 aids in the retention of water and salts in the kidneys. PGE2 also is required for healthy brain and synapse functioning. The three types of prostaglandins serve as a system of checks and balances within the body.

However, if AA and its derivative, PGE2, are overproduced or imbalanced with PGE1 and PGE3, they can cause illness or disease. The over-consumption of land-based meats and the under-consumption of cold-water fish and unprocessed oils can lead to an over-production of inflammation-producing PGE2 and an under-production of anti-inflammatory agents PGE1 and PGE3. A healthy diet includes omega-6 fatty acids in a balance with omega-3 fatty acids. An optimal ratio is four parts omega-6 to one part omega-3. Ratios of healthy populations range from 2.5:1 in Inuit **diets** to 6:1 in other traditional diets.

Daily consumption of omega-6 fatty acids by many people may be excessive, due to the presence of omega-6 fatty acids in common cooking vegetable oils and processed foods. The ratio of omega-6 to omega-3 fatty acid consumption can reach 20:1. Achieve a more desirable ratio requires eliminating sources of omega-6 fatty acids, especially those hidden in processed foods, and increasing the amount of omega-3 fatty acids consumed through **fish oil** or **flaxseed** supplements. In addition, converting omega-6 fatty acids present in oils (such as corn, safflower, or soybean) to GLA requires that the oils be unprocessed and unheated and in the natural form (*cis* form). When oils undergo processing (heating and/or hydrogenation) to prolong shelf life or to form a solid at room temperature (e.g., shortening and margarine), the fatty acid structure is changed to the *trans* form, and the conversion process of omega-6 fatty acids to GLA may be inhibited.

General use

Most people receive sufficient amounts of omega-6 fatty acids in their diet. Deficiencies are rare and limited to people with severe malabsorption, short bowel syndrome, or extremely low-fat diets. For those who are unable to convert LA to GLA, dietary supplements containing GLA can be taken to increase the production of prostaglandins. Evening primrose, black currant, and **borage oil** all contain GLA. For individuals with diabetes, GLA supplementation can improve nerve function and help prevent diabetic nerve disease. Long-term exclusive or excessive use of flaxseed oil, which contains large amounts of omega-3 fatty acids, can result in omega-6 fatty acid deficiency and require the addition of oils containing omega-6 fatty acids to the diet.

Preparations

Omega-6 fatty acids may be consumed either as linoleic acid in oils that contain high levels of linoleic acid or in the converted form, GLA, in dietary supplements. Oils high in linoleic acid include soybean, peanut, corn, sunflower seed, cottonseed, soy, sesame,

KEY TERMS

Age-related macular degeneration (ARMD)—Degeneration of the macula (the central part of the retina where the rods and cones are most dense) that leads to loss of central vision in people over 60.

Atopic eczema—Inflammation of the skin caused by allergic reaction.

Multiple sclerosis (MS)—A progressive, autoimmune disease of the central nervous system characterized by damage to the myelin sheath that covers nerves. In most types, the disease, which causes progressive paralysis, is marked by periods of exacerbation and remission.

Omega-6 fatty acid—A fatty acid with its first double bond at the sixth carbon in its carbon chain.

and safflower. There is no official recommended daily dose for omega-6 fatty acids. The Food and Nutrition Board of the U.S. Department of Agriculture has, however, established recommended daily intakes of linoleic acid based on age and sex. Recommendations for pregnant and lactating women are also available. For males over the age of 19, the recommendation is for 17 grams per day; for females over the age of 19, the recommended intake is 11–12 grams per day, depending on age. Younger children, pregnant women, and women who are lactating generally need somewhat less linoleic acid than these levels.

For GLA supplementation, primrose oil, borage oil, and **black currant seed oil** are available in capsule form.

Precautions

Stress, alcohol consumption, and prescription medicines can interfere with the conversion of linoleic acid to its derivatives. Therefore, those with such conditions may benefit from the use of GLA supplementation to improve the production of prostaglandins. In addition, the use of unprocessed, unheated omega-6 oils in the cis form is recommended for improving prostaglandin production.

Side effects

Overconsumption of omega-6 oils in relation to consumption of omega-3 oils may lead to an overproduction of inflammation-producing prostaglandins (PGE2s) and a scarcity of anti-inflammatory prostaglandins (PGE1s and PGE2s), which may lead to a variety of health problems.

Linoleic acid appears to have at least one negative effect on the human body. It appears to increase a person's risk of developing age-related **macular degeneration** (ARMD), a disease of the eye that causes progressive loss of vision and eventual blindness.

Interactions

Nutrients essential for the use of omega-6 fatty acids in the body include **magnesium**, **selenium**, **zinc**, and vitamins A, carotene, B_3, B_6, C, and E.

Ophiopogon

Description

Ophiopogon is a perennial herbaceous plant that is native to the Orient. Under the name *mai men dong*, its tuberous root is a highly prized and indispensable part of Chinese herbal medicine. In addition, this

Ophiopogon. *(© Organica / Alamy)*

plant's graceful, grass-like leaves and tiny bell-shaped flowers have made it a popular landscaping ground cover. It is commonly known in the Western world as lily-turf or *Liriope spicata*, and is a member of the lily, or Liliaceae, family.

The tufted mounds that ophiopogon forms are usually about 1 ft (30cm) in height and diameter. On closer examination, the individual leaves of the plant resemble straps 0.25 in (0.6 cm) to almost 2 in (5 cm) in width and up to 16 in long (40.6 cm), depending upon the species. Ophiopogon leaves are evergreen and have a leathery appearance. *Ophiopogon japonicus* , the species most used in Oriental herbal medicine, has leaves with serrated edges. Subspecies of ophiopogon include several with a great variety of ornamental leaves, ranging from all-green to green with white, cream-colored or golden edges. The more decorative ophiopogon plants, such as *Liriope muscari* (blue lily-turf) or Christmas tree lily-turf, have larger **lavender**, blue-violet, or white bell-shaped flowers in clusters growing from upward-reaching spikes 4–6 in (approximately 10–15 cm) high. The flowers appear in mid-summer, and are followed by shining blackberry-like seeds that remain throughout the winter.

Ophiopogon grows best in warm climates, but is remarkably adaptable. There are species of this plant that grow and thrive in either full sun or full shade. Ophiopogon is able to tolerate a very wide variety of adverse conditions, including extreme heat, soil that is dry even to the point of drought, or high humidity. There are both erect and creeping types of ophiopogon. *Liriope spicata*, also known as *Ophiopogon japonicus*, is a creeping variety with fast-spreading, slender tuberous roots that can prove to be quite invasive. It forms a rhizome with smaller fibrous roots growing outward; the tuber itself has a bittersweet taste. *Ophiopogon japonicus* is also better able to tolerate cold than other varieties. All types of ophiopogon are propagated by division.

General use

Ophiopogon japonicus has long been used in Oriental herbal medicine. The earliest reference to its use is in the *Shennong Bencao Jing*, or *Herbal Classic of the Divine Plowman*. The oldest known edition of this classic was printed around A.D. 300. Ophiopogon is thought to be effective in clearing away what Chinese medical practitioners call "heat in the heart" and irritability. Ophiopogon is an antiseptic that is particularly useful in the healing of mouth sores. Its sedative qualities provide relief for **insomnia**, heart palpitations, **anxiety**, and restlessness. It is similar to the many chemical sedatives used in Western medicine in that it reduces muscle spasm.

Ophiopogon also moistens the mucous membranes of the body by stimulating the production of mucosal fluids. Moisturizing of the lungs reduces coughing. In the intestines, increasing the level of moisture improves elimination. Because of these qualities, ophiopogon is used in formulas to treat **constipation**, dry throat, and chronic dry bronchitis. Because ophiopogon has been shown to lower blood sugar and regenerates necessary cells in the pancreatic isles of Langerhans, it is also considered useful in treating the fluid imbalance caused by diabetes, as evidenced by excessive thirst and urination.

According to the United States Department of Agriculture phytochemical database developed at the Beltsville Agricultural Research Center in Maryland, the following varieties of ophiopogon all have medicinal uses:

- *Ophiopogon japonicus* is the species of this plant most commonly used in Oriental herbal medicine. It is useful in treating intestinal, kidney, and liver problems. It has been found to stimulate the production of milk in nursing mothers and to reduce inflammation. It has cough suppressing properties, and is used in treating nearly all lung-related illnesses, including bronchitis, whooping cough, tuberculosis, hemoptysis (coughing up blood), sore throat, laryngitis , and cough. A chemical present in the plant has shown effectiveness in the treatment of lung tumors. It is also used to treat fever, constipation, and stomach problems.
- *Ophiopogon ohwii* is used for its cough suppressant qualities. It is also an expectorant, a cardiac tonic, and an anti-inflammatory agent.

KEY TERMS

Aphrodisiac—A substance thought to stimulate erotic desire and enhance sexual performance. Aphrodisiacs are named for Aphrodite, the ancient Greek goddess of love.

Cardiac tonic—Any of a diverse group of remedies intended to relieve heart symptoms. Most tonics contain herbal extracts, vitamins, and minerals.

Diuretic—A group of medications that increase the amount of urine produced and relieve excess fluid buildup in body tissues. Diuretics may be used in treating high blood pressure, lung disease, premenstrual syndrome, and other conditions.

Galactogogue—A substance or medication that increases the flow of breast milk in nursing mothers.

Isles of Langerhans—Cellular masses of tissue in a space within the pancreas that secrete insulin.

Rhizome—The fleshy underground horizontal root of certain plants. Valerian preparations are made from dried rhizomes as well as from roots of the valerian plant.

Tuber—The thick, fleshy, underground stem of a plant.

- *Ophiopogon pendulus* has diuretic properties that are useful in reducing fluid retention in the body caused by either heart or kidney disease.
- *Ophiopogon spicatus* is considered an aphrodisiac, a treatment for digestive disturbance, and a galactogogue, or stimulator of lactation in nursing mothers.

Preparations

The slender, tuberous roots of ophiopogon are dug in summer, and the smaller, more fibrous roots are cut away. The rhizomes are dried in the sun, then pulverized and stored in a cool place in an airtight container. The usual daily dosage in Chinese herbal medicine is 4–10 g, when the plant is used in an infusion or decoction.

Precautions

It is important to remember that Chinese herbal medicine is based upon individual prescriptions developed for each patient and his or her unique symptoms. Chinese herbs should not be taken either individually or in combination formulas unless a practitioner of Chinese herbal medicine has been consulted.

It should also be remembered that coughing is a normal and helpful bodily reaction to irritation of the airway or lungs. It is designed to expel such harmful substances as excess phlegm or irritants from the lungs. **Cough** suppression can actually prevent or postpone recovery. It is persistent coughing that needs treatment. Moreover, a cough is merely a symptom of some other bodily illness, as are digestive problems. Therefore, ophiopogon preparations should not be taken for an extended period of time, and then only for dry, ticklish coughs. These preparations should only be used for temporary relief of symptoms. If the patient is bringing up a lot of phlegm, ophiopogon will make the cough worse. A physician should be consulted for persistent cough or gastrointestinal problems.

Side effects

Ophiopogon does not appear to produce serious side effects when used as directed.

Oregano essential oil

Description

Oregano (*origanum vulgare*)is a member of the Labiatae family (commonly referred to as the mint family). Its name is from the Greek word oreganos, which loosely translated means "joy of the mountains."

Native to Mediterranean regions, such as Greece and Crete, oregano is a perennial plant with an aromatic scent. With flowers that bloom from July to September, the plant is generally 2.5ft (75 cm) high

Oregano and oregano essential oil. *(© Arco Images / Alamy)*

and 2–3 ft (60–90 cm) wide. Its hairy, oval-shaped leaves are approximately 1.5 in (3.75 cm) in diameter and grow opposite of one another.

Oregano essential oil is produced from the oregano plant through the process of steam distillation. There are a variety of species referred to as oregano, but only a few qualify as high grade and are suitable for making oregano essential oil.

Oregano essential oil contains the following components:

- carvacrol (share 40–70%)
- gamma-terpinene (8–10%)
- p-cymene (5–10%)
- alpha-pinene
- myrcene
- thymol
- flavonoids
- caffeic acid derivatives

It should be noted that the *Physicians' Desk Reference for Herbal Medicines, Second Edition* also points out that there are various chemotypes with differing essential oil composition of thymol, linalool + terpinene-4-ol, linalool, caryophyllene + germacren D, or germacren D as chief components. However, those **strains**, especially ones high in thymol, are not suitable for preparing oregano essential oil intended for internal consumption. Some of these **essential oils** are toxic to the liver and kidney in very small quantities. However prudent, short term, topical use of these variants may be safe.

General use

Historically, Greek physicians used oregano essential oils for **wounds**, headaches, and venomous **bites** and even hemlock poisoning. It wasn't long before its medicinal benefits were used to treat lung conditions, **bronchitis**, sinusitis, and cold symptoms including **cough**. During the seventeenth century, it was heralded throughout Great Britain as an effective remedy for head colds. Used by physicians to induce **menstruation** as early as the nineteenth century, the benefits of using oregano essential oil have captured the interest of modern-day researchers.

Today, oregano essential oil has antiviral, antibacterial, antifungal, antiparasitic, and antiseptic properties. For external use, oregano essential oil is valued as a strong analgesic and antirheumatic agent. The diluted oil (usually 5 drops essential oil to 25 drops of carrier oil, like jojoba) can even be rubbed on a **toothache** to relieve **pain**. The oil is also believed to reduce the discomfort associated with insect bites. Its powerful antimicrobial properties are said to assist in the prevention of **infections** and to treat skin fungi such as **athlete's foot**. It has also been used to eliminate lice infestations and intestinal **worms**.

Oregano as a culinary spice became popular in the United States after World War II when the soldiers returned from Italy having developed a taste for pizza spiced with oregano. The problem is that medicinally speaking not all oregano is created equal. Growing conditions (soil, climate, rainfall, altitude) and harvesting and processing can produce variations in constituents and effects.

Having penned over ten books, Dr. Cass Ingram who is considered an expert on oregano essential oil, further explains the seriousness of mislabeled oregano oil in his book *The Cure is in the Cupboard*. He states that although many companies list products such as wild oregano or oil of oregano in their catalogues, "the problem is that the commercially available oil is almost exclusively **thyme** oil or marjoram oil," neither of which possesses the same medicinal properties as true oregano essential oil. Furthermore, Ingram states that thyme oil is usually made from a non-oregano plant, such as *Thymus capitus* from Spain, and even though it comes from an edible herb, thyme oil may be toxic. James A. Duke, Ph.D., a leading authority on healing herbs, agrees that thyme oil can be toxic; using it can lead to serious side effects and, in some cases, even cause death.

Therefore, it is critical when using oregano essential oil to be sure that its primary component is carvacrol and not thymol. As Ingram states, "true oregano

grows only under specific soil and climate conditions and cannot be reproduced in your backyard." Oregano essential oil should be made only from high-grade oregano that grows wild in the mountains of the Mediterranean. Ingram provides seven key factors to consider when determining if the oil has been derived from a high-grade oregano plant. He suggests that it should be: 1) a wild spice, not farm-raised, 2) from a proven edible species of oregano, 3) a species high in carvacrol, 4) a type used in modern research at prestigious institutions such as Georgetown University, 5) extracted in a natural process (steam distilled), 6) free of all chemical residues, and 7) relatively low in thymol (less than 5%).

Provided that the oregano essential oil being used is authentic and high grade, there is a great deal of scientific evidence to support its medicinal properties. Indeed, several studies have shown that oregano essential oil can inhibit or destroy many strains of bacteria, fungi, and parasites.

One ambiguous study, published in the *Journal of Applied Microbiology* in 1999, compared 52 plant oils and extracts. Oregano essential oil was found to have significant antibacterial action against a wide number of bacteria including E coli, Staph, Salmonella enterica, and Klebsiella pneumonie, which is a **pneumonia** that frequently occurs in people with a weakened immune system. The following year, the *Journal of Applied Microbiology* published a study by Scottish researchers that showed oregano essential oil to be effective against 25 different bacteria. Other studies, such as the one done by researchers at the University of Tennessee in 2001, also showed oregano essential oil to have powerful antibacterial properties.

Research published in the *International Journal of Food Microbiology* in 1988 found oil of oregano to be an excellent antifungal, completely inhibiting the growth of the nine fungi tested. Since that time, numerous research studies have been published that repeatedly show the ability of oregano essential oil to kill yeast, including Candida albicans. In 2002, oregano essential oil was put to the test in an interesting study by researchers in Yugoslavia and the results were published in *Nahrung*. Among the 13 fungi tested were **food poisoning**, plant, animal, and human pathogenic species. Oregano essential oil high in carvacrol possessed the best and broadest antifungal properties.

A small clinical trial published in 2000 examined the effects of oregano oil in adults with intestinal parasites. Of the 14 adult participants, 11 tested positive for the intestinal parasite, Blastocystis hominis, which is known to cause **diarrhea**, anal **itching**, and weight loss. The 11 test-positive participants took 600 mg of emulsified oregano essential oil daily for six weeks. Eight were completely free of the parasite and the remaining three participants had a reduction in parasitic presence and symptoms.

Preparations

Oregano essential oil should never be used undiluted. Always dilute it in a suitable carrier oil, such as olive oil, almond oil, or v-6 mixing oil. As with any product used for medicinal purposes, it is important to read and follow the label instructions and warnings.

A skin patch test should be conducted prior to using oregano essential oil for the first time. To do this, place a small amount of diluted essential oil on the inside of your elbow and apply a bandage. Wait 24 hours to see if there is any negative reaction, such as redness or irritation, before proceeding with more extensive use

Because oregano essential oil is concentrated, a little bit goes a long way. At first, it may be wise to start out cautiously by using only 1 drop of oregano essential oil to 3 parts olive oil and massage into the affected area once or twice a day.

To topically treat **fungal infections** on the skin and nails, Dr. Jennifer Brett, a naturopathic physician and chair of the **botanical medicine** department at the University of Bridgeport College of **Naturopathic Medicine** in Connecticut suggests the following: Dilute 1 teaspoon oregano essential oil in 2 teaspoons olive oil and apply with a cotton swab to the affected area up to three times a day.

To treat bacterial and fungal infections in other parts of the body, 1 drop of oil may be placed in an 8-ounce glass of water or juice once or twice a day. One drop may also be placed under the tongue twice a day, but it should be mixed with 1 teaspoon of honey, maple syrup, or olive oil.

For use in the bath, mix 1 to 3 drops of diluted oregano essential oil with body gel or shampoo and add it to the bath water. As an antiseptic, the diluted oil can be used in cloths to wipe down kitchen and bathroom countertops.

Precautions

Do not use oregano essential oil, either topically or internally, while pregnant.

Nursing mothers should avoid applying the oil to their nipples, because it can be difficult to wash off and may be ingested inadvertently by their infants. During the weaning process, nursing mothers wishing to use a

breast massage oil that contains oregano essential oil as a method to reduce milk production should do so with caution and be sure that all the oil is removed before breastfeeding. Because of safety issues regarding breast milk and infant care, nursing mothers should always obtain the approval of an obstetrician and/or pediatrician before using oregano essential oil either topically or internally.

Topically, oregano essential oil may be irritating to the skin, especially mucous membranes, and can cause burning. Therefore, it should always be suitably diluted, and according to Tisserand and Balacs, never applied topically to mucous membranes in concentrations greater than 1%. They also caution that people with damaged or very sensitive skin as well as children less than two years of age should not use the oil.

Special care should be taken when using oregano essential oil internally, because many of the commercially available products are erroneously labeled and are not made from high grade oregano. In fact, many contain dangerous levels of thymol. Some experts caution that oregano essential oil should never be taken internally, while others suggest that it is safe for internal use provided that it is suitably diluted and its source and contents are verified; it must be extracted from high grade oregano and meet seven strict requirements.

Internal use (swallowed or as a rectal suppository) should be highly restricted (ie, a few drops only of the pure essential oil per dose, and limiting duration of use to a few days to weeks) This is because essential oils represent highly concentrated extracts through distillation compared to the whole crude plant (essential oils have 100's of times more essential oil per drop due to purification, than does fresh or dried oregano herb) And although therapeutic in small, short term doses, these oils are toxic to liver, kidneys and the nervous system if taken in excess.

Always be sure to use true oregano essential oil (containing less than 5% thymol) and not thymol oil, which should never be taken internally and used topically only with extreme caution after being diluted in a suitable carrier oil.

People with any medical condition should use oregano essential oil only after consulting with a physician.

Side effects

The use of oregano essential oil can cause skin irritation, redness, and burning. If any of these negative side effects occur, discontinue use immediately.

When used either topically or internally to treat thrush, it has the potential to decrease a nursing mother's milk supply.

In low doses over a short period of time, oregano essential oil is considered generally safe. However, high doses may be toxic to the liver.

Interactions

In general, essential oils tend to be photosensitive. To avoid this interaction, stay away from direct sunlight or sun beds after applying oregano essential oil to prevent skin burn.

Do not apply oregano essential oil after perspiring; the combination of the oil and sweat could cause irritation.

Organic food

Definition

Organic foods are not specific foods, but are any foods that are grown and handled after harvesting in a particular way. In the United States, organic foods are crops that are raised without using synthetic pesticides, synthetic fertilizers, or sewage sludge fertilizer, and they have not been altered by genetic engineering. Organic animal products come from animals that have been fed 100% organic feed and raised without the use of growth hormones or antibiotics in an environment where they have access to the outdoors. Standards for organic foods vary from country to country. The requirements in Canada and Western Europe are similar to those in the United States. Many developing countries have no standards for certifying food as "organic."

Purpose

The organic food movement has the following goals:

- improve human health by decreasing the level of chemical toxins in food
- decrease the level of agricultural chemicals in the environment, especially in groundwater
- promote sustainable agriculture
- promote biodiversity
- promote genetic diversity among plants and animals by rejecting genetically modified organisms (GMOs)
- provide fresh, healthy, safe food at competitive prices

Pesticides in fruits and vegetables

Highest level	Lowest level
Peaches	Onions
Apples	Avocados
Sweet bell peppers	Corn, sweet, frozen
Celery	Pineapples
Nectarines	Mango
Strawberries	Peas, sweet, frozen
Cherries	Kiwi
Pears	Bananas
Grapes, imported	Cabbage
Spinach	Broccoli
Lettuce	Papaya
Potatoes	Blueberries

KEY TERMS

Biodiversity—The presence of many different species of plants and animals within a limited geographical region.

Pathogen—An organism that causes a disease.

Toxin—A general term for something that harms or poisons the body.

Description

Organic farming is the oldest method of farming. Before the 1940s, what is today called organic farming was the standard method of raising crops and animals. World War II accelerated research into new chemicals that could be used either in fighting the war or as replacements for resources that were in short supply because of their usefulness to the military. After the war ended, many of the new technological discoveries were applied to civilian uses and synthetic fertilizers, new insecticides, and herbicides became available. Fertilizers increased the yield per acre and pesticides encouraged the development of single-crop megafarms, resulting in the consolidation of agricultural land and the decline of the family farm.

Organic farming, although only a tiny part of American agriculture, originally offered a niche market for smaller, family-style farms. In the early 1980s this method of food production began to gain popularity, especially in California, Oregon, and Washington. The first commercial organic crops were vegetables that were usually sold locally at farmers' markets and health food stores.

By the late 1980s interest in organic food had reached a level of public awareness high enough that the United States Congress took action and passed the Organic Food Production Act of 1990. This act established the National Organic Standards Board (NOSB) under the United States Department of Agriculture (USDA). NOSB has developed regulations and enforcement procedures for the growing and handling of all agricultural products that are labeled "organic." These regulations went into effect on October 21, 2002.

Since the 1990s, the market for organic food has expanded from primarily fruits and vegetables to eggs, dairy products, meat, poultry, and commercially processed frozen and canned foods. In 2000, for the first time, more organic food was purchased in mainstream supermarkets than in specialty food outlets. By 2005, every state had some farmland that was certified

organic, and some supermarket chains had begun selling their own brand-name organic foods. The demand for organic food is expected to continue to grow rapidly through at least 2010.

Organic certification is voluntary and applies to anyone who sells more than $5,000 worth of organic produce annually. (This exempts most small farmers who sell organic produce from their own farm stands). If a product carries the USDA Organic Seal indicating that it is "certified organic" it must meet the following conditions:

- The product must be raised or produced under an Organic Systems Plan that demonstrates and documents that the food meets the standards for growing, harvesting, transporting, processing, and selling an organic product.
- The producer and/or processor are subject to audits and evaluations by agents certified to enforce organic standards.
- The grower must have distinct boundaries between organic crops and non-organic crops to prevent accidental contamination with forbidden substances through wind drift or water runoff.
- No forbidden substances can have been applied to the land organic food is raised on for three years prior to organic certification.
- Seed should be organic, when available, and never genetically altered through bioengineering.
- Good soil, crop, and animal management practices must be followed to prevent contamination of groundwater, contamination of the product by living pathogens, heavy metals, or forbidden chemicals, and to reduce soil erosion and environmental pollution.

To meet these requirements, organic farmers use natural fertilizers such as composted manure to add nutrients to the soil. They control pests by crop rotation and interplanting. Interplanting is growing several different species of plants in an alternating pattern in the same field to slow the spread of disease. Pest control is also achieved by using natural insect predators, traps, and physical barriers. If these methods do not control pests, organic farmers may apply certain non-synthetic pesticides made from substances that occur naturally in plants. Weed control is achieved by mulching, hand or mechanical weeding, the use of cover crops, and selective burning.

Animals products that are USDA certified organic must come from animals that are fed only organic feed, are not given growth hormones, antibiotics, or other drugs for the purpose of preventing disease, and have access to the outdoors. This last requirement is rather vague, as regulations set neither a minimum amount of time the animal must spend outdoors nor any minimums concerning the amount of outdoor space available per animal.

Selecting organic food

The USDA allows three label statements to help consumers determine if a food is organic.

- Labels stating "100% organic" indicate that all of the ingredients in the product are certified organic. These items have the USDA Organic Seal on the label.
- Labels stating "organic" indicate that at least 95% of the ingredients are certified organic. These items also carry the USDA Organic Seal on the label.
- Labels stating "made with organic ingredients" indicate that at least 70% of the ingredients are certified organic. These items are not permitted to have the USDA Organic Seal on the label.
- Items that contain fewer than 70% organic ingredients are not permitted to use either the word "organic" or the USDA Organic Seal on the label.

Consumers may be bewildered by other words on food labels such as "natural" or "grass-fed" that may be confused with organic. Natural and organic are not interchangeable. "Natural" foods are minimally processed foods but, they are not necessarily grown or raised under the strict conditions of organic foods. "Grass-fed" indicates that the livestock were fed natural forage ("grass"), but not necessarily in open pasture or for their entire lives.

Debate continues about the exact requirements to label animal products "cage-free," "free-range," or "open pasture." Cage-free simply means the animals were not kept caged, but does not necessarily mean that they were raised outdoors or allowed to roam freely. There is no certification process for the designation "cage-free." Animals can spend as little as five minutes per day outdoors and still be considered "free-range." Animal rights organizations are working to clarify these designations and improve the conditions under which all animals, are raised.

Organic food and health

Certified organic food requires more labor to produce, which generally makes it more expensive than non-certified food. Some consumers buy organic food primarily because the way it is raised benefits the environment. Others believe absolutely in the health benefits of organic food. A larger group of consumers are uncertain if organic food offers enough health benefits to justify the additional cost.

Discussions of the health benefits of organic food can become quite heated and emotional. Advocates of buying organic foods firmly believe that they are preserving their health by preventing their bodies from becoming receptacles for poisonous chemicals that can cause **cancer**, **asthma**, and other chronic diseases. Non-organic food buyers take the position that the level pesticide and fertilizer residue in non-organic food is small and harmless. Neither side is likely to change the other's view. However, below are some conclusions from studies done comparing organic and non-organic foods.

- The food supply in the United States, whether organic or non-organic, is extremely safe.
- Fresh organic and non-organic produce are equally likely to become contaminated with pathogens such as *E. coli* that cause health concerns.
- Many, but not all, chemical contaminants can be removed from non-organic food by peeling or thorough washing in cool running water.
- Organic foods are not 100% pesticide and chemical free. However, their chemical load appears to be lower than that of non-organic foods.
- The nutrient value of identical organic and non-organic foods is the same.
- The long-term effect on humans of trace amounts of hormones, antibiotics, and drugs found in milk, meat, and other non-organic animal products is unclear.
- The long-term effect of genetically modified foods on both humans and the environment cannot yet be known.

Precautions

Individuals should be informed about food labeling requirements and read food labels carefully so that they can make informed decisions about their purchases.

Interactions

Organic food does not interact with drugs or other foods in a way that is different from non-organic foods.

Complications

No complications are expected from eating organic food.

Parental concerns

Chemicals found in foods may have a greater effect on the growth and development of younger children than older ones. Young children are rapidly growing while still developing their nervous system, immune system, and other organs. Chemicals may have a greater effect on these developing tissues than on adult tissues.

Ornish diet

Definition

The Ornish diet was developed by Dean Ornish, M.D. Ornish was the first physician to demonstrate that **heart disease** can be reversed by natural methods, including specific dietary and lifestyle changes.

Origins

Dean Ornish, who was born in 1953, was a professor of clinical medicine at the University of California, San Francisco, and a practicing physician as of 2008. He received his Bachelor of Arts degree from the University of Texas, Austin, then attended Baylor College of Medicine and Harvard Medical School. He received further medical training at Massachusetts General Hospital. He is the founder and president of the Preventive Medicine Research Institute located in Sausalito, California.

While Ornish was a medical student he became interested in heart disease. In 1978 he began doing research on patients with coronary artery disease (a common form of heart disease). He created a diet that was very low in fat and completely vegetarian and studied its effects on the symptoms experienced by these patients. The patients also learned a variety of **stress** reduction techniques. He discovered that for many patients this diet caused a significant lessening of their symptoms. This was the beginning of his research on the effects of low fat, low or no-meat **diets** on weight loss, health, and heart disease.

It took Dr. Ornish several published studies before conventional medicine accepted his position that simple and inexpensive treatments, including diet, **exercise**, and stress reduction, could reverse heart disease. In a study begun in 1980, Ornish studied 48 people with severe heart disease. Half of them were assigned to a control group and were treated by conventional methods, while the other half participated for three weeks in Ornish's program of an ultra-low fat diet, **yoga**, **meditation**, social support groups, and no cigarettes. The diet that Ornish designed was similar to the regimen developed in the 1970s by Nathan Pritikin to combat heart disease, which continued to be used as of 2008 in several clinics. Both diets emphasize foods that are very low in fat and yet filling, including high-fiber grains and legumes (beans and peas).

Over the course of the study, Ornish's group experienced improvement in symptoms and significant drops in **cholesterol** and blood pressure. Dr. Ornish published the results in the prestigious *Journal of the American Medical Association*, and his study generated controversy. To convince his critics, Dr. Ornish set up a long-term controlled study. After one year, patients treated with Dr. Ornish's methods showed convincing results: 82% of them had significantly less blockage in their heart arteries and there was a drop of 91% in reported chest **pain**. After that study was published in the British medical journal *Lancet*, Dr. Ornish became internationally famous, and the Ornish diet was adopted by many heart disease patients.

Benefits

Because the Ornish diet includes almost only plant products, it is high in substances thought to promote health such as **antioxidants** and fiber, as well as low in substances that are harmful to the health such as fat and cholesterol. Following the diet's recommendation of light exercise can also be very beneficial. Walking 20 or 30 minutes a day instead of being completely sedentary has significant health benefits and may even reduce by half the chance of early death.

Although the Ornish diet is effective at causing weight loss and improved overall health, the most researched and discussed benefit of the program is the prevention and even reversal of heart disease. Dr. Ornish and colleagues have done extensive research showing that following a very strict, completely vegetarian form of his diet cannot only prevent heart disease from occurring or getting more severe, but it can actually cause a reverse of artery constriction allowing blood to flow to the heart better. Dr. Ornish also believes his diet may be effective at preventing or reversing other forms of disease such as **prostate cancer**.

Description

Heart disease develops when arteries that supply the heart with oxygen become narrowed due to the buildup of plaque on their walls. Plaque deposits are caused by cholesterol, a type of fat found in animal products and also made by the body from saturated fats in the diet. The narrowing of arteries is called **atherosclerosis**, a condition that develops over many years. When the coronary (heart) arteries become too blocked to supply the heart with enough oxygen, a **heart attack** occurs.

The first principle of the Ornish diet is to eliminate cholesterol, so all foods containing cholesterol and saturated fats are removed from the diet. Saturated fats are found in meat, dairy products, oils, nuts, seed, and avocados, which are all forbidden by the Ornish diet. Furthermore, the level of fat in the diet is reduced to only 10% of the total calories. This level is much lower

than the diet recommended by the American Heart Association, which recommends up to 30% of calories from fat. The typical American diet consists of up to 50% fat. The Ornish diet is vegetarian, since cholesterol-containing meats are eliminated. The diet allows the use of egg whites and nonfat dairy products; technically it can be classified as a lacto-ovo-vegetarian diet.

Another feature of the Ornish diet is the ratios assigned to fat, protein, and carbohydrates, respectively. The typical American diet is 45% fat, 25% protein, and 30% carbohydrates, with nearly 500 mg of cholesterol per day. The Ornish diet is 10% fat, 20% protein, and 70% carbohydrates. The Ornish diet consists mainly of complex carbohydrates, commonly called starches. Complex carbohydrates are present in fruits, vegetables, grains, and beans. Simple carbohydrates include sugar, honey, and alcohol, which tend to be "empty calories," because they contain lots of calories but little fiber or nutrients. The Ornish diet restricts but does not eliminate simple carbohydrates. The Ornish diet also emphasizes high-fiber foods, which includes most complex carbohydrates. High-fiber diets have been shown to reduce cholesterol and have other beneficial effects.

The Ornish diet is slightly lower in protein than the American average, and lower protein intake has been shown by research to have potential health benefits for Americans. For those worried about the lack of protein in a vegetarian diet, the Ornish program teaches ways to ensure an adequate supply of complete proteins in the diet. Proteins are said to be complete when the body can fully utilize them. They can be obtained by combining grains with legumes (beans) or grains with nonfat dairy products. For instance, complete proteins in the Ornish diet are obtained by combining rice and beans, tofu and rice, pasta and beans, baked beans and wheat bread, or oatmeal with nonfat yogurt over the course of a day. Egg whites are another source of protein on the Ornish diet.

Another principle of the Ornish diet is that people are allowed to eat as much food as they wish, as long as the 10%-of-calories-from-fat rule is maintained, and as long as only approved foods are eaten. By allowing people to eat as much as they like, the Ornish diet reduces the risk of binge eating, to which many dieters resort when forced to restrict calories. Many diets have been shown to fail when calories are restricted.

To summarize, the Ornish diet excludes cholesterol and saturated fat, excluding all animal products (except egg whites and nonfat dairy products), nuts, seeds, avocados, chocolate, olives, and coconuts. Oils are eliminated except a small amount of canola oil for cooking, and oil that supplies omega-3 **essential fatty acids**. The Ornish diet also prohibits **caffeine** but allows a moderate intake of alcohol, sugar, and salt.

It should be noted that Ornish himself states that his diet alone is not sufficient for reversing heart disease but is only one part of an overall program that includes exercise, yoga, meditation, stress reduction, and lifestyle changes. In fact, Ornish calls some of his work "opening the heart" therapies because patients are encouraged to confront emotional aspects of their healing as well as physical concerns such as diet and high cholesterol.

KEY TERMS

Atherosclerosis—A disease process whereby plaques of fatty substances are deposited inside arteries, reducing the inside diameter of the vessels and eventually causing damage to the tissues located beyond the site of the blockage.

Cholesterol—A steroid fat found in animal foods that is also produced in the human body from saturated fat. Cholesterol is used to form cell membranes and process hormones and vitamin D. High cholesterol levels contribute to the development of atherosclerosis.

Complete protein—A protein food that has all the essential amino acids the body requires to digest it.

Essential fatty acids—Fats that are essential to the diet because the body cannot make them. Omega-3 and omega-6 are the two major categories of essential fatty acids.

Plaque—A deposit, usually of fatty material, on the inside wall of a blood vessel. Also refers to a small, round demyelinated area that develops in the brain and spinal cord of an individual with multiple sclerosis.

Saturated fat—Fat that is usually solid at room temperature, found mainly in meat and dairy products but also in vegetable sources such as some nuts, seeds, and avocados.

Preparations

Anyone thinking of beginning a new diet should consult their physician. Requirements of calories, fat, and nutrients can differ significantly from person to person, depending on gender, age, weight, and many other factors such as the presence of any diseases or conditions. Pregnant or breastfeeding women should be especially cautious because deficiencies of vitamins or minerals can have a significant negative impact on a baby.

DEAN ORNISH (1953-)

Dr. Dean Ornish was born on July 16, 1953, in Dallas, TX. He attended Rice University and University of Texas at Austin, where he received his B.A. in 1975. He went on to graduate from Baylor College of Medicine in 1980 and completed his internship and residency at Massachusetts General Hospital and Harvard Medical School.

In 1989, Ornish began issuing data showing that the atherosclerotic patients he had been treating without drugs or invasive surgery had reduced the overall blockages in their arteries. That attention became international in 1990 with the issuance of the physician's best selling book, *Dr. Dean Ornish's Program for Reversing Heart Disease: The Only System Scientifically Proven to Reverse Heart Disease without Drugs or Surgery.*

Ornish provides readers with information to help them make the comprehensive lifestyle changes he advocates. Among the alterations Ornish recommends is the incorporation of stress management techniques such as meditation, imagery, breathing, and yoga exercises into their lives. Ornish also offers suggestions for healthier methods of coping with the emotional pain he believes everyone experiences in one form or another.

Although Ornish's lifestyle recommendations are similar to those advocated by most cardiologists, his prescription for health is much stricter. However, his research patients, all seriously ill at one time, have reduced their arterial blockages without the aid of pharmaceuticals or invasive surgical techniques.

Founder and president of the Preventive Medicine Research Institute of the University of California at San Francisco, Ornish believes there is a link between the causes of depression and heart disease and that bypasses and angioplasty only treat the symptoms, not the causes, of heart disease. Furthermore, he believes that having deeply intimate, loving relationships can be invaluable in preventing and treating heart disease.

Patients with heart disease should be especially careful when beginning a diet. Although Dr. Ornish has published data about how his diet may be able to prevent or reverse heart disease, everyone reacts differently and no major dietary changes should be made without consulting a physician. The Ornish diet is not a replacement for cholesterol-lowering drugs or any other medications prescribed by a doctor and is not a replacement for medically recommended procedures. It is important to discuss all possible options with a physician and make all decisions based on professional recommendations.

Ornish states that one emphasis of his program is increasing the awareness of eating habits and the ingredients of food products. Those beginning the Ornish diet can prepare by becoming thoroughly familiar with the Ornish list of recommended and prohibited foods and by learning to read food labels and count calories. Another preparation dieters can make is determining their ideal weight for their particular height and body type. Daily calorie and fat allowances can then be derived from this ideal weight. Ornish has authored or co-authored several books that provide hundreds of recipes consistent with the diet.

Precautions

The Ornish diet is not a substitute for medical care of cardiovascular disease. Furthermore, the Ornish diet is designed to be used in conjunction with a holistic health program that includes exercise, yoga, meditation, lifestyle changes, and stress reduction. As with any diet program, research continued as of 2008 on its effectiveness. Critics of the program maintain that Dr. Ornish has not produced sufficient clinical research to support his claims; they also assert that a diet high in carbohydrates drives up insulin levels, increasing the risk of diseases such as diabetes. A 2003 study comparing low-fat diets to low-carbohydrate diets reported that obese patients lost more weight on the low-carbohydrate diet compared to a fat and calorie-restricted diet. They also appeared to have lower triglyceride levels and improved insulin sensitivity.

The Ornish diet is very low in fat and limits meat and animal product intake to little or none. Many important vitamins and minerals such as **zinc** and vitamin B-12 are acquired from these sources in a normal diet. Without these sources there is a significant possibility of deficiency. Also, because of the very low fat allowance of the diet there is some concern that people on this diet may not get enough **vitamin E**, which is found mainly in nuts and oil. These are too high in fat to be eaten regularly while on this diet. Dr. Ornish often recommends taking supplements while following his diet, and taking a complete multivitamin may help reduce the risk of a deficiency. Multivitamins and supplements, however, have their own risks, especially for pregnant or breast-feeding women and individuals with medical issues such as renal disease.

Ortho-bionomy

Definition

Ortho-bionomy is a form of therapeutic bodywork, based on the principle that gentle and non-invasive body alignment has a positive influence on physical and emotional disorders.

Origins

Ortho-bionomy was developed in the 1970s by Dr. Arthur Lincoln Pauls, a British osteopathic physician who was also an accomplished martial artist. Pauls was influenced by the principles of **osteopathy** that state that the function of the body is related to its physical (skeletal) alignment; that proper circulation of the blood and lymph is crucial to health; and that the body contains built-in mechanisms that can be triggered to correct imbalances and diseases. Influenced also by Eastern philosophy, Dr. Pauls searched for a system of healing that was gentle, non-invasive, and that worked with the body's inherent wisdom, rather than using forceful methods to manipulate problems involving posture.

Dr. Pauls was guided toward his system of bodywork in the 1960s, when an American osteopath named Lawrence Jones published a paper on a phenomenon he called "Spontaneous Release Through Positioning." Jones claimed that **muscle spasms** and painful injuries can be treated by the gentle repositioning of the part of the body that was painful. For instance, if a person injures a knee, the muscles and tendons around that area tighten, sometimes to the point of **pain** and spasm. The tightening protects the knee from further injury. When the injury begins to heal, the muscles and tendons around the area retain the memory of the injury, and have changed in structure. This change affects the bones, joints, and overall alignment of the body. By gentle and comfortable repositioning of the area into its proper alignment, a therapist can prompt the muscles to self-correct, releasing tension and trauma while re-educating the body's memory of the injury, and speeding the healing process.

Dr. Pauls built upon this concept when developing Ortho-bionomy. Influenced by Eastern **martial arts**, Pauls built his idea on the premise that the physical body and the emotions are deeply connected. Pauls developed "Phased Reflex Techniques," which is based on the body healing itself in phases. In effect, there is a gradual release of the emotions and traumas that occur after physical injuries. Pauls also believed that reflex actions in the muscles play a key role in healing injuries, and that by utilizing knowledge of these reflexes the therapist can gently and effectively boost the body's ability to self-correct. These reflexes are contained in the proprioceptive nerves (nerves that are present in the muscles and tendons that provide feedback on the body's movement and alignment). These nerves are influenced by emotions, and they affect the movement of the body. Healing begins by re-educating these nerves toward correct alignment and movement. Emotions held inside are released. Pauls developed a detailed system of bodywork techniques based on these principles. For instance, he found that the greater the stored trauma around an

KEY TERMS

Osteopathy—System of health care that emphasizes the musculoskeletal system.

Reiki—Form of therapeutic bodywork that strives to heal the body's energy field.

injury, the longer the therapist must reposition the area to provide a full release of healing potential.

Dr. Pauls termed his system Ortho-bionomy, which means, "the correct application of the laws of life." In the mid-1970s, he began teaching his system in the United States and Europe.

Benefits

Ortho-bionomy is used to alleviate chronic pain associated with injuries, muscle and joint problems, and arthritis; reduce **stress**; increase circulation; enhance **relaxation**; and improve problems of posture or structural alignment. Its gentle technique is recommended for acute pain and rehabilitative injuries. Ortho-bionomy is incorporated into other healing treatments. For example, massage therapists may use this technique to relieve knotted muscles. Some of the techniques may be used to relieve cramps, back pain, sore muscles, and headaches.

Ortho-bionomy is safe for newborns, the elderly, and those in post-operative conditions. Athletes and dancers may improve performances with the therapy by increased balance and flexibility.

Description

A session with an Ortho-bionomy therapist is similar to other therapeutic massage sessions. The patient remains clothed. Emphasis is placed on comfort, and on a trusting and open relationship between patient and therapist. Open communication from the patient provides feedback and assists in the discovery and release of emotional issues. The therapist may use a range of hands-on techniques, including light touch, smooth movements, gentle pressure on reflex points, finding and working with points of tension and pain, gentle prolonged body-positioning for release, and re-education exercises. Therapeutic movements are done slowly and gently, so that they do not create additional stresses. Some therapists may employ non-physical touch, to work upon the energy field of the body, similar to the touch used in **reiki**. Generally, a series of treatments is recommended, as Ortho-bionomy is based on the idea that healing occurs in gradual phases. The goal of treatment is to ultimately increase the patient's awareness on the physical and emotional levels and—through this awareness—to promote re-education and elimination of unhealthy patterns.

Preparations

No special preparation is needed prior to Ortho-bionomy treatments.

Precautions

Consumers may check with a practitioner to determine the level of Ortho-bionomy training he or she has completed.

Side effects

There are no reported side effects of Ortho-bionomy. The therapy is gentle, painless, and non-invasive.

Research & general acceptance

Ortho-bionomy is done in countries around the world, indicating that it has grown in popularity since the early work of Dr. Pauls.

Training and certification

Ortho-bionomy is taught and practiced worldwide. Some **massage therapy** schools offer Ortho-bionomy as a specialty course in conjunction with general massage therapy. Ortho-bionomy is also done by other health practitioners including naturopathic and osteopathic physicians.

The Society of Ortho-bionomy International has developed two training programs for professionals, a basic practitioner program and a senior practitioner program. Both offer theoretical coursework and supervised hands-on training. Students choose individual advisors during their training. The Society's Web site has links to Ortho-bionomy practitioners in a number of states, as well as countries such as Australia and New Zealand.

Douglas Dupler

KEY TERMS

Pellagra—A condition caused by a dietary deficiency of niacin, one of the B vitamins. The patient will have dementia, diarrhea and dermatitis.

Titration—Gradually adjusting dosage of a supplement until the desired result is obtained, but no unwanted side effects appear.

Orthomolecular medicine

Definition

Orthomolecular medicine is the prevention and treatment of disease by administering nutritional supplements. The patient's state of health, external or environmental factors and quality of diet are taken into account. The architect of orthomolecular medicine, Nobel Prize laureate Linus Pauling, coined the term in 1968. The aim of orthomolecular medicine is not merely to eliminate disease, but to aim for "optimum health."

Origins

Linus Carl Pauling was born in 1901 in Portland, Oregon. He published his first scientific paper at the age of 22. In 1925, he graduated summa cum laude from the California Institute of Technology with a Ph.D. in chemistry. He was to remain at this institute for the next 38 years.

Though by no means the first to investigate the properties of the nutrients contained in foods, or the first to consider the medical application of nutritional supplements, his contribution to our understanding of how nutrients work in our bodies and how supplements can affect our health, has not been matched, either before or since. It was not until 1966, after a long and distinguished career, that he changed direction in response to a letter from Irwin Stone and began to research the properties of micronutrients.

In 1970, Pauling published *Vitamin C and the Common Cold* , which established **vitamin C** as a favorite and effective remedy for colds and flu. In 1973, he founded the Institute of Orthomolecular Medicine, a non-profit research organization, with Arthur B. Robinson and Keene Dimick. The institute later became the Linus Pauling Institute of Science and Medicine. In the years that followed, Pauling published many research papers and books detailing his findings in the field of orthomolecular medicine until his death in 1994.

As a result of Pauling's research, orthomolecular medicine has become a specialized branch of alternative medicine, and its realm of application has widened to include not only **cancer** and other diseases, but many mental illnesses, including schizophrenia.

Benefits

In summarizing their philosophy, practitioners of orthomolecular medicine cite Hippocrates's watchword which was "First, do no harm." With their policy of rectifying **nutrition** first and then administering supplements in treating disease, they feel that they already have an advantage over allopathic methods such as chemotherapy, drug therapy, surgery and radiotherapy, which orthomolecular practitioners believe have potentially disastrous effects on the human organism. Despite the fact that when taken in "mega-doses" nutritional supplements have been known to cause harm, they can have a significantly lower potential for toxicity than allopathic drugs.

Orthomolecular practitioners recommend that patients improve their lifestyle and eating habits to consolidate benefits felt from the supplements themselves. Many of their "discoveries" have now become more or less common knowledge, for example the fact that a combination of vitamin C and **zinc** can speed the departure of a virus—particularly a cold—by many days.

Orthomolecular medicine can be of benefit to anyone for a wide range of illnesses and symptoms.

Some illnesses which have been treated with orthomolecular medicine are:

- depression, anxiety, and schizophrenia
- Raynaud's disease, heart problems, and therosclerosis
- digestive disorders, irritable bowel syndrome, Crohn's disease, diverticulitis, obeisity, and endometriosis
- chronic fatigue syndrome
- heavy metal toxicity and radiation sickness
- osteoarthritis and rheumatoid arthritis

- infertility and other reproductive disorders
- high blood pressure
- asthma and other respiratory problems
- eczema and other skin disorders
- candidiasis
- cancer, AIDS, and other immune system problems
- neural tube defects in the fetus.

Description

The basic concept of orthomolecular medicine is that according to their genetic makeup, and other factors such as environment, stress levels, and levels of nutrition, individuals will have nutritional needs that are peculiar to themselves alone; no two people will be alike in this respect. Consequently, what will cause illness for one person, will produce good health in another.

Many degenerative diseases and even mental abnormalities are quite possibly the result of biochemical imbalances. Linus Pauling's research demonstrated that all illness and disease can be treated to some extent with nutritional supplements, such as vitamins, **amino acids**, trace minerals, electrolytes, and fatty acids.

Theoretically, fresh food that is of high quality should provide all the nutrients necessary for good health. However, the depletion of nutrients in soil result from over-use of pesticides and artificial fertilizers and intensive farming practices also means a gradual decline in the levels of nutrients in produce. Orthomolecular practitioners, therefore, recommend that laboratory tests should be conducted to assess nutritional status so that possible areas of insufficiency may be addressed with the use of supplements.

Orthomolecular psychiatric therapy

This is the treatment of diseases of the mind by providing optimum nutrients, thus enhancing the "chemistry of the brain." It has been found to be very effective in the treatment of mental illness, even schizophrenia.

For those in the allopathic medical profession who are sceptical, practitioners remind them that when nicotinic acid was introduced, it cured hundreds of thousands of pellagra patients of psychoses in addition to the physical symptoms of this disease. Vitamin C has been used successfully to treat some mental symptoms, in particular **depression**.

Many other micronutrients have been found to influence brain function, among them:

- thiamine
- pyridoxone
- folic acid
- tryptophan
- L(+)-glutamic acid
- cyanocobalamin

Preparations

Nutritional supplements are a growing business and can be obtained almost anywhere, even in the supermarket. It is advisable to obtain supplements from an establishment that specializes in this area, and to ensure that products are fresh and potent.

A reputable health store will have staff on hand to advise customers about what is suitable for them and how supplements should be taken.

Precautions

If taken incorrectly nutritional supplements can have a detrimental effect on the health. Some supplements can produce adverse effects when taken in combination with certain medications. Certain supplements also cause unwanted effects during **pregnancy**. Instructions should always be followed, and if in doubt, a nutritionally-oriented practitioner or a physician should be consulted. The U.S. Food and Drug Administration (FDA) has drawn up maximum and minimum recommended doses for the guidance of the public. However, orthomolecular practitioners point out that these levels are intended for normal healthy individuals and sometimes doses far in excess of the RDA (recommended daily allowance) are required to bring a sick person back to health.

In early 2002, the U.S. Pharmacopeial (USP) Convention announced that it would launch a voluntary dietary supplement verification program. Manufacturers of supplements can supply the USP with documentation that shows they have a quality standard system in place to address label accuracy, safety and efficacy of products. The USP then arranges for a quality audit to verify that good quality and safety practices are in place.

Patient should not try to prescribe their own supplements, but should instead consult a qualified practitioner for safer and more beneficial results. It should be noted that blood tests do not always give an accurate picture of nutritional status and most orthomolecular practitioners recommend titration of doses to suit the patient.

Side effects

Orthomolecular medicine, while generally harmless, can be dangerous if safe doses of nutritional

supplements are not observed. Some supplements, notably the oil-based ones such as vitamins A, D, and E, can build up and cause undesirable consequences. Too much vitamin A, for example can cause very dry skin, among other things. Vitamin D can cause calcification of soft tissue if taken in excessive amounts, and all these items can cause liver damage if taken in excess.

Research and general acceptance

Since the beginning of this century, both nutrition and its "offshoot," orthomolecular medicine, have been extensively researched. Both the United States and British governments have special departments which determine safe doses of all supplements.

Orthomolecular medicine is possibly the branch of alternative therapies that has been the subject of most scientific research, and has certainly been validated by that research. Therefore, it is the one branch of alternative medicine that it is very difficult for allopathic medicine to call into question.

Linus Pauling was undoubtedly one of the most distinguished scientists of the twentieth century, and left over 400,000 research papers and other scientific documents to record his findings. Orthomolecular medicine research is based strongly on such other scientific fields as biochemistry, physiology, immunology, endocrinology, pharmacology, and toxicology.

Training and certification

Among those qualified to advise on treatment with nutritional supplements are board certified physicians, licensed nutritionists, and naturopaths. Although specialists in orthomolecular medicine tend to be highly qualified, it is advisable to check the credentials of any therapist or physician before consultation.

Osha

Description

Osha, whose botanical name is *Ligusticum porteri*, is a plant native to the western United States and Mexico. A member of the Umbelliferae family, osha has been used for centuries by Native Americans and Mexicans as a treatment for sore throats, fevers, and **influenza**. The plant belongs to the same family as **parsley** and dill, and it has the same long thin hollow stalk with large divided leaves. These leaves can reach heights of 2 ft (0.6 m). Osha's seeds and flowers are at the top of the plant and spread out in the form of an umbrella, whence its Latin family name. Osha flowers are white and the seeds have a sweet celery-like smell, as does the entire plant. The root is very hairy, brown on the outside and yellow on the inside. The plant has several other names: chuchupate, Indian parsley, Porter's lovage, mountain lovage, Colorado **cough** root. A plant related to osha, *Ligusticum wallichii*, is used in **traditional Chinese medicine**; most laboratory studies of osha have used this Chinese species.

General use

Osha root is a powerful antiviral and antibacterial agent, used for bronchial **infections** and sore throats. Taking a tincture or decoction of osha root, or chewing directly on the root, causes perspiration and enhances the body's immune function. Although osha has a bitter taste, its root has a numbing effect that soothes sore throats. Since it is also an expectorant, it is very useful for coughs and pharyngitis, and can also be used for very early stages of **tonsillitis**.

KEY TERMS

Decoction—An herbal extract produced by mixing an herb in cold water, bringing the mixture to a boil, and letting it simmer to evaporate the excess water. The decoction is then strained and drank hot or cold. Decoctions are usually chosen over infusion when the botanical or herb in question is a root, seed, or berry.

Expectorant—A drug that promotes the discharge of mucus from respiratory system.

Infusion—Introduction of a substance directly into a vein or tissue by gravity flow.

Tincture—A solution of alcohol and water containing plant matter. One available tincture of osha is 70% alcohol.

Osha root tea helps with gastrointestinal discomfort, in particular **indigestion** and stomach upset associated with **vomiting**. It can be used to increase appetite. Both osha root tincture and tea can be used topically on **cuts** and scrapes, as osha also has strong antibacterial qualities. Michael Moore, a contemporary American herbalist associated with the Southwest School of Herbal Medicine, states that osha can be used for head colds with dry cough; certain stages of pharyngitis; early stages of tonsillitis; coughs; influenza with persistent coughing; dry, hot fevers; and acute brochial **pneumonia**. Osha can be given together with **echinacea** for leukocytosis.

Preparations

Osha is available as whole or powdered dried roots. Dried osha root can be chewed directly. Michael Moore suggests taking a "walnut-sized root" every three to four hours. A cold infusion of osha, two to six ounces, can be taken as needed. Other products that contain osha come in different concentrations and should be mixed or diluted according to label instructions. If osha is used in tincture form, 20–60 drops can be taken up to five times a day. One part osha to two parts honey works well as a cough syrup, and is more appealing to children, who often dislike the plant's bitter taste.

Precautions

The most important precaution to take with osha is correct identification. The plant is often confused with hemlock parsley, which it closely resembles. Osha is also sometimes mistaken for poison hemlock, which can be fatal to humans if ingested. Osha has also been detected in the milk of lactating mothers, and should not be used by women who are pregnant or nursing.

Side effects

There are no known side effects with using osha other than allergy or hypersensitivity to it or to its plant family. High doses of osha taken over extended periods of time, however, may cause kidney or liver toxicity.

Interactions

No known adverse reactions have been reported with osha.

Osteoarthritis

Definition

Osteoarthritis (OA), which is also known as osteoarthrosis or degenerative joint disease (DJD), is a progressive disorder of the joints caused by gradual loss of cartilage and resulting in the development of bony spurs and cysts at the margins of the joints. The name osteoarthritis comes from three Greek words meaning bone, joint, and inflammation.

Description

OA is one of the most common causes of disability due to limitations of joint movement, particularly in people over 50. It is estimated that 2% of the United States population under the age of 45 suffers from osteoarthritis; this figure rises to 30% of persons between 45 and 64, and 63–85% in those over 65. About 90% of the American population will have some features of OA in their weight-bearing joints by age 40. Men tend to develop OA at earlier ages than women.

Osteoarthritis of the hand of a 78 year old woman. *(© Scott Camazine / Alamy)*

OA typically develops gradually over a period of years. Patients with OA may have joint **pain** on only one side of the body. It primarily affects the knees, hands, hips, feet, and spine.

Causes and symptoms

Osteoarthritis results from deterioration or loss of the cartilage that acts as a protective cushion between bones, particularly in weight-bearing joints such as the knees and hips. As the cartilage is worn away, the bone rubbing against bone forms spurs, areas of abnormal hardening, and fluid-filled pockets in the marrow known as subchondral cysts. As the disorder progresses, pain results from deformation of the bones and fluid accumulation in the joints. The pain is relieved by rest and made worse by moving the joint or placing weight on it. In early OA, the pain is minor and may take the form of mild stiffness in the morning. In the later stages of OA, chronic inflammation develops. The patient may experience pain even when the joint is not being used; and he or she may suffer permanent loss of the normal range of motion in that joint.

Until the late 1980s, OA was regarded as an inevitable part of **aging**, caused by simple "wear and tear" on the joints. This view has been replaced by recent research into cartilage formation. OA is now considered to be the end result of several different factors contributing to cartilage damage, and is classified as either primary or secondary.

Primary osteoarthritis

Primary OA results from abnormal stresses on weight-bearing joints or normal stresses operating on weakened joints. Primary OA most frequently affects the finger joints, the hips and knees, the cervical and lumbar spine, and the big toe. The enlargements of the finger joints that occur in OA are referred to as Heberden's and Bouchard's nodes. Some gene mutations appear to be associated with OA. **Obesity** also increases the pressure on the weight-bearing joints of the body. Finally, as the body ages, there is a reduction in the ability of cartilage to repair itself. In addition to these factors, some researchers have theorized that

Osteoarthritis

Risk Factors
- Age-related
- Overuse of joints
- Excessive weight

Physical Effects
- Affects joints
- Bony spurs
- Enlarged or malformed joints

Treatment Options
- Weight Management
- Non-steroidal anti-inflammatory drugs

Pain Management
- Support groups
- Exercise
- Joint splitting
- Physical therapy
- Passive exercise
- Joint replacement
- Heat and cold
- Message therapy
- Acupuncture
- Psychological approaches (relaxation, visualization)
- Tai Chi
- Low stress yoga

(Illustration by Corey Light. Cengage Learning, Gale)

primary OA may be triggered by enzyme disturbances, bone disease, or liver dysfunction.

Secondary osteoarthritis

Secondary OA results from chronic or sudden injury to a joint. It can occur in any joint. Secondary OA is associated with the following factors:

- trauma, including sports injuries
- repetitive stress injuries associated with certain occupations (like the performing arts, construction or assembly line work, computer keyboard operation, etc.)
- repeated episodes of gout or septic arthritis
- poor posture or bone alignment caused by developmental abnormalities
- metabolic disorders

Colored x ray of the knee showing osteoarthritis. *(Phanie / Photo Researchers, Inc.)*

Diagnosis

History and physical examination

The two most important diagnostic clues in the patient's history are the pattern of joint involvement and the presence or absence of **fever**, rash, or other symptoms outside the joints. As part of the physical examination, the doctor will touch and move the patient's joint to evaluate swelling, limitations on the range of motion, pain on movement, and crepitus (a cracking or grinding sound heard during joint movement).

Diagnostic imaging

There is no laboratory test that is specific for osteoarthritis. Treatment is usually based on the results of diagnostic imaging. In patients with OA, x rays may indicate narrowed joint spaces, abnormal density of the bone, and the presence of subchondral cysts or **bone spurs**. The patient's symptoms, however, do not always correlate with x-ray findings. Magnetic resonance imaging (MRI) and computed tomography scans (CTscans) can be used to determine more precisely the location and extent of cartilage damage.

KEY TERMS

Bouchard's nodes—Swelling of the middle joint of the finger.

Cartilage—A tough, elastic connective tissue found in the joints, outer ear, nose, larynx, and other parts of the body.

Heberden's nodes—Swelling or deformation of the finger joints closest to the fingertips.

Subchondral cysts—Fluid-filled sacs that form inside the marrow at the ends of bones as part of the development of OA.

Treatment

Diet

Food intolerance can be a contributing factor in OA, although this is more significant in **rheumatoid arthritis**. Dietary suggestions that may be helpful for people with OA include emphasizing high-fiber, complex-carbohydrate foods, while minimizing fats. Plants in the Solanaceae family, such as tomatoes, peppers, eggplant, and potatoes, should be avoided, as should refined and processed foods. Citrus fruits should also be avoided, as they may promote swelling. Foods that are high in **bioflavonoids** (berries as well as red, orange, and purple fruits and vegetables) should be eaten often. Black cherry juice (2 glasses twice per day) has been found to be particularly effective for partial pain relief.

Nutritional supplements

In the past several years, a combination of **glucosamine** and **chondroitin** sulfate has been proposed as a dietary supplement that helps the body maintain and repair cartilage. Studies conducted in Europe have shown the effectiveness of this treatment but effects may not be evident until a month after initiating this treatment. These substances are nontoxic and do not require prescriptions. Other supplements that may be helpful in the treatment of OA include the antioxidant vitamins and minerals (vitamins A, C, E, **selenium**, and **zinc**) and the B vitamins, especially vitamins B_6 and B_5.

Naturopathy

Naturopathic treatment for OA includes **hydrotherapy**, **diathermy** (deep-heat therapy), nutritional supplements, and botanical preparations, including **yucca**, **devil's claw** (*Harpagophytum procumbens*), and **hawthorn** (*Crataegus laevigata*) berries.

Electromagnetic field therapy is believed to increase blood flow and oxygen exchange to enhance the body's natural healing processes. This treatment is not suggested for use over an open wound or in combination with transdermal drug delivery patches, or by those who are pregnant or have insulin pumps or pacemakers. Magnets may be worn within a shoe insole, anklet, bracelet, or back support.

Traditional Chinese medicine

Practitioners of **Traditional Chinese medicine** treat arthritis with suction cups, massage, **moxibustion** (warming an area of skin by burning a herbal wick a slight distance above the skin), the application of herbal poultices, and internal doses of Chinese herbal formulas.

Daily **acupressure** can also provide relief for stiff, achy joints. Massage of the achy joints with a blend of aromatic oils, especially **rosemary** and **chamomile** is beneficial. Periods of imagery are another suggested treatment—for 10-20 minutes twice daily—where the joint pain is pictured as transformed into a liquid that trickles from the body into the nearest body of water and eventually into the ocean waves.

Physical therapy

Patients with OA are encouraged to **exercise** as a way of keeping joint cartilage lubricated. Exercises that increase balance, flexibility, and range of motion are recommended for OA patients. These may include walking, swimming and other water exercises, **yoga** and other stretching exercises, or isometric exercises. Physical therapy may also include massage, moist hot packs, or soaking in a hot tub.

Allopathic treatment

Treatment of OA patients is tailored to the needs of each individual. Patients vary widely in the location of the joints involved, the rate of progression, the severity of symptoms, the degree of disability, and responses to specific forms of treatment. Most treatment programs include several forms of therapy.

Patient education and psychotherapy

Patient education is an important part of OA treatment because of the highly individual nature of the disorder and its potential impacts on the patient's life. Patients who are depressed because of changes in employment or recreation usually benefit from counseling. The patient's family should be involved in discussions of coping, household reorganization, and other aspects of the patient's disease and treatment regimen.

Medications

Patients with mild OA may be treated only with pain relievers such as acetaminophen (Tylenol) or propoxyphene (Darvon). Most patients with OA, however, are given nonsteroidal anti-inflammatory drugs, or NSAIDs. These include compounds such as ibuprofen (Motrin, Advil), ketoprofen (Orudis), and flurbiprofen (Ansaid). The NSAIDs have the advantage of relieving inflammation as well as pain. They also have potentially dangerous side effects, including stomach ulcers, sensitivity to sun exposure, kidney disturbances, and nervousness or **depression**.

Some OA patients are treated with corticosteroids injected directly into the joints to reduce inflammation and slow the development of Heberden's nodes. Injections should not be regarded as a first-choice treatment and should be given only two or three times a year. A series of hyaluronic acid injections into the affected joint may help to lubricate and protect cartilage.

Surgery

Surgical treatment of osteoarthritis may include the replacement of a damaged joint with an artificial part or appliance; surgical fusion of spinal bones; scraping or removal of damaged bone from the joint; or the removal of a piece of bone in order to realign the bone.

Protective measures

Depending on the location of the affected joint, patients with OA may be advised to use neck braces or collars, crutches, canes, hip braces, knee supports, bed boards, or elevated chair and toilet seats. They are also advised to avoid unnecessary knee bending, stair climbing, or lifting of heavy objects.

New treatments

Since 1997, several new methods of treatment for OA have been investigated. Although they are still being developed and tested, they appear to hold promise. They include:

- Disease-modifying drugs. These compounds may be useful in assisting the body to form new cartilage or improve its repair of existing cartilage.
- Gene therapy.
- Cartilage transplantation. This technique is presently used in Sweden.

Osteopathy

Definition

Osteopathy is a "whole person" philosophy of medicine, where doctors of osteopathic medicine (DOs) endorse an approach that treats the entire person, rather than a specific complaint. Attention is given to prevention, wellness, and helping the body to heal itself. Because the body is viewed as a single organism or unit, special focus is given to understanding body mechanics and the interrelationship of the body's organs and systems. A particular emphasis is placed on the musculoskeletal system. DOs may utilize physical manipulation of muscles and bones in conjunction with, or as an alternative to, conventional treatments, drug therapies, and surgery to provide complete health care.

Origins

Dr. Andrew Still developed the osteopathic approach to medicine. Still, whose father was a Methodist minister and physician, was himself a medical doctor who served as a Union surgeon during the Civil War. After the war, personal tragedy struck the Still household when three of his children died from spinal **meningitis**. This event angered and disillusioned him. He became dissatisfied with the state of medical knowledge and treatments available at that time. Consequently, he began an intense study of the human body to find underlying causes and cures for ailments.

Upper spine examination. *(Paul Rapson / Photo Researchers, Inc.)*

Still gave great attention to anatomy. He recognized the importance of the musculoskeletal system, the body's ability for self-healing, and focused on prevention and the concept of "wellness." In an era when drug treatment was frequently dangerous and overused, and surgery often fatal, Still was able to develop alternative treatments. For example, by manipulating the ribs and spine, Still provided treatments for **pneumonia**. He gave attention to the lymphatic system (which filters foreign matter and removes excess fluids, proteins, and waste products from the tissues and transports them to the blood to be circulated and eliminated) and manipulating the fascia (connective tissue that is tough, but thin and elastic; it forms an uninterrupted three-dimensional network from head to foot, sheathing every muscle, bone, nerve, gland, organ, and blood vessel), allowing him to address a range of other ailments.

Still's sons learned his philosophies and techniques, but demand overwhelmed their ability to supply care. In 1892, Still founded the first college of osteopathic medicine, the American School of Osteopathy, in Kirksville, Missouri. When he died in 1917, there were more than 5,000 practicing osteopaths in the United States. Today, osteopaths are the fastest growing segment of the total population of physicians and surgeons in the United States. In 2002, there were more than 49,000 doctors of osteopathy. Osteopathy has spread outside of the United States and is now practiced in countries throughout the world.

Benefits

The osteopathic focus on prevention and wellness may help individuals to avoid illness by teaching healthy behaviors and encouraging health-promoting lifestyle changes. In addition to conventional treatments, drugs, and surgeries, DOs may offer manipulative therapies not available from their allopathic counterparts (MDs). Many people seek care from an osteopath for back or neck pains, joint pains, or injuries. However, DOs may use manipulative therapies to treat a variety of ailments and conditions including arthritis, **allergies**, **asthma**, **dizziness**, **carpal tunnel syndrome**, menstrual **pain**, migraine headaches, **sciatica**, sinusitis, **tinnitus** (ringing in the ears), and problems in the jaw joints. Manipulative therapies may be incorporated into the treatment plan to speed recovery from various conditions, such as **heart attack** or disc surgery, and to address pediatric concerns, such as otitis media (**ear infection**) and birth traumas. Various manipulative therapies may also be appropriate in alleviating discomforts associated with **pregnancy**, for example, back pain or digestive problems. Some osteopaths even feel that regular osteopathic treatments may help minimize the effects of **aging** on the spine and joints. Also, as noted by the American Osteopathic Association (AOA), the field of sports medicine has found particular benefit in osteopathic practitioners because of their emphasis on "the musculoskeletal system, manipulation, diet, **exercise**, and fitness. Many professional sports team physicians, Olympic physicians, and personal sports medicine physicians are DOs."

Description

Osteopathic medicine considers the human body to be a complex unit of interrelated parts, a unified organism. Organs and systems do not function independently and should not be treated as such. A disturbance in one part of the body affects the entire body. Illness is also impacted by many variables, such as emotions, **stress**, lifestyle, and environment. Therefore, illness must be addressed by taking a whole

Elderly woman receiving osteopathy treatment. *(© Sally and Richard Greenhill / Alamy)*

person approach to treatment. Because the body is seen as self-regulating and self-healing, the osteopath gives special attention to illness prevention and helping the body maintain or re-establish wellness.

The nervous and circulatory systems play crucial roles in maintaining the functioning of the body's organs and systems; negative body-wide effects may occur when these two major systems are not functioning optimally. Relieving blocked blood flow or nerve impulses will help the body to heal itself by promoting blood flow through affected tissues. The blood supply will be better able to deliver vital nutrients and boost the immune system, the nerve supply to the area will be improved, and systemic balance can be restored.

The musculoskeletal system is key in this effort to achieve and maintain systemic balance and health. The musculoskeletal system is comprised of the bones, tendons, muscles, tissues, nerves, and spinal column. As the body's largest system, it encompasses over 60% of body mass and can suffer mechanical disorders or amplify illness processes anywhere in the body. Therefore, structural evaluation and attention to the musculoskeletal system is central to osteopathy.

In addition to conventional care such as drug therapies and surgery, osteopaths may use a variety of manipulative procedures to help the body systems function at peak levels. These techniques are commonly referred to as Osteopathic Manipulative Treatment (OMT). OMT is a form of noninvasive, "hands-on" care used for prevention, diagnosis, and treatment to reduce pain and restore motion, as well as help the body heal itself. OMT may be used to facilitate the movement of body fluids and normal tissue functioning, and release painful joints or dysfunctional areas. These therapies take different forms depending on patient needs.

In addition to easing the pain of physical disorders, OMT appears to be helpful in some psychiatric conditions as well. A recent study performed at the College of Osteopathic Medicine in Downers Grove, IL, found that OMT as an adjunct to **psychotherapy** alleviated the symptoms of **depression** in women, as measured by the Zung Depression Scale, a standard diagnostic instrument.

Manipulative procedures may be categorized and discussed in a variety of ways. According to the

American Association of Colleges of Osteopathic Medicine, the following groupings encompass some of the most commonly used procedures. Descriptions are compiled from the American Academy of Osteopathy, Leon Chaitow, N.D., DO, and others.

- Articulatory techniques. Procedures that move joints through their range of motion (articulating the joints) may be used to restore normal functioning.
- Counterstrain. This type of therapy is used to alleviate trigger points localized areas of hyperirritability in the muscles). The procedure involves first finding a body position that relieves the patient's pain. Through a process in which the patient and practitioner repeatedly use coordinated techniques of pushing (or compression), relaxing, and changing position, the trigger point is eased.
- Cranial treatment. Cranial treatments focus on the craniosacral system which consists of the brain, spinal cord, cerebrospinal fluid, dura (the membrane covering the brain and spinal cord), cranial bones, and the sacrum (triangular bone comprised of five fused vertebrae, and forming posterior section of the pelvis). Craniosacral release is a gentle technique that focuses on normalizing imbalances in the natural rhythms of this system. A light touch is used to detect and release restrictions in the system and encourage the body's own healing processes. Craniosacral therapies arose from the work of Dr. William Sutherland, a DO who developed and explored the concept that the bones of the skull allowed movement and could be manipulated to improve the system's rhythmic movements. Some DOs choose to specialize in cranial osteopathy. Craniosacral therapy is also practiced by a wide variety of health care professionals. As listed by the Upledger Institute, these practitioners include MDs, chiropractors, doctors of Oriental medicine, naturopaths, nurses, psychiatric specialists, psychologists, dentists, physical therapists, occupational therapists, acupuncturists, massage therapists, and other professional bodyworkers.
- Myofascial release treatment. Various direct or indirect treatments are applied to release fascia tissues.
- Lymphatic techniques. These techniques focus on improving lymphatic circulation, improving the ability of the lymphatic system to do its job of waste removal.
- Soft tissue techniques. Applied to tissue other than bone, these techniques use varying pressure and may stretch, roll, or knead, resulting in the relaxation or release of tissues.
- Thrust techniques. A quick, sharp thrust (which is often described as high velocity/low amplitude) to the area requiring treatment is used to force a correction, restoring normal joint function and movement. This is similar to chiropractic adjustment.

Precautions

DOs use the full range of conventional diagnostic techniques, drug therapies, treatments, and surgical interventions available to MDs. If deemed appropriate by the DO, OMT may be employed in addition to these conventional diagnoses, and treatments or may serve as an alternative to drug therapies. During the course of treatment, manipulative therapies may be interrupted or stopped if complications occur—for example, a rise in blood pressure. In some situations, the osteopath may determine that no further benefit will be gained from continuing manipulative treatment. Manipulation should not be applied in several medical conditions. As listed by Chris Belshaw, these conditions are mainly "acute **infections**; **fractures**; bone disease; **cancer**; gross structural deformities; such severe general medical conditions as gross high blood pressure or heart attack; vascular disease, for example, thrombosis; neurological conditions with nerve damage; spinal cord damage; and severe prolapse of an intervertebral disc." Additionally, as in any area of medicine, there is the possibility of mistaken diagnosis. Patients should always discuss all medical conditions, treatments, questions, and concerns with their physicians.

Side effects

Some patients, as noted by Belshaw, may experience mild headaches following neck treatments or discomfort after back manipulation. Some flushing and bruising may appear on those with sensitive skin. These reactions may last for several hours. Such symptoms may recur as treatment continues. Symptoms may return if treatment is stopped too soon.

Research and general acceptance

Research has shown the benefits of osteopathic care in a range of ailments and through improved recovery times. In addition to many of the conditions discussed above, the American Osteopathic Healthcare Association reports ongoing research on patient recovery times, length of hospital stays, chronic pain, **chlamydia** infection in women, reduction of deep vein thrombosis, and fall prevention for the elderly. Osteopathic colleges have increased their attention to biomedical research opportunities for students and those who desire to pursue research careers. The AOA Board of Research encourages and supports development of

ANDREW TAYLOR STILL (1828–1917)

(Betmann/CORBIS. Reproduced by permission.)

Andrew Taylor Still, the father of osteopathy, was born on August 6, 1828, in Virginia to Abram and Martha Still. Growing up on the frontier lands of Tennessee and Missouri provided the impetus for his first studies of the musculoskeletal system. Skinning squirrels and deer, Still became familiar with the relationship between bones, muscles, nerves, and veins long before he picked up an anatomy book. He later studied medicine under his doctor preacher father and served as a Union surgeon during the Civil War.

Following the war, his distrust of traditional medicine grew when three of his children died of cerebrospinal meningitis. Still decided that the medications of his day were useless and that there had to be another way.

Still studied the attributes of good health so he could understand disease. He saw the body as a complex machine that, when working properly, stayed free of disease. He turned to a drugless, manipulative therapy believing disease was caused by a failure of the human machinery to carry the fluids necessary to maintain health. He called his holistic approach osteopathy for the Greek words *osteon,* meaning bone, and *pathos,* to suffer.

Still gained a following working as an itinerant healer, and in October 1892, he opened the American School of Osteopathy in Kirksville, Missouri. Still welcomed women even as other medical schools denied them access.

As of 2000, there were 16 osteopathic medicine colleges in the United States and 35,000 practicing doctors of osteopathy. The Kirksville College of Osteopathic Medicine remains open.

scientific research in the osteopathic medical profession. The AOA has also conducted several campaigns to educate the public on osteopathy. In 2000, the AOA started a Women's Health Initiative, a three-year campaign to promote women's healthcare among osteopathic physicians and the public.

Training and certification

Training and certification for DOs exceed those of chiropractors and physical therapists, two groups to which their manipulative techniques are sometimes compared. **Chiropractic** training focuses on spinal manipulation only. Chiropractors typically have fewer years and types of required postgraduate training, and are more limited legally in their practice. DOs also have training and licensing well beyond that of physical therapists.

Osteopathic physicians, like their allopathic physician counterparts, are complete physicians. This means they are trained and licensed to prescribe medication and perform surgery, and qualified to render complete healthcare. DOs are fully licensed in all 50 states and the District of Columbia, to serve in the military medical corps, Veterans Administration, and Public Health Service, and are recognized by the American Medical Association as physicians. They hold the same practice rights as MDs, have passed the same or similar state licensing examinations, and practice in fully accredited hospitals. DOs can practice in all branches of medicine and surgery, and can specialize in any area, but the majority are primary care physicians.

As of spring 2002, the AOA lists 20 AOA-accredited colleges of osteopathic medicine. Training for DOs and MDs parallel in many ways. Osteopathic colleges, like medical schools, offer a basic, comprehensive four-year medical education. Added to this curriculum are the osteopathic philosophies and a holistic care emphasis on prevention and community care. In addition to stressing the interrelatedness of body organs and systems, students of osteopathy are taught to consider the whole person, including lifestyle, emotional factors, and environmental factors. Training also focuses on the musculoskeletal system

and manual medicine. Manipulative therapies are taught for prevention, diagnosis, and treatment, and the osteopathic principle of helping the body toward good health.

After graduation from the four-year curriculum, DOs complete a one-year rotating internship, followed by several years in a residency program, if a specialty is desired. The areas covered during the internship period ensure that each DO is first trained as a primary care physician. Over half of all DOs are primary care physicians. Conversely, MDs are more likely to be specialists.

After the formal education process, the AOA requires members to earn continuing medical education (CME) credits every three years. To further enhance postgraduate medical education, the AOA has implemented the concept of Osteopathic Postdoctoral Training Institutions (OPTIs), which reflect the osteopathic emphasis on community care. These OPTIs are community-based consortia that include at least one hospital and college of osteopathic medicine. The intention of these is to promote institutional collaboration and enhance training opportunities that reflect the settings in which many osteopaths will practice. In early 2002, a new Osteopathic Research Center opened at the University of North Texas Health Science Center in Fort Worth. The new Research Center is the result of collaboration among the American Colleges of Osteopathic Medicine, the American Osteopathic Foundation, and the American Osteopathic Association.

Many aspects of traditional osteopathic philosophy, such as advice about diet and **smoking**, have entered mainstream medicine to the point that the lines between DOs and MDs are blurring. In addition, the dedication of osteopaths to **holistic medicine** and primary care has been a great benefit to rural areas of the United States that are often underserved by mainstream practitioners.

Osteoporosis

Definition

The word osteoporosis literally means porous bones. It occurs when bones lose an excessive amount of their protein and mineral content, particularly **calcium**. Over time, bone mass and, therefore, bone strength are decreased. As a result, the bones become fragile and break easily. Even a sneeze or a sudden movement may be enough to break a bone in someone with severe osteoporosis.

Description

Osteoporosis is a serious public health problem. Some 10 million people in the United States have osteoporosis and another 34 million have low bone mass, placing them at risk for osteoporosis. The disease is responsible for 1.5 million **fractures** (broken bones) annually. These fractures, which are often the first sign of the disease, can affect any bone, but the most common locations are the hip, spine, and wrist. Breaks in the hip and spine are of special concern because they almost always require hospitalization and major surgery and may lead to other serious consequences, including permanent disability and even death.

To understand osteoporosis, it is helpful to understand the basics of bone formation. Bone is living tissue that is constantly being renewed in a two-stage process (resorption and formation) that occurs throughout life. In the resorption stage, old bone is broken down and removed by cells called osteoclasts. In the formation stage, cells called osteoblasts build new bone to replace the old. During childhood

U.S. and FAO/WHO recommended amounts of calcium and vitamin D

Calcium

Age	Recommended dietary allowance, U.S.	FAO/WHO recommendations
Children 1-3 yrs.	500 (mg/day)	500 (mg/day)
Children 4-6 yrs.		600 (mg/day)
Children 4-8 yrs.	800 (mg/day)	
Children 7-9 yrs.		700 (mg/day)
Children 9-13 yrs.	900 (mg/day)	
Children 10-18 yrs.		1,300 (mg/day)
Adolescents 14-18 yrs.	1,300 (mg/day)	
Adults 19-50 yrs.	1,000 (mg/day)	
Adults 19-65 yrs.		1,000 (mg/day)
Adults > 50 yrs.	1,200 (mg/day)	
Adults ≥ 65 yrs.		1,300 (mg/day)
Postmenopausal women		1,300 (mg/day)

Vitamin D

Age	Adequate intake, U.S.		FAO/WHO recommendations	
Up to 50 yrs.	200 IU/day	5 mcg/day	200 IU/day	5 mcg/day
Adults 51-65 yrs.			400 IU/day	10 mcg/day
Adults 51-70 yrs.	400 IU/day	10 mcg/day		
Adults ≥ 65 yrs.			600 IU/day	15 mcg/day
Adults ≥ 71 yrs.	600 IU/day	15 mcg/day		

FAO/WHO = Food and Agriculture Organization and World Health Organization
IU = International Unit
mcg = microgram
mg = milligram

and early adulthood, more bone is produced than removed, reaching its maximum mass and strength by the mid-30s. After that, bone is lost at a faster pace than it is formed, so the amount of bone in the skeleton begins to slowly decline. Most cases of osteoporosis occur as an acceleration of this normal **aging** process, which is referred to as primary osteoporosis. The condition can also be caused by other disease processes or prolonged use of certain medications that result in bone loss; if so, it is called secondary osteoporosis.

Osteoporosis occurs most often in older people, especially in women after **menopause**. It affects nearly half of all adults, men and women, over the age of 75. Women, however, are five times more likely than men to develop the disease. They have smaller, thinner bones than men to begin with, and they lose bone mass more rapidly after menopause (usually around age 50), when they stop producing a bone-protecting hormone called estrogen. In the five to seven years following menopause, women can lose about 20% of their bone mass. By age 65 or 70, though, men and women lose bone mass at the same rate.

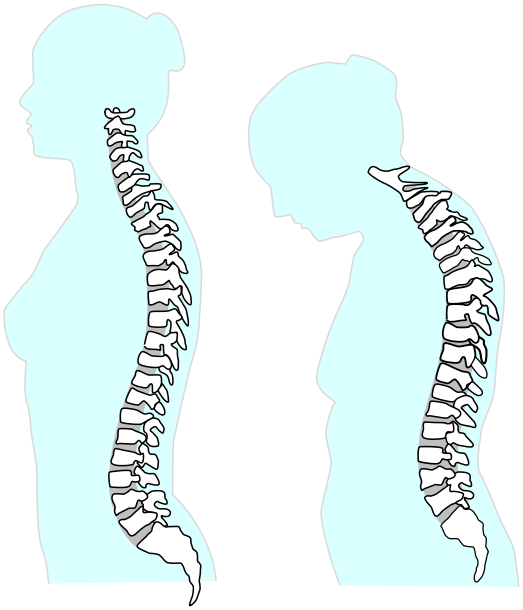
As an increasing number of men live longer, health professionals are increasingly aware that osteoporosis is an important health issue for men as well. In fact, men account for about 20% of all spinal fractures and up to 30% of all hip fractures due to osteoporosis.

Causes and symptoms

A number of factors increase the risk of developing osteoporosis. They include:

- Age. Osteoporosis is more likely as people grow older and their bones lose strength.
- Sex. Women are more likely to have osteoporosis because they start out with less bone. They also lose bone tissue more rapidly as they age. While women commonly lose 30 to 50% of their bone mass over their lifetimes, men lose only 20 to 33% of theirs.

Osteoporosis in the vertebrae



SOURCE: National Women's Health Center, U.S. Department of Health and Human Services

Osteoporosis is most common in the hips, wrist, and vertebrae (spine). The vertebrae are most important because these bones support the body to stand and sit upright. The vertebrae on the left is normal and the vertebrae on the right has been affected by osteoporosis. *(Illustration by GGS Information Services. Cengage Learning, Gale)*

- Race. Caucasian and Asian women are most at risk for the disease, but African American and Hispanic women can get it too.
- Body type. Women with small bones or thin frames are more liable to develop osteoporosis.
- Early menopause. Women who begin menopause early because of heredity, surgery, or lots of physical exercise may lose large amounts of bone tissue early in life. Such conditions as anorexia and bulimia may also lead to early menopause and osteoporosis.
- Lifestyle. People who smoke or drink too much or do not get enough exercise have an increased chance of getting osteoporosis.
- Medications. Certain prescription medications may speed up the loss of bone. These drugs include methotrexate, cimetidine, corticosteroids, and heparin.
- Diet. Adults who do not get enough calcium or protein may be more likely to have osteoporosis. People who constantly diet are more prone to the disease.

Osteoporosis is often called the silent disease because bone loss occurs without symptoms. People often do not know they have the disease until a bone breaks, frequently in a minor fall that would not typically cause a fracture. A common occurrence is compression fractures of the spine. These can happen even after a seemingly normal activity, such as bending or twisting to pick up a light object. The fractures can cause severe back **pain**, but sometimes they go unnoticed. Either way, the vertebrae collapse on themselves, and the person actually loses height. The hunchback appearance of many elderly women, sometimes called dowager's hump or widow's hump, is due to the effect of osteoporosis on the vertebrae.

Diagnosis

Certain types of doctors may have more training and experience than others in diagnosing and treating people with osteoporosis. These include a geriatrician, who specializes in treating the aged; an endocrinologist, who specializes in treating diseases of the body's endocrine system (glands and hormones); and an orthopedic surgeon, who treats fractures, such as those caused by osteoporosis.

Before making a diagnosis of osteoporosis, the doctor usually takes a complete medical history, conducts a physical examination, and orders x rays, as well as blood and urine tests, to rule out other diseases that cause loss of bone mass. The doctor may also recommend a bone density test, which is the only way to know for certain if osteoporosis is present. It can also show how far the disease has progressed.

Several diagnostic tools are available to measure the density of a bone. The ordinary x ray is one, though it is the least accurate for early detection of osteoporosis because it does not reveal bone loss until the disease is advanced and most of the damage has already been done. Two other tools that are more likely to catch osteoporosis at an early stage are computed tomography (CT) scans and machines called densitometers, which are designed specifically to measure bone density.

The CT scan, which takes a large number of x rays of the same spot from different angles, is an accurate test but uses higher levels of radiation than other methods. The most accurate and advanced of the densitometers uses a technique called DEXA (dual energy x ray absorptiometry). With the DEXA scan, a double x-ray beam takes pictures of the spine, hip, or entire body. It takes about 20 minutes, is painless, and exposes the patient to only a small amount of radiation—about 1/50 that of a chest x ray.

Medicare covers a test that measures bone resorption, an important measure for tracking a patient's response to osteoporosis therapy. The relatively inexpensive test measures a baseline amount then compares amounts from later tests to track progress. The test consists of simple urine collection.

People should talk to their doctors about their risk factors for osteoporosis and if and when to have a bone density test. Ideally, women should have bone density measured at menopause and periodically afterward, depending on the condition of their bones. Men should be tested starting at age 65. Men and women with additional risk factors, such as those who take certain medications, may need to be tested earlier.

Treatment

Alternative treatments for osteoporosis focus on maintaining or building strong bones. They include nutritional and herbal therapies and **homeopathy**.

Nutritional therapy

A healthful diet low in fats and animal products and containing whole grains, fresh fruits and vegetables, and calcium-rich foods (such as dairy products, dark-green leafy vegetables, sardines, salmon, and almonds), along with nutritional supplements (such as calcium, **magnesium**, and **vitamin D**) are important components of nutritional approaches to treating this disease.

Women should also eat more soy products such as tofu, soy burgers, other soy-based products, or miso. Soy beans contain a substance called isoflavones which have estrogen-like activity. Isoflavones may help to increase bone density, alleviate **hot flashes** and other menopausal symptoms, lower the risk of **cancer**, and even reduce the risk of heart attacks. Natural hormone therapy, such as the use of soy products, is a safer alternative to synthetic estrogenic hormones, which may increase the risk of **breast cancer**.

In addition, women should avoid foods that may accelerate bone loss. They should avoid having too much salt in their diet, not only because salt raises the blood pressure but also because it may contribute to osteoporosis. They should also cut down on coffee, caffeinated sodas, and alcohol. High consumption of these beverages, studies have shown, are associated with accelerated drop in bone density and increase risk of bone fracture in old age. Caffeinated sodas are especially bad for the bones because in addition to containing **caffeine**, they have high amounts of phosphoric acid. Phosphoric acid increases bone resorption, thus decreasing bone density.

Herbal supplements

Herbal supplements for osteoporosis emphasize such calcium-containing plants as **horsetail** (*Equisetum arvense*), oat straw (*Avena sativa*), **alfalfa** (*Medicago sativa*), **licorice** (*Glycyrrhiza glabra*), **marsh mallow** (*Althaea officinalis*), and sourdock (*Rumex crispus*). There are, however, few data from clinical trials to support the use of these herbs.

Homeopathy

Homeopathic remedies for osteoporosis focus on treatments believed to help the body absorb calcium. These remedies may include such substances as *Calcarea carbonica* (calcium carbonate) or *Silica* (flint). Again, there are few data other than isolated case reports regarding the effectiveness of these remedies.

Allopathic treatments

There are a number of good treatments for primary osteoporosis, most of them medications. For people with secondary osteoporosis, treatment may focus on curing the underlying disease.

Drugs

For most women who have gone through menopause, the best treatment for osteoporosis is hormone replacement therapy (HRT), also called estrogen replacement therapy. In addition to alleviating hot flashes, synthetic estrogens protect women against **heart disease** and they help to relieve and prevent osteoporosis. HRT increases a woman's supply of estrogen, which helps build new bone while preventing further bone loss.

The Women's Health Initiative (WHI), a large 15-year government-funded research study, concluded in a 2006 report that the drug Prempro (estrogen combined with progestin), which is used in hormone therapy, is associated with a modest increase in the risk of breast cancer, **stroke**, and **heart attack**. The WHI also demonstrated that in patients who had a hysterectomy, estrogen therapy alone was associated with an increase in the risk of stroke, but not of breast cancer or cardiovascular (heart) disease. A large study from the National Cancer Institute indicated that long-term use of estrogen therapy may be associated with an increased risk of **ovarian cancer**. Estrogen therapy is approved for treatment of menopausal symptoms but should be prescribed for the shortest period of time possible. When used solely for the prevention of postmenopausal osteoporosis, any estrogen/hormone therapy regimen should only be considered for women at significant risk of osteoporosis, and non-estrogen medications should

be carefully considered first. The women in the WHI were participating in a follow-up phase of the study that was anticipated to last until 2010.

For people who cannot or decide not to take estrogen/hormone therapy, other medications can be good choices. These include a class of drugs called bisphosphonates, such as alendronate (Fosamax), risedronate (Actonel), and ibandronate (Boniva). Another bisphosphonate, zoledronic acid (Reclast), is approved to treat postmenopausal osteoporosis. Alendronate and another drug, calcitonin (Miacalein, Fortical), both stop bone loss, help build bone, and decrease fracture risk by as much as 50%. Both drugs attach to bone that has been targeted by bone-eating osteoclasts. They protect the bone from these cells. Osteoclasts help the body break down old bone tissue. Calcitonin is a hormone that has been used as an injection for many years. A subsequent version was on the market as a nasal spray in 2008. Side effects of these drugs are minimal, but calcitonin builds bone by only 1.5% a year. Fosamax has proven safe in very large multi-year studies and is as of 2008 indicated for treatment of osteoporosis in most men. Boniva is a pill that is taken once a month.

Another drug approved by the FDA to treat and prevent osteoporosis is raloxifene (Evista). It is from a class of drugs called estrogen agonists/antagonists, commonly called selective estrogen receptor modulators. Raloxifene appears to prevent bone loss in the spine, hips, and total body. It has been shown to benefit bone mass and turnover and can decrease the risk of vertebral fractures. Also approved for postmenopausal women and men with osteoporosis who have a high risk for fracture, is teriparatide (Forteo), an injectable form of human parathyroid hormone. Unlike other osteoporosis drugs, teriparatide works by stimulating new bone formation in the spine and hips.

Medications under study in the late 2000s include other biphosphonates that slow bone breakdown (such as alendronate), **sodium** fluoride, and vitamin D metabolites.

Surgery

Unfortunately, much of the treatment for osteoporosis is for fractures that result from advanced stages of the disease. For complicated fractures, such as broken hips, hospitalization and a surgical procedure are required. In hip replacement surgery, the broken hip is removed and replaced with a new hip made of plastic or a combination of metal and plastic. Despite often-successful surgeries, a large percentage of those who survive are unable to return to their previous level of activity, and many end up moving from self-care to a supervised living situation or nursing home. That is why prevention, getting early treatment, and taking steps to reduce bone loss are vital.

Expected results

There is no cure for osteoporosis, but it can be controlled. Most people who have osteoporosis fare well once they get treatment. The medicines available build bone, protect against bone loss, and halt the progress of this disease.

Prevention

Building strong bones, especially before the age of 35, and maintaining a healthy lifestyle are the best ways of preventing osteoporosis. To build as much bone mass as early as possible in life and to help slow the rate of bone loss later in life, individuals should do the following:

- Get calcium in foods: Experts recommend 500 to 1,300 milligrams (mg) of calcium per day for children, 1,300 mg for adolescents, 1,000 mg for ages 19 to 50, and 1,200 mg for people 51 and older. The dosage for pregnant or lactating women ages 14 to 18 is 1,300 mg daily and 1,000 mg for age 19 and older. Foods are the best source for this important mineral. Milk, cheese, and yogurt have the highest amounts. Other foods that are high in calcium are green leafy vegetables, tofu, shellfish, Brazil nuts, sardines, and almonds.
- Take calcium supplements: Many people, especially those who do not like or cannot eat dairy foods, do not get enough calcium in their diets and may need to take a calcium supplement. Supplements should be taken with meals and accompanied by six to eight glasses of water a day.
- Get vitamin D: Vitamin D helps the body absorb calcium. People can get vitamin D from sunshine with a quick (15–20 minute) walk each day or from foods such as liver, fish oil, and vitamin D fortified milk. During the winter months it may be necessary to take supplements. Four hundred mg daily is usually the recommended amount.
- Avoid smoking and alcohol: Smoking reduces bone mass, as does heavy drinking. To reduce risk, individuals ought not to smoke, and ought to limit alcoholic drinks to no more than two per day. An alcoholic drink is 1.5 oz of hard liquor, 12 oz of beer, or 5 oz of wine.
- Exercise regularly: Exercising regularly builds and strengthens bones. Weight-bearing exercises, in which bones and muscles work against gravity, are best.

KEY TERMS

Alendronate—A non-hormonal drug used to treat osteoporosis in postmenopausal women.

Anticonvulsants—Drugs used to prevent convulsions or seizures. They often are prescribed in the treatment of epilepsy.

Biphosphonates—Compounds (such as alendronate) that slow bone loss and increase bone density.

Calcitonin—A naturally occurring hormone made by the thyroid gland that can be used as a drug to treat osteoporosis and Paget's disease of the bone.

Estrogen—Female hormone produced mainly by the ovaries and released by the follicles as they mature. Responsible for female sexual characteristics, estrogen stimulates and triggers a response from at least 300 tissues. After menopause, the production of the hormone gradually decreases and eventually stops.

Glucocorticoids—A general class of adrenal cortical hormones that are mainly active in protecting against stress and in protein and carbohydrate metabolism. They are widely used in medicine as anti-inflammatories and immunosuppresives.

Osteoblasts—Cells in the body that build new bone tissue.

Osteoclasts—Cells that break down and remove old bone tissue.

Selective estrogen receptor modulator—A hormonal preparation that offers the beneficial effects of hormone replacement therapy (HRT) without the increased risk of breast and uterine cancer associated with HRT.

These include aerobics, dancing, jogging, stair climbing, tennis, walking, and lifting weights. People who have osteoporosis may want to attempt gentle exercise, such as walking, rather than jogging or fast-paced aerobics, which increase the chance of falling. Individuals ought to exercise three to four times per week for 20 to 30 minutes each time.

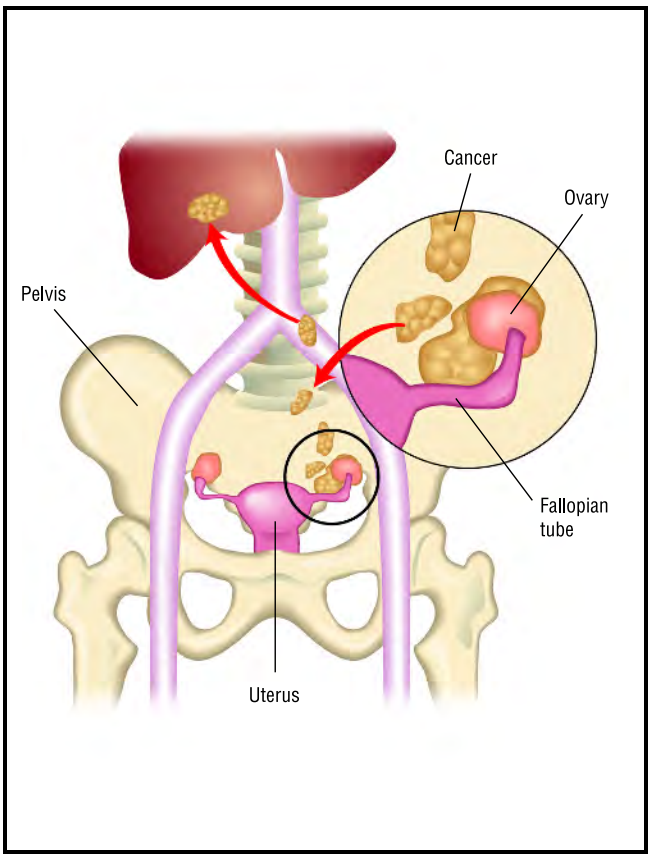
Ovarian cancer

Definition

Ovarian **cancer** is a disease in which the cells in the ovaries become abnormal, start to grow uncontrollably, and form tumors. Ninety percent of all ovarian cancers develop in the cells that line the surface of the ovaries and are called epithelial cell tumors.

Description

The ovaries are a pair of almond-shaped organs that lie in the pelvis on either side of the uterus. The fallopian tubes connect the ovaries to the uterus. The



A close-up of a cancerous growth on the ovary. *(Illustration by GGS Information Services, Inc. Cengage Learning, Gale)*

ovaries produce and release usually one egg each month during the menstrual cycle. Along with the adrenal gland, the ovaries also produce the female hormones estrogen and progesterone, which regulate and maintain the secondary female sexual characteristics.

Ovarian cancer is the fifth most common cancer among women in the United States. It accounts for 4% of all cancers in women. However, the death rate due to this cancer is higher than that of any other cancer among women. About 1 in 70 women in the United States was anticipated to develop ovarian cancer, and 1 in 100 was anticipated to die from it. The National Cancer Institute (NCI) estimated that 21,650 new cases of ovarian cancer would be diagnosed in the United States in 2008, and that 15,520 women would die from the disease.

Ovarian cancer can develop at any age, but more than half the cases occur among women who are 65 years old or older. The incidence of the disease is highest among Native American women, followed by Caucasian, Vietnamese, Hispanic, and Hawaiian women. Only 50% of the women who are diagnosed with ovarian cancer survive five years after initial diagnosis. This low survival rate is because at the time of initial diagnosis, the cancer is usually in an advanced stage. It is difficult to diagnose ovarian cancer early because often there are no warning symptoms, and the disease spreads relatively quickly. In addition, the ovaries are situated deep in the pelvis and small tumors cannot be detected easily during a routine physical examination.

Causes and symptoms

The actual cause of ovarian cancer is not known, but several factors are known to increase a woman's chances of developing the disease. These are called risk factors. The major risk factors for cancer in general are tobacco, alcohol, diet, sexual and reproductive behavior, infectious agents, family history, occupation, environment, and pollution. There are several risk factors particularly associated with ovarian cancer.

- Age. The incidence of the disease increases with age. Half of all cases are diagnosed after age 65.
- Race. The incidence of the disease is highest among Native American women and lowest among Korean and Chinese women.
- High-fat diet. When Asian women move to the more affluent Western countries and adopt a diet that is rich in fat, the incidence of ovarian cancer among them rises. Furthermore, ovarian cancer is highest in those countries with the highest consumption of dairy foods (Switzerland, Denmark, and Sweden) and lowest in those countries with the lowest dairy intake (Japan, South Korea, Singapore). Ovarian cancer is also linked to high socioeconomic status in women.
- Family history. Women who have even one close relative with the disease have a threefold increase in risk. In addition, if a woman has had breast cancer, she is at an increased risk for ovarian cancer.
- Early menstruation/late menopause. Menstruating early (before age 12) and experiencing menopause late seem to put women at a higher risk for ovarian cancer. It is believed that the longer a woman ovulates, the higher her risk of ovarian cancer (some researchers think exposure to estrogen during the monthly cycles is the cause). Since ovulation occurs only during the childbearing years, the longer she menstruates, the greater her risk. Pregnancy gives a break from ovulation and exposure to estrogen for nine months. Hence, multiple pregnancies actually appear to reduce the risk of ovarian cancer. Similarly, since oral contraceptives suppress ovulation and reduce exposure to estrogen, women who take birth control pills have a lower incidence of the disease.

- Fertility drugs. One study has shown that prolonged use of certain fertility drugs, such as clomiphene citrate, may increase a woman's risk of developing ovarian tumors.
- Talcum powder. Some studies have suggested that the use of talcum powder in the genital area may double a woman's risk of getting the cancer. The incidence of ovarian cancer is higher than normal among female workers exposed to asbestos. Since talc contains particles of asbestos, some researchers believe that is what accounts for the increased risk.

Ovarian cancer has no specific signs or symptoms in the early stages of the disease. There may be some vague, nonspecific symptoms that are often ignored. However, if any of the symptoms persist, it is essential to have them evaluated by a doctor immediately. Only a doctor can determine whether the symptoms are an indication of early ovarian cancer; however, the presence of two or more of the following symptoms is reason for concern. The patient may experience:

- pain or swelling in the abdomen
- bloating, and a general feeling of abdominal discomfort
- constipation, nausea, or vomiting
- loss of appetite, fatigue
- unexplained weight gain (generally due to an accumulation of fluid in the abdomen)
- vaginal bleeding in postmenopausal women.

Diagnosis

Patients with ovarian cancer were once thought to exhibit no symptoms in the early stage of the disease. But newer studies have shown that certain symptoms are more common in women with early stage ovarian cancer. These symptoms include bloating, pelvic or abdominal **pain**, difficulty eating or feeling full early, and urinary problems, such as frequency or urgency, according to the National Comprehensive Cancer Network. If ovarian cancer is suspected, the doctor typically begins the diagnosis by taking a complete medical history to assess all the risk factors. A thorough pelvic examination is conducted. Blood tests to determine the level of a particular blood protein, CA125, may be ordered. This protein is usually elevated in women with ovarian cancer. However, it is not a definitive test because the levels may also rise in other gynecologic conditions, such as **endometriosis** and ectopic **pregnancy**. Researchers have found another biological marker, a protein called prostasin that appears to be specific to ovarian cancer. While prostasin should not be used as the only blood test for ovarian cancer, assessment of prostasin levels together with CA125 levels improves the likelihood of early detection. Ultrasound is almost always used to check the size of the ovaries. Standard imaging techniques such as computed tomography scans (CT scans) and magnetic resonance imaging (MRI) may be used to determine the condition of the ovaries and if the disease has spread to other parts of the body. Ultrasonography, which uses ultrasound waves to produce images of the ovaries, is also used to diagnose ovarian cancer.

A noninvasive technique for early detection of ovarian cancer involves a genetically altered virus. Researchers at the University of Alabama engineered a **common cold** virus to infect ovarian cancer cells with a green fluorescent protein that reveals the cancer cells. The technique can also be used to monitor the effectiveness of therapy.

Other tests for the early detection of ovarian cancer were undergoing development as of 2008. One of the most promising is a blood test for asymptomatic early-stage ovarian cancer. The test, developed by researchers at Yale University, has shown a 99% accuracy rate in early trials. Further testing was underway as of early 2008, and if approved by the U.S. Food and Drug Administration (FDA), the test could be available in late 2008 or early 2009.

In order to determine if the tumor is benign or cancerous, surgery is necessary. If the tumor appears to be small from the imaging tests, then a procedure known as laparoscopy may be used. A tiny incision is made in the abdomen and a slender, hollow, lighted instrument is inserted through it. This device lets the doctor view the ovary more closely and to obtain a piece of tissue for microscopic examination. If the tumor appears large, a laparotomy is performed under general anesthesia. This procedure combines both diagnosis and treatment for ovarian cancer because the tumor is often completely removed at this time. A piece of the tissue that is removed will be examined under a microscope to determine whether the tumor was benign or malignant.

Surgery confirms the diagnosis, but ovarian cancer is often strongly suspected before surgery based on symptoms and ultrasound. The goal of surgery is to completely remove the cancer, but often this is not possible.

Diagnosis in alternative treatment uses mainstream diagnostic techniques and supplements them with thorough physical and psychological examinations. Considerations such as lifestyle, relationships, and emotional and psychological histories are used to complete an overall portrait of a patient's health in order to develop holistic strategies for healing.

Treatment

There are many alternative treatments available to help with ovarian cancer. Alternative treatments can be used in conjunction with, or separate from, surgery, chemotherapy, and radiation therapy. When used with conventional treatment, alternative treatments have been shown to decrease pain and side effects, aid in the recovery process, and improve the quality of life of cancer patients.

Alternative treatment of cancer is complicated, and there are many choices in therapies and alternative practitioners. Consumers should consult as many trained healthcare practitioners as possible when choosing alternative therapies. If consumers are willing to ask questions and thoroughly research their options, they can increase their chances of getting the best possible alternative support for the difficult task of treating cancer.

Alternative medicine generally views cancer as a holistic problem. That is, cancer represents a problem with the body's overall health and immunity. As such, treatment is holistic as well, striving to strengthen and heal the physical, mental, and emotional aspects of patients. Alternative cancer treatments may emphasize different basic approaches, which include traditional medicines, mind/body approaches, physical approaches, nutritional and dietary approaches, integrated approaches, and experimental programs.

Traditional medicines

Traditional Chinese medicine uses **acupuncture**, **acupressure** massage, herbal remedies, and movement therapies such as t'ai chi and **qigong** to treat cancer. Traditional Chinese herbal remedies have already contributed a significant number of anticancer drugs, and studies have shown their anticancer properties. Acupuncture has been shown to reduce some tumors, significantly reduce pain, and support and improve immune system activity.

Ayurvedic medicine uses **detoxification**, herbal remedies, massage, **exercise**, **yoga**, breathing techniques, and **meditation** as part of its cancer treatment. *Panchakarma* is an extensive detoxification and strengthening program that is recommended for cancer patients and those undergoing chemotherapy and radiation. **Panchakarma** uses **fasting**, special vegetarian **diets**, enemas, massage, herbal medicines, and other techniques to rid the body of excess toxins (believed to contribute to chronic diseases such as cancer) and to strengthen the immune system. Some Ayurvedic herbs may also have significant anticancer properties.

Naturopathy and **homeopathy** are traditional Western healing systems using herbal medicines and other techniques to strengthen the immune system and reduce the pain of cancer treatment. **Western herbalism** is also beginning to compile studies of many herbs that have potential anticancer and immune strengthening properties (such as **mistletoe**).

Mind/body approaches

Mind/body treatments seek to help patients with the mental and spiritual challenges posed by cancer and to mobilize the body's own defenses and immune system. Some of these therapies include **psychotherapy**, support groups, **guided imagery**, visualization techniques, meditation, **biofeedback**, hypnosis, breathing techniques, and yoga. Mind/body approaches work with the idea that the mind and emotions can profoundly influence the health of the body. These techniques help patients manage the **stress** and **anxiety** that accompany cancer. Mind/body techniques have also been shown to stimulate the immune system and to reduce the pain of symptoms and conventional treatments.

Physical approaches

Physical approaches to cancer include exercise; massage therapies; movement therapies, including yoga, t'ai chi, and qigong; breathing techniques; and **relaxation** techniques. These therapies strive to increase immune system response, promote relaxation and stress reduction, and reduce side effects (such as pain, **nausea**, **vomiting**, weakness, and physical immobility) of conventional treatments.

Nutritional and dietary approaches

Cancer patients have heightened needs for diets free of toxic chemicals and full of cancer-fighting nutrients. Diet and **nutrition** may improve both a cancer patient's chances for recovery and the patient's quality of life during treatment. In laboratory studies, vitamins such as A, C, and E, as well as compounds such as isothiocyanates and dithiolthiones found in broccoli, cauliflower, and cabbage, and beta-carotene found in carrots, tomatoes, and salad greens, have been shown to protect against cancer. The minerals **selenium** and **zinc** are also important nutrients in the ovarian cancer diet. Omega-3 **essential fatty acids** such as **flaxseed** oil or **evening primrose oil** are recommended as well.

Dietary approaches for ovarian cancer include **vegetarianism**, the raw food diet, and macrobiotics. Cancer diets generally emphasize raw and fresh fruits,

vegetables, whole grains, beans, and peas. These diets also restrict or eliminate intake of fat, meat, dairy products, sugar, hydrogenated oils, processed foods, and foods with additives and artificial ingredients. **Caffeine** and alcohol are generally prohibited, and overeating is strongly discouraged.

Many herbs have been shown to have anticancer, immune enhancing, and symptom reducing properties. Some of the herbs used for ovarian problems include burdock, **mullein**, **yarrow**, vitex, **dandelion**, **black cohosh**, St. John's wort, red **raspberry**, nettles, and **Siberian ginseng**. Chinese herbs include **astragalus**, **ginger**, **dong quai**, cinnamon, rehmannia root, and scrophularia root. Patients should consult a competent herbalist or naturopathic doctor for individualized herbal support for ovarian cancer.

At least five plant extracts and 69 compounds isolated from plants have been shown to have antitumor activity against ovarian cancers. Recent additions to the list include triterpenes isolated from *Manihot esculenta*, a plant found in the Suriname rain forest, and from *Ligulariopsis shichuana*, a plant used in traditional Chinese medicine to bring down inflammation. **Green tea** consumption also improved the survival rate of women with epithelial ovarian cancer, a Chinese study reported in 2007. Green tea is high in polyphenols, which studies have shown to have powerful antioxidant and antitumor properties.

Integrated approaches

Keith Block, a conventional doctor and oncologist (cancer specialist), integrates many alternative practices into his cancer treatment center affiliated with the Chicago Medical School. His program seeks to provide individualized cancer treatment using both conventional therapies while integrating alternative healing techniques. Block advocates a special diet (based on vegetarianism and macrobiotics), exercise, psychological support, and herbal and nutritional supplements. Block's program has received acclaim for both treatment success and satisfaction of patients.

Experimental programs

Antineoplaston therapy was developed by Stanislaw Burzynski, a Polish doctor, who began practicing in Houston, Texas. Burzynski has isolated a chemical, deficient in those with cancer that he believes stops cancer growth, and his treatment has shown some promise.

Joseph Gold, the director of the Syracuse Cancer Research Institute, discovered that the chemical hydrazine sulfate has many positive effects in cancer patients, including stopping weight loss, shrinking tumors, and increasing survival rates.

The Livingston therapy was developed by the late Virginia Livingston, an American doctor. She asserted that cancer is caused by certain bacteria that she claimed are present in all tumors. She advocated a detoxification program and special diet that emphasized raw or lightly cooked, primarily vegetarian foods, with special vitamin and nutritional supplements.

The **Gerson therapy** has been the best known nutritional therapy for cancer. It is available in two clinics in California and Mexico. It consists of a basic vegetarian diet low in salt and fat, with high dosages of particular nutrients using raw fruit and vegetable juices. The Gerson therapy also requires patients to drink raw calf's liver juice, believed to aid the liver, and advocates frequent coffee enemas (thought to help the body evacuate toxins). There is no scientific evidence that supports the effectiveness of Gerson therapy.

Allopathic treatment

The cornerstone of allopathic treatment for ovarian cancer is surgery. The goal is to remove as much of the cancer as possible. Chemotherapy, which involves the use of powerful anticancer drugs to kill the cancer cells, is usually administered after the surgery to destroy any remaining cancer. As of 2008 some drugs to treat ovarian cancer were in the clinical trial stage, including monoclonal antibody treatment for advanced ovarian cancer. Radiation therapy is not routinely used for ovarian cancer.

The type of surgery depends on the extent of the disease. In most procedures, the ovaries, uterus, and fallopian tubes are completely removed. In rare cases, if the cancer is not very aggressive and the woman is young and has not had children, a more conservative approach may be adopted. Only one ovary may be removed, and, if possible, the fallopian tubes and the uterus may be left intact. Occasionally, in addition to the female reproductive organs, the appendix may also be removed. The liver and the intestine will be examined for signs of cancer and may be biopsied. Ovarian cancer spreads contiguously, which means that it moves to the organs that are next to it. In some cases, extensive surgery may be needed to remove as much of the cancer as possible.

If the patient's cancer is advanced, she may be treated with radiation therapy, chemotherapy, or both. Chemotherapy may be either systemic or intraperitoneal (IP), which means that the drugs are injected into the abdomen. The most common drug used is paclitaxel (Taxol), combined with either cisplatin or

carboplatin. Cancers that do not respond to these combinations may be treated with topotecan (Hycamtin) or with a combination of paclitaxel and epirubicin (Ellence).

One drug treatment for ovarian cancer under development in 2008, enzastaurin, was undergoing clinical trial in combination with two existing drugs, docetaxel and prednisone, in several European countries. The clinical trials were expected to be completed in January 2010. The drug is also being tested in Europe to treat breast and colorectal cancers.

Expected results

Most often ovarian cancer is not diagnosed until it is in an advanced stage, making it the most deadly of the female reproductive cancers. More than 50% of the women who are diagnosed with the disease die within five years. If ovarian cancer is diagnosed while it is still localized to the ovary, more than 90% of the patients will survive five years or more. However, only 24% of all cancers are found at this early stage.

There are no clinical studies that show alternative medicine can cure cancer, but many treatments have been shown to help improve symptoms, control the pain and side effects of conventional treatments, speed healing, and increase the quality of life for cancer patients. Alternative therapies may be strongest as preventative measures, before major problems such as cancer occur in the body, and as supportive measures, used with allopathic medicine.

Prevention

There are ways to reduce one's risks of developing ovarian cancer. As of 2008, genetic tests were available that could help to determine whether a woman who has a family history of breast, endometrial, or ovarian cancer has inherited the mutated gene that predisposes her to these cancers. (However, this mutation affects only a few women.) If the woman tests positive for the mutation, then she may opt to have her ovaries removed (a procedure called an oophorectomy). Allopathic medicine often recommends removing the ovaries as prevention even when a clear genetic component is not found, and this procedure is called a prophylactic oophorectomy.

Having one or more children, preferably having the first before age 30, and breast-feeding may decrease a woman's risk of developing the disease. High-risk women are advised to undergo periodic screening with transvaginal ultrasound or a blood test for CA125 protein. The American Cancer Society recommends annual pelvic examinations for all women after age 40, in order to increase the chances of early detection of ovarian cancer.

Alternative medicine stresses preventative measures that avoid removing the ovaries, unless a clear genetic risk has been established. Some studies have shown that removal of the ovaries does not necessarily reduce the risk of cancer, and does not necessarily increase longevity rates in women.

Having sound physical and mental health can significantly reduce the chances of getting cancer of any type. The following guidelines are generally recommended by doctors, nutritionists, and alternative practitioners for cancer prevention and recovery.

- Do not smoke.
- Do not drink alcohol excessively.
- Exercise regularly, at least 20 minutes per day. It is better to exercise outdoors in the fresh air.
- Avoid exposure to radiation. This includes avoiding unnecessary x rays, not residing near sources of natural or man-made radiation, and avoiding occupational exposure to radiation.
- Avoid exposure to harmful chemicals, in food, the home, and the workplace.
- Maintain proper body weight and avoid obesity.
- Protect the skin from overexposure to sunlight. People should avoid direct exposure to sunlight between 11 a.m. and 3 p.m., and take other necessary precautions against sunburn.
- Eat a healthy diet. People should become educated on and practice dietary principles that reduce the risk of cancer. These principles include eating plenty of raw and fresh fruits, vegetables, beans, and whole grains. People should consume organically grown foods when possible, minimize overeating, reduced the intake of meat and dairy products, increase fiber, avoid processed and artificial foods. They should also avoid canned foods, including soft drinks; avoid sugar and refined starch products, such as white flour; reduce the intake of fat; avoid hydrogenated vegetable oils such as margarine and shortening; and drink filtered or spring water. A study of nearly 50,000 women, called the Women's Health Initiative, reported in 2008 that women who reduced their fat intake for at least four years had a 40% reduced risk of ovarian cancer compared to women who did not reduce their dietary intake of fat.
- Strive to maintain sound mental and emotional health. It is helpful to learn a technique such as yoga, t'ai chi, or meditation to reduce stress and promote relaxation. People should maintain healthy relationships and social support systems.

KEY TERMS

Computed tomography (CT) scan—A series of x rays that are put together by a computer in order to form detailed pictures of areas inside the body.

Ectopic pregnancy—A pregnancy that develops outside of the uterus, such as in the fallopian tube. Ectopic pregnancies often cause severe pain in the lower abdomen and are potentially life-threatening because of the massive blood loss that may occur as the developing embryo/fetus ruptures and damages the tissues in which it has implanted.

Endometriosis—A condition in which the tissue that normally lines the uterus (endometrium) grows in other areas of the body, causing pain, irregular bleeding, and frequently, infertility.

Magnetic resonance imaging (MRI)—An imaging technique that uses a large circular magnet and radio waves to generate signals from atoms in the body. These signals are used to construct detailed images of internal body structures and organs, including the brain.

Monoclonal antibody—A protein substance that is produced in the laboratory from a single clone of a B-cell, the type of cell of the immune system that makes antibodies. Monoclonal antibodies are used in cancer treatment.

Paclitaxel—A drug derived from the common yew tree (*Taxus baccata*) that is the mainstay of chemotherapy for ovarian cancer.

Prostasin—A blood protein that appears to be a reliable early indicator of ovarian cancer.

Transvaginal ultrasound—A technique for imaging the ovaries using sound waves generated by a probe inserted into the vagina. This diagnostic imaging procedure serves as the baseline for a hysterosonographic examination.

Ovarian cysts

Definition

Ovarian cysts are fluid-filled sacs that form inside or on the surface of the ovaries, which are the female reproductive organs that lie in the lower abdomen. Ovarian cysts appear and disappear regularly as part of the normal menstrual cycle. The cysts can, however, become a medical problem if they remain in the ovaries, enlarge, and cause **pain** or other symptoms.

Description

Ovarian cysts develop as a normal part of a healthy menstrual cycle; mature ovaries very often have cysts in them. The cysts that appear during the regular activity of the ovaries are called functional cysts. There are two types of functional cysts, known as follicular cysts and luteal cysts respectively.

Ovarian cyst (on the left). *(VEM / Photo Researchers, Inc.)*

KEY TERMS

Antiandrogen—A substance that blocks the action of androgens, the hormones responsible for male characteristics.

Dermoid tumor—A skin-like benign growth that may appear on the ovary and resemble a cyst.

Ectopic pregnancy—A pregnancy that develops outside of the mother's uterus, such as in the fallopian tube. Ectopic pregnancies often cause severe pain in the lower abdomen and are potentially life-threatening because of the massive blood loss that may occur as the developing embryo/fetus ruptures and damages the tissues in which it has implanted.

Functional cyst—A benign cyst that forms on the ovary and resolves on its own without treatment.

Hirsutism—An abnormal growth of hair on the face and other parts of the body caused by an excess of androgens. Also known as hypertrichosis.

McCune-Albright syndrome (MCAS)—A genetic syndrome characterized in girls by the development of ovarian cysts and puberty before the age of 8, together with abnormalities of bone structure and skin pigmentation.

Mittelschmerz—A German word for the pain that some women experience at ovulation.

Ovulation—The monthly process by which an ovarian follicle ruptures releasing a mature egg cell.

Polycystic ovarian syndrome (PCOS)—A condition in which the eggs are not released from the ovaries and instead form multiple cysts.

In the ovaries, immature eggs are stored in the follicles, which are tiny tube-like membranes. When **menstruation** begins in the early teens, women have nearly 400,000 follicles that store and produce eggs in the ovaries. During each menstrual cycle, an egg matures inside one of the follicles, and the follicle sac fills up with a liquid (*liquor folliculi*) that nourishes the growing egg. This swollen follicle is a follicular cyst. When the egg is released into the fallopian tube during ovulation, the follicle opens or ruptures and the fluid drains away. Sometimes there is pain associated with ovulation, known as *Mittelschmerz*, which is a German word that means middle pain. *Mittelschmerz* may last from a few minutes to several days. A small amount of bleeding may also accompany the normal release of an egg from the follicle.

After ovulation, another functional cyst forms on the ovary where the egg was released. This cyst is called the *corpus luteum*, or luteal cyst. The luteal cyst has the function of secreting progesterone, an important female hormone that regulates the reproductive cycle. If no **pregnancy** occurs, the luteal cyst should disappear with the continuation of the menstrual cycle.

Abnormalities in the menstrual cycle may cause cysts to remain and grow irregularly. Sometimes the follicles stay filled with liquid after the egg is released, or the egg does not get released in the proper way and the follicle continues to grow. These follicular cysts can reach 2 in (5 cm) or more in diameter, and may cause pain and pressure. They may rupture completely. Luteal cysts can also become abnormal. These cysts can grow quite large, to 3 in (8 cm)or more in diameter, and can cause sharp pain in the abdomen. Luteal cysts are often misdiagnosed as ectopic (tubal) pregnancies, particularly when they break open and cause bleeding and severe pain. Sometimes a cyst can bleed; it is then known as a *corpus hemorrhagicum*, meaning a body that bleeds. Bleeding often occurs when the cyst naturally breaks and begins to go away. When bleeding lasts for longer than several days and a large cyst remains, surgical intervention is sometimes called for. Surgery on the ovaries is usually performed through an instrument called a laparoscope. A laparoscope is a small device with a tiny camera.

Other types of cysts and growths may occur on the ovaries as well. Neoplastic (new growth) cysts may appear, which are benign (noncancerous) growths. These cysts occur when cells of the ovaries not related to ovulation begin to grow abnormally. Dermoid tumors are a type of benign growth that may occur on the ovaries and resemble cysts. Abnormal cysts may contain fluid or blood, and may be inside the ovary or next to it under the surface. Other cysts can be solid or contain cellular debris. All abnormal cysts require close watch by a doctor.

There is also a condition known as **polycystic ovary syndrome** (PCOS), in which the eggs and follicles are not released from the ovaries and instead form multiple cysts. **Obesity** is linked to this condition, as 50% of women with PCOS are also obese. Hormonal imbalances play a major role in this condition, including high levels of the hormone androgen and low levels of progesterone, the female hormone necessary for egg release. High levels of insulin, the hormone that regulates blood sugar, are often found in women with PCOS. PCOS is also characterized by irregular menstrual periods, **infertility**, and hirsutism (excessive hair growth on the body and face). Although PCOS was formerly thought to be an adult-onset condition, more recent research indicates that it begins in childhood, possibly even during fetal development.

In adolescent girls, ovarian cysts may be associated with a genetic disorder known as McCune-Albright syndrome, which is characterized by abnormal bone growth, discoloration of the skin, and early onset of puberty. The ovarian cysts are responsible for the early sexual maturation.

Causes and symptoms

The causes of nonfunctional ovarian cysts are not yet fully understood. Many factors are believed to play a role in the development of cysts, including a woman's general state of health, weight, diet, personal history, and lifestyle. The mind/body connection may also be a factor with cysts, as **stress** and **anxiety** may be prominent factors. Some alternative practitioners and psychotherapists believe that unexpressed creativity and repressed emotions like guilt and anger may be linked to problems in the ovaries. For PCOS, obesity, hormonal imbalances and high blood insulin levels are closely linked to the condition. For example, women with PCOS are five to ten times more likely to develop type 2 (adult-onset) diabetes than women in the general population.

PCOS is also known to run in families, which suggests that genetic factors contribute to its development. The specific gene or genes responsible for PCOS have not yet been identified; however, several groups of researchers in different countries have been investigating genetic variations associated with increased risk of type 2 diabetes in order to determine whether the same genetic variations may be involved in PCOS.

McCune-Albright syndrome is known to be associated with mutations in the GNAS1 gene. The mutation is sporadic, which means that it occurs during the child's development in the womb and that the syndrome is not inherited.

Some cysts can be asymptomatic (without symptoms), while others can cause swelling, aching, sharp pain, and bleeding. Pain from cysts may last from a few minutes to a few days. Other symptoms of cysts include late or missed periods, feelings of pressure or weight in the lower abdomen, and **constipation** and problems urinating due to internal pressure from cysts. Ruptured cysts can cause intense pain, and produce symptoms resembling those of appendicitis, infection or ectopic pregnancy. Medical attention should be sought at once for the following symptoms:

- sudden sharp pain in the lower abdomen
- persistent pain on the right side of the abdomen accompanied by sickness, fever, or vomiting
- abdominal pain along with vaginal discharge, fever, or swelling
- intermittant bursts of pain in the lower abdomen during intercourse, bowel movements, or exercise

Diagnosis

The majority of ovarian cysts in adults are found during routine pelvic examinations performed by doctors or gynecologists (specialists in women's sexual organs and health issues). An ultrasound test can be given to identify the location, size and probable type of cyst. Cysts less than 1.6 in (4 cm) in diameter are considered normal in premenopausal women. Doctors examine cysts closely to make certain they are not fibroid tumors or **cancer**. The cysts may be watched for a few months to allow them to go away or shrink on their own. For abnormal, painful or bleeding cysts, a biopsy may be performed. A biopsy is a procedure in which a small amount of tissue is surgically removed and examined to determine the exact type of growth. In alternative treatment, practitioners will closely consider lifestyle, diet, and emotional and psychological profiles in order to identify all the factors that may be playing a role in the development of cysts.

Ovarian cysts can be diagnosed in female fetuses by transabdominal ultrasound during the mother's pregnancy.

Treatment

Alternative treatment strives to reduce the possible causes and symptoms of cysts. Consumers should search for practitioners who have experience treating women's problems in general and ovarian cysts in particular. Because cysts may have many possible causes, ranging from hormone imbalances to emotional stress,

a holistic approach to healing should include measures to balance and improve physical, emotional, and mental health. Preventive and supportive measures include dietary and nutritional changes, herbal supplementation, hot/cold compresses, daily **exercise**, and stress management through mind/body techniques. Treatments for existing cysts include such traditional healing systems as **traditional Chinese medicine**, Ayurveda, **homeopathy**, and **naturopathic medicine**.

Diet and nutrition

Dietary guidelines for treatment and prevention of cysts include:

- Eliminating caffeine and alcohol.
- Reducing intake of sugars, including honey and maple syrup, and refined starches such as white flour products.
- Increasing use of foods rich in vitamin A and carotenoids; good choices include carrots, tomatoes, and salad greens.
- Eating foods high in B vitamins such as whole grains.
- Including a dietary source of iodine such as seaweed for thyroid support.

Nutritional supplements include:

- Omega-3 essential fatty acids, such as flaxseed oil or evening primrose oil to promote hormonal balance. Essential fatty acids are also found in fatty fish like salmon and trout.
- Vitamins A, C, and E, and the minerals zinc and selenium. Zinc and selenium should be taken at different times. A good multivitamin and mineral supplement is also recommended.

Herbal therapies

Herbs that promote hormonal balance, steady blood sugar levels, and immune system strengthening are generally recommended. Herbs used to treat cysts include burdock, **mullein**, **yarrow**, vitex, **dandelion**, **black cohosh**, **St. John's wort**, red **raspberry**, nettles and **Siberian ginseng**. Chinese herbs include **astragalus**, **ginger**, **dong quai**, cinnamon, rehmannia root, and scrophularia root, although the specific formula that is given is tailored to the symptoms of the specific patient. A competent herbalist or naturopathic doctor should be consulted for herbal treatment of ovarian cysts.

Compresses

Compresses can be used to stimulate circulation and healing in the ovaries. A hot water bottle covered with a towel soaked in castor and **essential oils** can be applied to the lower abdomen near the ovaries. **Lavender**, **rosemary**, and **chamomile** are recommended essential oils. A hot compress can also be made by heating in a warm oven a cloth soaked in castor and essential oils, which is then applied to the lower abdomen. Bags of ice covered with towels can be used alternately as cold treatments to increase local circulation.

Exercise and bodywork

Daily exercise for twenty minutes or more is recommended. Exercising outdoors in plenty of sunlight may help regulate hormones. **Yoga** includes exercises specifically designed to increase circulation and healing in the lower abdomen, and is an excellent stress-reduction technique as well.

Mind/body therapies

Mind/body therapies seek to heal the emotional and psychological components that may be contributing to cyst formation. Stress reduction can be achieved through yoga, **meditation**, **t'ai chi**, breathing techniques, progressive **relaxation**, and others. Visualization techniques, yoga, and **qigong** may help stimulate healing in the internal organs. Some practitioners have theorized that problems in the ovaries may be linked to certain emotional states. For instance, the ovaries are the organs that create life, and blocked creativity in women may contribute to their dysfunction. Furthermore, the ovaries are the specific female organs, and some healers have proposed that women who suffer abuse, low self-esteem, guilt and anger may be susceptible to ovarian problems. **Psychotherapy**, support groups, and other mind/body therapies seek to help women uncover and confront emotional issues.

Other systems

Traditional Chinese medicine utilizes **acupuncture**, **acupressure**, dietary and herbal remedies for ovarian cysts. **Ayurvedic medicine** uses herbal remedies, diet, exercise, yoga, massage, and **detoxification**. Homeopathic practitioners prescribe the remedies *Apis* for cysts on the right ovary and *Colocynthis* for cysts on the left ovary, as well as other remedies for hormone and immune system balance. Naturopathy tends to view ovarian cysts as associated with blood sugar problems, and uses herbal, dietary and other natural remedies to balance hormone and insulin levels.

Allopathic treatment

The treatment of ovarian cysts may vary according to the type of cyst and the patient's symptoms. Some cysts can be drained of fluid with the use of a fine

needle, although this treatment has been shown to be no more effective in eliminating cysts than leaving them alone. Many cysts, particularly small ones, can be watched closely for several months to determine if they will go away on their own. Ultrasound is used to view cysts. A laparoscopy is a surgical procedure that may be used to correct bleeding cysts and other cyst conditions without removing the ovary, and allows doctors to view the ovaries. Doctors advise surgical removal for cysts that are larger than 4 in (10 cm) and for complex cysts. Complex cysts are solid or have additional growths inside them.

Most uncomplicated ovarian cysts in female infants resolve on their own shortly after delivery. Complicated cysts are treated by laparoscopy or laparotomy after the baby is born.

McCune-Albright syndrome is treated with testolactone (Teslac), an anti-estrogen drug that corrects the hormonal imbalance caused by the ovarian cysts.

Long-term management of PCOS has been complicated in the past by lack of a clear understanding of the causes of the disorder. Most commonly, hormonal therapy has been recommended, including estrogen and progesterone and such other hormone-regulating drugs as ganirelix (Antagon). Birth control pills have also been prescribed by doctors to regulate the menstrual cycle and to shrink functional cysts. In severe and painful cases, the ovaries have been removed by surgery.

More recent studies have shown that increasing sensitivity to insulin in women with PCOS leads to improvement in both the hormonal and metabolic symptoms of the disorder. This sensitivity is increased by either weight loss and exercise programs or by medications. Metformin (Glucophage), a drug originally developed to treat type 2 diabetes, has been shown to be effective in reducing the symptoms of hyperandrogenism as well as **insulin resistance** in women with PCOS.

Another strategy that is being tried with PCOS is administration of flutamide (Eulexin), a drug normally used to treat **prostate cancer** in men. Preliminary results indicate that the antiandrogenic effects of flutamide benefit patients with PCOS by increasing blood flow to the uterus and ovaries.

A surgical procedure known as ovarian wedge resection appears to improve fertility in women with PCOS who have not responded to drug treatments. In an ovarian wedge resection, the surgeon removes a portion of the polycystic ovary in order to induce ovulation.

Expected results

Neither type of functional ovarian cyst, follicular or luteal, has been shown to progress to cancer. When cysts do not go away on their own, they often can be removed without harming the ovaries. Some women have opted to live with large cysts instead of surgery without negative consequences. The chances for cysts recurring can vary. Some women never have cysts, others get them once or occasionally, while others see them appear and disappear almost constantly. Likewise, ovarian cysts can be painful and bothersome for some women, while other women experience no symptoms.

Oxygen/ozone therapy

Definition

Oxygen/ozone therapy is a term that describes a number of different practices in which oxygen, ozone, or hydrogen peroxide are administered via **gas** or water to kill disease microorganisms, improve cellular function, and promote the healing of damaged tissues. The rationale behind bio-oxidative therapies, as they are sometimes known, is the notion that as long as the body's needs for **antioxidants** are met, the use of certain oxidative substances will stimulate the movement of oxygen atoms from the bloodstream to the cells. With higher levels of oxygen in the tissues, bacteria and viruses are killed along with defective tissue cells. Healthy cells survive and multiply more rapidly. The result is a stronger immune system. The use of oxygen and/or ozone for therapeutic treatment is sometimes called hyperbaric, meaning high-pressure therapy.

These men are receiving oxygen treatments at an oxygen bar. *(Jeff Greenberg / Alamy)*

Ozone itself is an allotrope (form) of oxygen, O_3, produced when ultraviolet light or an electric spark passes through air or oxygen. It is a toxic gas that creates free radicals, the opposite of what antioxidant vitamins do. Oxidation, however, is good when it occurs in harmful foreign organisms that have invaded the body. Ozone inactivates many disease bacteria and viruses.

Origins

The various forms of oxygen and ozone therapy have been in use since the late nineteenth century. The earliest recorded use of oxygen to treat a patient was by French surgeon J. A. Fontaine. who built a mobile operating device for the treatment in 1879. **Cancer** researchers first began using hyperbaric oxygen in the 1950s. The term hyperbaric means that the oxygen is given under pressure higher than normal air pressure. Recently, oxygen therapy has also been touted as a quick purification treatment for mass-market consumers. Oxygen bars can be found in airports and large cities, and provide pure oxygen in 20-minute

sessions for less than $20. While proponents claim that breathing oxygen will purify the body, most medical doctors do not agree. What is more, oxygen can be harmful to people with severe lung diseases, and these people should never self-treat with oxygen.

Ozone has been used since 1856 to disinfect operating rooms in European hospitals and since 1860 to purify the water supplies of several large German cities. Ozone was not, however, used to treat patients until 1915, when the German doctor Albert Wolff began to use it to treat skin diseases with the gas. During World War I, the German Army used ozone to treat **wounds** and anaerobic **infections**. In the 1950s, several German physicians used ozone to treat cancer alongside mainstream therapeutic methods. According to some estimates, in the 2000s there were more than 15,000 ozone practitioners in Europe, although the number was much smaller in the United States. The European figure includes medical doctors as well as naturopaths and homeopaths.

Hydrogen peroxide is familiar to most people as an over-the-counter preparation that is easily available at supermarkets as well as pharmacies; it is used as an antiseptic for cleansing minor **cuts** and scrapes. It was first used as an intravenous infusion in 1920 by a British physician in India, T. H. Oliver, to treat a group of 25 Indian patients who were critically ill with **pneumonia**. Oliver's patients had a mortality rate of 48%, compared to the standard mortality rate of 80% for the disease. In the 1920s, an American physician William Koch experimented with hydrogen peroxide as a treatment for cancer. He left the United States after a legal battle with the Food and Drug Administration (FDA). In the early 1960s, researchers at Baylor University studied the effects of hydrogen peroxide in removing plaque from the arteries as well as its usefulness in treating cancer, but their findings were largely ignored.

Benefits

Oxygen and ozone therapies are thought to benefit patients in the following ways:

- Stimulating white blood cell production
- Killing viruses (ozone and hydrogen peroxide)
- Improving the delivery of oxygen from the blood stream to the tissues of the body
- Speeding up the breakdown of petrochemicals
- Increasing the production of interferon and tumor necrosis factor, thus helping the body to fight infections and cancers
- Increasing the efficiency of antioxidant enzymes
- Increasing the flexibility and efficiency of the membranes of red blood cells
- Speeding up the citric acid cycle, which in turn stimulates the body's basic metabolism

Description

Oxygen, ozone, and hydrogen peroxide are used therapeutically in a variety of different ways.

Hyperbaric oxygen therapy (HBO)

Hyperbaric oxygen therapy (HBO) involves putting the patient in a pressurized chamber in which he or she breathes pure oxygen for a period of 90 minutes to two hours. HBO may also be administered by using a tight-fitting mask, similar to the masks used for anesthesia. A nasal catheter may be used for small children.

Ozone therapy

Ozone therapy may be administered in a variety of ways:

- Intramuscular injection: A mixture of oxygen and ozone is injected into the muscles of the buttocks.
- Rectal insufflation: A mixture of oxygen and ozone is introduced into the rectum and absorbed through the intestines.
- Autohemotherapy: Between 10–15 mL of the patient's blood is removed, treated with a mixture of oxygen and ozone and reinjected into the patient.
- Intra-articular injection: Ozone-treated water is injected into the patient's joints to treat arthritis, rheumatism, and other joint diseases.
- Ozonated water: Ozone is bubbled through water that is used to clean wounds, burns, and skin infections, or to treat the mouth after dental surgery.
- Ozonated oil: Ozone is bubbled through olive or safflower oil, forming a cream that is used to treat fungal infections, insect bites, acne, and skin problems.
- Ozone bagging: Ozone and oxygen are pumped into an airtight bag that surrounds the area to be treated, allowing the body tissues to absorb the mixture.

Hydrogen peroxide

Hydrogen peroxide may be administered intravenously in a 0.03% solution. It is infused slowly into the patient's vein over a period of one to three hours. Treatments are given about once a week for chronic illness but may be given daily for such acute illnesses as pneumonia or **influenza**. A course of intravenous hydrogen peroxide therapy may range from one to 20 treatments, depending on the patient's condition

and the type of illness being treated. Injections of 0.03% hydrogen peroxide have also been used to treat rheumatoid and **osteoarthritis**. The solution is injected directly into the inflamed joint.

Hydrogen peroxide is also used externally to treat stiff joints, **psoriasis**, and **fungal infections**. The patient soaks for a minimum of 20 minutes in a tub of warm water to which 1 pint of 35% food-grade hydrogen peroxide (a preparation used by the food industry as a disinfectant) has been added.

Preparations

Oxygen is usually delivered to the patient as a gas; ozone as a gas mixed with oxygen or bubbled through oil or water; and hydrogen peroxide as an 0.03% solution for intravenous injection or a 35% solution for external **hydrotherapy**.

Precautions

Patients interested in oxygen/ozone therapies must consult with a physician before receiving treatment. Hyperbaric oxygen treatment should not be given to patients with untreated pneumothorax, a condition in which air or gas is present in the cavity surrounding the lungs. Patients with a history of pneumothorax, chest surgery, **emphysema**, middle ear surgery, uncontrolled high fevers, upper respiratory infections, seizures, or disorders of the red blood cells are not suitable candidates for oxygen/ozone therapy. In addition, patients should be aware that oxygen should not be used near open flames since it greatly increases the rate of combustion.

Side effects

Typical side effects of oxygen or ozone therapy can include elevated blood pressure and ear pressure similar to that experienced while flying. Side effects may also include **headache**, numbness in the fingers, temporary changes in the lens of the eye, and seizures.

Research and general acceptance

Oxygen/ozone therapies are far more widely accepted in Europe than in the United States. In the 2000s, the most intensive research in these therapies was being conducted in the former Soviet Union and in Cuba. In the United States, the work of the Baylor researchers was not followed up. The National Center for Complementary and Alternative Medicine (NCCAM) of the National Institutes of Health sponsored four studies at the University of Pennsylvania on the use of hyperbaric oxygen in the treatment of four medical conditions.

KEY TERMS

Autohemotherapy—A form of ozone therapy in which a small quantity of the patient's blood is withdrawn, treated with a mixture of ozone and oxygen, and reinfused into the patient.

Hydrogen peroxide—A colorless, unstable compound of hydrogen and oxygen (H_2O_2). An aqueous solution of hydrogen peroxide is used as an antiseptic and bleaching agent.

Hyperbaric oxygen therapy (HBO)—A form of oxygen therapy in which the patient breathes oxygen in a pressurized chamber.

Ozone—A form of oxygen with three atoms in its molecule (O_3), produced by an electric spark or ultraviolet light passing through air or oxygen. Ozone is used therapeutically as a disinfectant and oxidative agent.

European research in ozone therapy has included studies in the oxygenation of resting muscles, the treatment of vascular disorders, and the relief of **pain** from herniated lumbar disks. Relatively little research on topics such as these was being conducted in the United States as of 2008.

Training and certification

In Europe, ozone therapies may be administered by licensed naturopaths and homeopaths as well as by medical doctors. In the United States and Canada, oxygen and ozone treatments are administered only by medical doctors.

Pain

Definition

Pain is an unpleasant feeling that is conveyed to the brain by sensory neurons. The discomfort signals actual or potential injury in the body. However, pain is more than a sensation or the physical awareness of pain; it also includes perception, the subjective interpretation of the discomfort. Perception gives information on the pain's location, intensity, and something about its nature. The various conscious and unconscious responses to both sensations and perception, including the emotional response, add further definition to the overall concept of pain.

Description

Pain arises from any number of situations. Injury is a major cause, but pain may also arise from a wide variety of illnesses. It may accompany a psychological condition, such as **depression**, or may even occur in the absence of a recognizable trigger.

Acute pain

Acute pain often results from ordinary tissue damage, such as a skin burn or broken bone. Acute pain can also be associated with headaches or **muscle cramps**. This type of pain usually goes away as the injury heals or the cause of the pain (stimulus) is removed.

To understand acute pain, it is necessary to understand the nerves that support it. Nerve cells, or neurons, perform many functions in the body. Although their general purpose, providing an interface between the brain and the body, remains constant, their capabilities vary widely. Certain types of neurons are capable of transmitting a pain signal to the brain.

As a group, these pain-sensing neurons are called nociceptors, and virtually every surface and organ of the body is wired with them. The central part of these cells is located in the spine, and they send threadlike projections to every part of the body. Nociceptors are classified according to the stimulus that prompts them to transmit a pain signal. Thermoreceptive nociceptors are stimulated by temperatures that are potentially tissue damaging. Mechanoreceptive nociceptors respond to a pressure stimulus that may cause injury. Polymodal nociceptors are the most sensitive and can respond to temperature and pressure. Polymodal nociceptors also respond to chemicals released by the cells in the area where the pain originates.

Nerve cell endings, or receptors, are at the front end of pain sensation. A stimulus at this part of the nociceptor unleashes a cascade of neurotransmitters (chemicals that transmit information within the nervous system) in the spine. Each neurotransmitter has a purpose. For example, substance P relays the pain message to nerves leading to the spinal cord and brain. These neurotransmitters may also stimulate nerves leading back to the site of the injury. This response prompts cells in the injured area to release chemicals that trigger an immune response and influence the intensity and duration of the pain.

Chronic and abnormal pain

Chronic pain refers to pain that persists after an acute injury heals, **cancer** pain, pain related to a persistent or degenerative disease, and long-term pain from an unidentifiable cause. It is estimated that one in three people in the United States experiences chronic pain at some point in their lives. Of these people, approximately 50 million are either partially or completely disabled.

Chronic pain may be caused by the body's response to acute pain. In the presence of continued stimulation of nociceptors, changes occur within the nervous system. Changes at the molecular level are dramatic and may include alterations in genetic transcription of neurotransmitters and receptors. These changes may also occur in the absence of an identifiable cause; one of the

frustrating aspects of chronic pain is that the stimulus may be unknown. For example, the stimulus cannot be identified in as many as 85% of individuals suffering lower back pain.

Other types of abnormal pain include allodynia, hyperalgesia, and phantom limb pain. These types of pain often arise from some damage to the nervous system (neuropathic). Allodynia refers to a feeling of pain in response to a normally harmless stimulus. For example, some individuals who have suffered nerve damage as a result of viral infection experience unbearable pain from just the light weight of their clothing. Hyperalgesia is somewhat related to allodynia in that the response to a painful stimulus is extreme. In this case, a mild pain stimulus, such as a pin prick, causes a maximum pain response. Phantom limb pain occurs after a limb is amputated; although an individual may be missing the limb, the nervous system continues to perceive pain originating from the area.

Causes and symptoms

Pain is the most common symptom of injury and disease, and descriptions can range in intensity from a mere ache to unbearable agony. Nociceptors have the ability to convey information to the brain that indicates the location, nature, and intensity of the pain. For example, stepping on a nail sends an information-packed message to the brain: The foot has experienced a puncture wound that hurts a lot.

Pain perception also varies depending on the location of the pain. The kinds of stimuli that cause a pain response on the skin include pricking, cutting, crushing, burning, and freezing. These same stimuli would not generate much of a response in the intestine. Intestinal pain arises from stimuli such as swelling, inflammation, and distension.

Diagnosis

Pain is considered in conjunction with other symptoms and individual experiences. An observable injury, such as a broken bone, may be a clear indicator of the type of pain a person is suffering. Determining the specific cause of internal pain is more difficult. Other symptoms, such as **fever** or **nausea**, help narrow the possibilities. In some cases, such as lower back pain, a specific cause may not be identifiable. Diagnosis of the disease causing a specific pain is further complicated by the fact that pain can be referred to (felt at) a skin site that does not seem to be connected to the site of the pain's origin. For example, pain arising from fluid accumulating at the base of the lung may be felt in the shoulder.

Since pain is a subjective sensation, it may be very difficult to communicate its exact quality and intensity to other people. There are no diagnostic tests designed to determine the quality or intensity of an individual's pain. Therefore, a medical examination includes a lot of questions about where the pain is located, its intensity, and its nature. Questions seek to reveal what increases or relieves the pain, how long it has lasted, and whether there are any variations in it. An individual may be asked to use a pain scale to describe the pain. One such scale assigns a number to the pain intensity. For example, 0 may indicate no pain, and 10 may indicate the worst pain the person could imagine. Scales are modified for infants and children to accommodate their level of comprehension. Among the most painful non-trauma experiences are **childbirth** and **kidney stones**.

Treatment

Both physical and psychological aspects of pain can be dealt with through alternative treatment. Some of the most popular treatment options include herbal therapies, nutritional therapies, **homeopathy**, **acupressure** and **acupuncture**, massage, **chiropractic**, **guided imagery**, and **relaxation** techniques, such as **yoga**, hypnosis, and **meditation**. **Hydrotherapy** can also be beneficial for pain relief. A 2006 study reported that patients who received complimentary or alternative medical therapies before and after open heart surgery experienced less pain and tension during recovery than patients who received standard pain treatment. The therapies included music, massage, and guided imagery. The study of 104 men and women was conducted by the Minneapolis Heart Institute at Abbott Northwestern Hospital in Minneapolis.

Herbal therapies

Mild natural painkillers are used as herbal remedies for pain. They should only be used for mild to moderate chronic pain. However, unlike prescription drugs, they are not addictive and do not dull the senses. In addition, they can help heal the nervous system as well as relieve pain. The following herbal remedies have been known to provide pain relief:

- Capsaicin: found naturally in cayenne pepper. Its cream or gel form may be able to relieve some arthritic pain.
- Bromelain: reduce inflammation.
- Curcumin: reduces inflammation.
- Kava kava: helps relax the body.
- Pine-bark and grape-seed extracts: reduces inflammation.

- Pain-relief tea: is composed of white willow bark, chamomile, skullcap, valerian root, and licorice root. This herbal preparation may be effective in relieving normal aches and pain. However, persons with high blood pressure or those allergic to aspirin should avoid using this preparation.

Nutritional therapy

Diet and **nutrition** can play important roles in controlling chronic pain. Patients with chronic pain sometimes find relief just by eating healthy foods and by adding nutritional supplements with pain-killing properties. A diet high in fiber and complex carbohydrates is recommended. Because inflammation is often caused by allergic reactions, patients should eliminate allergic foods from their **diets**. They should also avoid foods high in fats or margarine, red meat, dairy products, shellfish, alcohol, and coffee. In addition, they may consider taking one of the following nutritional supplements: **flaxseed** oil, **bromelain**, **calcium** taken with **magnesium**, **vitamin C** taken with **bioflavonoids**, and **glucosamine**. Glucosamine sulfate is one of the best natural remedies available for arthritic pain, although studies show mixed results. Several studies have shown that it effectively reduces pain and improves joint movement in 80% of arthritic patients. It works by healing and regenerating new connective tissues damaged by the inflammatory process. It may also increase the level of endorphins, the body's natural painkillers, and reduces inflammation in most arthritic patients.

Researchers also have reported what thousands of people with arthritis have known for a long time—that cod liver oil eases the pain of arthritis. Several studies report that the **omega-3 fatty acids** in cod liver oil break down joint cartilage, slowing destruction of the joints and easing pain. This has been good news for arthritis sufferers who cannot tolerate the prescription drugs available for arthritis treatment. However, the Glucosamine/Chondroitin Arthritis Intervention Trial reported in 2006 that glucosamine and **chondroitin** did not reduce effectively pain in people with **osteoarthritis** of the knee. Nearly 1,600 patients with osteoarthritis of the knee took part in the study conducted at 16 centers across the United States. Not all of the news from the study was bad for the two-supplement combination. Study participants who reported moderate to severe pain, as opposed to mild pain, 79% reported significant pain reduction when taking glucosamine and chondroitin supplementation. The study lasted for six months and a majority of the participants said they suffered from mild osteoarthritis of the knee.

Homeopathy

Depending on a patient's specific condition, a homeopathic physician may prescribe one of the following medications for pain management:

- Arnica: for treatment of acute pain after an injury.
- Hypericum: for treatment of pain in nerves, fingers, or toes after injury or surgery.
- Ledum: for treatment of pain associated with black-and-blue bruises and puncture wounds.

In 2006, Miralus Healthcare began aggressively marketing its homeopathic **headache** formula HeadOn, which is applied topically to the forehead. In its now-famous television commercial, which many viewers deemed as annoying, an announcer quickly repeats three times the slogan, "HeadOn, apply directly to the forehead." It is not a coincidence that the ads are careful not to say that the product is for headache pain or can relieve headache pain. Making unsubstantiated medical claims is a violation of federal law. HeadOn is composed almost entirely of wax, with trace amounts of **potassium** bichromate (a chemical) and white bryony (a botanical) as active ingredients. As of early 2008, it came in six formulas: migraine relief, tension headache relief, headache relief, p.m. pain relief/sleep aid, sinus headache relief, and extra strength headache relief. The products cost about $8 to $10 and are primarily sold at discount pharmacies (Walgreens, CVS) and discount department store chains (Wal-Mart, Kmart). An article published in the September 2007 issue of *Consumer Reports* stated that HeadOn may "possibly" work "if users believe it will work." The article also stated that Miralus claimed clinical studies have been conducted on the product but refused to provide the magazine with details or copies of the studies. As of March 2008, there were no clinical studies posted on the Miralus Website (http://www.miralus.com). In 2006, the National Advertising Division (NAD) of the Council of Better Business Bureaus requested Miralus discontinue its ad claims regarding the performance and efficacy (effectiveness) of HeadOn due to insufficient evidence. In a written reply to NAD, Miralus disagreed with the conclusion but said it would consider the recommendation in developing future advertising. It did not provide NAD with any clinical studies of HeadOn. Miralus makes a number of other topical pain relief medications, including three formulations of RenewIn for joint care and ActivOn for arthritis pain. RenewIn and ActivOn retail for $12 to $15. As with HeadOn, Miralus does not claim RenewIn relieves pain, only that it provides "joint comfort."

Acupuncture

Acupuncture involves inserting needles at various points on the skin. These needles direct chi (life force) to organs or functions of the body. This therapy possibly works by triggering the release of endorphins, therefore dulling the perception of pain. Acupuncture can effectively reduce most chronic pain. However, it may require up to 10 sessions before results are noticeable. A 2002 study showed that acupuncture worked well for chronic **neck pain** and range of motion but that its long-term effects were limited. It is important that patients request disposable needles to prevent transmission of **AIDS**, **hepatitis**, and other infectious diseases.

Acupressure

There are some acupressure techniques that patients can train themselves to do to help relieve pain. Using thumbs or fingers to apply pressure at appropriate acupressure points in the body, a person can release muscular tension in the head, neck, or shoulder; calm the nervous system; and relieve painful symptoms. Like acupuncture, acupressure probably works by releasing endorphins.

Massage

Massage involves using physical manipulation techniques to make various parts of the body, such as muscles, connective tissues, and vertebrae, work together and function properly. This form of therapy may effectively reduce **stress** and physical pain.

Chiropractic

Chiropractors treat patients by manipulating joints and the spine. It is believed that pain, especially back pain, is caused by misalignment of the spine. This form of treatment is most effective in patients with persistent back pain and neck problems. It is also effective in some patients with acute, uncomplicated **low back pain**.

Relaxation therapy

Relaxation techniques include meditation, yoga, music, guided imagery, **biofeedback**, and **hypnotherapy**. When practiced regularly, these techniques have been shown to relax muscles and reduce tension and stress-related pain.

Lifestyle changes

Lifestyles can be changed to include a healthier diet and regular **exercise**. Regular exercise, aside from relieving stress, has been shown to increase endorphins.

Hydrotherapy

This form of therapy uses hot and cold compresses, whirlpools, saunas, and alternating cold/warm showers or body wraps to reduce the soreness of aching joints, inflamed muscles, chronic muscle **strains**, and backache. Some of these treatments can be done at home.

Allopathic treatment

There are many drugs aimed at preventing or treating pain. Nonopioid analgesics, narcotic analgesics, corticosteroids, anticonvulsant drugs, and tricyclic antidepressants work by blocking the production, release, or uptake of neurotransmitters. Nonopioid analgesics are used for treatment of minor pain. They include common over-the-counter medications such as aspirin, acetaminophen (Tylenol), and ibuprofen (Advil). Narcotic analgesics such as codeine, morphine, and methadone are used for more severe pain, such as cancer pain. These medications are available with a doctor's prescription. Initially developed to treat seizures and depression, some anticonvulsants and antidepressants also have pain-killing applications. Finally, corticosteroid injections directly into or near the nerve that is transmitting the pain signal are reserved for intractable (unrelenting) pain that is not treatable by other medications.

Drugs are not always effective in controlling pain. Surgical methods are used as a last resort if drugs and local anesthetics fail. Electrode implants are the least destructive surgical procedure. However, this method may not completely control pain and is not used frequently. Other surgical techniques involve destroying or severing the nerve, but the use of this technique is limited by side effects, including unpleasant numbness.

Expected results

Successful pain treatment is highly dependent on successful resolution of the pain's cause. Acute pain stops when an injury heals or when an underlying problem is treated successfully. Chronic pain and abnormal pain are more difficult to treat, and finding a successful resolution may take more time. Some pain is intractable and requires extreme measures for relief.

Prevention

Pain is generally preventable only to the degree that the cause of the pain is preventable; diseases and injuries are often unavoidable. However, increased pain, pain from surgery and other medical procedures, and continuing pain are preventable through drug treatments and alternative therapies.

KEY TERMS

Neuron—The fundamental nerve cell of the nervous system.

Neurotransmitters—Chemicals within the nervous system that transmit information from or between nerve cells.

Nociceptor—A nerve cell that is capable of sensing pain and transmitting a pain signal.

Referred pain—Pain that is experienced in one part of the body but originates in another organ or area. The pain is referred because the nerves that supply the damaged organ enter the spine in the same segment as the nerves that supply the area where the pain is felt.

Stimulus—Anything capable of eliciting a response in an organism or a part of that organism.

For many years, experts thought that arthritis patients should not exercise because it would damage their joints. However, a 2002 report stated that regular low-impact exercise such as water aerobics or riding a stationary bicycle can actually help arthritic patients prevent pain.

Paleolithic diet

Definition

The Paleolithic, or caveman, diet is a reversion to the foods eaten by humans prior to the advents of civilization, agriculture, and technology. Before those developments, the human diet during the Stone Age is thought to have consisted largely of lean red meat and vegetation. Modern-day adherents to Paleolithic **diets** add vigorous physical activity to mimic the Stone Age's hunter-gatherer lifestyle. In some cases, modern-day "Paleos" actually adopt such a lifestyle, hunting their own food in the natural environment.

Origins

The Paleolithic Period of human development, characterized by the use of chipped, stone tools, began about 2.5 million years ago. Whenever possible, Paleolithic peoples consumed large amounts of animal meat and offal, deriving 45-65% of their energy from animals. Among those aboriginal, hunter-gatherer societies in Australia, Africa, and South America that survived into the twentieth century, the rates of **cancer**, **rheumatoid arthritis**, **obesity**, diabetes, **osteoporosis**, **heart disease**, and other conditions were remarkably low until they switched to modern diets. In most other cultures, this switch to modern diets happened about 10,000 years ago, when it was discovered that many inedible plants could be

rendered suitable for human consumption by cooking. This resulted in the introduction of grains, beans, and potatoes as foods, and later followed by sugar, milk, and milk products.

Benefits

Many nutritionists and scientists believe a Paleolithic diet and lifestyle might be an effective weapon against the adverse effects of modern affluence, reducing risk of heart disease, cancer, obesity, rheumatoid arthritis, and other conditions. Since this was the diet practiced during much of human evolution, advocates argue, it is the food that humans were designed to eat. Additionally, these advocates endorse the idea that milk (after weaning) and grains were never intended for human consumption.

Description

There is really no single Paleolithic diet. Hunter-gatherer cultures in different parts of the world ate widely differing diets, due to the availability in each locality. Stone Age diets also varied significantly depending on the season. Generally, however, such diets included much lean red meat from game, as well as eggs, fish, fruit, nuts, and vegetables. Excluded from most Paleolithic diets were grains (e.g., breads, pasta, cereals, corn), milk, refined sugars, beans, soy beans, or lentils. For twenty-first century adherents to Caveman diets, potatoes and peanuts are also forbidden. These diets are high in high-quality protein, fiber, vitamins, minerals, **iron**, mono-unsaturated fats, omega-3 fats, phytochemicals, and **antioxidants**. They are low in salt, saturated fats, enzyme inhibitors such as protease or amylase inhibitors, exorphins, and glycoalkaloids.

Precautions

Concerns have been expressed about the environmental effects of millions of people switching to diets heavy in red meats, requiring many agricultural operations to switch from growing crops to raising livestock. Sensitive wild areas could be ravaged in the search for insufficient quantities of Paleolithic foods. The global food supply is widely thought to be incapable of supporting widespread adoption of this diet. It is also believed that Stone Age peoples had access to a broader range of wild foods than are currently available, and modern-day "Paleos" should monitor their consumption to ensure a balanced diet. Some nutritionists caution against total dietary exclusion of milk and milk products, arguing that low-fat dairy products can be useful to maintain sufficient levels of **calcium**.

KEY TERMS

Offal—Waste parts of an animal that are usually discarded.

Side effects

A balanced Paleolithic diet is thought to be generally free of harmful side effects, although anyone excluding milk and dairy products should be careful to maintain sufficient dietary levels of calcium to avoid problems such as osteoporosis, osteomalacia, rickets, and tetany.

Research and general acceptance

Many aspects of the Paleolithic diet have proven health benefits. There is absolutely no question that people who get plenty of **exercise** and eat lots of fruits and vegetables and avoid saturated fats tend to be healthier. Some experts are dubious, however, as to whether the benefits of the caveman diet extend into old age. They argue that diseases such as cancer, heart disease, and arthritis are found less frequently in hunter-gatherer societies because few members of those societies survive to an age at which those conditions become problems.

Training and certification

There is no organization dedicated specifically to training and certification of Paleolithic diet advisors, although a substantial number of scientists, physicians, and nutritionists are interested in the subject and can provide advice.

Panchakarma

Definition

Panchakarma is the purification therapy used in **Ayurvedic medicine**. The word panchakarma means five actions, and refers to five procedures intended to intensively cleanse and restore balance to the body, mind, and emotions. Ayurvedic physicians use Panchakarma as a treatment for a wide variety of health conditions and as a preventative measure.

Origins

Ayurvedic medicine is the oldest healing system in the world, originating in the ancient civilizations of India some 3,000–5000 years ago. Ayurveda means knowledge of life in Sanskrit. Panchakarma is based on central concepts of Ayurveda, which state that disease is caused by the build-up of toxic substances in the body, and by imbalances in the body and mind.

Today, Ayurvedic medicine is used by millions of people, including at least half of the population of India. Ayurveda has become an increasingly accepted alternative medical treatment in America during the last couple of decades, aided by the efforts of Deepak Chopra, a conventionally trained M.D. who has written bestselling books based in part on Ayurvedic principles. Several Ayurvedic institutes and health clinics in America now perform panchakarma and conduct studies of its healing effects. A study in 2004 estimated that about three-quarters of a million Americans had used Ayurveda at least once, and 154,000 people had used it within the previous 12 months.

The ideas behind panchakarma have influenced other alternative treatments: Environmental medicine studies how the accumulation of environmental substances in the body may cause disease, and **detoxification** therapy relies upon cleansing the body as its central treatment.

Benefits

Panchakarma is used in Ayurvedic medicine to treat almost all diseases, particularly those that are chronic, metabolic, or stress-related in origin. Practitioners have used panchakarma to treat **allergies**, **asthma**, arthritis, **cancer**, **chronic fatigue syndrome**, **colitis**, high **cholesterol**, **depression**, diabetes, digestive disorders, **heart disease**, **hypertension**, immune problems, **infections**, inflammation, **insomnia**, nervous disorders, **obesity**, skin problems, and ulcers. Practitioners may use panchakarma alongside intensive conventional treatments, including chemotherapy and surgery, as a way to support healing and recovery. Panchakarma is limited in treating traumatic injuries, acute **pain**, and conditions requiring immediate surgery or invasive procedures.

Description

The first step of any Ayurvedic treatment is a thorough examination and diagnosis by an Ayurvedic practitioner, who determines the type and extent of panchakarma treatment required. According to Ayurvedic theory, physical and emotional traits are classified as three doshas—vata, kapha, and pitta. Each individual has all three doshas with one predominating. If an imbalance occurs, diseases or conditions appear. Panchakarma rebalances the doshas, bringing them back to equilibrium and returning the individual to good health. The physician may prescribe herbal remedies, and recommend that dietary and lifestyle changes be enacted before, during and after panchakarma.

Ayurvedic doctors believe that disease generally starts in the digestive tract. Poor **diets**, bad health habits, and other causes can lead to impaired digestion, and cause a toxic substance called *ama* to accumulate in the body. Ama interferes with normal functioning and the flow of energy, creating imbalances and disease. One goal of panchakarma is to cleanse the body of excess ama, and to restore the body's digestive power (*agni*).

A key part of panchakarma is *Shamana*, which is a collection of supportive therapies that include the preparation and post-therapy measures. The main treatment is called *shodhana* and refers to panchakarma's five main cleansing and elimination procedures. During preparation for panchakarma, oil therapy (termed *snehana* in Ayurveda) is the first treatment. Patients are given oil massages—*abhyanga* is full body massage and *shirodhaya* is forehead massage. They are fed dietary oils to lubricate the digestive tract, and are sometimes administered oil enemas. For stress-related and mental conditions, a special oil massage is given during which oil is steadily poured onto the patient's forehead. Practitioners may give oil therapy for up to a week before beginning the main treatment. Another preparation is sweating therapy (*swedana*). This employs saunas, steam rooms, heated clothing, herbal poultices, and **exercise**.

The five main methods of panchakarma are:

- therapeutic vomiting (*vamana*)
- purgation (*virechana*), which is the evacuation of the bowels
- medicated enema therapy (*niruha basti*)

- oil enema therapy (*anuvasana basti*)
- nasal cleansing (*nasya*).

Depending on an individual's health problem, one or more of these methods are used to cleanse the body and promote healing. Other Ayurvedic therapies may be used in conjunction with these methods.

Vamana uses herbal solutions or salt water to induce **vomiting**. This treatment is used for skin problems, asthma, diabetes, chronic sinus or lung infections, **epilepsy**, heart disease, and digestive disorders. Niruha basti uses special herbal solutions in a means to treat such conditions as skin diseases, liver problems, abdominal tumors, parasites, and chronic fevers. For therapeutic enemas, medicinal oils and herbal solutions are used to cleanse the lower bowels. Niruha and anuvasana basti are used to treat conditions such as **constipation**, arthritis, nervous disorders, colitis, headaches, muscle weakness, and lower back pain. During nasya, medicated oils or powders are administered into the nostrils to cleanse the sinuses. This therapy is used to treat conditions of the head, including mental disorders, headaches, and problems of the ear, nose, and throat.

After cleansing methods are performed, patients go through an important aftercare stage called *paschata karma*. Patients are advised to rest and avoid certain activities. In addition, they often receive attention from nurses and doctors. Psychological care and counseling may be part of the healing program, as panchakarma strives to cleanse the patient of emotional problems in addition to physical ones. Patients are also counseled about preventative practices. Dietary changes are carefully planned, and lifestyle considerations are examined and recommended. Exercise programs, such as **yoga**, and stress-management techniques, including **meditation**, may be introduced to patients during or after panchakarma, and herbal remedies may be prescribed as well.

Panchakarma treatment can vary in length from a couple of days to several weeks. Some clinics offer in-patient services, during which patients have medical supervision and are intensively treated around the clock with dietary therapy, exercise, yoga, meditation, massage, and other therapies. Most clinics offer out-patient services, during which panchakarma treatments may take two or more hours per day until completed. Some clinics provide housing arrangements for visiting patients.

Panchakarma treatment from Ayurvedic clinics typically cost $200–$400 per day, not including initial physician fees and herbal prescriptions. In addition, clinics with in-patient services are more expensive, and the costs vary with services. Insurance coverage of panchakarma varies, depending on the policy and whether the practitioner is a licensed physician.

KEY TERMS

Agni—Ayurvedic term for strength of digestion.

Meditation—A practice of concentrated focus upon a sound, object, visualization, the breath, movement, or attention itself in order to increase awareness of the present moment, reduce stress, promote relaxation, and enhance personal and spiritual growth.

Yoga—A method of joining the individual self with the divine, universal spirit, or cosmic consciousness. Physical and mental exercises are designed to help achieve this goal, also called self-transcendence or enlightenment. On the physical level, yoga postures, called asanas, are designed to tone, strengthen, and align the body. On the mental level, yoga uses breathing techniques (pranayama) and meditation (dyana) to quiet, clarify, and discipline the mind.

Preparations

Patients should be thoroughly diagnosed and cared for by a qualified Ayurvedic practitioner. Patients should seek panchakarma treatment from reputable clinics with adequate staff and facilities.

Precautions

Certain panchakarma methods are not appropriate for specific health problems, and some should not be performed on children, pregnant women, and the elderly. Panchakarma treatments should only be administered by qualified and experienced practitioners.

Individuals should note that some Ayurvedic herbal products have been linked with unsafe levels of toxins. A 2004 study that appeared in *JAMA (the Journal of the American Medical Association)* cautioned that some Ayurvedic herbal medicine products may contain potentially harmful levels of heavy metals, including lead, mercury, and/or arsenic. Also in 2004, the Centers for Disease Control received a dozen reports of **lead poisoning** that was associated with the use of Ayurvedic products.

In addition, the National Center for Complementary and Alternative Medicine cautions that possible interactions may occur between certain Ayurvedic herbal products and other medications. For example,

it notes that the extract of an Ayurvedic herb called **guggul** may enhance the activity of aspirin and possibly promote bleeding problems.

Side effects

During panchakarma, **fatigue**, malaise, headaches, congestion, general illness, and an increase in symptoms may occur as side effects. Also, because panchakarma seeks to release stored emotional problems from the patient, some people can experience mental disturbances and depression during treatment.

Research and general acceptance

The majority of the research surrounding Ayurveda has been conducted at research institutions in India, and its findings have mainly been published in Indian and European scientific journals. Much of the research in America is being supported by the Maharishi Ayur-Ved organization, which studies the Ayurvedic products it sells and its clinical practices, including panchakarma. Various studies have reported that panchakarma and/or Ayurvedic treatments have been successful in treating and in some cases, curing chronic illnesses such as asthma, **bronchitis**, hypertension, and diabetes. Other studies have shown that panchakarma can lower cholesterol and improve digestive disorders, and that Ayurvedic remedies can successfully treat diabetes, **acne**, and allergies. Proponents also claim that Ayurvedic treatments, including panchakarma, have been used successfully to support the healing process of patients undergoing chemotherapy.

As of 2007, however, the National Center for Complementary and Alternative Medicine cautions that most clinical trials of Ayurvedic approaches have been small, had problems with research designs, lacked appropriate control groups, or had other issues that affected how meaningful the results were.

Training and certification

In America, there is no standardized program for the certification of Ayurvedic practitioners. Many practitioners have primary degrees, either as MDs, homeopaths, or naturopathic physicians, with additional training in Ayurveda. Some institutions that provide training in Ayurvedic medicine include the following.

- The American Institute of Vedic Studies offers a program of Ayurvedic study.
- The Ayurvedic Institute offers training through classes and seminars, and performs panchakarma treatment. Its founder was Dr. Vasant Lad, one of the leading Ayurvedic practitioners in India and later America.
- Bastyr University of Natural Health Sciences offers training in Ayurvedic medicine.
- The Center for Mind-Body Medicine offers health services and professional training programs in Ayurveda. Dr. Deepak Chopra was one of its founders.
- The Rocky Mountain Institute of Yoga and Ayurveda offers a Panchakarma Practitioners Certification program that includes courses on Ayurvedic massage.

Pancreatic enzymes *see* **Digestive enzymes**

Pancreatitis

Definition

Pancreatitis is an inflammation of the pancreas, an organ that is important in digestion. Pancreatitis can be acute, beginning suddenly, usually with the patient recovering fully; or chronic, progressing slowly with permanent injury to the pancreas.

Description

The pancreas is located in the midline of the back of the abdomen, closely associated with the liver, stomach, and duodenum, the first part of the small intestine. The pancreas is considered a gland. A gland is an organ whose primary function is to produce chemicals that pass either into the main blood circulation (called an endocrine function), or pass into another organ (called an exocrine function). The pancreas is unusual because it has both endocrine and exocrine functions. Its endocrine function produces three hormones. Two of these hormones, insulin and glucagon, are central to the processing of sugars in the diet (carbohydrate metabolism or breakdown). The third hormone produced by the endocrine cells of the pancreas affects gastrointestinal functioning. This hormone is called vasoactive intestinal polypeptide (VIP). The pancreas's exocrine function produces a variety of **digestive enzymes** (trypsin, **chymotrypsin**, **lipase**, and amylase, among others). These enzymes are passed into the duodenum through a channel called the pancreatic duct. In the duodenum, the enzymes begin the process of breaking down a variety of food components, including, proteins, fats, and starches.

Acute pancreatitis occurs when the pancreas suddenly becomes inflamed but improves. Patients usually recover fully from the disease, and in almost 90% of cases, the symptoms disappear within about a week after treatment. The pancreas returns to its normal structure and functioning after healing from the illness. After an attack of acute pancreatitis, the tissue and cells of the pancreas typically return to normal. With chronic pancreatitis, damage to the pancreas occurs slowly over time. Symptoms may be persistent or sporadic, but the condition does not disappear and the pancreas is permanently impaired. Pancreatic tissue is damaged, and the tissue and cells function poorly.

Causes and symptoms

There are a number of causes of acute pancreatitis. The most common, however, are gallbladder disease and **alcoholism**. These two diseases are responsible for more than 80% of all hospitalizations for acute pancreatitis. Other factors in the development of pancreatitis include:

- certain drugs
- infections
- structural problems of the pancreatic duct and bile ducts (channels leading from the gallbladder to the duodenum)
- injury to the abdomen resulting in injury to the pancreas (including injuries occurring during surgery)
- abnormally high levels of circulating fats in the bloodstream
- malfunction of the parathyroid gland, with high blood levels of calcium
- complications from kidney transplants
- a hereditary tendency toward pancreatitis (recent advances in gene mapping have led to the discovery that a mutation in the gene responsible for cystic fibrosis is associated with a greatly increased risk of pancreatitis)

Pancreatitis caused by drugs accounts for about 5% of all cases. Some drugs that are definitely related to pancreatitis include:

- azathioprine, 6–mercaptopurine (Imuran)
- dideoxyinosine (Videx)
- estrogens (birth control pills)
- furosemide (Lasix)
- pentamidine (NebuPent)
- sulfonamides (Urobak, Azulfidine)
- tetracycline
- thiazide diuretics (Diuril, Enduron)
- valproic acid (Depakote)

Some drugs that are probably related to pancreatitis include:

- acetaminophen (Tylenol)
- angiotensin–converting enzyme (ACE) inhibitors (Capoten, Vasotec)
- erythromycin

KEY TERMS

Abscess—A localized collection of pus in the skin or other body tissue caused by infection.

Acute—Refers to a disease or symptom that has a sudden onset and lasts a relatively short period of time.

Autodigestion—A process in which pancreatic enzymes are activated prematurely and begin to digest the pancreas itself.

Chronic—Refers to a disease or condition that progresses slowly but persists or recurs over time.

Diabetes—A disease characterized by an inability to process sugars in the diet, due to a decrease in or total absence of insulin production.

Duodenum—The first of the three segments of the small intestine. The duodenum is about 10 in (25 cm) long and connects the stomach and the jejunum.

Endocrine—Refers to glands that secrete hormones circulated in the bloodstream or lymphatic system.

Enzyme—A protein that catalyzes a biochemical reaction without changing its own structure or function.

Exocrine—Refers to a system of organs that produces chemicals that go through a duct (or tube) to reach other organs or body surfaces whose functioning they affect.

Glands—Collections of tissue that produce chemicals needed for chemical reactions elsewhere in the body.

Necrosis—Localized tissue death due to disease or injury, such as a lack of oxygen supply to the tissues.

Pseudocyst—A fluid-filled space that may arise in the setting of pancreatitis.

Ranson's signs—A set of 11 signs used to evaluate the severity of a case of pancreatitis.

- methyldopa (Aldomet)
- metronidazole (Flagyl, Protostat)
- nitrofurantoin (Furadantin, Furan)
- nonsteroidal anti–inflammatory drugs (NSAIDs) (Aleve, Naprosyn, Motrin)
- salicylates (aspirin)

All of these causes of pancreatitis seem to have a similar mechanism in common. Under normal circumstances, many of the extremely potent enzymes produced by the pancreas are not active until they enter the duodenum, in which contact with certain other chemicals allows them to function. In pancreatitis, these enzymes become prematurely activated and actually begin their digestive functions within the pancreas. The pancreas, in essence, begins to digest itself. This process is known as autodigestion. A cycle of inflammation begins, including swelling and loss of function. Digestion of the blood vessels in the pancreas results in bleeding. Other active pancreatic chemicals cause the blood vessels to become leaky, and fluid begins to leak out of the normal circulation into the abdominal cavity. The activated enzymes also gain access to the bloodstream through the eroded blood vessels, and begin circulating throughout the body.

Pain is a major symptom of pancreatitis. The pain is usually quite intense and steady, located in the upper right hand corner of the abdomen, and often described as "piercing" or "boring." This pain is also often felt all the way through to the patient's back. The patient's breathing may become quite shallow because deeper breathing tends to cause more pain. Patients usually find some relief of pain by sitting up and bending forward; this postural relief is characteristic of pancreatic pain. **Nausea** and **vomiting**, and abdominal swelling are all common, as well. A patient will often have a slight **fever**, with an increased heart rate and low blood pressure.

Classic signs of shock may appear in more severely ill patients. Shock is a very serious syndrome that occurs when the volume (quantity) of fluid in the blood is very low. In shock, a patient's arms and legs become extremely cold, the blood pressure drops dangerously low, the heart rate is quite fast, and the patient may begin to experience changes in mental status.

In very severe cases of pancreatitis (called necrotizing pancreatitis) the pancreatic tissue begins to die and bleeding increases. Due to the bleeding into the abdomen, two distinctive signs may be noted in patients with necrotizing pancreatitis. Turner's sign is a reddish purple or greenish brown color in the flank area (the area between the ribs and the hip bone). Cullen's sign is the appearance of a bluish color around the navel.

Some of the complications of pancreatitis are due to shock. When shock occurs, all of the body's major organs are deprived of blood and the oxygen it carries, resulting in damage. Kidney, respiratory, and heart failure are serious risks of shock. The pancreatic enzymes that have begun circulating throughout the body (as well as various poisons created by the abnormal digestion of the pancreas by those enzymes) have severe effects on the major body systems. Any number of complications can occur, including damage to the

heart, lungs, kidneys, lining of the gastrointestinal tract, liver, eyes, bones, and skin. As the pancreatic enzymes work on blood vessels surrounding the pancreas, and even blood vessels located at a distance, the risk of **blood clots** increases. These blood clots complicate the situation by blocking blood flow in the vessels. When blood flow is blocked, the supply of oxygen is decreased to various organs and the organ can be damaged.

The pancreas may develop additional problems, even after the pancreatitis decreases. When the entire organ becomes swollen and suffers extensive cell death (pancreatic necrosis), the pancreas becomes extremely susceptible to serious infection. A local collection of pus (called a pancreatic **abscess**) may develop several weeks after the illness subsides, and may result in increased fever and a return of pain. Another late complication of pancreatitis, occurring several weeks after the illness begins, is called a pancreatic pseudocyst. This occurs when dead pancreatic tissue, blood, white blood cells, enzymes, and fluid that has leaked from the circulatory system accumulates. In an attempt to enclose and organize this abnormal accumulation, a kind of wall forms from the dead tissue and the growing scar tissue in the area. Pseudocysts cause additional abdominal pain by putting pressure on and displacing pancreatic tissue, resulting in more pancreatic damage. Pseudocysts also press on other nearby structures in the gastrointestinal tract, causing more disruption of function. Pseudocysts are life-threatening when they become infected (abscess) and rupture. Simple rupture of a pseudocyst causes death 14% of the time. Rupture complicated by bleeding causes death 60% of the time.

As the pancreatic tissue is increasingly destroyed in chronic pancreatitis, many digestive functions become disturbed. The quantity of hormones and enzymes normally produced by the pancreas begins to seriously decrease. Decreases in the production of enzymes result in the inability to appropriately digest food. Fat digestion, in particular, is impaired. A patient's stools become greasy as fats are passed out of the body. The inability to digest and use proteins results in smaller muscles (wasting) and weakness. The inability to digest and use the nutrients in food leads to malnutrition and a generally weakened condition. As the disease progresses, permanent injury to the pancreas can lead to diabetes.

Diagnosis

Diagnosis of pancreatitis can be made very early in the disease by noting high levels of pancreatic enzymes circulating in the blood (amylase and lipase). Later in the disease, and in chronic pancreatitis, these enzyme levels will no longer be elevated. Because of this fact, and because increased amylase and lipase can also occur in other diseases, the discovery of such elevations are helpful but not mandatory in the diagnosis of pancreatitis. Other abnormalities in the blood may also point to pancreatitis, including increased white blood cells (occurring with inflammation and/or infection), changes due to dehydration from fluid loss, and abnormalities in the blood concentration of **calcium**, **magnesium**, **sodium**, **potassium**, bicarbonate, and sugars.

X rays or ultrasound examination of the abdomen may reveal **gallstones**, perhaps responsible for blocking the pancreatic duct. The gastrointestinal tract will show signs of inactivity (ileus) due to the presence of pancreatitis. Chest x rays may reveal abnormalities due to air trapping from shallow breathing, or due to lung complications from the circulating pancreatic enzyme irritants. Computed tomography scans (CT scans) of the abdomen may reveal the inflammation and fluid accumulation of pancreatitis, and may also be useful when complications like an abscess or a pseudocyst are suspected.

In the case of chronic pancreatitis, a number of blood tests will reveal the loss of pancreatic function that occurs over time. Blood sugar (glucose) levels will rise, eventually reaching the levels present in diabetes. The levels of various pancreatic enzymes will fall, as the organ is increasingly destroyed and replaced by nonfunctioning scar tissue. Calcification of the pancreas can also be seen on x rays. Endoscopic retrograde cholangiopancreatography (ERCP) may be used to diagnose chronic pancreatitis in severe cases. In this procedure, the doctor uses a medical instrument fitted with a fiber-optic camera to inspect the pancreas. A magnified image of the area is shown on a television screen viewed by the doctor. Many endoscopes also allow the doctor to retrieve a small sample (biopsy) of pancreatic tissue to examine under a microscope. A contrast product may also be used for radiographic examination of the area.

Treatment

Pancreatitis is a serious condition that requires medical diagnosis and treatment. Alternative therapies should be used only to complement conventional treatment.

Nutritional therapy

Before taking nutritional supplements, patients should consult their doctors to make sure these

supplements do not interfere with their overall treatment program. The following nutritional changes are recommended to help support pancreatic function and relieve pancreatitis symptoms:

- Follow a diabetic diet and avoid alcohol consumption.
- Limit intake of hydrogenated/saturated fats, sugar, and highly processed foods.
- Increase intake of yellow and orange fruits and dark-green vegetables, which are good sources of beta-carotene, whole foods, vitamin C, and other antioxidants.
- Take high-potency multivitamin/mineral supplements.
- Use chromium (300 mcg daily) supplements to help control blood sugar level and enhance insulin effectiveness.
- Take lipotrophic agents(which increase bile flow to and from the liver), such as vitamin B_6, vitamin B_{12}, folic acid, choline, betaine, and methionine.
- Take pancreatic enzymes at mealtime.

Other therapies

Other alternative treatments such as **acupuncture** or **relaxation** techniques can help patients cope with painful symptoms associated with pancreatitis. Reduce **stress** by **meditation**, **yoga**, **t'ai chi**, or other relaxation techniques. Stress can stimulate pancreatitis attacks.

Allopathic treatment

Treatment of acute pancreatitis involves quickly and sufficiently replacing lost fluids by giving the patient new fluids through a needle inserted in a vein (intravenous or IV fluids). Pain is treated with a variety of medications. In order to decrease pancreatic function (and decrease the discharge of more potentially harmful enzymes into the bloodstream), the patient is not allowed to eat. A thin, flexible tube (nasogastric tube) may be inserted through the patient's nose and down into his or her stomach. Oxygen may need to be administered by nasal prongs or by a mask.

Complications, such as **infections** that often occur in cases of necrotizing pancreatitis, abscesses, and pseudocysts, will require antibiotics administered intravenously. Severe necrotizing pancreatitis may require surgery to remove part of the dying pancreas. A pancreatic abscess can be drained by a needle inserted through the abdomen and into the collection of pus (percutaneous needle aspiration) or surgically removed, if necessary. Pancreatic pseudocysts may shrink on their own (in 25–40% of cases) or may continue to expand, requiring needle aspiration or surgery. When diagnostic exams reveal the presence of gallstones, surgery may be necessary for their removal.

Because chronic pancreatitis often includes repeated flares of acute pancreatitis, the same kinds of basic treatment are necessary. Patients receive IV replacement fluids, receive pain medication, and are monitored for complications. Treatment of chronic pancreatitis caused by alcohol consumption requires that the patient stop drinking alcohol entirely. As chronic pancreatitis continues and insulin levels drop, a patient may require insulin injections in order to be able to process sugars in his or her diet. Pancreatic enzymes can be replaced with oral medicines, and patients sometimes have to take as many as eight pills with each meal. Drugs can be used to reduce the pain, but when narcotics are used for pain relief, there is danger of the patient becoming addicted.

Expected results

A number of systems have been developed to help determine the prognosis of an individual with pancreatitis. A very basic evaluation of a patient will allow some prediction to be made based on the presence of dying pancreatic tissue (necrosis) and bleeding. When necrosis and bleeding are present, as many as 50% of patients may die.

More elaborate systems have been created to help determine the prognosis of patients with pancreatitis. Ranson's signs, the most commonly used system, identifies 11 different signs that can be used to determine the severity of the disease. The first five categories are evaluated when the patient is admitted to the hospital:

- age over 55 years
- blood sugar level over 200 mg/Dl
- serum lactic dehydrogenase over 350 IU/L (increased with increased breakdown of blood, as would occur with internal bleeding, and with heart or liver damage)
- AST over 250 μ (a measure of liver function, as well as a gauge of damage to the heart, muscle, brain, and kidney)
- white blood count over 16,000 μL

The next six of Ranson's signs are reviewed 48 hours after admission to the hospital. These are:

- greater than 10% decrease in hematocrit (a measure of red blood cell volume)
- increase in BUN (blood urea nitrogen, an indicator of kidney function) greater than 5 mg/dL
- blood calcium less than 8 mg/dL

- PaO_2 (a measure of oxygen in the blood) less than 60 mm Hg
- base deficit greater than 4 mEg/L (a measure of change in the normal acidity of the blood)
- fluid sequestration greater than 6 L (an estimation of the quantity of fluid that has leaked out of the blood circulation and into other body spaces).

Once a doctor determines how many of Ranson's signs are present and gives the patient a score, the doctor can better predict the risk of death. The more signs present, the greater the chance of death. A patient with less than three positive Ranson's signs has a less than 5% chance of dying. A patient with three to four positive Ranson's signs has a 15–20% chance of dying.

The results of a CT scan can also be used to predict the severity of pancreatitis. Slight swelling of the pancreas indicates mild illness. Significant swelling, especially with evidence of destruction of the pancreas and/or fluid buildup in the abdominal cavity, indicates more severe illness. With severe illness, there is a worse prognosis.

Surgical treatment of pancreatitis is frequently followed by complications because of the leakage of pancreatic enzymes from the remaining portion of the organ. A team of French surgeons has reported that treating patients with somatostatin-14, a hormone that inhibits pancreatic secretion as well as pancreatic blood flow, appears to be effective in lowering the rate of complications from pancreatic surgery. In spite of recent advances in surgical technique, however, the mortality rate following surgery for pancreatitis is still 3%–10%.

Prevention

Alcoholism is essentially the only preventable cause of pancreatitis. Patients with chronic pancreatitis must stop drinking alcohol entirely. The drugs that cause or may cause pancreatitis should also be avoided.

Panic disorder

Definition

A panic attack is a sudden, intense experience of fear coupled with an overwhelming feeling of danger, accompanied by physical symptoms of **anxiety**, such as a pounding heart, sweating, and rapid breathing. A person with panic disorder may experience repeated panic attacks (at least several a month) and feel severe anxiety about having another attack.

Description

Each year, panic disorder affects one in every 63 Americans. While many people experience moments of anxiety, panic attacks are sudden and unprovoked, having little to do with real danger.

Panic disorder is a chronic, debilitating condition that can have a devastating impact on a person's family, work, and social life. Typically, the first attack strikes without warning. A person might be walking down the street, driving a car, or riding an escalator when suddenly panic strikes. Pounding heart, sweating palms, and an overwhelming feeling of impending doom are common features. While the attack may last only seconds or minutes, the experience can be profoundly disturbing. A person who has had one panic

KEY TERMS

Agoraphobia—Abnormal anxiety regarding public places or situations from which the person may wish to flee or in which he or she would be helpless in the event of a panic attack.

Aromatherapy—The therapeutic use of plant-derived, aromatic essential oils to promote physical and psychological well-being.

Benzodiazepines—A class of drugs that have a hypnotic and sedative action, used mainly as tranquilizers to control symptoms of anxiety or panic.

Cognitive-behavioral therapy—A type of psychotherapy in which people learn to recognize and change negative and self-defeating patterns of thinking and behavior.

Selective serotonin reuptake inhibitors (SSRIs)—A class of antidepressants that work by blocking the reabsorption of serotonin in the brain, thus raising the levels of serotonin. SSRIs include fluoxetine (Prozac), sertraline (Zoloft), and paroxetine (Paxil)

Tricyclic antidepressants—A class of antidepressants named for their three-ring structure that increase the levels of serotonin and other brain chemicals. They are used to treat depression and anxiety disorders, but have more side effects than the newer class of antidepressants called SSRIs.

attack typically worries that another one may occur at any time.

As the fear of future panic attacks deepens, the person begins to avoid situations in which panic occurred in the past. In severe cases of panic disorder, the victim refuses to leave the house for fear of having a panic attack. This fear of being in exposed places is often called agoraphobia.

People with untreated panic disorder may have problems getting to work or staying on the job. As the person's world narrows, untreated panic disorder can lead to **depression**, **substance abuse**, and in rare instances, suicide.

Causes and symptoms

Scientists aren't sure what causes panic disorder, but they know that a tendency to develop the condition can be inherited. In 2001, a team of geneticists pinpointed an abnormal duplication (known as DUP25) of a segment of human chromosome 15q as implicated in panic disorder. In addition to genetic factors, some experts think that people with panic disorder may have a hypersensitive nervous system that unnecessarily responds to nonexistent threats. Research suggests that people with panic disorder may not be able to make proper use of their body's normal stress-reducing chemicals. And in some cases, panic disorder develops as a drug intolerance reaction to medications given to reduce high blood pressure.

People with panic disorder usually have their first panic attack in their 20s. Four or more of the following symptoms during panic attacks would indicate panic disorder if no medical, drug-related, neurologic, or other psychiatric disorder is found:

- pounding, skipping, or palpitating heartbeat
- shortness of breath or the sensation of smothering
- dizziness or lightheadedness
- nausea or stomach problems
- chest pains or pressure
- choking sensation or a "lump in the throat"
- chills or hot flashes
- sweating
- fear of dying
- feelings of unreality or being detached
- tingling or numbness
- shaking and trembling
- fear of losing control

A panic attack is often accompanied by the urge to escape, together with a feeling of impending doom. Others are convinced they are about to have a **heart attack**, suffocate, lose control, or "go crazy." Once people experience one panic attack, they tend to worry so much about having another attack that they avoid the place or situation associated with the original episode.

Diagnosis

Because its physical symptoms are easily confused with other conditions, panic disorder often goes undiagnosed. A thorough physical examination is needed to rule out a medical condition. Because the physical symptoms are so pronounced and frightening, panic attacks can be mistaken for a heart problem. Some people experiencing a panic attack go to an emergency room and endure batteries of tests until a diagnosis is made.

Once a medical condition is ruled out, a mental health professional is the best person to diagnose panic and panic disorder, taking into account not just the actual episodes, but how the patient feels about the attacks, and how they affect everyday life.

Treatment

One approach used in several medical centers focuses on teaching patients how to accept their fear instead of dreading it. In this method, the therapist repeatedly stimulates a person's body sensations (such as a pounding heartbeat) that can trigger fear. Eventually, the patient gets used to these sensations and learns not to be afraid of them. Patients who respond report almost complete absence of panic attacks.

Neurolinguistic programming and hypnotherapy can also be beneficial in treating panic attacks, since these techniques can help bring an awareness of the root cause of the attacks to the conscious mind.

Herbs known as *adaptogens* may also be prescribed by an herbalist or holistic healthcare provider to treat anxiety related to panic disorder. These herbs are thought to promote adaptability to **stress**, and include Siberian ginseng (*Eleutherococcus senticosus*), ginseng (*Panax ginseng*), wild yam (*Dioscorea villosa*), borage (*Borago officinalis*), licorice (*Glycyrrhiza glabra*), chamomile (*Chamaemelum nobile*), **milk thistle** (*Silybum marianum*), and nettles (*Urtica dioica*). Herbal preparations of **skullcap** (*Scutellaria lateriafolia*), **lemon balm** (*Melissa officinalis*), **passionflower** (*Passiflora incarnata*), and oats (*Avena sativa*) may also be recommended to ease the symptoms of panic disorder. Nutritional supplementation with B vitamins, magnesium, and antioxidant vitamins are also useful for relieving anxiety.

Chinese medicine regards anxiety as a disruption of *qi*, or energy flow, inside the patient's body. The practitioner of Chinese medicine chooses **acupuncture** and/or herbal therapy to rebalance the entire system. In acupuncture, the kidney meridian is associated with fear and may be out of balance. Reishi (*Ganoderma lucidum*), or ling-zhi is a medicinal mushroom prescribed in TCM to reduce anxiety and **insomnia**. It is available in extract form, but because reishi can interact with other prescription drugs and is not recommended in patients with certain medical conditions, individuals should consult their healthcare practitioner before taking the remedy. Other TCM herbal remedies for panic disorder include the **cordyceps** mushroom (also known as caterpillar fungus.) There are several herbal formulas, depending on the pattern of imbalance in an individual.

Meditation and mindfulness training can be beneficial to patients with **phobias** and panic disorder. **Hydrotherapy**, massage therapy, and **aromatherapy** are useful to some anxious patients because they can promote general **relaxation** of the nervous system. Popular aromatherapy prescriptions for anxiety relief include **essential oils** of lavender, ylang-ylang, and **chamomile**. Relaxation training, which is sometimes called anxiety management training, includes breathing exercises and similar techniques intended to help the patient prevent hyperventilation and relieve the muscle tension associated with the fight-or-flight reaction of anxiety. **Yoga**, aikido, **t'ai chi**, and dance therapy help patients work with the physical, as well as the emotional, tensions that either promote anxiety or are created by the anxiety.

Finally, patients can make certain lifestyle changes to help keep panic at bay, such as eliminating **caffeine** and alcohol, cocaine, amphetamines, and **marijuana**.

There are also homeopathic remedies that may be helpful by seeing a trained homeopathic practitioner.

It is important for patients who are using alternative treaments for panic disorder alongside allopathic medications or treatments to keep their health care provider informed about any herbal remedies they may be taking that could interact with prescription medications. A study done in 2001 found that Americans are more likely to seek alternative treatment for anxiety disorders than standard allopathic therapies, and that the percentage of alternative therapy users was the same in both sexes. In addition, the percentage was not affected by age, race, education, income, place of residence, marital status, or employment.

Allopathic treatment

Most patients with panic disorder respond best to a combination of cognitive-behavioral therapy and medication. Cognitive-behavioral therapy usually runs from 12–15 sessions. It teaches patients:

- How to identify and alter thought patterns so as not to misconstrue bodily sensations, events, or situations as catastrophic.
- How to prepare for the situations and physical symptoms that trigger a panic attack.
- How to identify and change unrealistic self-talk (such as "I'm going to die!") that can worsen a panic attack.
- How to calm down and learn breathing exercises to counteract the physical symptoms of panic.
- How to gradually confront the frightening situation step by step until it becomes less terrifying.
- How to "desensitize" themselves to their own physical sensations, such as rapid heart rate.

At the same time, many people find that medications can help reduce or prevent panic attacks by changing the way certain chemicals interact in the brain. People with panic disorder usually notice whether or not the drug is effective within two months, but most people take medication for at least six months to a year.

Several kinds of drugs can reduce or prevent panic attacks, including:

- Selective serotonin reuptake inhibitor (SSRI) antipressants like paroxetine (Paxil) or fluoxetine (Prozac), some approved specifically for the treatment of panic.
- Tricyclic antidepressants such as clomipramine (Anafranil).
- Benzodiazepines such as alprazolam (Xanax) and clonazepam (Klonopin).
- A combination of sertraline, another SSRI, with clonazepam has been reported as especially effective in treating panic disorder.

Expected results

While there may be occasional periods of improvement, the episodes of panic rarely disappear on their own. Fortunately, panic disorder responds very well to treatment; panic attacks decrease in up to 90% of people after six to eight weeks of a combination of cognitive-behavioral therapy and medication.

Unfortunately, many people with panic disorder never get the help they need. If untreated, panic disorder can last for years and may become so severe that a normal life is impossible. Many people who struggle with untreated panic disorder and try to hide their symptoms end up losing their friends, family, and jobs.

Prevention

There is no way to prevent the initial onset of panic attacks. Antidepressant drugs or benzodiazepines can prevent future panic attacks, especially when combined with cognitive-behavioral therapy. There is some suggestion that avoiding stimulants (including caffeine, alcohol, or over-the-counter cold medicines) may help prevent attacks as well.

Pantothenic acid

Description

Pantothenic acid, also known as vitamin B_5, is a member of the water-soluble B vitamin family. Every living organism needs pantothenic acid to survive. Humans do not make this vitamin and must obtain it from the food they eat. It is an essential ingredient of two substances, coenzyme A and acyl carrier protein, which are needed to metabolize carbohydrates and fats. The same coenzymes play a part in production of certain hormones, **vitamin D**, red blood cells, and the neurotransmitter acetylcholine. Pantothenic acid is necessary for proper growth and development. Studies of Mexican infants whose **diets** are deficient in micronutrients have shown that those who receive dietary supplements containing pantothenic acid do not show the growth retardation that appears in control groups.

General use

Pantothenic acid was discovered in 1936 and soon afterward was recognized as a vitamin essential to growth. Pantothenic acid is found in all living things. Its name is derived from the Greek word "pantos," which means "everywhere."

Pantothenic acid joins with another molecule to form coenzyme A (CoA). Coenzymes are small molecules that regulate enzyme reactions. CoA is involved in many essential metabolic reactions that produce energy and synthesize new molecules. Without pantothenic

Recommended dietary allowance of pantothenic acid

Age	mg/day
Children 0-6 mos.	1.7
Children 7-12 mos.	1.8
Children 1-3 yrs.	2
Children 4-8 yrs.	3
Children 9-13 yrs.	4
Children 14-18 yrs.	5
Adults ≥ 19 yrs.	5
Pregnant women	6
Breastfeeding women	7

Foods that contain pantothenic acid

	mg
Liver, beef, cooked, 3.5 oz.	5.3
Salmon, baked, 3.5 oz.	1.4
Yogurt, 8 oz.	1.35
Chicken, dark meat, cooked, 3.5 oz.	1.3
Chicken, light meat, cooked, 3.5 oz.	1.0
Milk, nonfat, 1 cup	0.80
Corn, cooked, 1/2 cup	0.72
Sweet potato, cooked, 1/2 cup	0.68

Egg, 1 large, cooked	0.61
Broccoli, steamed, 1/2 cup	0.40
Tuna, canned, 3 oz.	0.18
Bread, whole wheat, 1 slice	0.16

mg = milligram

(Illustration by GGS Information Services. Cengage Learning, Gale)

acid, there would be no CoA, and life would cease. Some of the activities that require CoA, and thus indirectly pantothenic acid, include:

- converting fats, carbohydrates, and proteins from food into energy that the body can use
- synthesizing heme, the molecule in red blood cells that picks up oxygen in the lung and carries it throughout the body
- synthesizing essential fatty acids, cholesterol, and steroid hormones needed to build new cells
- synthesizing acetylcholine, a neurotransmitter that carries electrical impulses between nerve cells
- stimulating chemical reactions in the liver that help rid the body of certain drugs and toxins (poisons).

The United States Institute of Medicine (IOM) of the National Academy of Sciences has developed values called Dietary Reference Intakes (DRIs) for vitamins and minerals. The DRIs consist of three sets of numbers. The Recommended Dietary Allowance (RDA) defines the average daily amount of the nutrient needed to meet the health needs of 97–98% of the population. The Adequate Intake (AI) is an estimate set when there is not enough information to determine an RDA. The Tolerable Upper Intake Level (UL) is the average maximum amount that can be taken daily without risking negative side effects. The DRIs are calculated for children, adult men, adult women, pregnant women, and breastfeeding women.

The IOM has not set RDA values for pantothenic acid because of incomplete scientific information. Instead, it has set AI levels for all age groups. AI levels for pantothenic acid are measured by weight (milligrams or mg). No UL levels have been set for this vitamin because large doses of pantothenic acid do not appear to cause any side effects.

The following are the daily AIs of pantothenic acid for healthy individuals:

- children birth–6 months: 1.7 mg
- children 7–12 months: 1.8 mg
- children 1–3 years: 2 mg
- children 4–8 years: 3 mg
- children 9–13 years: 4 mg
- children 14–18 years: 5 mg
- adults age 19 and older: 5 mg
- pregnant women: 6 mg
- breastfeeding women: 7 mg

Pantothenic acid and pantethine are both available as supplements, and do appear to function somewhat differently. Pantethine can be used to lower serum **cholesterol** and triglycerides. It is more expensive and less effective than using **niacin** (vitamin B_3) for the same purpose, but does not have the potential side effects that niacin does. Generally a dose of 300 mg taken three times a day is recommended for this purpose. Pantethine may be a good cholesterol-lowering alternative for people with diabetes, who cannot take niacin due to the potential side effects on blood sugar regulation. Taking supplements of pantothenic acid does not affect cholesterol, as in this form it is immediately converted into coenzymes.

One very small study indicated that large daily doses of pantothenic acid (2 g of **calcium** pantothenate) were helpful to relieve symptoms of **rheumatoid arthritis**. Consult a healthcare provider regarding use of supplements for this purpose.

Panthenol is a derivative of pantothenic acid and is frequently an ingredient of shampoos and other hair care products. Experiments with rats have shown that a deficiency of pantothenic acid can cause hair to turn gray and fall out. Neither oral nor topical use of any

form of pantothenic acid has been shown to prevent or treat gray hair or balding in humans. Some skin care products contain another form of pantothenic acid, called panthoderm, which may be helpful in treatment of minor skin injuries.

Other claims for pantothenic acid that remain unproven are that it improves immune function, decreases **allergies**, and acts as an anti-aging substance.

Preparations

Natural sources

Pantothenic acid is found small quantities in a wide variety of foods. Good sources include liver, kidney, fish, shellfish, egg yolk, broccoli, lentils, and mushrooms. Pantothenic acid is unstable. Much of it is lost during cooking, canning, freezing, and processing. Frozen meats and processed grains, for example, can lose up to half their pantothenic acid content.

The following list gives the approximate pantothenic acid content of some common foods.

- liver, beef, cooked, 3.5 ounces: 5.3 mg
- chicken, dark meat, cooked 3.5 ounces: 1.3 mg
- chicken, light meat, cooked 3.5 ounces: 1.0 mg
- salmon, baked, 3.5 ounces: 1.4 mg
- tuna, canned, 3 ounces: .18 mg
- egg, 1 large, cooked: .61 mg
- milk, nonfat, 1 cup: .80 mg
- yogurt, 8 ounces: 1.35 mg
- broccoli, steamed, 1/2 cup: .40 mg
- sweet potato, cooked 1/2 cup: .68 mg
- lentils, cooked, 1/2 cup: .64 mg
- corn, cooked 1/2 cup: .72
- bread, whole wheat, 1 slice: .16 mg

In order to get the most value out of the pantothenic acid contained in natural sources, use fresh foods whenever possible. Cook with minimal amounts of water since the water-soluble vitamin content may be leached out. Frozen foods lose some of their water-soluble vitamin content as they thaw. Processing can also destroy a significant amount of the vitamin content of foods. Pantothenic acid is fairly heat-stable, and is not broken down by cooking although it is destroyed by extremes of pH as may be created by adding such things as baking soda or vinegar.

Supplemental sources

Oral supplements of both pantothenic acid and pantethine are available. The latter is quite expensive, and less stable than other types. Calcium pantothenate is one form of pantothenic acid made for oral use. Dexpanthenol is formulated for topical, intramuscular, or intravenous use. It is generally recommended that the B-vitamin family be taken in balanced amounts. Taking an excessive amount of an individual B-vitamin may have a detrimental effect on the absorption of others. As with all supplements, pantothenic acid should be stored in a cool, dry place, away from direct sunlight, and out of the reach of children. A dose of up to 500 mg is often recommended.

Deficiency

Pantothenic acid deficiency is so rare that it has only been seen in humans in severely malnourished prisoners of war in Asia after World War II and in research volunteers who were given a pantothenic-free diet. The main symptoms these groups experienced were burning, tingling, and numbness in the feet and **fatigue**. These symptoms disappeared when pantothenic acid was added to their diet.

It is possible for individuals to have low levels of pathothenic acid in conjunction with other B vitamins under certain conditions. This category may include people with severe nutritional deficiencies; and those with conditions affecting absorption, such as sprue or removal of portions of the gastrointestinal tract. People who chronically abuse alcohol or other drugs, and those under excessive amounts of **stress** including debilitating illnesses or recovery from **burns** or surgery are also at higher risk of general vitamin deficiency. The elderly are more susceptible both to poor nutritional status and decreased vitamin absorption. Use of tobacco is also detrimental to B vitamin absorption. Athletes who have a strenuous, daily physical regimen and people with physically active occupations may require larger than average amounts of pantothenic acid.

Precautions

People with hemophilia should not use dexpanthenol as it may prolong bleeding time. Anyone with a known or suspected obstruction of the gastrointestinal tract should also not use this product.

Side effects

Taken in very large doses, pantothenic acid may cause **diarrhea**. Topical use of dexpanthenol may cause a skin reaction.

Interactions

Using oral contraceptives may mildly increase the body's need for pantothenic acid. The effects of the

KEY TERMS

Coenzyme—A substance needed by enzymes to produce many of the reactions in energy and protein metabolism in the body.

Hyperreflexia—Reflexes that are abnormally brisk.

Neurotransmitter—A chemical messenger that transmits an impulse from one nerve cell to the next.

medication levodopa may be decreased by supplemental pantothenic acid. This problem is not seen with combination carbidopa and levodopa products. These medications are often used to treat symptoms of **Parkinson's disease**. Anyone taking medication for this condition should consult a health care provider before taking nutritional supplements.

Parasitic infections

Definition

Parasites are organisms that live inside humans or other organisms who act as hosts. They are dependent on their hosts because they are unable to produce food or energy for themselves. Parasites are harmful to humans because they consume needed food, eat away body tissues and cells, and eliminate toxic waste, which makes people sick.

Because of sanitary living conditions in the United States, parasites do not cause widespread life-threatening **infections**. In other parts of the world, however, parasitic infections are epidemic. They kill and disable millions of people every year. Parasitic infection cases in the United States in the 2000s were on the rise, however, due to increased travel to and from underdeveloped countries. In addition, parasitic infections can cause severe infections in **AIDS** patients and other patients with weakened immune systems.

Because parasites can live inside the human body for years without making their presence known, they are more common than one might think. According to one study, approximately half of all Americans have at least one form of parasite. Their presence causes a variety of chronic diseases and conditions such as chronic **fatigue**, weakness, low energy levels, skin **rashes**, **pain**, **constipation**, and frequent colds and **influenza**.

Description

There are two types of parasites: large and small. Large parasites such as intestinal **worms** are easily seen with the naked eye. These are roundworms, flukes, and tapeworms. They usually lay their eggs on the intestinal walls. As they hatch, the young larvae feed on the food in the intestinal tract. Then they grow, reproduce, and start the cycle all over again. They sometimes dig through the digestive tract to get into the bloodstream, muscles, and other organs where they cause even more havoc. These types of parasites often cause malnutrition and **anemia** because they tend to rob the body of essential nutrients.

Small parasites—mostly protozoa and amoebae—are so tiny that they can only be seen with a microscope. These tiny parasites are even more dangerous to the body than the large ones. Although they usually stay in the intestines, they can migrate virtually anywhere in the body: into the bloodstream, muscles, and even vital organs such as the brain, the lungs, or the liver, where they do substantial damage.

Because parasites are everywhere, it is not difficult to become infected. People can become infested through the following ways:

- being bitten by insects
- walking barefoot
- eating raw or undercooked pork, beef, or fish
- eating contaminated raw fruits and vegetables
- eating foods prepared by infected handlers
- drinking contaminated water
- having contact with infected persons (including sexual contact, kissing, sharing drinks, shaking hands, or sharing toys)
- inhaling dust that contains parasitic eggs or cysts
- playing with or picking up pet litter contaminated with parasitic eggs or cysts

In 2002, the Centers for Disease Control (CDC) announced the first documented cases of transplant patients contracting a dangerous parasitic disease from infection with T. cruzi from organs harvested from a Central American donor. The infection caused Chagas disease, causing two of the three donor recipients to die. The CDC identified two additional cases of Chagas diseased in transplant patients. In one case, reported in 2006, the patient received a heart transplant in 2005 and showed symptoms of Chagas in January 2006. The patient was treated medically and recovered. However, he died several months later due to organ rejection. It was found that his donor lived in the United States but had traveled to a portion of Mexico infected with T. cruzi. Another case of Chagas disease was reported in February 2006, one month following a heart transplant. The patient's symptoms disappeared following treatment. He died several months later as a result of cardiac arrest. These represent the fourth and fifth reported cases of Chagas disease caused by T. cruzi. The fact that they occurred in Los Angeles prompted the CDC to encourage physicians in the area to suspect T. cruzi in transplant and transfusion patients, if appropriate symptoms are present.

Causes and symptoms

Risk factors for getting parasitic infections include:

- an immune system weakened by disease or long-term exposure to toxic chemicals or environmental pollution
- prolonged antibiotic use
- alcohol and/or drug abuse
- smoking
- emotional and/or physical stress
- diet high in fat and sugar and low in fiber
- food allergies
- malabsorption syndrome
- obesity

Causes

There are more than 100 types of human parasites. The following describe some of the most common species in the United States.

ARTHROPODS (INSECTS). In the United States, because of high sanitary standards and a temperate climate, parasitic insects do not flourish. Common bugs such as ticks, mites, fleas, lice, and bedbugs may cause intense **itching** in affected areas. They are a nuisance but generally not a major health risk. One exception is the deer tick, which is associated with the debilitating **Lyme disease**. Other parasites, spread by mosquitoes, cause more serious diseases such as western and eastern equine encephalitis, **malaria**, Dengue **fever**, and yellow fever.

INTESTINAL PARASITES. Some of the most common intestinal parasites are:

- Pinworms. This is the most common parasitic infection in the United States. The worm resides in the colon, yet it lays eggs outside the body, usually near the anus, a process that causes severe itching. The disease can be transmitted from one individual to another through dirty hands, clothing, bedclothes, and toys.
- Tapeworms. The two most common tapeworms are *Taenia solium* (pork tapeworm) and *Taenia saginata* (beef tapeworm). *Taenia solium* infestation is caused by eating undercooked pork while *Taenia saginata* (pork tapeworm) infestation is associated with consuming raw beef. Adult tapeworms may become quite big, some as long as 20 feet (6.1 m). Of the two, pork tapeworm is the more harmful. It often causes anemia and weight loss. More seriously, when adult pork tapeworm eggs, excreted in human feces, are ingested by other people (which can happen with poor hygiene and sanitation), the parasitic life cycle that occurs in pigs and cattle takes place in the human host. Once in the human digestive system, the tapeworm eggs, called proglottids, develop into an embryonic form of the parasite called onchospheres that burrow through the intestinal wall and into the bloodstream. From there they migrate into the muscles, eyes, and the brain, a condition called cysticercosis. Cysts in the brain often cause epileptic seizures.
- Protozoa (one-celled organisms) such as *Giardia lamblia, Entamoeba histolytica,* or *Cryptosporidium*. These organisms are some of the most common and infectious parasites in the world. They can be transmitted through contaminated food and water. They can also

be spread from one person to another. Protozoa may spread throughout the body, causing abscesses in the lungs, liver, heart, and brain. Cramps, watery diarrhea, abdominal pain, and serious weight loss are common symptoms of Giardia infection. *Entamoeba histolytica* can cause dysentery, a severe form of intestinal infection, as well as liver and lung damage. Cryptosporidia can cause severe diarrhea in AIDS or cancer patients who have weakened immune systems.

According to the Centers for Disease Control and Prevention (CDC), cases of *Cryptospordium* in the United States increased from 3,505 in 2003 to 8,269 cases in 2005. The largest portion of the increase was related to an outbreak in New York that was traced to use of a recreational water fountain. In 2003, 425 cases were linked to unpasteurized apple cider produced from contaminated apples.

CNS PARASITIC INFECTIONS. *Toxoplasma gondii* is the most common parasite that invades the central nervous system (CNS). Humans become infected with this organism by eating raw or undercooked meat or by handling infected cat litter, which can contain eggs. Pregnant women who are infected may miscarry or deliver stillborn babies. Infected babies are born with congenital toxoplasmosis and have symptoms that include eye inflammation, blindness, **jaundice**, seizures, abnormally small or large heads, and mental retardation. In people with weakened immune systems, such as AIDS patients, toxoplasmosis can affect the whole body, causing inflammation, convulsions, trembling, **headache**, confusion, paralysis in half of the body, or coma.

Symptoms

Parasitic infections are difficult to diagnose because many patients exhibit only vague symptoms or no symptoms at all. The following symptoms, however, may indicate parasitic infections:

- Diarrhea with foul-smelling stool that becomes worse in the later part of the day.
- Sudden changes in bowel habits (e.g. constipation that changes to soft and watery stool).
- Constant rumbling and gurgling in the stomach area unrelated to hunger or eating.
- Heartburn or chest pain.
- Flu-like symptoms such as coughing, fever, and nasal congestion.
- Nonspecific food allergies.
- Itching around the nose, ears, and anus, especially at night.
- Losing weight with constant hunger.

Other symptoms of parasitic infections include anemia, blood in the stool, bloating, **diarrhea**, **gas**, loss of appetite, intestinal obstruction, **nausea**, **vomiting**, sore mouth and gums, excessive nose picking, grinding teeth at night, chronic fatigue, headaches, muscle aches and pains, shortness of breath, skin rashes, **depression**, and **memory loss**.

Diagnosis

The following tests may be used to help doctors diagnose parasitic infections:

- *Ova and parasite (O & P) test*. Three to six stool samples are collected every one or two days to look for eggs and parasites.
- *Cellophane tape* (applied to the anal area). Ova (eggs) that stick to the tape prove pinworm infestation.
- *Endoscopy*. This procedure is used to obtain samples from the duodenum (the upper part of the small intestine), which are then analyzed for the presence of parasites.
- *Urine sample* and vaginal swab to detect *Trichomonas*, a parasite that causes vaginitis.
- *Blood tests*. High levels of eosinophils (a type of white blood cell) indicate infections. Antibodies against the parasites may also be detected. A study released in 2008 found that blood testing is often necessary to obtain a specific diagnosis. An increase in eosinophils, in particular, is associated with parasitic infections.
- *X ray, MRI, and CT scans*. X rays detect lesions in internal organs. Computed axial tomography (CT) scans and magnetic resonance imaging (MRI) are used to diagnose CNS parasitic infections.

Infected patients who are treated with anti-parasitic drugs or herbal remedies should be retested twice at the end of the treatment program; the two tests should be given one month apart.

Treatment

Alternative therapies for parasitic infections reduce parasitic infections by improving **nutrition** and strengthening the immune system through herbal therapy and **Ayurvedic medicine**. Some herbal remedies are directly anti-parasitic and actually eliminate the organisms that cause disease. Patients taking allopathic anti-parasitic remedies should consult their doctor before using any of these herbs. Care should be taken before giving them to children as they easily overdose.

Nutritional therapy

The following dietary changes may help prevent or treat parasitic infections:

- Eating a well-balanced diet with lots of fiber, vegetables, fruits, whole grains, nuts, and seeds. Fiber helps eliminate worms from the intestines; good nutrition improves immune function and protects the body against parasitic invasion.
- Limiting dairy foods, sugar, and fat. Parasites thrive on these foods.
- Avoiding raw or undercooked fish, pork, or beef.
- Take daily multivitamin/mineral supplements to prevent malnutrition and improve immune function.
- Supplementing the diet with probiotics such as *Lactobacillus acidophilus, Bifidobacteria*, and other beneficial intestinal bacteria that cultivate normal intestinal flora and suppress the spreading of parasites.

Herbal therapy

Herbal treatment should be given in combination with supportive dietary treatment and continued until the worms are completely eradicated. The following herbs are helpful in treating parasitic infestations:

- *Melaleuca alternifolia* (tea tree) oil. First discovered by Australian aborigines, tea tree oil has many uses, including treating intestinal parasites, lice, and ticks.
- *Artemisia annua* (wormwood herb) and citrus seed extract. These can be used together to help eliminate intestinal parasites such as *Giardia lamblia*.
- *Berberine-containing herbs*. Berberine is an antimicrobial alkaloid that can prevent parasites from attaching to the intestinal walls of human hosts. One study found that berberine was as effective against amoebal *Giardia lamblia* as metronidazole, the standard treatment. Herbs that contain berberine include goldenseal *(Hydrastis canadensis)*, barberry *(Berberis vulgaris)*, Oregon grape *(Berberis aquifolium)*, and goldthread *(Coptis chinensis)*.

Ayurvedic medicine

Momordica charantia (**bitter melon**) is a very safe remedy for pinworm infection. The melon is a vegetable shaped like a cucumber with a bitter taste. It can be found in most Oriental markets. It should be sliced thinly and eaten raw with other vegetables to reduce its bitter taste. Daily consumption of one to two bitter melons for seven to 10 days can eliminate pinworm infection. Patients may want to repeat the regimen after several months to prevent reinfection. Chinese herbal combinations also help treat parasitic infections by supporting the gastrointestinal system, stimulating immune response, and killing parasites.

Allopathic treatment

Insect infestations

Infestations with lice, ticks, fleas, or bedbugs can be controlled by insecticides and attention to hygiene and household or environmental contact.

Intestinal parasites

Treatment for intestinal parasites usually involves anti-parasitic drugs. Depending on the severity of the condition and the species involved, treatment may include one (or more) of the following drugs: albendazole, furazolidone, iodoquinol, mebendazole, metronidazole, niclosamide, paromomycin, pyrantel pamoate, pyrimethamine, quinacrine, sulfadiazine, or thiabendazole. Nitrazoxinide was approved in 2002 for treatment of *Cryptosporidium* in children ages 1 to 11 years. In 2004, the drug was approved for people older than age 11, including adults. The approval of this drug may have led to a rise in the number of reported cases.

To prevent reinfection and transmission of disease, thorough cleaning of hands, clothes, sheets, and toys is recommended. Treatments should involve all members of the family and repeated treatments may be necessary.

CNS parasitic infections

Babies or AIDS patients with toxoplasmosis are often given spiramycin or sulfadiazine plus pyrimethamine. Treatment may be continued indefinitely for AIDS patients to prevent recurrence.

Expected results

Though parasitic infections are difficult to diagnose, complete recovery from infestation can be achieved with appropriate herbal therapy or anti-parasitic drugs. Because reinfestation is common, multiple treatments may be necessary.

Prevention

The following measures can help prevent parasitic infections:

- Washing hands before eating and after using the restroom.
- Wearing gloves when gardening or working with soil or sand because soil can be contaminated with eggs or cysts of parasites.

KEY TERMS

Contaminated—Unclean or infected by contact with or the addition of something.

Eosinophil—A type of white blood cell that increases in number in response to certain medical conditions, such as allergy or parasitic infection.

Infest—To be parasitic in a host.

Intestines—Also called the bowels and divided into the large and small intestine. They extend from the stomach to the anus, where waste products exit the body. The small intestine is about 20 ft (6.1 m) long and the large intestine, about 5 ft (1.5 m) long.

Protozoa—Single-celled microorganisms belonging to the subkingdom Protozoa that are more complex than bacteria. About 30 protozoa cause diseases in humans.

- For pregnant women, avoiding handling of cat litter.
- Not allowing children to be licked by pets; not allowing children to kiss pets that are not dewormed regularly.
- Washing fresh vegetables carefully. Many people get *Entamoeba histolytica* by eating contaminated raw fruit and vegetables.
- Avoiding eating raw meat, which may contain *Giardia lamblia*.
- Wearing long-sleeved shirts, long pants, and boots when walking in the woods. In addition, spraying insect repellent on clothing to prevent tick bites.

Parkinson's disease

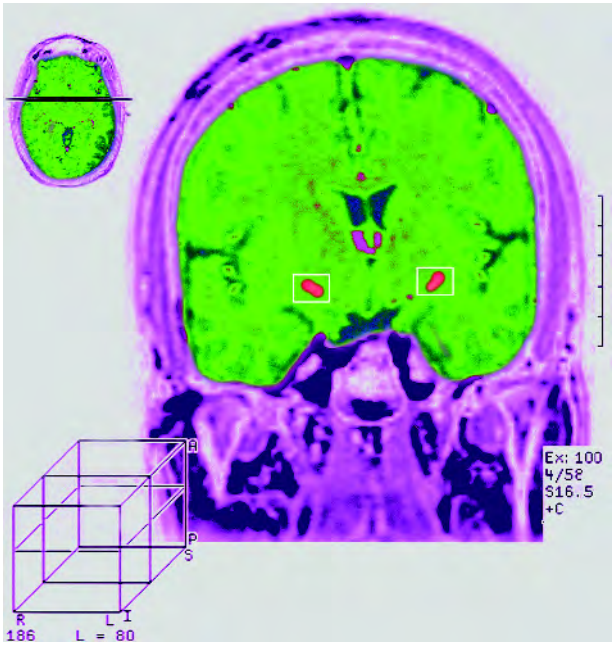
Definition

Parkinson's disease (PD) is a motor system disorder caused by the chronic, progressive degeneration of neurons (nerve cells) in regions of the brain that control movement. PD causes a decline in the initiation, speed, and smoothness of movement. Over time it may come to affect many bodily functions.

Description

Parkinson's Disease (PD) was first described in 1817 by James Parkinson. It affects more than one million people in the United States, including some 500,000 people who have yet to be diagnosed. About 50,000 new cases are diagnosed each year. The average age of PD onset is 60. Symptoms of PD are seen in as many as 15% of those between the ages 65 and 74 and almost 30% of those between the ages of 75 and 84. Only 5 to 10% of PD cases occur before the age of 50. Young-onset PD occurs in those under age 40. A parent or sibling with PD increases one's risk of developing the disease.

PD results from the degeneration and death of neurons in the substantia nigra, movement control centers on each side of the brain. These cells secrete dopamine, a neurotransmitter that attaches to receptors on cell surfaces in another part of the brain—the corpus striatum—that controls muscle action. When dopamine levels fall, the neurons of the corpus striatum begin to misfire. It is estimated that dopamine-producing cells begin dying about 13 years before PD symptoms become evident. The symptoms of PD begin when about 60% of the dopamine-producing cells have died.



MRI image of Parkinson's Disease. *(James Cavallini / Photo Researchers, Inc.)*

Causes and symptoms

Causes

Although the cause of Parkinson's Disease (PD) is unknown, it appears to result from a combination of environmental and hereditary factors as well as oxidative damage and **aging**. Factors for PD may include:

- herbicide and pesticide exposure
- an as-yet-unidentified toxin or virus
- cellular damage from oxidation by free-radicals (atoms or molecules with an unpaired electron)
- loss of dopamine-secreting cells with age, particularly with accelerated aging
- fewer dopamine-secreting cells at birth

Symptoms

Early symptoms of PD often are quite subtle, developing on one or both sides of the body. The primary symptoms of PD are:

- tremors (shaking) while at rest. The classic PD tremor is the rubbing of the thumb and forefinger at a frequency of about three rubs per second. Tremors may spread to the hands, arms, legs, feet, jaw, and face. The tremors increase with stress. However, many people with PD do not experience tremors.
- slow movement (bradykinesia) or freezing during movement (akinesia).
- stiffness or rigidity of the limbs and trunk
- poor balance leading to frequent falls

Other early symptoms of PD include:

- short, shuffling steps
- stooped posture
- masking (reduction) of facial expression and infrequent blinking
- slow or rapid, soft, monotonic (without inflection) speech
- other speech changes
- insomnia, restlessness, and nightmares
- depression
- emotional changes, including fear, irritability, and insecurity
- incontinence
- constipation
- small, illegible handwriting
- frequent, dramatic swings in mobility and moods

Later-stage PD symptoms may include:

- frozen muscles that prevent the initiation of movement
- oily or very dry skin
- sweating
- digestive tract shutdown causing difficulties in swallowing, digesting, and elimination
- auditory and/or visual hallucinations
- progressive deterioration of intellectual function
- dementia, affecting 30 to 40% of those with late-stage PD
- loss of contact with reality (psychosis)

Medications for PD can also cause some of these symptoms.

Diagnosis

There is no definitive test for PD. Diagnosis is based on a careful medical history and complete neurological examination.

In addition to PD, anything that damages the substantia nigra can cause Parkinson's-like symptoms, called parkinsonism. Possible causes of parkinsonism include:

- infection
- nausea
- trauma
- stroke
- exposure to manganese or other toxins
- medications for psychiatric disorders, such as haloperidol (Haldol) or chlorpromazine (thorazine)

- a chemical called MPTP, present as an impurity in some illegal drugs
- epilepsy
- Alzheimer's disease
- other neurodegenerative diseases that sometimes are referred to as Parkinson's plus or parkinsonism plus syndromes

Brain scans, blood tests, lumbar puncture, or x rays may be used to rule out causes of parkinsonism other than PD.

Treatment

There is no cure for Parkinson's disease. In a study released in 2007, gene therapy showed promise. Study participants were given either low, medium, or high doses of a gene involved in the production of dopamine. The gene was injected directly into the brain cells of the participants. Three months following the injection, researchers found improvements that were similar to those previously seen after surgical intervention, such as deep brain stimulation. No side effects were noted; however, scientists believe that more research is needed.

Many factors can help relieve PD symptoms, at least temporarily:

- maintaining general health
- regular, moderate, muscle-building exercise
- frequent rest
- smaller, more frequent, meals to accommodate gastrointestinal slowdowns
- physical, occupational, and/or speech therapies
- encouragement and emotional support

Fatigue, **anxiety**, and **depression** can aggravate PD symptoms significantly.

Therapies that may relieve muscle tightness in PD include:

- acupuncture
- massage
- yoga
- Feldenkrais
- t'ai chi
- qigong
- meditation

A physical therapist can design an appropriate **exercise** program and suggest strategies and techniques for improving balance and stimulating movement during slowdowns or freezing.

Supplementation therapies for PD include:

- amino acids
- essential fatty acids, including omega-3 and omega-6 fatty acids, fish oil, and flax oil
- antioxidants, including carotenoids (dark green and orange fruits and vegetables) and other bioflavonoids (antioxidants derived from foods)
- vitamins A, B, C, and E
- selenium and zinc
- calcium and magnesium
- coenzyme Q_{10} (CoQ_{10}).

For more than 4,000 years, practitioners of Ayurveda—traditional Indian medicine—have prescribed mucuna seeds (*Mucuna pruriens*) to treat Parkinson's disease. Mucuna contains a natural form of levodopa.

Allopathic treatment

Drugs

The pharmacological treatment of Parkinson's disease is very complex. Although many drugs may relieve at least some symptoms of PD, their effectiveness varies with the patient and the progression of the disease. Side effects may preclude the use of the most effective dose or require another drug to counteract them.

A study released in 2007 found that a blood pressure medication known as israpidine forced the neurons of mice to use dopamine in a more youthful manner of generating electrical impulses. Researchers hoped that further investigation would show a link to slowing the progression of PD.

LEVODOPA. Levodopa (L-dopa, L-3,4-dihydroxyphenylalanine) has been the standard treatment for PD since the 1960s and remains one of the best drugs for treating symptoms, particularly tremors and movement problems. Levodopa (Laradopa) is a naturally occurring derivative of dopamine that is converted into dopamine in the brain. However, unlike dopamine, levodopa can reach the brain from the bloodstream. Levodopa treatment may begin at the onset of PD symptoms or when the symptoms begin to interfere with daily life. At least 75% of patients are helped to some degree by levodopa, and the drug enables many people with PD to live relatively normal lives for a number of years. Levodopa normally is prescribed only in combination with other drugs.

Side effects of levodopa include:

- nausea and vomiting
- low blood pressure, particularly when standing up, resulting in dizziness and fainting
- dyskinesias (abnormal movements, including twisting and tics) in at least 50% of patients
- agitation
- hallucinations

These effects usually lessen after several weeks on levodopa.

After five or more years on levodopa, many patients develop the following:

- motor fluctuations, including "peak-dose" dyskinesias when the drug is at its highest level in the brain
- on-off phenomena—significant changes in response as the drug levels fluctuate
- unpredictable responses to the drug

The levodopa dosage is usually increased when these changes occur. However, dyskinesias may increase with increasing dosages.

Levodopa is an amino acid that is absorbed from the digestive system by the same transporters that carry **amino acids** from dietary proteins. Therefore some healthcare practitioners may limit or redistribute protein intake to improve levodopa adsorption into the bloodstream.

ENZYME INHIBITORS. Since levodopa and dopamine are amino acids, they can be broken down by the same enzyme systems that break down other amino acids. Therefore, the two most commonly prescribed forms of levodopa are an amino-acid-decarboxylase (AADC) inhibitor: carbidopa (in Sinemet) or benzaseride (in Madopar). These drugs enable more levodopa to enter the brain and may reduce some side effects. Controlled-release formulations (Sinemet CR) can prolong the interval between doses. Carbidopa also prevents vitamin B_6 (pyridoxin) from interfering with levodopa.

Catechol-O-methyltransferase (COMT) also breaks down levodopa. The COMT inhibitor entacapone (Comtan) prolongs the effects of levodopa and may moderate its fluctuations. Stalevo contains levodopa, carbidopa, and entacapone. Although the COMT inhibitor tolcapone (Tasmar) reduces the average required dosage of levodopa by 25%, as of 2008 it was no longer commonly used because of severe side effects and possible liver damage and failure.

Selegiline (deprenyl) inhibits monoamine oxidase B (MAO-B), which metabolizes dopamine in the brain. Selegiline can delay levodopa treatment for an average of nine months and also is used in combination with levodopa (Eldepryl) in early-stage PD. Common side effects include dyskinesias, **dry mouth**, and mood swings.

DOPAMINE AGONISTS. Dopamine agonists (DAs) are drugs that activate dopamine receptors, mimicking the effects of dopamine. In younger adults with early-stage PD, DAs appear to be more effective than levodopa. More often, DAs are used in conjunction with Sinemet to prolong the action of levodopa and reduce levodopa-induced dyskinesias. Although they are expensive, DAs may postpone or prevent the need for expensive neurosurgery at later stages of PD.

DAs include the following:

- bromocriptine (Parlodel)
- pergolide (Permax)
- pramipexole (Mirapex)
- ropinirole (Requip)

Side effects of DAs are similar to those of levodopa, including drowsiness and confusion. DAs may cause dyskinesias in at least 50% of patients. Pergolide has been associated with a type of **heart disease**.

ANTICHOLINERGIC DRUGS. The neurotransmitters dopamine and acetylcholine balance one another's effects in the brain. Anticholinergics help maintain this balance when dopamine levels fall. Although they may control tremors in early-stage PD, their side effects—including dry mouth, urine retention, severe **constipation**, blurred vision, confusion, **memory loss**, and hallucinations—are usually too severe for older patients or those with **dementia**. Anticholinergics rarely work for very long. Trihexyphenidyl (Artane) and benztropine (Cogentin) are the most common anticholinergics for PD.

OTHER DRUGS. Other common PD medications include:

- Diphenhydramine (Benadryl), an antihistamine, and antidepressants such as amitryptiline (Elavil), have similar effects as anticholinergics and may be appropriate for older patients.
- Amantadine (Symmetrel) is an antiviral drug used in later-stage PD, particularly to treat tremors and levodopa-induced dyskinesias. Its effects include increased dopamine release and blocking of glutamate, an amino acid that destroys neurons. Side effects include swollen ankles and purple mottling of the skin.
- Clozapine (Clozaril) is particularly effective for psychiatric symptoms of late-stage PD, including psychosis and hallucinations.

Although drug therapies can relieve most symptoms of early-stage PD, as the disease advances, drug responses begin to fluctuate and their overall effectiveness decreases.

Surgery

Surgery may be used to help manage severe or debilitating PD symptoms when drug treatments fail.

Pallidotomy uses an electrical current to destroy a small amount of brain tissue in the globus pallidus,

KEY TERMS

Acetylcholine—A major neurotransmitter that balances the effects of dopamine in the brain.

Akinesia—Inability to move.

Allopathic—The practice of medicine that combats disease with remedies that produce effects different from those produced by the disease.

Amino acid decarboxylate (AADC) inhibitors—Drugs, such as carbidopa and benserazide, that block the enzyme AADC, which breaks down levodopa in the blood.

Antioxidants—Nutrients in food that help maintain health by slowing the destructive aging process of cell molecules and improving immune responses.

Ayurveda—India's traditional health system.

Bioflavonoids—A group of chemical compounds naturally found in certain fruits, vegetables, teas, wines, nuts, seeds, and roots. Not considered vitamins, they function nutritionally as antioxidants to prevent cell destruction.

Bradykinesia—Slow movement.

Catechol-O-methyltransferase (COMT) inhibitors—Drugs, such as entacapone and tolcapone, that block COMT, an enzyme that breaks down levodopa in the blood.

Corpus striatum—Regions on each side of the brain that transmit signals for movement in response to dopamine from the substantia nigra.

Dopamine—A brain neurotransmitter that sends signals that help to control movement.

Dopamine agonist (DA)—A drug that binds to dopamine receptors on cell surfaces and mimics the effects of dopamine.

Dyskinesia—An abnormal involuntary movement or tic.

Feldenkrais—An educational method dedicated to improved movement and enhanced functioning originated by Moshe Feldenkrais (1904 1984), an engineer, physicist, and Judo expert.

Globus pallidus—Areas on each side of the brain that transmit signals controlling movement.

Levodopa—A naturally occurring amino acid that is converted to dopamine in the brain; the primary treatment for Parkinson's disease.

Monoamine oxidase (MAO-B) inhibitors—Drugs such as selegiline that inhibit the enzyme MAO-B that breaks down dopamine in the brain.

Neurotransmitter—A chemical that helps to transmit signals between two nerves or between a nerve and a muscle.

Pallidotomy—Surgery that destroys a small amount of tissue in the globus pallidus, which is over-stimulated by the corpus striatum in PD. The surgery can improve tremors, rigidity, and bradykinesia.

Parkinsonism—A disease or condition with symptoms similar to those of Parkinson's disease.

Substantia nigra—Movement control centers of the brain containing dopamine-producing cells.

T'ai chi—An ancient Chinese martial art consisting of slow, rhythmic movements to relieve stress, anxiety, and depression, and provide cardiovascular, respiratory, and pain relief benefits. Qigong is a form of T'ai chi.

Thalamotomy—Surgery that destroys a small amount of tissue in the thalamus to control PD tremors.

Thalamus—An important relay center for sensory signals in the cerebral cortex of the brain.

which is over-stimulated by the corpus striatum in PD. Pallidotomy may relieve tremors and slow, rigid movements, and decrease dyskinesia caused by drug therapy, by interfering with the neural pathway between the globus pallidus and the thalamus (a major transmission center in the brain). The benefits often do not last and the surgery may cause slurred speech, disabling weakness, and vision problems, particularly with a double pallidotomy (surgery on both sides of the brain).

Thalamotomy reduces hand and arm tremors by destroying small amounts of tissue in the thalamus. Because a double thalamotomy leaves patients extremely weak and with slurred speech, it usually is performed on only one side of the brain, relieving tremors on the opposite side of the body.

With deep brain stimulation (DBS), a device similar to a heart pacemaker sends signals to fine electrodes implanted in the subthalamic nuclei or the globus pallidus (Activa Therapy). The electrical pulses appear to interrupt signals from the thalamus that are involved in tremors. DBS restores a balance between excitatory (tending to excite) and inhibitory (interfering or retarding) signals in brain signal transmission centers, thereby

decreasing or abolishing dyskinesias without slowing normal movement. Patients use a magnetic device to adjust stimulation in one or both halves of the brain, as the response dictates. DBS usually results in a significant improvement in some motor symptoms, including tremors and peak-dose dyskinesias and improves motor function and mobility. It also enables patients to take higher doses of levodopa. The best candidates for DBS are persons who have been afflicted with PD for 10 to 20 years and who have wearing-off motor fluctuations, periods of extreme slowness in movement, and twisting motions caused by medications. Risks may be as minor as drowsiness or **headache** or as serious as hemorrhage, **stroke**, or infection.

The implantation of fetal cells to replace the dopamine-producing cells of the substantia nigra appears to benefit only patients under age 60. It can have serious side effects and about 15% of patients later develop severe dyskinesia due to dopamine-overproduction.

The use of stem cells derived from embryos discarded by **infertility** clinics is a potentially useful treatment for PD. However, it remains morally and ethically controversial, and as of 2008, the treatment was linked to law-making decisions and opinions.

Prognosis

There is no way to predict the course of PD. Many people live active, productive lives for 12 to 15 years. However, in others the disease progresses rapidly. Regardless of treatment, PD symptoms worsen with time and become less responsive to drug therapy. Most people with PD experience some additional problem every year. A small number of patients eventually become completely incapacitated. Although PD is not fatal, its effects can lead to fatal accidents or illnesses.

Prevention

There are no clear risk factors or preventions for PD. Central body **obesity** may increase the risk. Some studies have found that coffee drinking or hormone replacement therapy (HRT) in postmenopausal women may decrease the risk of PD. However, heavy coffee drinking in combination with HRT appears to increase the risk of Parkinson's disease.

Parsley

Description

Parsley (*Petroselinum crispum* and *P. sativum*) is a member of the Apiaceae family of plants. Relatives of this common culinary herb include the garden vegetables carrot, parsnip, and celery. Parsley belongs to the same family as poison hemlock (*Conium maculatum L.*), a deadly narcotic herb. Parsley is native to the Mediterranean area but is now naturalized and cultivated throughout the world. Nicolas Culpeper, the seventeenth-century English herbalist and astrologer, placed parsley under the dominion of the planet Mercury. Common names for

Fresh parsley. *(Photo by Kelly Quin. Reproduced by permission.)*

this herb include parsley breakstone, garden parsley, rock parsley, persely, and petersylinge. A variety known as Hamburg parsley (*P. crispum, "Tuberosum"*), first cultivated in Holland, has a root as much as six times as large as garden parsley.

In ancient times parsley was dedicated to Persephone, the wife of Hades and goddess of the underworld. Parsley is slow to germinate. Folk legend explains this characteristic with the myth that parsley must first visit Hades seven times before it may freely germinate and flourish on the earth. It was also believed that the herb would flourish only in gardens where a strong woman presides over the household. Parsley was used as a ceremonial herb in ancient Greek and Roman cultures. The herb was sprinkled on corpses to cover the stench, and planted on the graves of loved ones. Roman gladiators ate parsley before facing foes in the arena. Victorious Greek athletes were crowned with parsley. In the Middle Ages this lovely herb was known as merry parsley and was credited with lethal powers. It was believed that one could bring certain death to an adversary by pulling a parsley root from the earth while calling out the enemy's name.

Parsley is a self-seeding biennial that thrives in rich, moist soil in full sun or partial shade. It grows from a single spindle-shaped taproot producing smooth, many-branched and juicy stems. The bright green leaves are feather-like in appearance, tri-pinnate and finely divided. Some varieties are flat-leafed, others are more compact and curly. Diminutive five-petaled flowers are yellow-green and borne in dense, flat-topped clusters. They bloom in midsummer. The gray-brown seeds are tiny, ribbed and ovate (egg-shaped). Parsley can grow as much as 3 ft (1 m) tall in its second year as the flower-bearing stems become nearly leafless and reach for the sun.

General use

Parsley's taproot, leaves, and seeds are used medicinally. The leaf is used extensively as a culinary herb and garnish. Parsley's volatile oil, particularly the oil from the seed, contains the chemicals apiole, also known as parsley camphor, and myristicin in varying quantities depending on the variety of parsley. These constituents are diuretic, and also act as uterine stimulants. The diuretic effect of parsley appears to be related to increased retention of **potassium** in the small intestine.

Internal uses

In folk tradition, parsley has been used to promote **menstruation**, facilitate **childbirth**, and increase female libido. Its emmenagogic properties can bring on delayed menstruation. Parsley juice also inhibits the secretion of histamine; it is useful in treating **hives** and relieving other allergy symptoms. A decoction of parsley root can help eliminate bloating and reduce weight by eliminating excess water gain. Parsley has also been used traditionally as a liver tonic and as a means of breaking up **kidney stones**. The German Commission E, an advisory panel on herbal medicines, has approved parsley for use in the prevention and treatment of kidney stones. The saponin content of parsley may help relieve coughs. Parsley root is laxative and its carminative action can relieve flatulence and **colic**. Parsley is rich in vitamins and minerals, including A and C, as well as **calcium**, thiamin, **riboflavin**, **niacin**, **zinc**, potassium, and **iron**. The **boron** and fluorine in parsley give strength to the bones. Parsley's high chlorophyll content makes this beneficial herb a natural as a tasty breath freshener.

More recently, the natural deodorizing activity of parsley has been put to use by the food industry. More particularly, parsley can be added to processed foods containing onions or **garlic** in order to minimize the odors associated with these vegetables.

External uses

The freshly gathered leaves of parsley have been used as a poultice to relieve breast tenderness in lactating women. Parsley poultices may also soothe tired, irritated eyes, and speed the healing of **bruises**. The juice will relieve the itch and sting of insect **bites**, and serves well as a mosquito repellent. A juice-soaked gauze pad can be applied to relieve **earache** or **toothache**, or used as a face wash to lighten freckles. The

KEY TERMS

Abortifacient—An agent that induces abortion.

Biennial—A plant that takes two years to complete its life cycle. It produces fruit and flowers only in the second year.

Carminative—A substance or preparation that relieves digestive gas.

Diuretic—A medication or substance that increases urine output.

Emmenagogue—A type of medication that brings on or increases a woman's menstrual flow.

Infusion—The most potent type of extraction of a herb into water. Infusions are steeped for a longer period of time than teas.

Photosensitivity—An abnormal reaction to light exposure caused by a disorder or resulting from the use of certain drugs.

Pinnate—Having leaflets arranged on each side of a common stalk. Parsley has a tripinnate leaf.

Saponin—A compound found in parsley, soapwort, and other plants, that forms a stable foam when added to water. Saponin is used commercially in beverages.

Tincture—An alcoholic solution of a chemical or drug.

powdered seeds, sprinkled on the hair and massaged into the scalp for three days, are a folk remedy said to stimulate hair growth. Parsley has also been used as a hair rinse in efforts to eradicate head lice.

Preparations

The root and seed of parsley should be harvested in the fall from plants in the second year of growth. The leaves can be harvested throughout the growing season. It is important not to confuse wild parsley with the herb *Aethusa cynapium*, also known as "fool's parsley." It would be a toxic mistake.

After harvesting, remove parsley leaves from the stems and place them in a single layer on a drying tray out of direct sunlight in an airy room. When the herb is thoroughly dry, store it in tightly sealed, clearly labeled dark glass containers.

Decoction: Many of parsley's medicinal properties are concentrated in the root and are best extracted by decoction. Add about 1 tsp of thinly-sliced fresh or dried parsley root to 8 oz of cold water in a glass or ceramic pot. Bring to a boil; reduce heat and simmer for about ten minutes and infuse for an additional ten minutes. Drink up to three cups daily.

Infusion: Place 2 oz of fresh parsley leaves or root in a warmed glass container. Bring 2.5 cups of fresh nonchlorinated water to the boiling point and add it to the herbs. Cover and infuse the tea for about ten minutes, then strain. Drink the herb after the infusion cools. The prepared tea can be kept for about two days in the refrigerator. Parsley tea may be enjoyed by the cupful up to three times a day.

Tincture: Combine 4 oz of finely-cut fresh or powdered dry herb with 1 pt of brandy, gin, or vodka in a glass container. There should be enough alcohol to cover the plant parts and have a 50/50 ratio of alcohol to water. Place the mixture away from light for about two weeks, shaking several times each day. Strain and store in a tightly capped dark glass bottle. A standard dose is 1/2–1 tsp of the tincture up to three times a day

Juice: Large amounts of organic fresh parsley are needed for juicing. An electric home juicer or food processor may be used. Squeeze any pulp through a sieve to extract all the juice. Prepare parsley juice fresh as needed, and store in clearly labeled glass containers. Keep refrigerated.

Precautions

A chemical found in the oil-rich seeds of parsley has abortifacient properties. For this reason, women should not use parsley during **pregnancy** or lactation. Parsley irritates the epithelial tissues of the kidney, increasing blood flow and filtration rate; therefore persons with kidney disease should not take this herb internally without consultation with a qualified herbalist or physician. According to the *PDR for Herbal Medicine*, the daily dose of parsley in medicinal preparations is 2.1 oz (6 g). Parsley's volatile oil is toxic in high doses, and overdose can lead to poisonings.

Side effects

Parsley contains furocoumarins—compounds that can cause photosensitivity in fair-skinned persons exposed to sunlight after "intensive skin contact" with the freshly harvested herb. Parsley may also cause allergy in sensitive persons.

Interactions

No interactions have been reported between parsley and standard allopathic medications.

Partridge berry *see* **Squawvine**

Pasque flower *see* **Pulsatilla**

Passionflower

Description

Passionflower (*Passiflora incarnata*) is a creeping perennial vine with white, purple-tinged flowers and orange berries that grows to a height of up to 30 ft (9 m). First used by Native Americans and the Aztecs of Mexico as a sedative, passionflower has been a popular folk remedy for centuries in Europe and North America. Other names for passionflower include maypop, granadilla, passion vine, and apricot vine. The herb, which is generally used today to alleviate **anxiety** and **insomnia**, received its curious name from the Spanish conquistadors who overran Mexico and Peru in the sixteenth century. In the flowers of the vine, they saw various symbols of the Passion of Christ, which in Christian tradition refers to the period of time between the Last Supper and Christ's death. In the Spaniard's elaborate analogy, the corona in the center of the flower was thought to resemble the crown of thorns worn by Jesus during the crucifixion. The flower's tendrils symbolized whips, the five stamens represented Christ's **wounds**, the total number of petals corresponded to the 10 faithful apostles (Peter and Judas did not make the cut), and so on.

While there are over 400 species belonging to the genus *Passiflora*, the variety used for medicinal purposes is called *incarnata*, which can be translated "embodied." The plant is obtained primarily from the southern United States, India, and the West Indies, though passionflower also grows in Mexico as well as Central and South America. Only the parts of the plant that grow above the ground are used as a drug, in fresh and dried form.

Some investigations of passionflower have been conducted in humans; in addition, animal and other studies suggest that the herb has sedative, anxiolytic, and antispasmodic properties. The German Commission E, considered an authoritative source of information on alternative remedies, reported that passionflower appears to reduce restlessness in animals. In a 1988 study involving rats that was published in a German journal of pharmacology, passionflower was shown to prolong sleep, reduce motor activity, and protect the rodents from convulsions. Despite findings such as these, researchers have been unable to identify the herb's active ingredients. Attention has focused on flavonoids (medicinal passionflower contains up to 2.5% of these chemicals); maltol; and harmala alkaloids such as harman, harmine, harmaline, and harmalol. (The Germans attempted to use harmine as a truth serum during World War II because of the chemical's reputation for inducing a euphoria-like state.) Some researchers speculate that it is the interaction, or synergy, of several chemicals in passionflower that is responsible for the herb's therapeutic effects.

General use

Although it has not been approved by the Food and Drug Administration (FDA), passionflower is mainly used in the United States and Europe to relieve anxiety, restlessness, and insomnia. It is also recommended for the relief of **nausea** caused by nervousness or anxiety. The herb appears to work, at least in part, by mildly depressing the central nervous system and preventing **muscle spasms**. In its capacity as a sedative and sleep aid, passionflower has been endorsed by

Passionflower blossom. *(©PlantaPhile, Germany. Reproduced by permission.)*

several important European research organizations. For over 15 years, passionflower has been approved by Commission E for the treatment of nervous unrest. The European Scientific Cooperative on Phytotherapy has approved the herb for use in people who experience tension, restlessness, and insomnia associated with irritability. Passionflower is listed in many national pharmacopoeiae as a drug plant.

Passionflower is often used in combination with other sedative plants. In the United Kingdom, it is an ingredient in several dozen over-the-counter (OTC) sedatives. In Germany, the herb is used as an ingredient in sedative preparations that also include **valerian** and **lemon balm**. The standardized sedative tea formula approved by Commission E contains 30% passionflower, 40% valerian root, and 30% lemon balm. Passionflower is also used in Germany in a special sedative tea for children. The ingredients of this tea typically include 30% passionflower, 30% lemon balm, 30% **lavender** flower, and 10% **St. John's wort**. In combination with **hawthorn**, passionflower is also used to alleviate digestive spasms associated with **gastritis** and **colitis**.

In the past, passionflower was approved by the FDA as an ingredient in OTC sleep aids and sedative products. This approval was revoked in 1978 during a review by the agency, but not because the reviewers found passionflower to be unsafe or ineffective. Drug manufacturers were responsible for submitting information about the safety and effectiveness of OTC medications under review by the FDA. No companies submitted data for passionflower, so the herb was denied approval because it had no sponsors.

Throughout its history, passionflower has been used to treat a variety of medical problems in addition to those mentioned above. These include **epilepsy**, **diarrhea**, **neuralgia**, **asthma**, **whooping cough**, seizures, painful **menstruation**, and **hemorrhoids** (when used externally). Some herbalists also recommend passionflower as a treatment for **Parkinson's disease**, based on their belief that the harmine and harmaline in the herb may help to counteract the effects of the disorder. As of 2000, these additional uses for passionflower are considered speculative.

In 2002, a team of American researchers published a report finding that passionflower shows

KEY TERMS

Antigen—Any substance that can stimulate the production of antibodies and combine with them.

Antispasmodic—A medication with the ability to prevent or relieve convulsions or muscle spasms.

Anxiolytic—A medication that alleviates anxiety.

Neuralgia—Sharp pain along the course of a nerve.

Sedative—A substance given to calm or soothe.

promise as a chemopreventive for **cancer**. The scientists found that passionflower extract inhibits an early antigen of Epstein-Barr virus, which suggests that it may also inhibit the growth of cancerous tumors.

Preparations

Recommended dosages of passionflower generally range from 4–8 g of herb a day. While it is typically used in preparations containing other sedative ingredients, it may also be used alone. Passionflower tea can be prepared by steeping 1 teaspoonful of the herb in 150 ml of simmering water. The mixture should be strained after about 10 minutes. Dosage is usually two or three cups of tea a day, taken during the day and a half-hour before going to bed. The liquid extract preparation is usually taken three times a day in doses of 0.5–1.0 ml. Dosage for the tincture is 0.5–2.0 ml three times a day. Tablets containing passionflower are available in the United Kingdom. Persons who use a combination product containing passionflower should follow the package directions for use.

Precautions

Passionflower is not known to be harmful when taken in recommended dosages, though there are some precautions to consider. The herb contains two potentially dangerous alkaloids called harman and harmaline. In large amounts, these chemicals may stimulate the tissue of the uterus. However, most authorities believe that the amounts of harman and harmaline contained in medicinal passionflower are too small to have an adverse effect when the herb is used in normal amounts. Caution should also be exercised when combining passionflower with certain medications (see below).

While self-care measures such as passionflower may be effective in relieving anxiety or insomnia, these problems may be a symptom of a more serious psychological disorder that requires consultation with a mental health professional. Nighttime sleep aids should not be used for longer than two weeks without seeking medical advice. Due to lack of sufficient medical study, passionflower should be used with caution in children, women who are pregnant or breast-feeding, and people with liver or kidney disease.

Side effects

When taken in recommended dosages, passionflower has not been associated with any significant or bothersome side effects.

Interactions

Passionflower has the potential to interact adversely with certain medications. The harman and harmaline in passionflower may increase the effects of prescription antidepressants called monoamine oxidase inhibitors (MAOIs), which are generally used to treat **depression**, panic attacks, and eating disorders. Passionflower may also increase the effects of OTC sedatives as well as those sold by prescription.

Past life therapy

Definition

Past life therapy is a therapy in which an individual is regressed to past lives in order to heal and resolve ailments and situations from the current life.

KEY TERMS

Regression therapy—Traveling back and reliving emotions experience through prior lives while meditating.

Origins

Past life therapy is based on the ancient belief of reincarnation. The foundation of Hindu philosophy, reincarnation dates back thousands of years. It is the notion that the soul is eternal and incarnates again and again, retaining all the knowledge of events that occur during each lifetime.

Karma is an important component of reincarnation. It is a Sanskrit word meaning action. The basis of karma is that every action has a reaction: cause and effect. Each lifetime is lived in order to resolve unwholesome actions in previous lifetimes. The circumstances of each life are determined by the growth and progress achieved in a past life. According to this theory, a person's actions in one lifetime determine the conditions, situations, relationships, environment, and opportunities of the next life.

The actions carried out in one lifetime are often carried through to the next life. For instance, someone who committed a murder in a previous life may encounter a lifetime in which he will have to deal with anger and violence. Although "past lives" began as a religious concept, since the 1960s it has been used in the therapeutic community to help people reframe current issues in their lives that are blocking their health and well-being. Whether or not there are past-life experiences and memories is debatable and ultimately unprovable. They may be metaphors of the mind. Even so, they can serve as useful processes for bringing understanding and resolution to present conflicts.

Benefits

Past life therapy is reported to have a myriad of benefits. Memories revealed from a past life allow individuals to alter their perspectives on their current lives. This therapy helps people to understand who they are, learn how past life events have affected present life circumstances, and to offer insight into hidden conflicts so that repeating patterns may be stopped.

Awareness created through regression therapy allows mental, physical, and emotional release. Patients may let go of deep-seated emotions, fears, and guilt that often result in the relief of such problems as chronic **pain**, **alcoholism**, jealousy, arthritis, claustrophobia, agoraphobia, migraine headaches, weight problems, **insomnia**, obsessive/compulsive behaviors, chemical dependencies, **depression**, and sexual dysfunctions. The release of fear and other painful emotions strengthens will and self-esteem and fosters forgiveness towards others and towards the self.

Throughout their lives individuals may have felt negativity towards certain persons or places. They may be averse to particular foods, be prone to illness or disease, or have recurring dreams. This may be the result of a past life connection. By becoming aware of the roots of these conditions the negativity is released and healing often occurs.

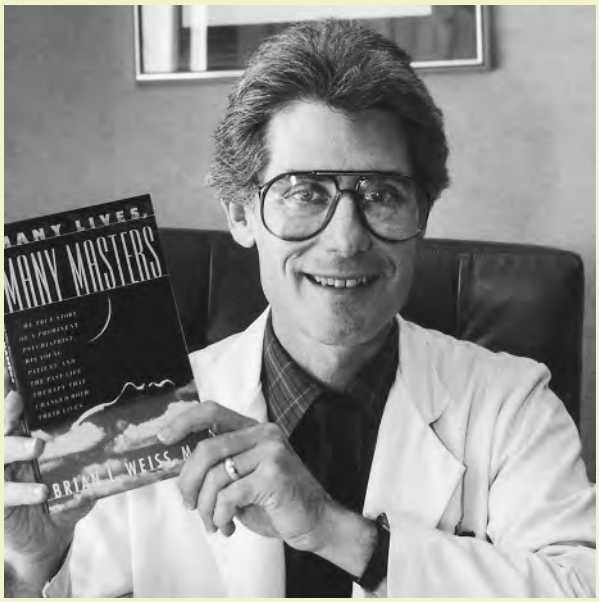
Description

Past lives may be accessed through regression therapy, hypnosis, **guided imagery**, dreams, craniosacral therapy and other types of bodywork, spontaneous regressions, automatic writing, **meditation**, or contact with one's higher self. Dealing with one's higher self is achieved through meditation and hypnosis and is based on the belief that the soul retains information of past lives and uses this to set the destiny of the current life. Contacting the higher self is said to help change one's destiny. The therapy is usually performed on an individual basis.

Past life therapy is usually undertaken to reach the source of problems or conflicts in the current life. The purpose of a regression session is to release guilt, fears, and other emotions tied to past events in order to make appropriate decisions in the present lifetime and gain an understanding of present relationships.

One common method of exploring past lives is through hypnosis. During a hypnotic regression, the patient is relaxed into a light trance state in which he or she is often completely aware of the surroundings. In order to achieve this state, the therapist may lead the patient through a guided fantasy. The patient may begin to intuit an awareness of a scene or see moving pictures as in a movie or on television. The patient may see or hear words describing a scene and feel emotions relating to that scene. The therapist acts as a coach, encouraging the patient to explain what she is seeing and feeling until the scene has stopped.

BRIAN WEISS (1944-)



(AP/Wide World Photos. Reproduced by permission.)

Brian L. Weiss graduated from Columbia University and Yale Medical School, where he received his degree in medicine with a specialty in psychiatry. He is Chairman Emeritus of Psychiatry at the Mount Sinai Medical Center in Miami and a former professor of psychiatry at the Uni versity of Miami School of Medicine. He is an advocate of the clinical applications of regression or past life therapy in treating phobias, addictions, depression, and psychoso matic disorders. Weiss uses hypnosis to access patients' memories of their childhood and past lives. His interest began when a woman he had hypnotized said she had communicated with his dead infant son through spirits called the Masters. The woman claimed to have lived at least 86 previous lives.

He conducts lectures around the world and is a fre quent guest on radio and television talk shows. Weiss is author of several books, including *Many Lives, Many Mas ters* (1988), *Through Time Into Healing* (1993), *Only Love is Real: A Story of Soulmates Reunited* (1995), and *Mes sages from the Masters* (2000). He is founder of the Weiss Institute and maintains a practice at 6701 SW 72nd St, Miami, FL.

In the past life regression, the patient may recognize people from her current life. According to the karmic theory, souls who are closely related in one life will meet in another. Often people who bond together in this lifetime, such as family, lovers, or friends, have also been together in previous lives. The significance of meeting again is to resolve karmic issues from other lives in order to promote growth and healing.

Past lives generally are not experienced in a sequential fashion. This is due to the karmic understanding that past lives are revealed at a time when the individual will benefit most by the lesson learned through the review.

Research and general acceptance

Much research has been conducted on past life therapy. One of the proponents of the past life movement, Dr. Brian Weiss, has written several books detailing the experiences he has encountered while performing past life regressions.

Dr. Ian Stevenson, professor of psychiatry at the University of Virginia, has conducted research on children who consciously recall their past lives. One of his cases involved a girl from India named Shanti Devi. When she was very young, Shanti began to talk about a husband and children. She gave the address of her "former" home and the identity of her husband. When she was nine, Shanti was taken to the house, where she retrieved some jewelry she had buried in the garden in her former life.

Past life therapy is not generally accepted by most Western medical practitioners. Although the idea of discovering past lives through hypnosis became popularized in the 1970s, it is now under criticism by modern psychologists. Many contend that patients under hypnosis are directed to remember past lives by the suggestions of hypnotherapists, and subsequently fabricate false memories of past lives.

Training and certification

Past life therapy may be performed by trained psychologists, persons trained in **hypnotherapy** or regression techniques, or psychics or mediums. The techniques used for past life regressions are the same techniques used for age regression therapy.

Pau d'arco

Description

Pau d'arco (pronounced pow-darko) is a large tree that grows in the Amazon rain forest and in tropical areas of South America. The botanical names for the species most commonly used are *Tabebuia heptaphylla* and *Tabebuia impetiginosa*. The tree is called taheebo or lapacho in South America. The inner bark of pau d'arco is used as an herbal medicine, most notably in the treatment of **cancer** and **infections**.

The pau d'arco tree grows up to 150 ft (45 m) tall and 10 ft (3 m) in diameter, and is prized for its lumber. The wood is extremely hard, and makes fine furniture. The tree produces large purple flowers, making it popular for landscaping and decoration. The bark of the tree has been used medicinally by native South American peoples for centuries. Rainforest medicine men scrape the inner bark and brew a tea from it. The tea has been used to treat conditions as varied as **malaria**, infections, **fever**, arthritis, skin problems, **syphilis**, **AIDS**, and cancer. Pau d'arco has long been a common herbal remedy for Europeans who moved to South America as well, and is sometimes drunk there as a refreshing tea. The tea has a cool, bitter flavor.

Pau d'arco became known to the mainstream medical community during the 1960s. At that time, a doctor named Theodore Meyer learned of the herb from a rainforest tribe, and used it to treat patients suffering from **leukemia** (cancer of the blood). He reported that the herb completely cured five cases of advanced cancer. Then, a hospital in South America used a tea made from the herb to treat cancer patients, and reported that pau d'arco reduced **pain** and cured tumors in some patients. These stories made it to the press, and pau d'arco was touted around the world as a miracle cancer cure.

Pau d'arco caught the attention of American researchers and drug companies, and scientific studies on it were performed. Scientists isolated an active chemical found in the bark, and termed it lapachol. Several studies showed that lapachol was effective against cancerous tumors in rats, giving it promise as a cancer cure. In 1974, however, the National Cancer Institute concluded that the amounts of lapachol required for beneficial effects against cancer in humans would result in toxic side effects, and stopped researching pau d'arco as a cancer treatment.

The inner bark of pau d'arco is used as an herbal medicine, most notably in the treatment of cancer and infections. *(Genevieve Vallee / Alamy)*

Although research in general did not support the huge claims made for pau d'arco, it continued to generate stories of miraculous cancer cures and other successes treating infections and chronic conditions. Some researchers have theorized that other ingredients in the bark besides lapachol may have therapeutic effects; and it has been shown that the use of the whole herb does not create the side effects that extracted lapachol causes. Researchers have isolated over 20 active chemicals in pau d'arco. Research, mainly on laboratory animals, has shown pau d'arco

KEY TERMS

Candidiasis—A common infection caused by a yeast called *Candida albicans*.

Lapachol—The name given to the active ingredient in pau d'arco, which appears to have some anti-cancer properties.

to have anti-microbial and anti-viral properties, helping to destroy bacteria, fungi, parasites and viruses by increasing the supply of oxygen to cells. It has demonstrated effectiveness against yeast infections, malaria, **tuberculosis**, strep, and dysentery. Pau d'arco has also been shown to influence the activity of the immune system. In small dosages, it increases immune system activity and in large doses suppresses some immune responses such as inflammation. Its anti-inflammatory actions have given pau d'arco promise as a remedy for **allergies**, arthritis, skin problems, ulcers and other inflammatory conditions.

General use

Pau d'arco is used frequently in the herbal treatment of cancer and infections, including candidiasis and other yeast infections. Pau d'arco is also used for allergies, arthritis, diabetes, flu, lupus, parasites, skin diseases, and ulcers.

Preparations

Pau d'arco is available in health food stores in capsules, tinctures, and as dried bark. The recommended dosage is 1-2 capsules or 1-2 droppersful of tincture taken one to four times per day, depending on the condition and patient.

Tea can be made from the bark by adding 1 tbsp of bark for every 3 cups of water. The tea should be boiled for 20 minutes or longer in a non-aluminum pot. One cup of tea can be taken three or four times daily for acute conditions. One-half cup three or four times daily is recommended for other conditions.

Precautions

Pregnant and lactating women should not use pau d'arco, as its effects during **pregnancy** have not been sufficiently researched. Pau d'arco has been shown to have blood-thinning actions in some people, and may cause **anemia** (shortage of red blood cells) when used over long periods. For this reason, pau d'arco should not be used before surgery or by patients with anemia or bleeding problems.

Another precaution consumers should take is assuring that the product they purchase is produced by a reputable manufacturer. Pau d'arco is a valuable resource in South America, and there has been a history of fraudulent products being exported. Some of these products have caused uncomfortable side effects that do not occur with real pau d'arco. In Canada in 1987, a chemical analysis of 12 commercial products revealed that only one contained the active ingredient lapachol, and that was in minute amounts. Some manufacturers have begun to offer products with standardized quantities of active ingredients to assure quality. The pau d'arco imported from Argentina is generally considered to be the highest quality bark.

Side effects

Possible side effects from ingesting too much pau d'arco include **nausea**, **vomiting**, **diarrhea**, **dizziness**, and stomach cramps. Long-term usage has been reported to cause anemia.

Interactions

Pau d'arco products should be avoided by those taking anticoagulant (blood thinning) medication.

Pelvic inflammatory disease

Definition

Pelvic inflammatory disease (PID) is a term used to describe any infection in the lower female reproductive tract that spreads upward to the upper female

Pelvic inflammatory disease (PID) risk factors

Age: the rate of infection in women drops as they get older. Risk is highest for sexually active women under 25 years of age.

Ethnicity: the rate of infection is higher in nonwhite groups.

Socioeconomic status: the rate of infection is higher in women of lower socioeconomic status.

IUD: the rate of infection is higher with the use of IUDs, and frequent douching.

Barrier contraception: consistent use of barrier contraceptives protects against PID, although they may not protect against other STDs, such as HPV.

Lifestyle: the rate of infection is higher in women who abuse drugs and alcohol, have had intercourse for the first time at an early age, and have had a higher number of sexual partners.

STDs: the rate of infection is higher in women who have had sexually transmitted diseases.

(Illustration by Corey Light. Cengage Learning, Gale)

reproductive tract. The lower female genital tract consists of the vagina and the cervix. The upper female genital tract consists of the body of the uterus, the fallopian or uterine tubes, and the ovaries.

Description

PID is the most common and the most serious consequence of infection with sexually transmitted diseases (STD) in women. Over one million cases of PID are diagnosed annually in the United States, and it is the most common cause for hospitalization of reproductive-age women. Sexually active women aged 15–25 are at highest risk for developing PID. The disease can also occur, although less frequently, in women having monogamous sexual relationships. The most serious consequences of PID are increased risk of infertility and ectopic **pregnancy**.

To understand PID, it is helpful to understand the basics of inflammation. Inflammation is the body's response to disease-causing (pathogenic) microorganisms. The affected body part may swell due to accumulation of fluid in the tissue or may become reddened due to an excessive accumulation of blood. A discharge (pus) may be produced that consists of white blood cells and dead tissue. Following inflammation, scar tissue may form by the proliferation of scar-forming cells (fibrosis). Adhesions of fibrous tissue form and cause organs or parts of organs to stick together.

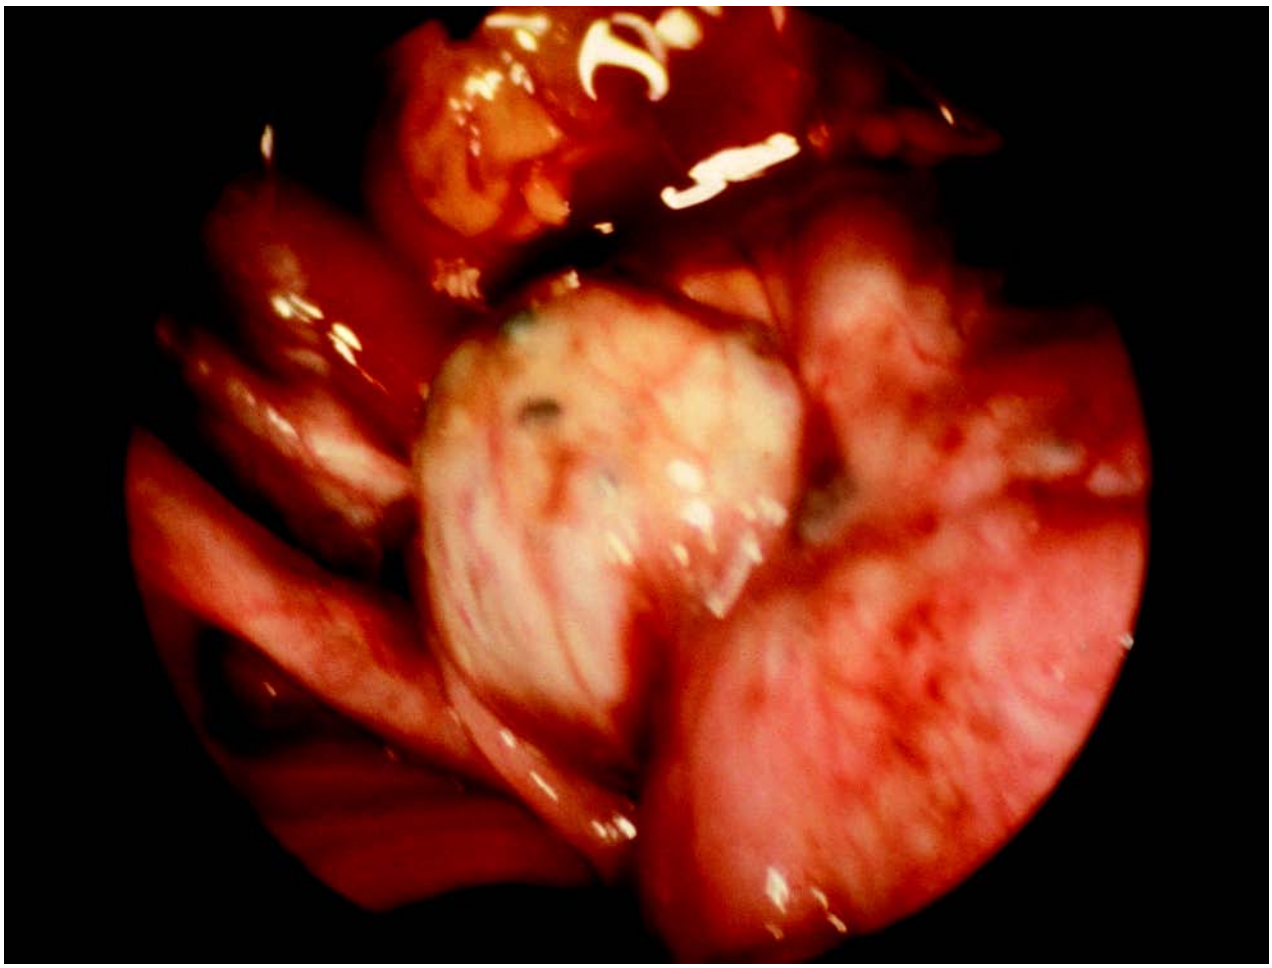
PID may be used synonymously with the following terms:

- salpingitis (inflammation of the fallopian tubes)
- endometritis (inflammation of the inside lining of the body of the uterus)
- tubo-ovarian abscesses (abscesses in the tubes and ovaries)
- pelvic peritonitis (inflammation inside of the abdominal cavity surrounding the female reproductive organs)

Causes and symptoms

A number of factors affect the risk of developing PID. They include:

- Age. The incidence of PID is very high in younger women and decreases as a woman ages.
- Race. The incidence of PID is 8–10 times higher in nonwhites than in whites.
- Socioeconomic status. The higher incidence of PID in women of lower socioeconomic status is due in part to a woman's lack of education and awareness of health and disease, and due in part to barriers to her accessibility to medical care.
- Use and method of contraception. Induced abortion, use of an IUD, nonuse of such barrier contraceptives as condoms, and frequent douching are all associated with a higher risk of developing PID.
- Lifestyle. Such high-risk behaviors as drug and alcohol abuse; early age at first intercourse; a high number of sexual partners; and smoking all are associated with a higher risk of developing PID.



Laparoscopic view of pelvic inflammatory disease. *(Custom Medical Stock Photo. Reproduced by permission.)*

- Specific sexual practices. Intercourse during the menses and frequent intercourse may offer more opportunities for the admission of pathogenic organisms to the inside of the uterus.
- The presence of a sexually transmitted disease. Sixty to seventy-five percent of PID cases are associated with STDs. A prior episode of PID increases the chances of developing subsequent infections.

The two major organisms that cause STDs are *Neisseria gonorrhoeae* and *Chlamydia trachomatis*. The main symptom of *N. gonorrheae* infection (**gonorrhea**) is a vaginal discharge of mucus and pus. Sometimes bacteria from the colon normally in the vaginal cavity may travel upward to infect the upper female genital organs, facilitated by the infection with gonorrhea. **Infections** with *C. trachomatis* and other nongonoccal organisms are more likely to have mild or no symptoms.

Although PID is unusual in women who are not sexually active, disease organisms other than the gonococcus and *C. trachomatis* can occasionally gain entrance to the upper female reproductive tract and cause PID. Cases have been reported from Canada, Norway, and South America of PID caused by pinworms, pneumococci, and *Entamoeba histolytica*, a pathogenic amoeba.

Normally the cervix produces mucus that acts as a barrier to prevent disease-causing microorganisms, called pathogens, from entering the uterus and moving upward to the tubes and ovaries. This barrier may be breached in two ways. A sexually transmitted pathogen, usually a single organism, invades the lining cells, alters them, and gains entry. Another way for organisms to gain entry happens when trauma or alteration to the cervix occurs. **Childbirth**, spontaneous or induced abortion, or use of an intrauterine contraceptive device (IUD) are all conditions that may alter or weaken the normal lining cells, making them susceptible to infection, usually by several organisms.

KEY TERMS

Adhesion—The joining or sticking together of parts of an organ that are not normally joined together.

C-reactive protein (CRP)—A protein present in blood serum in various abnormal states, like inflammation.

Ectopic—Located away from normal position; ectopic pregnancy results in the attachment and growth of the fertilized egg outside of the uterus, a life-threatening condition.

Endometriosis—The presence and growth of functioning endometrial tissue in places other than the uterus; often results in severe pain and infertility.

Erythrocyte sedimentation rate (ESR)—The rate at which red blood cells settle out in a tube of unclotted blood, expressed in millimeters per hour; elevated sedimentation rates indicate the presence of inflammation.

Fibrosis—The formation of fibrous, or scar, tissue which may follow inflammation and destruction of normal tissue.

Hysterectomy—Surgical removal of the uterus.

Laparoscope—A thin flexible tube with a light on the end which is used to examine the inside of the abdomen; the tube is inserted into the abdomen by way of a small incision just below the navel.

Ligase chain reaction—A laboratory technique for detecting sexually transmitted disease organisms in urine by rapidly copying and recopying the organism's DNA, thus making the presence of infection easier to detect.

During **menstruation**, the cervix widens and may allow pathogens entry into the uterine cavity.

Recent evidence suggests that bacterial vaginosis (BV), a bacterial infection of the vagina, may be associated with PID. BV results from the imbalance of normal organisms in the vagina— by douching, for example. While the balance is altered, conditions then favor the overgrowth of anaerobic bacteria that thrive in the absence of free oxygen. A copious discharge is usually present. Should some trauma occur in the presence of anaerobic bacteria, such as menses, abortion, intercourse, or childbirth, these organisms may gain entrance to the upper genital organs.

The most common symptom of PID is pelvic pain. However, many women with PID have symptoms so mild that they may be unaware that they are infected.

In acute salpingitis, a common form of PID, swelling of the fallopian tubes may cause tenderness on physical examination. Fever may be present. Abscesses may develop in the tubes, ovaries, or in the surrounding pelvic cavity. Infectious discharge may leak into the peritoneal cavity and cause peritonitis; or abscesses may rupture, causing a life-threatening surgical emergency.

Chronic salpingitis may follow an acute attack. Subsequent to inflammation, scarring and resulting adhesions may result in chronic **pain** and irregular menses. Due to blockage of the tubes by scar tissue, women with chronic salpingitis suffer a high risk of having an ectopic pregnancy. An ectopic pregnancy develops when a fertilized ovum is unable to travel down the fallopian tube to the uterus and implants itself in the tube, on the ovary, or in the peritoneal cavity. This condition can also be a life-threatening surgical emergency.

IUDs

The use of intrauterine devices, or IUDs, has been strongly associated with the development of PID. Bacteria may be introduced to the uterine cavity while the IUD is being inserted or may travel up the tail of the IUD from the cervix into the uterus. Surrounding uterine tissue may show areas of inflammation, increasing its susceptibility to pathogens.

Some researchers, however, maintain that the connection between IUDs and PID has been exaggerated and that further research is necessary.

Susceptibility to STDs

Susceptibility to STDs involves many factors, some of which are not known. The ability of the organism to produce disease and the circumstances that place the organism in the right place at a time when a trauma or alteration to the lining cells has occurred are factors. The woman's own immune response also helps to determine whether infection occurs.

Diagnosis

If PID is suspected, the physician will take a complete medical history and perform an internal pelvic examination. Other diseases that may cause pelvic pain, such as appendicitis and **endometriosis**, must be ruled out. If pelvic examination reveals tenderness or pain in that region, or tenderness on movement of the cervix, these are good physical signs that PID is present.

Specific diagnosis of PID is difficult to make because the upper pelvic organs are hard to reach for samplings. The physician may take samples directly

from the cervix to identify the organisms that may be responsible for infection. Two blood tests may help to establish the existence of an inflammatory process. A positive C-reactive protein (CRP) and an elevated erythrocyte sedimentation rate (ESR) indicate the presence of inflammation. The physician may take fluid from the cavity surrounding the ovaries called the *cul de sac*; this fluid may be examined directly for bacteria or may be used for culture. Diagnosis of PID may also be done using a laparoscope, but laparoscopy is expensive, and it is an invasive procedure that carries some risk for the patient.

A newer diagnostic technique that has dramatically improved the accuracy of laboratory testing for PID and other STDs is the ligase chain reaction (LCR) technique. The LCR technique detects DNA from *N. gonorrhoeae* and *C. trachomatis* in a patient's urine sample. LCR technology is less invasive as well as more accurate.

Treatment

Alternative therapy should be complementary to antibiotic therapy. Because of the potentially serious nature of this disease, a patient should first consult an allopathic physician to start antibiotic treatment for infections. Traditional medicine is better equipped to quickly eradicate the infection, while alternative treatments can help the body fight the disease and relieve painful symptoms associated with PID. Some of the alternative treatments include **diets**, nutritional supplements, herbal remedies, **homeopathy**, **acupressure**, and **acupuncture**.

General recommendations

- Bed rest. Patients need to rest and reduce physical activity to help the body recuperate faster.
- Avoid sexual activity. Both patient and her partner should be treated for PID infections. They should also avoid sexual activity until their infections are completely eradicated.
- Healthy diet. Diet should include a variety of fresh fruits and vegetables. These foods contain high amount of phytonutrients and essential vitamins that help keep the body strong and stimulate the immune system to fight infections.

Nutritional supplements

The following nutritional supplements may be helpful:

- Daily vitamin and mineral supplements. These supplements can ensure that the body receives all the essential nutrients for normal body function. They also help keep the body strong to fight diseases including PID.
- Vitamin C. High-dose vitamin C (1–2 g) boost the immune function and help the body fight infection better.

Herbal treatment

The following herbal remedies may be helpful:

- Castor oil packs. Patients can make warm packs by pouring castor oil on a clean piece of cloth wrapped in layers and warming it before placing on the lower part of their abdomen for up to 20 minutes. It is recommended that patients repeat this therapy every day for up to seven days.
- *Echinacea* spp., goldenseals and *Calendula officinalis*. These herbs are believed to have antimicrobial activity and may be taken to augment the action of prescribed antibiotics.
- Grapefruit seed extract. This herb has been used to fight a variety of infections including bacterial, viral, fungal, parasitic, and worm infections.
- Blue cohosh (*Caulophyllum thalictroides*) and false unicorn root (*Chamaelirium luteum*). These remedies are recommended as tonics for the general well-being of the female genital tract.

Homeopathy

A homeopathic practitioner may prescribe a patient-specific remedy to help reduce some of the symptoms associated with PID. Herbs that are used in PID patients include **Apis** mellifica, **Arsenicum album**, **Belladonna**, Colocynthis, Magnesia phosphorica, and Mercurius vivus.

Acupressure

Acupressure (applying pressure on specific pressure points) can increase blood flow to the pelvic region, reduce pain, and promote general health.

Acupuncture

Acupuncture involves inserting needles at various points on the skin of the body. These needles are like antennae that direct qi (life force) to organs or functions of the body. This treatment may help with pain and also strengthen immunity. It is important that patients request disposable needles to prevent transmission of **AIDS**, hepatitis, and other infectious diseases.

Allopathic treatment

If acute salpingitis is suspected, treatment with antibiotics should begin immediately. The patient is usually treated with at least two broad-spectrum antibiotics that can kill both *N. gonorrhoeae* and *C. trachomatis* plus other types of bacteria that may have the potential to cause infection. Hospitalization may be required to ensure compliance. Treatment for chronic PID may involve hysterectomy. Early treatment of suspected PID is essential because some **strains** of *N. gonorrhoeae* are showing increasing resistance to standard antibiotics as of 2002.

If a woman is diagnosed with PID, she should see that her sexual partner is also treated to prevent the possibility of reinfection.

Expected results

PID can be cured if the initial infection is treated immediately. If infection is not recognized, as frequently happens, the process of tissue destruction and scarring that results from inflammation of the tubes results in irreversible changes in the tube structure that cannot be restored to normal. Subsequent bouts of PID increase a woman's risk of complications. Thirty to forty percent of female **infertility** cases are due to acute salpingitis.

With modern antibiotic therapy, death from PID is almost nonexistent. In rare instances, death may occur from the rupture of tubo-ovarian abscesses and the resulting infection in the abdominal cavity. One recent study has linked infertility, a consequence of PID, with a higher risk of **ovarian cancer**.

Prevention

The prevention of PID is a direct result of the prevention and prompt recognition and treatment of STDs or of any suspected infection involving the female genital tract. The main symptom of infection is an abnormal discharge. To distinguish an abnormal discharge from the mild fluctuations of normal discharge associated with the menstrual cycle takes vigilance and self-awareness. Sexually active women must be able to detect symptoms of lower genital tract disease. Frank dialogue regarding sexual history, risks for PID, and treatment options is necessary with a physician. Also, open discussions with sexual partners regarding symptoms and possible infection is imperative.

Lifestyle changes should focus on preventing the transfer of organisms when the body's delicate lining cells are unprotected or compromised. Barrier contraceptives, such as condoms, diaphragms, and cervical caps, should be used. Women in monogamous relationships should use barrier contraceptives during menses and take their physician's advice regarding intercourse following abortion, childbirth, or biopsy procedures.

Pennyroyal

Description

Pennyroyal (*Hedeoma pulegioides*), known as American pennyroyal, and *Mentha pulegium*, known as English or European pennyroyal, are both members of the Lamiaceae or mint family. These two beneficial herbs, though classified in different genera, have similar chemical constituents and medicinal properties.

American pennyroyal is also known as mock pennyroyal, mosquito plant, fleabane, tickweed, stinking balm, and hedeoma. This aromatic American native thrives in limestone-rich soil, in fields, and in sunny patches of open woodlands throughout North America. American pennyroyal was used extensively by Native Americans to treat a variety of ailments from **headache** and stomach distress to **itching**, watery eyes, and fevers. For external use, the leaves were crushed and applied to the skin to repel mosquitoes and other insects. American pennyroyal came to be called squawmint and squaw balm because of its traditional use by native women to promote menstrual flow. Women in some Native American tribes reportedly drank hot pennyroyal tea regularly as a method of contraception. Pennyroyal was listed as a medicinal drug in official publications from 1831–1931. It was included in the *U.S. Pharmacopoeia* as an abortifacient (an agent that induces abortion) until 1931.

Pennyroyal. *(© dk / Alamy)*

American pennyroyal is an annual mint with small, oval leaves arranged opposite each other on a square stem. Leaves are entire and may be sparsely-toothed or smooth on the margins. The erect stems grow to 1 ft (31 cm) high from a many-branched root system. The tiny blue-violet flowers grow in whorls from the leaf axils on the top half of the stems. The fragrant herb blossoms in midsummer. The entire plant exudes a strong, acrid aroma and has a mint flavor. The scent is offensive to fleas, chiggers, mosquitoes, and other irritating insects.

European pennyroyal, also known as English pennyroyal, is a perennial mint native to Europe and Asia. The herb has naturalized throughout North America since its introduction to the continent by early European colonists. European pennyroyal was mentioned in Greek literature as early as 421 B.C. in the plays of Aristophanes where it was noted for its use as an abortifacient. In the first century A.D. the herbalist and physician Pliny wrote of pennyroyal's action to repel fleas. The specific name for the herb is from the Latin word *pulex*, meaning flea. European pennyroyal thrives in moist areas along stream banks, around ponds, in irrigated fields, and in boggy grasslands. This growing habit is reflected in some of European pennyroyal's other common names, including run-by-the-ground, lurk-in-the-ditch, and pudding grass.

European pennyroyal can be distinguished from the American native pennyroyal not only by its preferred habitat, but also, with careful observation, by its appearance. European or English pennyroyal hugs the ground where it grows, with only the flower stalk rising to a height of about 1 ft (31 cm). The oval leaves are opposite along the square stem, but are smaller than those of the American pennyroyal, measuring about 0.5 in (1.3 cm) long. The tiny, tubular blossoms each have four stamens in the European herb, and bear only two stamens in the American native.

General use

Pennyroyal has been used traditionally as a stimulating tea to relieve digestive disorders, gall bladder disorders, **gout**, **nausea**, and nervous conditions. Pennyroyal leaf, prepared as a hot infusion, will promote perspiration. Some herbalists suggest the additional treatment of a hot footbath while drinking the herbal infusion as a remedy at the onset of colds and flu. Pennyroyal may relieve headache, bring down **fever**, and quiet coughs. It has also been used to treat **bronchitis** and sinusitis. As a carminative (gas-reliever),

KEY TERMS

Abortifacient—A drug or other substance that causes abortion.

Emmenagogue—A herbal remedy or medication that brings on a woman's menstrual period.

Hepatotoxic—Poisonous to the liver.

Pulegone—The toxic chemical found in pennyroyal oil.

pennyroyal is considered an effective remedy for flatulence, a virtue it shares with other mints. The herbal infusion has also been used traditionally to treat suppressed **menstruation**.

By far the most controversial and dangerous use of pennyroyal is as an abortifacient. Its emmenagogic properties stimulate uterine contraction and promote menstrual flow. The essential oil has been used for centuries to induce abortion. This use of the essential oil of pennyroyal is extremely risky, and has sometimes been lethal to both the mother and the fetus. The U.S. Food and Drug Administration reported on a 1998 fatal case of pennyroyal overdose in a self-induced abortion. Both pennyroyals contain as much as 85% of the toxic phytochemical pulegone in the essential oil.

Pennyroyal is also considered potentially dangerous because of its hepatotoxicity, or ability to harm the liver. Of four cases of pennyroyal poisoning reported in San Francisco in 1996, one patient died from liver damage. As of late 2001, researchers are studying the pathways of pulegone metabolism in the human body in order to determine the degree of toxicity more precisely.

The best use for this potent herb is an external application as an insect repellent to deter mosquitoes, fleas, chiggers, and other pests. It is also soothing as a skin wash to relieve itching and rash. Pet collars, woven from the freshly gathered stems and leaves, will deter fleas, and bunches of the herb, hanging to dry, will also keep pests at bay. Many commercial products contain the oil of pennyroyal in insect-repellent preparations. Other chemical constituents in pennyroyal include tannins, such as rosmaric acid, and flavonoids, including diosmin and **hesperidin**.

Preparations

The essential oil of pennyroyal and the fresh or dried leaves and stems are medicinally active. Gather fresh leaves in the summer, on a dry and sunny day when the herb is in blossom. Hang bundles of the herb to dry in a light, airy room out of direct sunlight. When the herb is thoroughly dry, strip the leaves from the stems and store in tightly sealed, clearly labeled, dark-glass containers.

Infusion: Place 2 oz of fresh, or 1 oz of dried, pennyroyal leaves in a warmed glass container. Bring 2.5 cups of fresh, nonchlorinated water to a boil and add it to the herbs. Do not boil the tea. Cover and infuse the tea for about 10 minutes. Strain. The prepared tea will store for about two days in the refrigerator. This infusion may be used externally as a soothing skin wash. According to some herbalists, pennyroyal leaf infusion may also be safely consumed as a medicinal tea, taking up to two cups throughout the day. Others, however, including the *PDR For Herbal Medicines*, recommend that pennyroyal not be ingested due to its hepatotoxicity. Other non-toxic herbs, such as **peppermint** (*Mentha piperita*) and **spearmint** (*Mentha spicata*) may be used to remedy many of the same conditions that pennyroyal treats without the toxic risk.

Precautions

Pregnant women should never ingest pennyroyal, particularly the oil, nor should they apply the oil externally as it may be absorbed through the skin. Pennyroyal essential oil contains as much as 85% of the ketone pulegone, an extremely toxic phytochemical. Overdose of the essential oil has been reported to cause severe liver damage, coma, and death. Quantities as small as 0.5 tsp of the essential oil have caused extremely toxic reactions. The effective abortifacient dosage is dangerously close to the lethal dose. Women have died when attempting to induce abortion by ingesting pennyroyal oil. American pennyroyal contains twice as much of the toxic volatile oil as European pennyroyal. The *PDR For Herbal Medicines* recommends that the drug not be used because of its hepatotoxicity, although with proper dosage and administration of the foliage drug, poisoning is not likely.

Side effects

Contact dermatitis is possible when using crushed leaf or the undiluted oil extract on the skin to repel insects.

Interactions

None reported.

Peppermint

Description

Peppermint (*Mentha piperita*) is an aromatic perennial plant that grows to a height of about 3 ft (1 m). It has light purple flowers and green leaves with serrated edges. Peppermint belongs to the Lamiaceae family and grows throughout North America, Asia, and Europe. There are more than 25 species of true mint grown throughout the world.

The plant is harvested when the oil content is highest. When ready for harvest, it is always collected in the morning, before noon sun reduces the leaf essential oil content. This generally takes place shortly before the plant blooms, which occurs in the summer (July through August) or during dry, sunny weather. The United States is responsible for producing 75% of the world's supply of peppermint.

History

Peppermint is a natural hybrid of water mint (*Mentha aquatica*) and **spearmint** (*Mentha spicata*) and was first cultivated in England in the late seventeenth century. The herb has been used as a remedy for **indigestion** since Ancient Egyptian times. In fact, dried peppermint leaves were found in Egyptian pyramids dating back to 1000 B.C. The ancient Greeks and Romans valued it as a stomach soother. During the eighteenth century, peppermint became popular in Western Europe as a folk remedy for **nausea**, **vomiting**, **morning sickness**, respiratory **infections**, and menstrual disorders. Peppermint was first listed in the *London Pharmacopoeia in 1721*. In modern times it appears in the *British Herbal Pharmacopoeia* as a remedy for intestinal **colic**, **gas**, colds, morning sickness, and **menstruation pain**.

Properties

Peppermint is a cooling, relaxing herb that contains properties that help ease inflamed tissues, calm **muscle spasms** or cramps, and inhibit bacteria and microorganisms. It also has pain-relieving and infection-preventing qualities.

The medicinal parts of peppermint are derived from the whole plant, and include a volatile oil, flavonoids, phenolic acids, and triterpenes. The plant is primarily cultivated for its oil, which is extracted from the leaves of the flowering plant.

The essential oil contains the principal active ingredients of the plant: menthol, menthone, and menthyl acetate. Menthyl acetate is responsible for peppermint's minty aroma and flavor. Menthol, peppermint's main active ingredient, is found in the leaves and flowering tops of the plant. It provides the cool sensation of the herb.

The menthol content of peppermint oil determines the quality of its essential oil. This varies depending upon climate, habitat, and where the peppermint is grown. For instance, American peppermint oil contains 50–78% menthol, while English peppermint oil has a menthol content of 60–70%. Japanese peppermint oil contains 85% menthol. Peppermint and its oils help with intestinal function.

Peppermint also contains vitamins A and C, **magnesium**, **potassium**, **inositol**, **niacin**, **copper**, **iodine**, silicon, **iron**, and **sulfur**.

Peppermint. *(© Arco Images / Alamy)*

General use

Peppermint is one of the most popular flavoring agents. Many products contain peppermint, including chewing gum, mints and candies, ice cream and other sweets, tobacco, toothpaste, mouthwash, **cough** drops, teas, alcoholic liqueurs, and digestive aids. It is also used to scent soaps, perfumes, detergents, lipsticks and other cosmetics, and is an ingredient in many over-the-counter medications. Therapeutically, peppermint is used to treat many ailments of the skin, circulatory system, respiratory system, digestive system, immune system, and nervous system.

Peppermint and headaches

Peppermint's pain-relieving effects on headaches have been known for many years. The first documented report to link peppermint and **headache** relief was published in 1879. A more recent study took place in Germany in 1996. In this double-blind study, researchers found that an ethanol solution containing 10% peppermint oil was as effective in relieving headache pain as 1,000 mg of acetaminophen. In another study, 32 people with headaches massaged peppermint oil on their temples. The results showed that the peppermint oil significantly relieved their pain.

When applied to the skin, peppermint reduces sensitivity and relieves pain. Rubbed on the temples, across the forehead, and behind the neck, peppermint oil helps to ease digestive-related headaches and migraines by generating a cooling effect on the skin and relaxing cranial muscles.

Peppermint as a digestive aid

Peppermint is employed in the treatment of various digestive ailments, such as **irritable bowel syndrome**, **Crohn's disease**, **diverticulitis**, liver and gallbladder complaints, loss of appetite, spastic colon, **diarrhea**, gas, bloating, colic, cramps, and **heartburn**. The infused herb tea of peppermint or a few drops of its essential oil stimulate the flow of digestive juices and the production

Peppermint. *((c) Photo Researchers, Inc. Reproduced by permission.)*

of bile, a substance that helps to digest fats. This eases indigestion, relieves gas, reduces colon spasms, and eases **motion sickness** and nausea. When peppermint is taken after a meal, its effects will reduce gas and help the digestion of food by reducing the amount of time the food is in the stomach. This is one reason after-dinner mints are so popular.

The compounds of the essential oil have antispasmodic properties that reduce spasms of the colon and intestinal tract and relax the stomach muscles. Peppermint has a soothing effect on the lining and muscles of the colon, which helps to relieve diarrhea and spastic colon.

Menthol acts to stimulate the stomach lining. Its cooling properties soothe the stomach and ease stomach pain. Peppermint oil is popular in the treatment of motion and sea sickness and nausea associated with **pregnancy**. It acts as an anesthetic to the stomach wall and eases vomiting and nausea. An account on the effects of peppermint on nausea appeared in the September 1997 issue of the *Journal of Advanced Nursing*, in which gynecological patients were given peppermint oil to counter post-operative nausea. The patients reported less nausea and required fewer drugs to treat the nausea.

A German health commission, German Commission E, has endorsed peppermint tea as a treatment for indigestion. Clinical trials in Denmark and Britain in the 1990s confirmed peppermint's actions as a therapeutic treatment for irritable bowel syndrome. In 1996, a German study was performed to research the therapeutic benefits of peppermint essential oil on irritable bowel syndrome. Subjects with irritable bowel syndrome were given enteric-coated capsules containing peppermint and caraway oils. Results showed that the pain symptoms, which ranged from moderate to severe, improved in 89.5% of the group.

Peppermint and respiratory ailments

Peppermint is an expectorant and decongestant. It is used to help treat many respiratory ailments including **asthma**, **bronchitis**, sinusitis, and coughs.

Peppermint is an element of many cough preparations, not only for its pleasant flavor, but also

KEY TERMS

Essential oil—A concentrated oil that has been distilled from a plant.

Expectorant—A substance that acts to promote coughing and clear mucus from the lungs and respiratory tract.

Perennial—A plant that blooms every year.

Tincture—The concentrated solution of an herbal extract, usually made with alcohol.

because it contains compounds that help ease coughs. Constituents of peppermint increase the production of saliva, causing frequent swallowing and suppressing the cough reflex.

German Commission E has officially recognized peppermint's ability to reduce inflammation of nasal passageways. When menthol vapors are inhaled, nasal passageways are opened to provide temporary relief of nasal and sinus congestion.

Peppermint essential oil is an ingredient in many commercial chest and cold rubs. These are popularly rubbed onto the chest to ease congestion.

A tea made from the leaves can stimulate the immune system and relieve the congestion of colds, flus, and upper respiratory infections.

Other conditions

Peppermint is an effective relaxant and can be helpful in treating nervous **insomnia**, **stress**, **anxiety**, and restlessness.

Many over-the-counter balms and liniments contain peppermint essential oil. These are applied externally to relieve muscle pain, arthritis, **itching**, and **fungal infections**.

Peppermint induces sweating and can help bring down fevers. It is said that it contains **antioxidants** that help prevent **cancer** and **heart disease**. The essential oil is a powerful antiseptic and is useful in treating bad breath and sore throats. It is also beneficial in preventing tooth decay and **gum disease**.

A plant with potent antiviral properties, peppermint can help fight viruses that cause ailments such as **influenza**, herpes, yeast infections, and **mumps**. Peppermint is also used as an **earache** remedy, to dissolve **gallstones**, to ease muscle tightness, and to ease menstrual cramps.

A 2002 report announced that peppermint also helped participants in a study run faster, do more pushups, and show greater grip strength than those who were not exposed to peppermint scent. Although researchers concluded the effect may have been psychological, a result of peppermint's effect on mood and increased motivation, it still resulted in measurable performance improvement.

Preparations

Peppermint is available as a tincture, tea, essential oil, oil capsules, and tablets. The fresh and dried leaves may be purchased in bulk.

Tablets and capsules are often coated so the oil's therapeutic properties are released in the intestine and not in the stomach. These enteric-coated pills are used in the treatment of irritable bowel syndrome, diverticulitis, and other chronic digestive ailments. Peppermint oil capsules are effective in treating lower intestinal disorders:

- Irritable bowel syndrome: 1–2 capsules three times daily between meals.
- Gallstones: 1–2 capsules three times daily between meals.

Peppermint tea

Peppermint tea may be used to relieve migraine headaches, minor colds, digestive ailments, and morning sickness, as well as many other conditions. Taken after a meal, the tea acts to settle the stomach and improve digestion. To prepare the tea, pour one cup of boiling water over 1–2 tsp of dried peppermint leaves, cover, and steep for 10 minutes. Strain the mixture before drinking.

DOSAGE. For relief of migraine pressure, drink 1–2 cups of cool tea daily.

For digestive disorders, drink one cup of tea with meals.

For cough relief, drink 3–4 cups of cool tea throughout the day, taking frequent sips (every 15–30 minutes).

For morning sickness, women may drink a tea that has been diluted.

Aromatherapy and peppermint

The essential oil of peppermint is a pale yellow or greenish liquid that is made by distilling the flowering herb. When inhaled, the oil can reduce **fever**, relieve nausea and vomiting, improve digestion, and soothe the respiratory system. Various studies have been

performed on the oil's ability to improve the sense of taste and smell and improve concentration and mental acuity when inhaled.

The oil blends well with other **essential oils** such as benzoin, **rosemary**, **lavender**, marjoram, lemon, **eucalyptus**, and other mints. Essential oils are available at many health food stores or through a qualified aromatherapist.

Peppermint essential oil can be used in several ways: inhaled, rubbed on **reflexology** points on the bottom of the feet, diffused into the air, or as a therapeutic bath. Below are some applications for the use of peppermint essential oil:

- Steam inhalation for congestion relief: A few drops of the essential oil of peppermint are placed in a large bowl of hot water. The person should cover his or her head with a towel, lean over the bowl, and inhale the steam.
- Motion sickness: A few drops of essential oil should be places on a tissue and inhaled.
- Headaches: A few drops can be placed on a cool, wet towel and used as a compress on the forehead. Or, massaged into the neck, back, temples, and/or forehead.
- Digestion: Several drops of diluted oil massaged on the stomach or the pure oil rubbed onto the bottoms of the feet.
- Breath freshener: Several drops placed on the tongue.
- Therapeutic bath: Several drops of diluted oil placed into a tepid bath to relieve stomach complaints, nasal congestion, headache, or menstrual cramps. If essential oil is not available, a bath can be made by adding to the water a cloth bag filled with several handfuls of dried or fresh peppermint leaves.

As with any essential oil, caution should be taken when using it. Essential oils are highly concentrated and should be diluted with a vegetable oil prior to external use to prevent adverse reactions, as some people are allergic to peppermint or its essential oil. The oil may cause a skin reaction if the dosage is excessive. Avoid contact with the eyes.

Precautions

Extreme caution should be used when administering to children under five years of age as the menthol can cause a choking reaction in young children.

Peppermint oil should not be applied to the faces of infants or small children.

The essential oil of peppermint should not be ingested unless under professional supervision.

Pure menthol or pure peppermint should not be ingested. Pure peppermint may cause an irregular heartbeat. Pure menthol is poisonous and fatal in doses as small as 1 tsp.

Pregnant women with a history of miscarriage should use peppermint with caution. Large amounts of peppermint may trigger a miscarriage. Additional caution should be practiced by women who are breast-feeding their infants.

Side effects

If the essential oil is not used properly it can cause **dermatitis** and other allergic reactions.

Rare reactions to enteric-coated capsules may occur. These reactions include skin rash, heartburn, slow heart rate, and muscle tremors.

Large internal doses of peppermint essential oil may result in kidney damage.

Interactions

Peppermint should not be used in conjunction with homeopathic treatment.

Peripheral neuropathy

Description

Peripheral neuropathy, sometimes called peripheral neuritis, is damage to the nerves that connect peripheral (outlying) portions of the body (especially the hands,

arms, legs, and feet) to the central nervous system. It may involve only one peripheral nerve (mononeuropathy) or several nerves (polyneuropathy).

Description

Similar to electrical wiring in a house, the body has a highly complex network of nerves made up of bundles of neurons, axons, and dendrites. This network originates in the brain and extends down through the spinal cord. These nerves branch off at junctures along this pathway to connect each portion of the body to the brain and spinal cord, the central nervous system. Nerves relay necessary information to and from every area, notifying the brain of sensations and external conditions. The brain, in turn, sends messages back to those areas. With peripheral neuropathy, damage has occurred to the nerves that connect peripheral portions of the body, and the patient feels **pain** or numbness.

Peripheral neuropathy is not usually considered a disease. It is more often thought of as a symptom of other diseases or conditions, or results from damage caused by the introduction of toxic substances. There are an estimated two million Americans who suffer from peripheral neuropathy. It becomes more common as people age, and the majority of its victims are 65 years old or older.

Causes and symptoms

The symptoms of peripheral neuropathy depend upon which type of nerve fiber is affected. Sensory nerve fiber damage is more likely to generate various sensations, while motor nerve fiber is more apt to result in weakening and wasting of muscle tissue in the affected area. It is a condition that develops quite gradually, usually over a period of months or even years. A tingling, prickly sensation in the toes and/or feet is commonly the first sign that is noticed, or there may be numbness in this area. Typically this feeling progresses to the lower legs, fingers, hands, arms, and then the trunk of the body in severe cases. As the situation worsens, the tingling sensation feels more like burning or severe discomfort followed by sharp, almost electric shock-like jabs of pain. These sensations may begin in the toes and feet, and then progress to other affected areas. Later symptoms often include increasing muscle weakness, poor coordination, numbness, and lack of feeling. **Urinary incontinence**, **diarrhea**, **constipation**, **impotence**, and postural hypotension (dramatic drops in blood pressure when a person stands) causing **dizziness** or dangerous falls are other potential negative effects, especially in the elderly.

KEY TERMS

Axons—The conducting fiber of a nerve cell. Axons vary from a fraction of an inch to several feet in length.

Carpal tunnel syndrome—Numbness, tingling, and pain in the thumb, index, and middle fingers that worsens at night. The condition may affect one or both hands and is sometimes accompanied by weakness in the thumb(s). The condition results from pressure on the median nerve where it passes into the hand via a gap (the carpal tunnel).

Charcot-Marie-Tooth syndrome (CMT)—The most common form of inherited peripheral neuropathy.

Dendrites—Branching projections that grow out of a nerve cell.

Intubation—The process of passing an endotracheal tube (breathing tube) into the trachea (windpipe).

Lupus—A chronic disease that causes inflammation of connective tissue. The more common type, discoid lupus erythematosus (DLE), affects exposed areas of the skin. The more serious and potentially fatal form, systemic lupus erythematosus (SLE), affects many systems of the body, including the joints and the kidneys.

Neurons—Nerve cells.

Rheumatoid arthritis—A type of joint inflammation where the joints of fingers, wrists, toes, and other joints in the body become painful, swollen, stiff, and in severe cases, deformed. The disease usually takes the form of recurring, moderate attacks.

Peripheral nerves are extended and delicate, easily damaged by a variety of things. Diabetes, **alcoholism**, diseases of the autoimmune system such as rheumatoid arthritis and lupus, and exposure to health damaging substances can cause peripheral neuropathy. Chronic liver and kidney disease, thyroid gland imbalances, bacterial or viral **infections**, and **cancer** can also cause the damage. Many of the strong anticancer drugs used and certain vitamin deficiencies can also lead to this condition. Repetitive mechanical actions that put pressure on a particular nerve, like the wrist in carpal-tunnel syndrome, or even inherited abnormalities in the body can cause peripheral neuropathy. However, in many cases no one single reason for this condition can be found.

Guillain-Barre syndrome, also called acute polyneuritis or ascending paralysis, is the only form of peripheral neuropathy that develops differently. It is a rare and very serious form that is believed to be caused by an autoimmune reaction to infection. Its primary difference from other types of peripheral neuropathy is the terrific rapidity of its onset.

A few rare forms of peripheral neuropathy are inherited. The best known inherited peripheral neuropathy is called Charcot-Marie-Tooth syndrome, or CMT. More than 20 different genes and loci on human chromosomes are now known to be associated with CMT.

Diagnosis

Because peripheral neuropathy can be caused by a variety of factors, outcomes vary depending upon the reason for the nerve damage. Some causes, such as vitamin or metabolic deficiencies, can be reversed if caught early; other causes may not be reversible. Because of these factors, early diagnosis is very important. A neurologist (a doctor who specializes in the nervous system) can diagnose the disorder, try to determine the cause, and assess the extent of the damage. Sensations of pain, temperature, and touch in various parts of the body are tested by observing the person's ability to respond to a stimulus. If areas of either hypersensitivity or loss of sensation are found, the boundaries of that feeling are mapped by further testing.

An electromyogram (EMG) tests the electrical activity occurring in muscles and can be used in the diagnostic process. X rays, blood tests, and muscle biopsies are common tests used in determining the cause of peripheral neuropathy. For example, blood tests that show elevated blood sugar would indicate diabetes, or elevated liver function tests or thyroid levels could indicate liver or thyroid disease.

Treatment

Treating the underlying cause of the peripheral neuropathy is the key to reversing this condition. For example, diabetics who closely follow their diabetic diet and keep their blood sugar in good control stand the best chance of recovering. Nutritional deficiencies often related to alcoholism may indicate that the person needs to stop drinking and requires vitamin supplements. Changes in lifestyle or treatment of the disease condition causing the neuropathy is a highly important facet of reversing, arresting, or simply reducing the symptoms of this uncomfortable condition.

Several simple self-care actions can also relieve symptoms. They include:

- That shoes and stockings should never be tight, but rather loose cotton socks and shoes with good support and padding should be worn. Good foot care includes daily or twice daily foot soaks in tepid to cool water for 15 minutes followed by application of a moistening cream.
- Keeping heavy bed covers off of feet at night either by turning back the covers or using a bed cradle.
- Improving circulation and stimulating regeneration of nerves by frequently massaging the affected areas and walking as much as possible. Hydrotherapy with whirlpool baths may also be used to improve circulation.
- Reducing the intake of caffeine and nicotine, both of which may increase pain.
- Lowering the stress level as much as possible, including taking steps to treat the depression and/or insomnia that often accompany peripheral neuropathy. This may include relaxation therapies or herbal remedies.

Herbal remedies used for peripheral neuropathy include gingko, **St. John's wort**, vervain, oats, and gotu kola. Nutritional supplements that may provide relief and are thought to help repair nerve fibers include supplemental **carnitine**, gamma-linolenic acid, alpha-lipoic acid, **magnesium**, **chromium**, **choline**, **inositol**, vitamins B_6 and B_{12}, **niacin**, **thiamine**, **biotin**, and **folic acid**. Additional therapies thought to provide relief include **detoxification** and **fasting**, used to cleanse the system and eliminate poisons that may cause nerve damage.

Control of symptoms is a significant part of the treatment. Pain relief is usually the highest priority. Bodywork such as massage and movement therapies like **t'ai chi** and **qigong** may provide relief. **Acupuncture** can also be used to promote general health and provide some symptomatic relief. **Meditation** or **yoga** may help with **relaxation** and pain control.

Another alternative approach to peripheral neuropathy is the **Feldenkrais** method, which works on improving the patient's sense of balance, and thus helps to prevent falls.

Allopathic treatment

It may take months for the symptoms to subside. Milder pain can be treated with over-the-counter pain medications, including Tylenol or aspirin, while more severe episodes of pain may require pain relievers such as nonsteroidal anti-inflammatory drugs (NSAIDs) like ibuprofen or naproxen, or narcotics such as codeine,

Demerol, or morphine. Sometimes tricyclic antidepressants such as Elavil, Tofranil, or Norpramin are used both for pain relief and the depression that may accompany chronic pain. Anticonvulsant medications such as Tegretol, Neurontin, or Dilantin are effective against electric-like, jabbing pain. Less frequently used drugs include heart and blood pressure drugs such as Mexitil and clonidine, which may alleviate burning sensations.

The acute onset and potentially serious symptoms that can develop in Guillain-Barre syndrome, including nerve and muscle damage affecting swallowing and breathing, make this the type of peripheral neuropathy most likely to require in-patient hospital treatment. The person suffering from this syndrome must be carefully monitored, may require intubation in order to breathe, and may even have blood plasma removed in order to reduce the number of antibodies in the blood.

Expected results

Full recovery from peripheral neuropathy is possible if the nerves are not damaged beyond repair. The outcome is dependent upon the extent of damage. Research is now being conducted that may lead to the manufacture of substances similar to the naturally produced chemicals in the body that stimulate repair of small nerve fibers.

The majority of people suffering from Guillain-Barre syndrome recover completely, often without even receiving medical treatment, but some will develop residual, permanent weakness in the affected area or have further episodes.

Prevention

The best way to prevent peripheral neuropathy is to treat the underlying disease or eliminate the toxic substance that may cause the symptoms.

Periwinkle

Description

An herbal remedy with a rich history in folk medicine, periwinkle is the common name for a pair of perennial flowering shrubs belonging to the dogbane (Apocynaceae) family. The herb has been used for centuries to treat a variety of ailments and was a favorite ingredient of magical charms in the Middle Ages. The purple-flowered plant was called sorcerer's violet by superstitious Europeans and was renowned for its

Periwinkle flower. *(©PlantaPhile, Germany. Reproduced by permission.)*

power to dispel evil spirits. There are two main varieties: lesser periwinkle (*Vinca minor*), which is also called common periwinkle, and greater periwinkle (*Vinca major*). Lesser periwinkle originated in Spain, France, and other areas of Europe but can now be found growing in many parts of the world, while greater periwinkle is native to southern Europe. While not widely recommended for medicinal purposes today, periwinkle is sometimes used to improve brain circulation and alleviate heavy menstrual periods. Only the aboveground parts of the plant are used as a drug.

It is important to distinguish lesser and greater periwinkle from a close relative called Madagascar periwinkle. The Latin name for this herb is *Catharanthus roseus*, but it was formerly classified as *Vinca rosea*, and is still called by that name in some of the herbal literature. Another member of the dogbane family, this plant originated on the island of Madagascar but now grows in the southern United States and many other temperate regions of the world. Madagascar periwinkle has been used for centuries to treat a variety of medical problems, from diabetes and eye **infections** to sore throats and tumors. Modern research has indicated that Madagascar periwinkle contains dozens of alkaloids, some of which may have the ability to lower blood sugar levels and stop bleeding. Two of these alkaloids, vincristine and vinblastine, are recognized by Western medicine as potent anticancer agents. (A shaman in Madagascar who used the plants to treat tumors and **cancer** gave Western scientists the lead.) They are used to make important prescription drugs. Madagascar periwinkle is not widely recommended as a dietary supplement because some of the alkaloids in the plant can cause serious and potentially dangerous side effects.

General use

While not approved by the Food and Drug Administration (FDA), periwinkle has been reported to have a number of beneficial effects. Unfortunately, there is scarcely any scientific evidence to support these claims. Both forms of the herb have been used as an astringent for centuries and may be useful in alleviating excessive bleeding during **menstruation**, according to some herbalists. Lesser periwinkle is generally recommended for improving circulation, particularly in the brain. Greater periwinkle has been used to combat nervousness or **anxiety** and help reduce high blood pressure. Periwinkle is also reputed to be effective in treating diabetes, perhaps by stimulating the pancreas.

While they do not recommend periwinkle for a wide variety of ailments, some practitioners of alternative medicine claim that the herb is useful in treating certain conditions. Periwinkle has been used as an effective astringent that can be used orally or topically. It is mainly used to treat excessive menstrual bleeding but may also be a helpful choice in cases of **colitis**, **diarrhea**, bleeding gums, **nosebleeds**, sore throats, and mouth ulcers.

Perhaps the most intriguing dietary supplement derived from periwinkle is vinpocetine, which is made from an alkaloid chemical in lesser periwinkle called vincamine. While vinpocetine is not what most people would consider a natural remedy, since it is produced via chemical manipulation in the laboratory, it is sold in the United States as a dietary supplement. Several studies of vinpocetine suggest that it may improve brain function and memory, particularly in people affected by diseases that decrease mental capacity such as **Alzheimer's disease** or **dementia**. In a double-blind, placebo-controlled trial published in the *Journal of the American Geriatrics Society* in 1987, vinpocetine appeared to improve the condition of several dozen elderly patients who suffered from mental impairment due to **aging**. Researchers found that the 42 patients who took vinpocetine for three months performed better on several tests of mental functioning than those in the placebo group. In the study, no significant side effects were associated with vinpocetine.

Exactly how vinpocetine works is unknown. According to one theory, vinpocetine may protect

KEY TERMS

Alkaloid—Any of a large class of bitter-tasting alkaline ring compounds that contain nitrogen and are common in plants. In addition to the alkaloids in periwinkle, nicotine, caffeine, morphine, and quinine belong to this class of compounds.

Astringent—An agent that helps to contract tissue and prevent the secretion of internal body fluids such as blood or mucus. Astringents are typically used to treat external wounds or to prevent bleeding from the nose or throat.

Diabetes—A disease in which the body either cannot produce adequate amounts of insulin or properly metabolize the hormone.

Pancreas—An organ behind the stomach that produces digestive enzymes and hormones such as insulin.

Placebo—A sugar pill or inactive agent often used in the control group of a medical study.

brain cells from damage caused by oxygen deprivation. The apparent effectiveness of vinpocetine, which is made partly from a chemical contained in lesser periwinkle, may help to explain the herb's traditional reputation as a brain booster. It is important to remember, however, that periwinkle itself has not been proven to have the same effects as vinpocetine.

Preparations

The optimum daily dosage of periwinkle has not been established with any certainty. Readers who wish to use this herb should follow the package directions for proper usage or consult a doctor experienced in the use of alternative remedies.

The dosage of vinpocetine is generally 30 mg a day, divided into three equal doses. Taking vinpocetine with food may enhance its effectiveness by increasing the amount of drug absorbed.

Precautions

Periwinkle is not known to be harmful when taken in recommended dosages, though it is important to remember that the long-term effects of taking the herb (in any amount) have not been investigated. Periwinkle should not be used by people with low blood pressure or **constipation**. Due to lack of sufficient medical study, periwinkle should be used with caution in children, women who are pregnant or breast-feeding, and people with liver or kidney disease.

Taking too much periwinkle can cause a potentially dangerous drop in blood pressure (symptoms include **dizziness** and fainting). In case of overdose, seek emergency care.

Vinpocetine should not be combined with certain medications or dietary supplements (see below).

Side effects

Periwinkle may cause flushing and gastrointestinal problems.

When taken in recommended dosages, vinpocetine is not associated with any bothersome or significant side effects.

Interactions

Periwinkle is not known to interact adversely with any drugs or dietary supplements. Periwinkle may be combined with cranesbill and agrimony. It may also be used in conjunction with beth root for menstrual problems.

Vinpocetine should not be combined with agents that thin the blood, except under medical supervision. These include drugs such as warfarin (Coumadin) and aspirin as well as dietary supplements like ginkgo, **vitamin E** in high dosages, and **garlic**.

Pet therapy

Definition

Animal-assisted therapy (AAT), also known as pet therapy, utilizes trained animals and handlers to achieve specific physical, social, cognitive, and emotional goals with patients.

Origins

The enjoyment of animals as companions dates back many centuries, perhaps even to prehistoric times. The first known therapeutic use of animals started in Gheel, Belgium in the ninth century. In this town, learning to care for farm animals has long been an important part of an assisted living program designed for people with disabilities.

Some of the earliest uses of animal-assisted healing in the United States were for psychiatric patients. The presence of the therapy animals produced a beneficial effect on both children and adults with mental health issues. It is only in the last few decades that AAT has been more formally applied in a variety of therapeutic settings, including schools and prisons, as well as hospitals, hospices, nursing homes, and outpatient care programs.

Pet therapy used to engage senior woman in an assisted living facility. *(© Mira / Alamy)*

KEY TERMS

Endorphins—A group of chemicals resembling opiates that are released in the body in response to trauma or stress. Endorphins react with opiate receptors in the brain to reduce pain sensations.

Benefits

Studies have shown that physical contact with a pet can lower high blood pressure, and improve survival rates for **heart attack** victims. There is also evidence that petting an animal can cause endorphins to be released. Endorphins are chemicals in the body that suppress the **pain** response. These are benefits that can be enjoyed from pet ownership, as well as from visiting therapeutic animals.

Many skills can be learned or improved with the assistance of a therapy animal. Patient rehabilitation can be encouraged by such activities as walking or running with a dog, or throwing objects for the animal to retrieve. Fine motor skills may be developed by petting, grooming, or feeding the animal. Patient communication is encouraged by the response of the animal to either verbal or physical commands. Activities such as writing or talking about the therapy animals or past pets also develop cognitive skills and communication. Creative inclusion of an animal in the life or therapy of a patient can make a major difference in the patient's comfort, progress, and recovery.

Description

The way in which AAT is undertaken depends on the needs and abilities of the individual patient. Dogs are the most common visiting therapy animals, but cats, horses, birds, rabbits, and other domestic pets can be used as long as they are appropriately screened and trained.

For patients who are confined, small animals can be brought to the bed if the patient is willing and is not allergic to the animal. A therapeutic plan may include a simple interaction aimed at improving communication and small motor skills, or a demonstration with educational content to engage the patient cognitively.

If the patient is able to walk or move around, more options are available. Patients can walk small animals outside, or learn how to care for farm animals. Both of these activities develop confidence and motor abilities. Horseback riding has recently gained great therapeutic popularity. It offers an opportunity to work on balance, trunk control, and other skills. Many patients who walk with difficulty, or not at all, get great emotional benefit from interacting with and controlling a large animal.

One advantage of having volunteers provide this service is that cost and insurance are not at issue.

Precautions

AAT does not involve just any pet interacting with a patient. Standards for the training of the volunteers and their animals are crucial in order to promote a safe, positive experience for the patient. Trained volunteers will understand how to work with other medical professionals to set goals for the patient and keep records of progress. Animals that have been appropriately trained are well socialized to people, other animals, and medical equipment. They are not distracted by the food and odors that may be present in the therapy environment and will not chew inappropriate objects or mark territory.

Animals participating in AAT should be covered by some form of liability insurance.

Research and general acceptance

The research evidence supporting the efficacy of AAT is slim, although the anecdotal support is vast. Although it may not be given much credence by medical personnel as a therapy with the potential to assist the progress of the patients, some institutions do at least allow it as something that will uplift the patients or distract them from their discomforts.

Training and certification

AAT is carried out by volunteers who are trained to provide therapy along with their animals. There are a growing number of groups that will provide screening and certification. These include Delta Society, Therapy Dogs Inc., Therapy Dogs International, and St. John Ambulance Therapy Dogs in Canada. Each program has somewhat different qualifications. The Pet Partners Program sponsored by Delta is exemplary. Animals receive a veterinary screening, an aptitude test to evaluate socialization, and a skills test of training and behavior. The owner also receives training hours and agrees to a code of ethics in order to join Pet Partners.

Phlebitis

Definition

Thrombophlebitis is the inflammation of a vein, with **blood clots** forming inside the vein at the site of inflammation. Thrombophlebitis is also known as phlebitis, phlebothrombosis, and venous thrombosis.

Description

There are two aspects of thrombophlebitis, inflammation of a vein and blood clot formation. If the inflammation component is minor, the disease is usually called venous thrombosis or phlebothrombosis. Thrombophlebitis can occur in both deep veins and superficial veins, but most often occurs in the superficial veins of the extremities (legs and arms). Most cases occur in the legs. When thrombophlebitis occurs in a superficial vein, one that is near the surface of the skin and is visible to the eye, the disease is called superficial thrombophlebitis. Any form of injury to a blood vessel can result in thrombophlebitis. In the case of superficial thrombophlebitis, the blood clot usually attaches firmly to the wall of the affected blood vein. Since superficial veins do not have muscles that massage the veins and help the blood to circulate, blood clots in superficial veins tend to remain where they form and seldom break loose. When thrombophlebitis occurs in a deep vein, a vein that runs deep within muscle tissue, it is called deep venous thrombosis. Deep venous thrombosis presents the threat of producing blood clots that will break loose to form emboli. Emboli are clumps of cells that are carried by the circulation to other tissues where they can lodge and block the blood supply. Emboli typically come to rest in the lungs and cause tissue damage that can sometimes be serious or fatal.

Causes and symptoms

The main symptoms of phlebitis are tenderness and **pain** in the area of the affected vein. Redness and/or swelling may also be seen. In the case of deep venous thrombosis, there is more swelling than is caused by superficial thrombophlebitis, and the patient may experience muscle stiffness in the affected area. There are many causes of thrombophlebitis. The main causes can be grouped into three categories: injury to veins, increased blood clotting, and blood stasis. When blood veins are damaged, collagen in the vein wall is exposed. Platelets respond to collagen by initiating the clotting process. Damage to a vein can occur as a consequence of in-dwelling catheters, trauma, infection, Buerger's disease, or the injection of irritating substances. Increased tendency of the blood to clot can be caused by malignant tumors, genetic disorders, high-fat **diets**, and oral contraceptives. Stasis, in which the blood clots due to decreased blood flow in an area, can happen following surgery, as a consequence of **varicose veins**, as a complication of postpartum states, and following prolonged bed rest. In the case of prolonged bed rest, blood clots form because of inactivity, allowing blood to move sluggishly and stagnate (collect) in the veins. Stasis can lead to blood clots. These clots (also called emboli) are sometimes released when the patient stands up and

KEY TERMS

Emboli, embolus—Emboli is the plural form of embolus. Embolus refers to any mass of air, blood clot, or foreign body that travels through the bloodstream and is capable of lodging in smaller blood vessels where it can obstruct the blood flow to that vessel.

Embolism—The obstruction of a blood vessel by a blot clot.

Phlebitis—Inflammation of a vein.

Stasis—Stagnation in the flow of blood or any body fluid.

Thrombus—A blood clot that forms within a blood vessel or the heart.

resumes activity. Emboli can present a problem if they lodge in vital organs. In the case of postpartum patients, a **fever** developing four to 10 days after delivery may indicate thrombophlebitis. It is also known that thrombophlebitis in some patients involves hereditary factors, including mutations of genes that control the amount of clotting factors in the blood.

Questions have been raised in recent years as to whether frequent long-distance air travel increases the risk of thrombophlebitis in airline pilots and passengers. As of 2001, studies of the effects of long-distance flights on blood circulation in human test subjects have yielded conflicting results.

Diagnosis

In superficial thrombophlebitis, the location of the clot can sometimes be seen by the unaided eye. Blood clots are hard and can usually be detected by a physician using palpation (massage). Deep venous thrombosis requires specialized diagnostic instruments to detect the blood clot. Among the instruments a physician may use are ultrasound and x ray, coupled with dye injection (venogram).

Treatment

While patients have to rely on conventional medicine to resolve major blood clots in the veins, alternative therapies help prevent future blood clots and bring relief from pain due to superficial thrombophlebitis.

Physical therapy

Physical therapy helps prevent blood clots in patients who are temporary bed-ridden after a major surgery or accidents. Physical therapists help patients **exercise** their arms and legs while they are restricted in bed, use massage to stimulate muscles, and encourage them to regain their mobility as soon as possible.

Nutritional therapy

The following dietary changes may help prevent phlebitis and further vein damage:

- Limit fat intake. Saturated and hydrogenated fats are associated with increased risk of thrombosis and poor blood circulation.
- Eat a heart-healthy, high-fiber diet with emphasis on fruits, vegetables, grains, beans, nuts and seeds, and fish.
- Eat lots of garlic, ginger, onions, and hot pepper. These spices have blood-thinning activity and prevent clot formation.
- Increase consumption of cherries, blueberries, and blackberries. They contain chemicals called proanthocyanidins and anthocyanidins that help improve vein function and keep veins healthy.
- Take nutritional supplements. Supplements that help prevent blood clots and keep veins healthy include B-complex vitamins, especially folic acid (2,500 mg/day), vitamin B_6 (25 mg/day) and vitamin B_{12} (2 mcg/day); vitamin C (500 - 3,000 mg/day) and vitamin E (800 - 1,200 IU).

Herbal therapy

Several herbs help keep veins healthy and strong and/or prevent blood clots. They include:

- Butcher's broom (*Ruscus aculeatus*)
- Gingko biloba
- Gotu Kola (*Centella asiatica*)
- Horse chestnut (*Aesculus hippocastanum*)
- Bromelain (a natural enzyme found in pineapple that inhibits clot formation, therefore preventing thrombophlebitis)

Allopathic treatment

Superficial thrombophlebitis usually resolves without treatment. Application of heat or anti-inflammatory drugs (aspirin or ibuprofen) can help relieve the pain. It can take from several days to several weeks for the clot to resolve and the symptoms to completely disappear. Rarely, anticoagulant drugs may be administered.

Deep venous thrombosis is a serious condition. To prevent pulmonary embolism, anticoagulant drugs are given and the patient's limbs are elevated. The primary objective in treating deep venous thrombosis (DVT) is prevention of a pulmonary embolism. The

patient usually is hospitalized during initial treatment. The prescribed anticoagulant drugs limit the ability of blood clots to grow and new clots to form. Sometimes, a drug that dissolves blood clots is administered. Recent advances in drug treatment of DVT include the use of low molecular weight heparin (LMWH), which is safer for use in pregnant women and also allows more patients with DVT to be treated on an outpatient basis.

Surgery may be used to treat DVT if the affected vein is likely to present a long term threat of producing blood clots that will release emboli. The affected veins are either removed or tied off to prevent the release of the blood clots. Tying off superficial blood veins is an outpatient procedure that can be performed with local anesthesia. The patient is capable of immediately resuming normal activities.

Expected results

Superficial thrombophlebitis seldom progresses to a serious medical complication, although non-lethal embolisms may be produced. Deep venous thrombosis may lead to embolism, especially pulmonary embolism. This is a serious consequence of deep venous thrombosis, and is sometimes fatal.

Prevention

To prevent phlebitis, people should eat a high-fiber, heart-healthy diet and engage in regular physical exercises such as walking, bicycling, or running. If temporarily bedridden, they should stretch their arms and legs frequently and try to become mobile as soon as possible.

Phobias

Definition

A phobia is an intense but unrealistic fear that can interfere with the ability to socialize, work, or go about everyday life, brought on by an object, event or situation.

Description

Just about everyone is afraid of something—an upcoming job interview or being alone outside after dark. But about 18% of all Americans are tormented by irrational fears that interfere with their daily lives. They aren't crazy—they know full well their fears are unreasonable—but they can't control the fear. These people suffer from phobias.

Phobias belong to a large group of mental problems known as **anxiety** disorders that include **obsessive-compulsive disorder** (OCD), **panic disorder**, and **post-traumatic stress disorder**. Phobias themselves can be divided into three specific types:

- specific phobias
- social phobia
- agoraphobia

Specific phobias

As its name suggests, a specific phobia is the fear of a particular situation or object, including anything

KEY TERMS

Agoraphobia—A phobia characterized by intense fear of open or public places with no way to leave or escape easily if panic develops.

Benzodiazepine—A class of drugs that have a hypnotic and sedative action, used mainly as tranquilizers to control symptoms of anxiety.

Beta blockers—A group of drugs usually prescribed to treat heart conditions, but are also used to reduce the physical symptoms of anxiety and phobias, such as sweating and palpitations.

Monoamine oxidase inhibitors (MAO inhibitors)—A class of antidepressants used to treat social phobia.

Neuroimaging—The use of x ray studies and magnetic resonance imaging (MRIs) to detect abnormalities or trace pathways of nerve activity in the central nervous system.

Selective serotonin reuptake inhibitors (SSRIs)—A class of antidepressants that work by blocking the reabsorption of serotonin in the brain, raising the levels of serotonin. SSRIs include Prozac, Zoloft, and Paxil.

Serotonin—One of three major types of neurotransmitters found in the brain that is linked to emotions.

Specific phobia—An intense but irrational fear of a specific place, object, or animal. Common specific phobias include fear of spiders, snakes, or dogs; fear of flying or highway driving; fear of blood; and fear of elevators and other closed spaces.

from airplane travel to dentists. Found in one out of every 10 Americans, specific phobias seem to run in families and are roughly twice as likely to appear in women. If the person doesn't often encounter the feared object, the phobia doesn't cause much harm. However, if the feared object or situation is common, it can seriously disrupt everyday life. Common examples of specific phobias, which can begin at any age, include fear of snakes, flying, dogs, escalators, elevators, high places, disease, or open spaces.

Social phobia

People with social phobia have deep fears of being watched or judged by others and being embarrassed in public. This may extend to a general fear of social situations—or be more specific, such as a fear of giving speeches or of performing (stage fright). More rarely, people with social phobia may have trouble using a public restroom, eating in a restaurant, or signing their name in front of others.

Social phobia is not the same as shyness. Shy people may feel uncomfortable with others, but they don't experience severe anxiety, they don't worry excessively about social situations beforehand, and they don't avoid events that make them feel self-conscious. On the other hand, people with social phobia may not be shy—they may feel perfectly comfortable with people except in specific situations. Social phobias may be only mildly irritating, or they may significantly interfere with daily life. It is not unusual for people with social phobia to turn down job offers or avoid relationships because of their fears.

Agoraphobia

Agoraphobia is the intense fear of feeling trapped and having a panic attack in a public place. It usually begins between ages 15 and 35, and affects three times as many women as men—about 3% of the population.

An episode of spontaneous panic is usually the initial trigger for the development of agoraphobia. After an initial panic attack, the person becomes afraid of experiencing a second one. Sufferers literally fear the fear, and worry incessantly about when and where the next attack may occur. As they begin to avoid the places or situations in which the panic attack occurred, their fear generalizes. Eventually the person completely avoids public places. In severe cases, people with agoraphobia can no longer leave their homes for fear of experiencing a panic attack.

Causes and symptoms

Experts don't really know why phobias develop, although research suggests they may arise from a complex interaction between heredity and environment. Some hypersensitive people have unique chemical reactions in the brain that cause them to respond much more strongly to **stress**. These people also may be especially sensitive to **caffeine**, which triggers certain brain chemical responses.

Advances in neuroimaging have also led researchers to identify certain parts of the brain and specific neural pathways that are associated with phobias. One part of the brain that is currently being studied is the amygdala, an almond-shaped body of nerve cells involved in normal fear conditioning. Another area of the brain that appears to be linked to phobias is the posterior cerebellum.

While experts believe the tendency to develop phobias runs in families and may be hereditary, a specific stressful event usually triggers the development of a specific phobia or agoraphobia. For example, someone predisposed to develop phobias who experiences severe turbulence during a flight might go on to develop a phobia about flying.

Social phobia typically appears in childhood or adolescence, sometimes following an upsetting or humiliating experience. Certain vulnerable children who have had unpleasant social experiences (such as being rejected) or who have poor social skills may develop social phobias. The condition also may be related to low self-esteem, unassertive personality, and feelings of inferiority.

A person with agoraphobia may have a panic attack at any time for no apparent reason. While the attack may last only a minute or so, the person remembers the feelings of panic so strongly that the possibility of another attack becomes terrifying. For this reason, people with agoraphobia avoid places where they might not be able to escape if a panic attack occurs.

While the specific trigger may differ, the symptoms of different phobias are remarkably similar (e.g., feelings of terror and impending doom, rapid heartbeat and breathing, sweaty palms, and other features of a panic attack). Patients may experience severe anxiety symptoms in anticipating a phobic trigger. For example, someone who is afraid to fly may begin having episodes of pounding heart and sweating palms at the mere thought of getting on a plane in two weeks.

Diagnosis

A mental health professional can diagnose phobias after a detailed interview and discussion of both mental and physical symptoms. Social phobia is often associated with other anxiety disorders, **depression**, or **substance abuse**.

Treatment

People who have a specific phobia that is easy to avoid (such as snakes) and that doesn't interfere with their lives may not need to seek treatment. In all types of phobias, symptoms may be eased by lifestyle changes, such as:

- eliminating caffeine
- cutting down on alcohol
- eating a good diet
- getting plenty of exercise
- reducing stress

Meditation and mindfulness training can be beneficial to patients with phobias and panic disorder. **Hydrotherapy**, **massage therapy**, and **aromatherapy** are useful to some anxious patients because they can promote general **relaxation** of the nervous system. Relaxation training, which is sometimes called anxiety management training, includes breathing exercises and similar techniques intended to help the patient prevent hyperventilation and relieve the muscle tension associated with the fight-or-flight reaction of anxiety. **Yoga**, aikido, **t'ai chi**, and **dance therapy** help patients work with the physical, as well as the emotional, tensions that either promote or are created by anxiety.

Herbs known as adaptogens may be prescribed to treat the anxiety related to phobias. These herbs are thought to promote adaptability to stress, and include **Siberian ginseng** (*Eleutherococcus senticosus*), and ginseng (*Panax ginseng*). Adrenal modulators such as **licorice** (*Glycyrrhiza glabra*) and borage (*Borago officinalis*), nervine herbs such as **chamomile** (*Chamaemelum nobile*) and **skullcap** (*Scutellaria lateriafolia*), and antioxidal herbs like **milk thistle** (*Silybum marianum*) are also beneficial. Tonics of skullcap and oats (*Avena sativa*) may also be recommended to ease anxiety.

Allopathic treatment

When phobias interfere with a person's daily life, a combination of **psychotherapy** and medication can be quite effective. Medication can block the feelings of panic, and when combined with cognitive-behavioral therapy, can be quite effective in reducing specific phobias and agoraphobia.

Cognitive-behavioral therapy adds a cognitive approach to more traditional **behavioral therapy**. It teaches patients how to change their thoughts, behavior, and attitudes, while providing techniques to lessen anxiety, such as deep breathing, muscle relaxation, and refocusing.

One cognitive-behavioral therapy is desensitization (also known as exposure therapy), in which people are gradually exposed to the frightening object or event until they become used to it and their physical symptoms decrease. For example, someone who is afraid of snakes might first be shown a photo of a snake. Once the person can look at a photo without anxiety, he might then be shown a video of a snake. Each step is repeated until the symptoms of fear (such as pounding heart and sweating palms) disappear. Eventually, the person might reach the point where he can actually

touch a live snake. Three-fourths of patients are significantly improved with this type of treatment.

Another more dramatic cognitive-behavioral approach is called flooding, which exposes the person immediately to the feared object or situation. The person remains in the situation until the anxiety lessens.

Several drugs are used to treat specific phobias by controlling symptoms and helping to prevent panic attacks. These include anti-anxiety drugs (benzodiazepines) such as alprazolam (Xanax) or diazepam (Valium). Blood pressure medications called beta blockers, such as propranolol (Inderal) and atenolol (Tenormin), appear to work well in the treatment of circumscribed social phobia, when anxiety gets in the way of performance, such as public speaking. These drugs reduce overstimulation, thereby controlling the physical symptoms of anxiety.

In addition, some antidepressants may be effective when used together with cognitive-behavioral therapy. These include the monoamine oxidase inhibitors (MAO inhibitors) phenelzine (Nardil) and tranylcypromine (Parnate), as well as selective serotonin reuptake inhibitors (SSRIs) like fluoxetine (Prozac), paroxetine (Paxil), sertraline (Zoloft), and fluvoxamine (Luvox).

A medication that shows promise as a treatment for social phobia is valproic acid (Depakene or Depakote), which is usually prescribed to treat seizures or to prevent migraine headaches. Researchers conducting a twelve-week trial with 17 patients found that about half the patients experienced a significant improvement in their social anxiety symptoms while taking the medication. Further studies are underway.

Treating agoraphobia is more difficult than other phobias because there are often so many fears involved, such as open spaces, traffic, elevators, and escalators. Treatment includes cognitive-behavioral therapy with antidepressants or anti-anxiety drugs. Paxil and Zoloft are used to treat panic disorders with or without agoraphobia.

Expected results

Phobias are among the most treatable mental health problems; depending on the severity of the condition and the type of phobia, most properly treated patients can go on to lead normal lives. Research suggests that once a person overcomes the phobia, the problem may not return for many years—if at all.

Untreated phobias are another matter. Only about 20% of specific phobias will go away without treatment, and agoraphobia will get worse with time if untreated. Social phobias tend to be chronic, and without treatment, will not likely go away. Moreover, untreated phobias can lead to other problems, including depression, **alcoholism**, and feelings of shame and low self-esteem.

A group of researchers in Boston reported in 2003 that phobic anxiety appears to be a risk factor for **Parkinson's disease** (PD) in males, although it is not yet known whether phobias cause PD or simply share an underlying biological cause.

While most specific phobias appear in childhood and subsequently fade away, those that remain in adulthood often need to be treated. Unfortunately, most people never get the help they need; only about 25% of people with phobias ever seek help to deal with their condition.

Prevention

There is no known way to prevent the development of phobias. Medication and cognitive-behavioral therapy may help prevent the recurrence of symptoms once they have been diagnosed. Early detection and treatments may decrease severity.

Phosphorus

Description

Phosphorus (chemical symbol P) is a chemical element discovered by the German alchemist Hennig Brand in 1669. It plays an essential part in multiple biochemical reactions for both plants and animals and is essential to all life. Phosphorus is found in living things and in soil and rock, mostly as chemical compounds known as phosphates. Rock and soil phosphorus are mined extensively throughout the world, but especially in the People's Republic of China and the United States.

Elemental phosphorus exists in a number of allotropic forms, primarily white, red, and black phosphorus. Allotropes are forms of an element with differing physical and chemical properties. White (also called yellow or common) phosphorus is a wax-like substance formed by heating phosphorus until it vaporizes and the condensate solidifies. One of this form's characteristics has given the English language the adjective *phosphorescent*, from white phosphorus's tendency to glow in the dark when exposed to air.

White phosphorus is highly toxic, causes **burns** if it comes in contact with skin, and is so combustible that it has to be stored underwater for safety. Red phosphorus is a rust-colored powder created by heating white phosphorus and exposing it to sunlight. It is not as combustible as the white form. Black phosphorus is made by heating white phosphorus under extremely high pressure until it resembles graphite.

In plants, phosphorus is necessary for photosynthesis to take place. In the human body, phosphorus works in tandem with another element, **calcium**, in much the same way that two other electrolyte components, **sodium** and **potassium**, do. Though phosphorus is found in every cell of the human body and accounts for 1% of the body's total weight, its primary function is working in conjunction with calcium to form teeth and bones.

Eighty-five percent of the phosphorus found in the body is located in these structures. In a delicately balanced chemical reaction, parathyroid hormone (PTH), alcitonin, and 25-dihydroxy **vitamin D** regulate the absorption of both calcium and phosphorus from the intestinal tract, thus making it available for the production of bones and teeth. If an excessive amount of phosphorus is absorbed, the phosphorus combines with all available calcium and prevents the calcium's efficient use in making and maintaining bones and teeth.

PTH balances the proportions of calcium and phosphorus in the body by increasing the release of calcium and phosphate from bone and the loss of phosphorus via the kidneys while limiting the excretion of calcium. PTH also increases the activity of the 25-Dihydroxy v25-Dihydroxy vitamin D, which, in contrast, increases the absorption of both phosphorus and calcium from the intestinal tract.

General use

Compounds of phosphorus are used to make fertilizers, detergents, and water softeners. They are also used in the manufacture of steel, plastics, insecticides, medical drugs, and animal feeds. Phosphorus is used in the manufacture of safety matches and pesticides, including rat poison.

Phosphorus found in the blood stream and in soft tissue has a highly significant role to play in a variety of body functions. Working with vitamin B, phosphorus is involved in the metabolism of fats and carbohydrates, in both the repair of damaged cells and tissues and the routine maintenance of healthy ones. Phosphorus is necessary for the regularity of the heartbeat and aids in the contraction of all other muscles throughout the body. Phosphorus is needed for the functioning of the kidneys and plays a part in the conduction of impulses along the network that makes up the nervous system.

Preparations

According to the American Dietetic Association, phosphorus intake in the United States is generally above what is needed and in the 1990s and 2000s actually increased. Therefore, under normal circumstances with normal food intake, there is seldom if ever a need to supplement intake of phosphorus. Persons suffering from eating disorders such as anorexia and bulimia can be deficient in phosphorus intake as well as other nutrients. As the best source of phosphorus is in protein foods such as meat, eggs, and milk products. Some vegetarians may also need to evaluate their intake of this element. Excess consumption of processed foods, inadequate intake of whole foods, and fertilizers and pesticides are some of the causes for excess phosphorus.

Beside high-protein foods, phosphorus is also found in decreasing quantities in wholegrain breads and cereals, especially unprocessed ones, and in minute amounts in fruits and vegetables. The phosphorus present in wholegrain breads and cereals, however, exists as a substance called *phytin*. Phytin combines with calcium to create a salt that the human body is incapable of absorbing, thus making grains that are unprocessed and not enriched a negligible source of phosphorus. But both commercially prepared cereals and breads may provide this element as they are frequently enriched with it. Phosphates can also be taken by mouth as a tablet.

Precautions

White phosphorus is poisonous. Red phosphorus is not. As noted, white phosphorus is a highly toxic, flammable substance capable of burning the skin on contact, and of igniting at room temperature. It should be handled with extreme care. Accidental phosphorus poisoning can happen from both fertilizers and pesticides. Humans rarely come into contact with elemental phosphorus, so these precautions apply primarily to

KEY TERMS

Anorexia nervosa—A serious and sometimes fatal eating disorder characterized by intense fear of being fat and severe weight loss. It primarily affects teenage and young adult females. Sufferers have a distorted body image wherein they see themselves as fat even when they are at normal weight or even emaciated.

Bulimia—An eating disorder characterized by bouts of gross overeating usually followed by self-induced vomiting.

Calcitonin—A hormone produced by the thyroid gland that controls the calcium level in the blood by slowing the rate that calcium is lost from bone.

Deciliter—A fluid measurement that is equal to one-tenth of a liter, or 100 cubic centimeters (27 fluid drams or teaspoonfuls).

Diabetic ketoacidosis—A potentially serious condition in which ketones become present in the blood stream because of the metabolism of fats *burned* in lieu of carbohydrates that would normally be used, which occurs because there is insufficient insulin available to cause carbohydrates to be used as fuel.

Electrolyte—Substances that split into ions, or electrically charged particles, within the body to regulate many important bodily processes. Examples of electrolytes are sodium, potassium, hydrogen, magnesium, calcium, bicarbonate, phosphates, and chlorides.

Multiple endocrine neoplasia—Tumor formation characterized by a progressive, abnormal multiplication of cells that are not necessarily malignant in any of the glands that secrete chemicals directly into the blood stream, such as the thyroid gland, adrenal glands, or ovaries.

Osteomalacia—Softening, weakening, and removal of the minerals from bone in adults caused by vitamin D deficiency.

Osteoporosis—Loss of formative protein tissue from bone, causing it to become brittle and easily fractured; considered a normal part of aging, but with hormonal causes that make it much more common in women than men.

Sarcoidosis—A rare disease of unknown cause as of 2008 that occurs mostly in young adults. Inflammation occurs in the lymph nodes and other tissues throughout the body, usually including the lungs, liver, skin, and eyes.

workers in the phosphorus industry. Phosphates sometimes are leached into water systems through sewage and can drastically alter the chemical makeup of lakes and rivers. In sufficient quantities, they can lead to the death of nearly all forms of aquatic life.

A normal blood serum level of phosphorus is 2.4–4.1 mg per deciliter of blood. An abnormal serum phosphorus level should be evaluated by a physician.

Phosphorus levels higher than normal can indicate a diet that includes an excessive phosphorus intake, inadequate intake of calcium, or lack of PTH (parathyroid hormone) in the system. It can be related to bone metastasis associated with **cancer**, liver or kidney disease, or *sarcoidosis*.

Serum phosphorus levels that are below normal can be related to insufficient phosphorus or vitamin D in one's diet leading to rickets in children and osteomalacia in adults. Disorders of the parathyroid gland, causing it to secrete excessive quantities of PTH, or of the pancreas, causing it to secrete too much insulin, also affect blood levels of phosphorus. Diabetic ketoacidosis or too much calcium are other possible causes. Multiple endocrine neoplasia (MEN) is yet another condition that often is associated with lower than normal levels of phosphorus.

Side effects

Phosphorus preparations taken to supplement low phosphorus levels in the body can cause **diarrhea**.

Interactions

Antacids can decrease the absorption of phosphorus. Laxatives and enemas that contain the chemical compound sodium phosphate and excessive intake of vitamin D can increase phosphorus levels in the body. Administration of intravenous glucose solutions will cause phosphorus to combine with the glucose that is being absorbed by the cells.

Phytolacca

Definition

Phytolacca is a genus of plants belonging to the family Phytolaccaceae, commonly known as the pokeweeds. That common name is also used for members of the genus Phytolacca. Some well known members of the genus include "P. americana", native to North America; "P. dioica" (South America); "P. decadra" (North America); "P. heteropetala" (Mexico); "P. icosandra (South America); and "P. octandra(New Zealand). Members of the Phytolacca genus are also known by a number of common names, including American nightshade, **cancer** root, cocum, inkberry, ombú, pigeon berry, poke, pokebush, pokeberry, pokeroot, polk salad, polk sallet, red ink plant, red nightshade, red weed, scoke, and shang–lu .

Description

Pokeweed is a perennial plant that adjusts readily to a variety of growing conditions. It prefers open areas, such as recently cleared spaces, open meadows, or pastureland. It is anchored by large, fleshy, bulbous root that sends out a single erect stem each year that may grow to a height of 10 feet (3 meters). One of the most robust examples of the plants grows on the South American pampas, where it attains the height and appears of a small tree. The stem is green at first, but turns red or purple later in the season as flowers appear. Leaves are alternate, pointed, and crinkly. White flowers, which form at the terminus of

pendulous stems, eventually change into round deep purple berries filled with a beautiful purple juice. American botanist Edmond Preston first noted in 1884 that leaves of the pokeweed emit a faint and continuous fluorescent light in the dark at the end of its growing season in fall.

Pokeweed contains a number of organic compounds toxic to mammals, including phytolaccine (an alkaloid), phytolaccatoxin (a resin), and phytolaccigenin (a saponin). Alkaloids are nitrogen–containing organic compounds with physiological effects on animals. Saponins are glycosides, sugar–like substances. Resins are semi–solid materials commonly produced by plants. Most animals avoid pokeweed, apparently because of its noxious taste. Small children are sometimes attracted to the colorful berries and may become ill if they eat the plant. The toxins in pokeweed act as an emetic, producing **nausea** and **vomiting** within a few hours of being ingested. Without treatment, symptoms because worse and may include convulsions, spasms, paralysis of the respiratory system, and death. Interestingly, birds appear to be immune to the toxic effects of the pokeweed plant. Scientists hypothesize that the plant seeds, which contain toxins, pass through a bird's digestive system unchanged, thus avoiding any harmful effects on the animals. This hypothesis helps explain the fact that pokeweed plants often grow in isolated areas where no parent plant has been able to drop seeds. The volunteer plants in such cases arise out of seeds that have passed through a bird's digestive system.

Uses

Physicians and public health authorities have long advised against the human consumption of phytolacca, pointing out the serious risk of poisoning. Nonetheless, pokeweed products have had a long history as foods and herbal remedies. In the American south, for example, the plant is often prepared by boiling it three times over (to remove toxic components) and then served as poke salad, pokeberry juice, or in combination with other juices and jellies.

The plant's appeal, in spite of its toxic risks, lies in a number of supposed therapeutic uses to which it can be put. It is taken either orally, as a tonic or infusion, or topically, by rubbing on the skin or other injured or diseased area. Proponents of it say that pokeweed is

- alterative (gradually improving one's overall health)
- anodyne (relieving pain and discomfort)
- anti–inflammatory
- cathartic (capable of relieving constipation)
- emetic (capable of inducing nausea and vomiting)
- expectorant (an agent that stimulates the expulsion of mucus from the lungs and throat)
- hypnotic (capable of inducing sleep)
- narcotic (capable of inducing deep sleep or unconsciousness)
- purgative (stimulating movement of the bowels)

Some specific conditions for which phytolacca has been recommended include **bronchitis**, catarrh (inflammation of the mucous membranes), chronic **eczema**, diphtheria, dysentery, glandular **fever**, immune disorders, **influenza**, **mumps**, **psoriasis**, rheumatism, **sore throat**, **sprains**, swollen glands, tender nipples and sore breasts, tinea capitis (**fungal infections** of the scalp), **tonsillitis**, and ulcers of the leg. On its website review of the medicinal uses of phytolacca in 2008, the Memorial Sloan–Kettering Cancer Center concluded that "[n]o study supports the use of pokeweed for any proposed claim."

In spite of that general observation, some researchers believe that phytolacca or one or more of its components may be effective in treating certain diseases, especially cancer and viral **infections**, such as autoimmundeficiency syndrome (**AIDS**). Since the late 1990s, for example, researchers have been exploring the use of pokeweed antiviral protein (PAP) as treatment for certain types of cancers and viral infections. The compound has been effective in killing viruses and cancer cells in vitro and in experimental animals. At this point, however, there is not enough evidence to assess the safety and efficacy of PAP for use with humans. Research also continues on the use of another product obtained from phytolacca called PAPF–s as an antifungal agent. So far, laboratory results are promising, but no human studies have been completed.

Side Effects

Some homeopathic practitioners claim that there are no side effects associated with the use of phytolacca preparations. Medical sources, however, report that a number of adverse effects have been reported during the use of the product. These effects include chest **pain**, difficulty in breathing, **hives**, itchy or swollen skin, nausea, vomiting, stomach cramps, **diarrhea**, muscular weakness, hypotension, and irregular heart beat. As indicated above, the product is also toxic if taken in sufficient amounts.

Interactions

Relatively little research has been conducted on possible interactions of phytolacca with drugs and other herbs. Some hypothesized interactions are the following:

KEY TERMS

Alkaloid—A nitrogen containing plant product that has pharmacological effects on animals.

Alterative—Having the tendency to improve one's general health gradually over time.

Anodyne—A substance that reduces pain and discomfort

Cathartic—Capable of reducing or relieving constipation.

Emetic—Having a tendency to induce nausea and vomiting

Expectorant—A substance that loosens phlegm in the lungs and throat, leading to its expulsion by coughing and spitting

Hypnotic—Capable of inducing sleep.

Narcotic—Capable of inducing deep sleep or unconsciousness.

Purgative—Having a tendency to stimulate movement of the bowels.

Resin—A gummy, semi solid material produced by many kinds of plants.

Saponin—Soapy like substances found in many plants with a chemical structure related to that of the simple sugar glucose.

- an increase in the action of anticoagulants
- inhibition, in general, of the action of drugs because of the increase in transit time through the gastrointestinal system
- an increase in the action of antidepressants
- a reduction in the efficacy of phytolacca with the use of chlorophenylalanine, cyproheptadine HCl, and phenobarbital
- an increase in the antibiotic activity of echinacea
- a reduction in pokeroot's efficacy if milk is used in tea concoctions

Pilates

Definition

Pilates or Physical Mind method, is a series of non-impact exercises designed by Joseph Pilates to develop strength, flexibility, balance, and inner awareness.

Origins

Joseph Pilates (pronounced pie-LAH-tes), the founder of the Pilates method (also simply referred to as "the method") was born in Germany in 1880. As a frail child with rickets, **asthma**, and **rheumatic fever**, he was determined to become stronger. He dedicated himself to building both his body and his mind through practices which included **yoga**, zen, and ancient Roman and Greek exercises. His conditioning regime worked and he became an accomplished gymnast, skier, boxer, and diver.

While interned in England during World War I for being a German citizen, Pilates became a nurse. During this time, he designed a unique system of hooking springs and straps to a hospital bed in order to help his disabled and immobilized patients regain strength and movement. It was through these experiments that he recognized the importance of training the core abdominal and back muscles to stabilize the torso and allow the entire body to move freely. This experimentation provided the foundation for his style of conditioning and the specialized **exercise** equipment associated with the Pilates method.

KEY TERMS

Yoga—A system of physical, mental, and breathing exercises developed in India.

Zen—A form of meditation that emphasizes direct experience.

Pilates emigrated to the United States in 1926 after the German government invited him to use his conditioning methods to train the army. That same year he opened the first Pilates studio in New York City. Over the years, dancers, actors, and athletes flocked to his studio to heal, condition, and align their bodies.

Joseph Pilates died at age 87 in a fire at his studio. Although his strength enabled him to escape the flames by hanging from the rafters for over an hour, he died from smoke inhalation. He believed that ideal fitness is "the attainment and maintenance of a uniformly developed body with a sound mind fully capable of naturally, easily, and satisfactorily preforming our many and varied daily tasks with spontaneous zest and pleasure."

Benefits

Pilates is a form of strength and flexibility training that can be done by someone at any level of fitness. The exercises can also be adapted for people who have limited movement or who use wheel chairs. It is an engaging exercise program that people want to do. Pilates promotes a feeling of physical and mental well-being and also develops inner physical awareness. Since this method strengthens and lengthens the muscles without creating bulk, it is particularly beneficial for dancers and actors. Pilates is also helpful in preventing and rehabilitating from injuries, improving posture, and increasing flexibility, circulation, and balance. Pregnant women who do these exercises can develop body alignment, improve concentration, and develop body shape and tone after **pregnancy**. According to Joseph Pilates, "You will feel better in 10 sessions, look better in 20 sessions and have a completely new body in 30 sessions."

Although Pilates is often associated with dancers, athletes, and younger people in general who are interested in improving their physical strength and flexibility, a simplified version of some Pilates exercises is also being used as of 2003 to lower the risk of hospital-related deconditioning in older adults. A Canadian study of hospitalized patients over the age of 70 found that those who were given a set of Pilates exercises that could be performed in bed recovered more rapidly than a control group given a set of passive range-of-motion exercises.

Description

During the initial meeting, an instructor will analyze the client's posture and movement and design a specific training program. Once the program has been created, the sessions usually follow a basic pattern. A session generally begins with mat work and passive and active stretching. In passive stretching, the instructor moves and presses the client's body to stretch and elongate the muscles. During the active stretching period, the client preforms the stretches while the instructor watches their form and breathing. These exercises warm up the muscles in preparation for the machine work. The machines help the client to maintain the correct positioning required for each exercise.

There are over 500 exercises that were developed by Joseph Pilates. "Classical" exercises, according to the Pilates Studio in New York involve several principles. These include concentration, centering, flowing movement, and breath. Some instructors teach only the classical exercises originally taught by Joseph Pilates. Others design new exercises that are variations upon these classical forms in order to make the exercises more accessible for a specific person.

There are two primary exercise machines used for Pilates, the Universal Reformer and the Cadillac, and several smaller pieces of equipment. The Reformer resembles a single bed frame and is equipped with a carriage that slides back and forth and adjustable springs that are used to regulate tension and resistance. Cables, bars, straps, and pulleys allow the exercises to be done from a variety of positions. Instructors usually work with their clients on the machines for 20-45 minutes. During this time, they are observing and giving feedback about alignment, breathing, and precision of movement. The exercises are done slowly and carefully so that the movements are smooth and flowing. This requires focused concentration and muscle control. The session ends with light stretching and a cool-down period.

Once the basics are learned from an instructor, from either one-on-one lessons or in a class, it is possible to train at home using videos. Exercise equipment for use at home is also available and many exercises can be performed on a mat.

A private session costs between $45–$75, depending on the part of the country one is in. This method is not specifically covered by insurance although it may be covered when the instructor is a licensed physical therapist.

Precautions

The Pilates method is not a substitute for good physical therapy, although it has been increasingly used and recommended by physical therapists since the mid-1980s. People with chronic injuries are advised to see a physician.

Research and general acceptance

As of early 2004, several physical therapists and gerontologists have done research studies on the Pilates method, although much more work needs to be done in this area. The appeal of the Pilates method to a wide population, coupled with a new interest in it on the part of rehabilitation therapists, suggests that further studies may soon be underway. Dancers and actors originally embraced the Pilates method as a form of strength training that did not create muscle bulk. Professional and amateur athletes also use these exercises to prevent reinjury. Sedentary people find Pilates to be a gentle, non-impact approach to conditioning. Pilates equipment and classes can be found in hospitals, health clubs, spas, and gyms.

Training and certification

There are two main centers for training and certification. The Pilates Studio in New York City certifies teachers in the "classical" exercises of "The Pilates Method." The teacher training program of The Pilates Studio involves seminar training and 600 apprenticeship hours. Perspective teachers need a strong background in Pilates. There is an extensive application and examination process. Classes are available throughout the United States and in 20 international locations.

The PhysicalMind Institute in Santa Fe, New Mexico, offers a 275-hour basic certification program in "The Method." Prerequisites include a 15-hour course, knowledge of functional anatomy, and 10 hours of private sessions. After completing an apprenticeship, students must pass a written and practical final exam. Advanced training is also offered. Students at this center receive training in the original exercises of Joseph Pilates, as well as the concepts of body mechanics. Understanding the concepts behind the exercises enables teachers to create appropriate variations for their clients. Classes are available throughout the United States and Canada.

Pinched nerve

Definition

A pinched nerve is caused by some anatomical structure putting pressure on a nerve and impairing its function. This problem may occur in many different

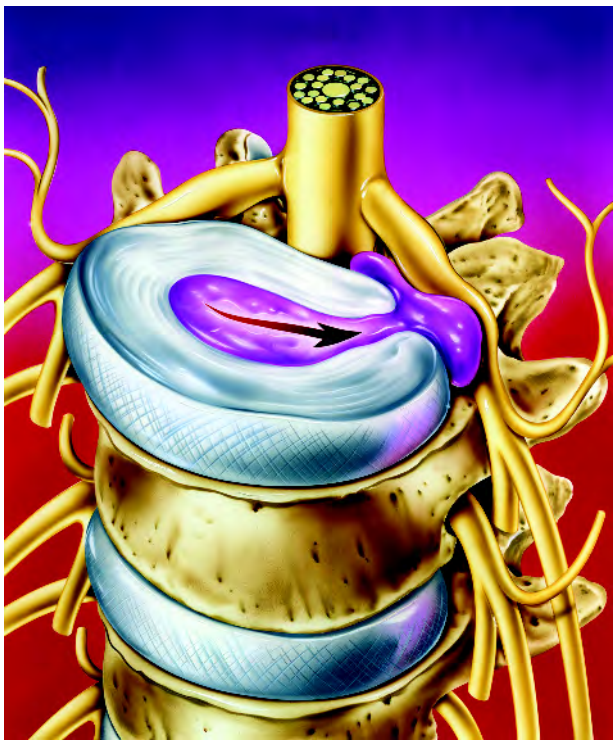

Illustration of an intervertebral disc that has ruptured, leading to the internal jelly-like material putting pressure on a nerve. *(John Bavosi / Photo Researchers, Inc.)*

areas of the body. The most common places are those in which a nerve must travel through a small space. Examples include the region where the nerve roots exit the spine called the intervertebral foramen, and the carpal tunnel at the wrist, where a nerve must travel through a tunnel created by the wrist bones and ligaments.

Description

A pinched nerve may go by several different names. It may be called nerve compression, entrapment, or impingement. Many problems involving pinched nerves will be called syndromes. Examples include **carpal tunnel syndrome**, thoracic outlet syndrome, and piriformis syndrome. If the nerve is pinched right near its root where it attaches to the spinal cord it is often called a radiculopathy.

The nerves that exit the spine and go down the upper limb and lower limb are gathered together in groups. Each group of nerves is called a plexus. In the neck region the nerves that leave the neck and go down the upper arm make up the brachial plexus. In the low back region, the nerves that go down the leg may come from the lumbar plexus or the sacral plexus. If a nerve is pinched where it is part of a plexus, it may be called a plexopathy. If the nerve is pinched farther along its length after it has left the plexus it is called a neuropathy.

A nerve is responsible for carrying two different types of signals. It carries sensory information, such as sensations of heat, pressure, texture, **pain**, or body position back to the spinal cord where that information will eventually be transmitted directly to the brain. These sensory signals that travel through the nerves are called afferent signals. A nerve also carries motor signals from the brain and spinal cord that tell the muscles when and how much to contract in order to create movement in the body. These motor signals that go from the brain and spinal cord out to the muscles are called efferent signals. When a nerve is pinched it may cause dysfunction with either the sensory (afferent) or motor (efferent) signals.

Causes and symptoms

A pinched nerve may occur from a direct blow. Most people are familiar with this sensation when they bang their elbow on a hard surface and get a sharp pain or prickling sensation down the arm. The symptoms of this kind of pinched nerve are usually very short-lived and are not a significant problem unless the force of the impact was severe.

What is much more common is the sensation of small amounts of pressure on the nerve from such adjacent structures as bones, muscles, tendons, and ligaments. This pressure most often occurs when the nerve has to travel through a small space between these structures. The nerve may get compressed with a small amount of pressure for a long period of time. It is the long time period of pressure on the nerve that causes the most damage. In many cases these long periods of pressure are related to the person's job. Occupations in which a person must hold the wrist, forearm or shoulder in one position for long periods of time and/or perform repetitive movements have a high rate of workers with pinched nerve syndromes. Dental hygienists, keyboard instrumentalists, violinists, data entry workers, assembly line and construction workers, and professional athletes are examples of workers at risk for pinched nerve syndromes.

When pressure is placed on the nerve a person may feel a variety of different symptoms. Paresthesia (the sensation of pins and needles) is often felt first. The sensations of paresthesia are usually felt anywhere along the nerve from the site of compression toward the far end of the extremity. Symptoms may also go from the site of compression toward the spinal cord, but it is not as common. In addition to paresthesia sensations, a person with a pinched nerve may also feel sharp, shooting pain, or pain that feels like an

KEY TERMS

Afferent—Sensory signals that go from the sensory cells at the periphery of the body back to the brain and spinal cord.

Chiropractic—A method of treatment based on adjustment or manipulation of the segments of the spinal column.

Cupping—A procedure in traditional Chinese medicine in which heated air is trapped underneath a specially shaped glass cup that is placed over the skin and then rubbed along the skin. The heated air trapped in the cup creates a suction effect on the skin. Sometimes cups are used with a vacuum pump instead of heating.

Efferent—Motor signals that go from brain and spinal cord out to the muscles of the body.

Neuropathy—Compression of a peripheral nerve somewhere along its length.

Paresthesia—The sensation of pins and needles or tingling that is often the result of nerve compression.

Plexopathy—Compression of a nerve where it is part of a bundle of nerves called a plexus.

Radiculopathy—Compression of a nerve root at the point where it exits the spinal cord.

Transcutaneous electrical nerve stimulation (TENS)—A form of treatment for chronic pain in which a self-operated portable device is used to send electrical impulses through electrodes placed on the skin over the affected area. The pain is relieved because the electrical impulses interrupt the transmission of pain signals traveling along the nerve.

electrical shock going down the extremity. All of these symptoms are from impairment of the afferent (sensory) nerve signal transmission. The sensation is not necessarily near the area where the pressure is occurring.

Motor (efferent) signals can also be impaired from nerve compression. This will most likely show up as muscle weakness or problems with coordination. For example, people with carpal tunnel syndrome will frequently report losing grip strength. This is because the nerve has been compressed and signals are not getting through to the muscles of the hand that produce the grip.

Diagnosis

Most pinched nerve conditions can be diagnosed with physical examination. The practitioner will take a thorough history, including an occupational history, and investigate the nature of the signs and symptoms to see if they indicate the likelihood of nerve compression. A number of physical examination tests may also be performed to see if nerve compression is aggravated with specific movements or pressure in certain areas. In addition to physical examination and information from the patient's history, nerve conduction tests may be run to see if the nerves are transmitting signals at the proper rate. If a nerve compression problem exists, there will be a slowing in the velocity of signal transmission in that nerve and it will likely be detected by the nerve conduction velocity test.

As of 2003, diagnostic imaging is being increasingly used to aid in the diagnosis of nerve entrapment and compression syndromes. Recent refinements in ultrasound and magnetic resonance imaging (MRI) provide doctors with detailed pictures of the anatomy of peripheral nerves and the changes that take place in them with compression syndromes.

Treatment

Alternative therapy practitioners who specialize in such manual therapy methods as **chiropractic**, **osteopathy**, or **massage therapy** will look closely at the mechanical factors in the region of pain to identify what is pinching the nerve. If it is determined that the nerve is being compressed by some structure like a muscle that is pressing on the nerve, then therapy will be aimed at reducing tightness in that muscle so that it no longer presses on the nerve. This will generally be done through a variety of soft tissue therapy methods. In some instances there are other postural or mechanical distortions that may lead to nerve compression, and those will be addressed through manual therapy or various movement retraining methods.

Treatment will also focus on changing mechanical factors that may have led to nerve compression. For example, in carpal tunnel syndrome it is often some repetitive use activity that has led to the problem. If that activity can be altered so there is not an accumulation of **stress** on the soft tissues, it is likely that the symptoms of the nerve compression will be resolved. However, nerve compression symptoms may be slow to fully resolve even after the primary cause of the compression has been addressed.

Acupuncture can be quite helpful in treating pinched nerves since it has been shown to be a very effective method for producing pain relief. The primary goals of an acupuncture treatment will be both to reduce pain sensations and to get proper energy moving along the pathways that have been impaired.

Needles will be inserted in areas that will help encourage proper neurological flow through the involved area. Acupuncture with electrical stimulation of the needles may also be used for treating pinched nerves.

In addition to acupuncture, other approaches from **traditional Chinese medicine** may be used. Both topical and oral herbal preparations may be used to help restore proper function and address any underlying causes of the pinched nerve symptoms. **Cupping** may be used to help free soft tissue restrictions that may be compressing the nerve structures in the area.

Allopathic treatment

Traditional allopathic treatment for pinched nerves will also focus on the site of nerve compression and try to manage the symptoms first through conservative therapy. Oral medications may be given to relieve pain or reduce any inflammation that may be contributing to the nerve compression. Physical therapy may be used to help address any mechanical factors that may be contributing to the nerve compression. Physical therapy approaches are likely to include stretching, joint mobilization, soft tissue treatments, or such other modalities as ultrasound to address the causative factors of the nerve compression. Splinting is an additional conservative approach to nerve compression syndromes.

Depending on where the nerve compression is located, surgical treatment may sometimes be necessary. Surgery is often performed for such common nerve compression problems as carpal tunnel syndrome and thoracic outlet syndrome. Most of these surgical procedures will be aimed at relieving pressure on the affected nerve.

Some newer allopathic treatments that are used to relieve the pain of pinched nerve syndromes include low-level laser therapy (LLLT) and transcutaneous electrical nerve stimulation (TENS). In LLLT, a continuous-wave red-beam laser is aimed at acupuncture points on the affected area. In TENS, the affected nerve is stimulated with high-frequency electrical signals, which disrupt the transmission of pain impulses along the nerve so that the pain is no longer felt. Both these approaches give good results in treating pinched nerve syndromes, as they are noninvasive and painless.

In some cases in which the pinched nerve is related to the patient's job, a change of occupation may be necessary.

Expected results

Most problems with pinched nerves will be resolved as soon the pressure on them is released. If the symptoms have been present for a long time, the relief of the condition may not be immediate. The longer the pressure has been applied, the longer it is likely to take for the symptoms to be resolved.

Prevention

Most pinched nerve conditions can be avoided with proper body mechanics. Repetitive motions of the upper extremity are notorious for causing pinched nerves in several places, and it is wise to make sure a person is conditioned for the level of activity he or she is engaging in so as to prevent this from occurring. The individual should also be careful of activities that might put pressure on nerves for long periods. For example, nerves can be compressed in the shoulder region from the wearing of heavy backpacks or handbags for long periods.

Pine bark extract is a new nutritional supplement used for its antioxidant properties, which are believed to be effective for a wide range of healing and preventative purposes. *(© Andrew Darrington / Alamy)*

Pine bark extract

Description

Pine bark extract is made from the bark of a European coastal pine tree called the Landes or maritime pine, whose scientific name is *Pinus maritima*. The maritime pine is a member of the Pineaceae family. Pine bark extract is a new nutritional supplement used for its antioxidant properties, which are believed to be effective for a wide range of healing and preventative purposes. Pine bark extract has been patented by a French researcher under the name Pycnogenol (pronounced pick-nah-jen-all).

Pine bark extract has a 450-year-old legend surrounding it. There is a written account of an event that happened in 1534, when a French ship led by explorer Jacques Cartier became stranded in ice near Quebec, Canada. Cartier's crew became severely sick from scurvy, which used to be a fatal disease caused by a lack of **vitamin C** in the diet. Cartier's crew was saved when a Quebec Indian instructed them to drink a brew made from pine bark and needles. Four centuries later, a French researcher named Jacques Masquelier discovered the reason for the effectiveness of this remedy. A substance found in pine bark acts as an antioxidant in the body, and greatly increases the effectiveness of the vitamin C found in the pine needles.

During the 1950s, Masquelier had heard the story of Cartier when he was in Canada performing research. He was investigating a group of substances called flavonols, which he originally found in peanut skins. Flavonols and **bioflavonoids** are substances in fruits and vegetables that give them their color. Masquelier found that these substances have beneficial

KEY TERMS

Antioxidant—A substance or compound that prevents free radical or oxidative damage. Pine bark extract contains powerful antioxidants called OPCs.

Atherosclerosis—Hardening of the arteries.

Bioflavonoids—Water-soluble plant pigments that have a wide variety of effects on the human body.

Cholesterol—A steroid fat found in animal foods that is also produced in the body for several important functions. Excess cholesterol intake is linked to many diseases.

effects in the body, particularly in improving circulation and repairing tissue. He later found that an abundant source of these substances was the bark of pine trees that grew on the coasts of southern France. Pine bark was also the most efficient source of the substance, because it took only warm water and pressure to extract the substance from trees that were considered a waste product. Masquelier called his pine bark extract Pycnogenol, and continued his research on pine bark extract and bioflavonoids for decades. In 1987, the United States awarded him a patent. Only Masquelier's pine bark extract can legally claim to have antioxidant properties.

Antioxidants play a key role of repairing and protecting cells in the body. They help protect against free radicals, which are damaging byproducts of metabolism and exposure to environmental pollutants. Free radical damage is believed to contribute to **aging**, as well as too severe conditions including **heart disease** and **cancer**. Common antioxidants are vitamins A, C, E, and the mineral **selenium**. Researchers have termed the group of antioxidants found in pine bark extract oligomeric proanthocyanidins, or OPCs for short. OPCs (also referred to as PCOs) are some of the most powerful antioxidants available.

OPCs are found in many common foods. In fact, OPCs are at the center of what has been called the French paradox. The French paradox has to do with the fact that the French eat as much **cholesterol** as Americans, yet have a significantly reduced incidence of heart disease. Researchers have theorized that one reason for this paradox is the French consumption of red wine with meals. Red wine is rich in bioflavonoids, including OPCs, which have been shown to protect blood vessels from cholesterol. Another OPC supplement on the market besides pine bark extract is **grape seed extract**, which is the cheapest and most widely used source of OPCs.

Much research has been conducted on OPCs and on pine bark extract. In France, pine bark extract and OPCs have been rigorously tested for safety and effectiveness, and pine bark extract is a registered drug. Pine bark extract has been shown to contain a powerful antioxidant that helps protect cells from free radical damage and increases the effectiveness of vitamin C. Pine bark extract has been shown to help lower cholesterol, and to decrease the risk and severity of **atherosclerosis**, or damage to the arteries. It has been demonstrated to help strengthen and repair tissues made of collagen, a protein that builds blood vessels, skin, and connective tissue. The OPCs in pine bark extract have also been shown to help reduce swelling and inflammation in the body.

General use

Pine bark extract is used to reduce the risk and severity of heart disease, strokes, high cholesterol, and circulation problems. It is used in the nutritional treatment of **varicose veins** and **edema**, which is swelling in the body due to fluid retention and leakage of blood vessels. Arthritis and inflammation have also been improved in studies using pine bark extract, as well as the uncomfortable symptoms of PMS and **menopause**. The OPCs in pine bark extract are recommended for various eye conditions that are caused by blood vessel damage, such as diabetic **retinopathy** and **macular degeneration**. Pine bark extract is recommended to improve the health and smoothness of the skin, including damage caused by overexposure to sunlight. Pine bark extract is a supplement used for anti-aging and preventive care as well.

Preparations

Pine bark extract is available in health food stores as powder and capsules. For prevention and general health, a daily dosage of 50 mg (1–2 capsules) is recommended. For treatment of health conditions, the dosage may be increased to 300 mg or more, depending on the advice of a physician and the specific condition. Pine bark extract can be taken either with or between meals.

Precautions

While pine bark extract is used in the nutritional treatment of many conditions, it is not meant to replace proper medical supervision.

Side effects

Pine bark extract has been extensively tested for safety, and no dangerous side effects have been observed with its use.

Interactions

The effectiveness of pine bark extract may be increased with the use of other antioxidants, including vitamins A, C, E, and the mineral selenium. **Diets** rich in foods that contain antioxidants and bioflavonoids, such as fresh fruits and vegetables, may also contribute to its effectiveness.

KEY TERMS

Adjuvant—A substance or medication used together with a vaccine or other drug to assist the effect of the main ingredient.

Antiemetic—A medication or preparation given to stop vomiting.

Chi—The Chinese name for "life force."

Decoction—An extract of a herb obtained by boiling the herb in water or alcohol.

Expectorant—A drug given to help bring up mucus or phlegm from the respiratory tract.

Goiter—Swelling of the thyroid gland caused by under or over production of thyroxine.

Materia medica—The branch of medical science concerned with the study of drugs or herbs.

Rhizome—A horizontal underground stem that sends up shoots from its upper surface.

Scrofula—Tuberculosis of the lymphatic glands.

Pinellia

Description

Pinellia (*Araceae pinellia ternatae*) is a member of the Aroid family. Originating from China and Japan, it is a small plant that is popular for ornamental use and known in Asia as "green dragon." Pinellia is a small plant, growing only to a height of 6–12 in (15–30 cm) high. It has black shiny stems, and glossy arrowhead-shaped leaves that are highlighted by a silver stripe along the veins. It produces purple tongue-like flowers in late summer.

General use

Athough not widely used in Western herbal medicine, pinellia is particularly useful for chest complaints. It relieves coughs and **cuts** through mucus, being especially good for sinus congestion and nasal discharge. It is also recommended for **asthma**, emphysema, and any form of **wheezing**, which makes it valuable as not many herbs are suited to the treatment of these particular ailments. It is more widely used in Oriental medicine than in Western natural therapies, however, and it is often an ingredient of herbal mixtures in both Western and Chinese herbal medicine.

Pinellia in Chinese herbalism

Known as "ban xia" or "wu bing shao" to the Chinese, Pinellia is widely used in a variety of combinations in Chinese herbal medicine. They consider that its properties are "pungent, warm, and toxic," and it is considered a treatment for the areas of the Chinese concepts of Spleen, Stomach, and Lung. Remedies are generally prepared from the roots and stems of the plant and are used to treat digestive and respiratory problems.

Pinellia is most useful for chest complaints, in which it is used in conjunction with **magnolia** bark or perilla leaf—both common ingredients of Chinese remedies. It is especially useful when dealing with phlegm and congestion, which are both cold in nature. Pinellia is also used in combination with other herbal ingredients for the treatment of **nausea** and **vomiting**. It is considered an antiemetic (nausea suppressant). Depending on the patient's body type, it may be used with fresh **ginger**, bamboo shavings, loquat leaf, perilla stem, or amomum fruit. It may also be used with ginseng or jujube.

Chinese herbalists also recommend pinellia for the treatment of swollen glands, and certain cases of goiter, for which it is used in conjunction with seaweed and fritillary bulb. It is recommended for sinus problems in which there is **pain** and a feeling of fullness across the sinus area.

Pinellia is also used for coughing and asthma. In addition, the Chinese use it for the treatment of scrofula and subcutaneous cysts.

Pinellia also appears to have antidepressant effects. It is the primary ingredient in Banxia Houpu decoction, a traditional Chinese formula that has been used for centuries to treat **depression**. A recent chemical analysis of this decoction showed that its antidepressant activity is close to that of fluoxetine (Prozac).

A new use for pinellia is its role as an adjuvant (substance given to assist the effectiveness of a vaccine or medication) to a nasal vaccine for **influenza**. Researchers isolated a compound called pinellic acid from pinellia, and found that an oral preparation of it measurably increased the effectiveness of a nasal vaccine against influenza without any harmful side effects.

Preparations

The parts of the plant used, particularly in Chinese herbalism, are generally the rhizomes, or tubers. These should be dug during late summer, early autumn. The bark and fibrous roots are then removed and the rhizomes should be dried in sunlight. The raw herbs are toxic and must be prepared bydrying them and then frying them in ginger and vinegar to make them usable. The preparation is called *fa ba xia* and is available in health food stores.

Dosage may be in the form of readily prepared pills, again especially in the case of Chinese herbalism, or in the form of a syrup, in which case the recommended dosage should be followed. The dried rhizome may be taken in doses of 5–10 grams.

Precautions

Pinellia is best used as an expectorant for congestive chest conditions. Another remedy should be used for dry coughs accompanied by chills, due to its drying and warming properties. Pinellia should not be used by pregnant women, those suffering from blood disorders, particularly if there is bleeding, **fever** or conditions which cause heat in the body. Pinellia is used to treat **morning sickness**, but only under the strict supervision of an experienced herbalist.

A general precaution to observe when using any Chinese patent medicine is to purchase only well-known brands recommended by a practitioner of **traditional Chinese medicine**. Cases have been reported of incorrect labeling, contamination with heavy metals, and substitution of Western pharmaceuticals for the Chinese ingredients. Any of these occurrences can present a serious health hazard.

Side effects

Pinellia is registered as a toxic herb in the United States and should be used with caution. The Chinese Materia Medica also acknowledges that it has toxic potential. Never use the herb in its raw form or exceed the recommended doses of herbal mixtures containing pinellia.

Pinellia has been reported to trigger asthmatic attacks in people who have been sensitized to it.

Interactions

Pinellia should not be taken in conjunction with aconite, as it may increase the toxic properties of this substance.

Pityriasis rosea

Definition

Pityriasis rosea is a skin disease of uncertain origin characterized by lesions bordered by collar-like areas that tend to peel off in tiny scales. Pityriasis comes from the Greek word for bran, *pityron*, because the flakes of skin shed from the lesions resemble small pieces of wheat bran. Rosea comes from a Latin word that means "rose-colored" or "pink."

Description

Pityriasis rosea is a common benign skin disease, or exanthem, that was first described by a French physician named Camille Gibert in 1860. It is classified as a papulosquamous disorder, which means that its lesions are marked by small raised areas (papules) as well as scaly areas. Pityriasis rosea begins in 60%–90% of patients with a pinkish-brown or salmon-colored herald patch—sometimes called a mother patch—on the chest, back, or neck. The herald patch is a small spot when it first appears, but enlarges over a period of several days to form a circular or oval-shaped area between 3/4-in and 2-1/2 in in diameter. The herald patch develops a scaly border known as a collarette, and is often misdiagnosed in its early stages as **eczema** or ringworm.

The herald patch is followed within 5–10 days by a series of similar but smaller oval-shaped patches that appear on the patient's chest, back, and legs, although the general eruption may appear as rapidly as a few hours after the herald patch or as long as three months later. The general rash lasts for about six weeks. The smaller patches range between 1/8 in and 1/2 in in diameter, and are sometimes described as resembling cigarette paper. Lesions on the trunk and abdomen are commonly distributed along the midline of the body in a pattern resembling the outline of a Christmas tree. The lesions of the general eruption are found most commonly on the chest, back, and upper arms, but are sometimes limited to such smaller areas of the body as the armpits, groin, palms of the hands, or feet. Between 9% and 16% of patients develop ulcers or plaques inside the mouth. It is relatively unusual, however, for patches to appear on the face. A small minority of patients may have the herald patch as the only sign of pityriasis rosea.

Pityriasis rosea is a common skin disorder, accounting for 3% of visits to dermatologists in the United States and Canada. The overall prevalence of the disease in the general North American population is thought to be about 0.13% in males and 0.14% in females. It is rare in infants and the elderly; most cases are diagnosed in persons between the ages of 10 and 35. Pityriasis rosea tends to cluster in families, which is one reason why some researchers have been investigating various viruses as possible causes; however, it is not known to spread by casual contact. The disease affects all races and ethnic groups equally.

Pityriasis rosea may occur at any time of year but is most common in temperate climates in the spring and fall.

KEY TERMS

Collarette—The slightly raised area of scaly skin that forms at the borders of the herald patch and later lesions of pityriasis rosea.

Exanthem—A skin eruption or rash. The term is also used for diseases that have skin rashes as a prominent feature (e.g., measles). Pityriasis rosea is an example of an exanthem.

Herald patch—The initial skin eruption of pityriasis rosea, usually on the back or chest, that occurs a week or two before the main outbreak. It is sometimes called the mother patch.

Papule—A small solid raised area of skin, no more than 1 cm in diameter. The skin lesions associated with pityriasis rosea may include papules as well as scales or flakes of skin.

Prodromal—Referring to warning symptoms that occur before the onset of a disease or disorder.

Pruritus—The medical term for itching. Pruritus is a common symptom of pityriasis rosea.

Topical—Referring to medications applied to the skin or exterior of the body.

Causes and symptoms

Causes

The cause of pityriasis rosea is debated as of early 2004. Various researchers have reported isolating a mycoplasma (a type of gram-negative bacterium), a picornavirus, and human herpesviruses 6 and 7 from skin samples of patients diagnosed with the disease, but these findings are not yet considered definitive. Certain medications, including diphtheria vaccines, barbiturates, gold, bismuth compounds, captopril (Capoten), metronidazole (Flagyl), isotretinoin (Accutane), clonidine (Catapres), omeprazole (Prilosec), penicillamine (Cuprimine or Depen), and terbinafine (Lamisil) have been reported to cause skin **rashes** that resemble the lesions of pityriasis rosea. High levels of emotional **stress** appear to increase the severity of the skin lesions in some patients.

Symptoms

The most common symptom associated with the lesions of pityriasis rosea is pruritus or **itching**, which affects about 75% of patients, with 25% reporting severe itching. Many patients find that athletic activity or hot weather makes the itching worse. In addition to pruritus, some patients have prodromal symptoms, which are warning symptoms that occur before the herald patch appears. Prodromal symptoms of pityriasis rosea may include **fever**, loss of appetite, **nausea**, **headache**, joint pains, and swelling of the lymph nodes. Lymph node swelling is more common among African Americans diagnosed with the disease than among Caucasian or Asian Americans.

Diagnosis

The diagnosis of pityriasis rosea is usually made through taking a patient history—with particular attention to prescription medications—and a skin biopsy ordered by a dermatologist. Although there is no blood test for pityriasis rosea itself, most primary care physicians will order a rapid plasma reagin (RPR) or Venereal Disease Research Laboratory (VDRL) blood test to screen for **syphilis**. The reason for this precaution is that the lesions of pityriasis rosea resemble the skin rash associated with secondary syphilis. The skin biopsy is done to distinguish between pityriasis rosea and such other skin diseases as lichen planus, **psoriasis**, ringworm, **Kaposi's sarcoma**, and seborrheic **dermatitis**.

Treatment

Pityriasis rosea is a self-limiting disease, which means that it goes away on its own even without alternative or allopathic treatment. Both mainstream physicians and naturopaths, however, recommend adding a cup of oatmeal or baking soda to a tub of warm (not hot) water to minimize itching. In addition, patients whose lesions increase in size or number due to emotional stress may be helped by **hydrotherapy**, **aromatherapy**, **meditation**, or other therapies intended to reduce stress. **Massage therapy**, however, is contraindicated because the disease usually affects large areas of skin.

Homeopathic practitioners suggest the following remedies for pityriasis rosea, to be taken in 6C potency four times daily for 7 days:

- *Arsenicum*. Recommended for patients whose rash is accompanied by anxiety, restlessness, and thirst.
- *Radium bromide*. For patients whose lesions are fiery red in color, burning, and painful.
- *Natrum muriaticum*. For patients whose lesions have a red appearance under thin white scales, or whose pruritus is made worse by warmth or exercise.

In addition, a homeopathic remedy known as *Urtica urens* is available in cream or ointment form for direct application to affected areas.

Allopathic treatment

Allopathic treatment of pityriasis rosea is directed toward symptom relief, as the cause of the disease is still uncertain. To relieve the itching, the doctor may prescribe calamine lotion, **zinc** oxide ointment, oral antihistamine medications, or topical ointments containing corticosteroids or a combination of phenol and 25% menthol. Some physicians prescribe creams containing pramoxine, a local anesthetic. Steroid medications taken by mouth are not recommended unless the pruritus is extremely severe; although these drugs relieve itching, they may also prolong the course of the disease or make the lesions worse.

Some patients are benefited by exposure to sunlight or by treatment with ultraviolet light; however, there is some risk that the skin lesions will develop hyperpigmentation (become darker than the surrounding skin) after ultraviolet treatment. Hyperpigmentation is most likely to occur in African American patients.

There is no need to keep children with pityriasis rosea from attending school, as the disease is not considered contagious.

Expected results

The prognosis for patients with pityriasis rosea is excellent. The disease does not cause long-term health problems, is not dangerous even during **pregnancy**, and usually clears completely in 6–8 weeks. A few patients have lesions that last as long as 3–4 months, but fewer than 3% of patients experience recurrences.

Prevention

As the cause of pityriasis rosea is still debated as of 2004, there are no known preventive measures.

Placebo effect

Definition

A placebo effect occurs when a treatment or medication with no therapeutic value (a placebo) is administered to a patient and the patient's symptoms improve. The patient believes and expects that the treatment is going to work; therefore, it does. The placebo effect is also a factor to some degree in clinically effective therapies and explains why some patients respond better than do others to treatment despite similar symptoms and illnesses.

Origins

The word placebo is from the Latin "I shall please." Throughout most of medical history, the placebo effect was the principal treatment physicians offered their patients; for example, reassurance, attention, and belief in treatment would mobilize patients' internal powers to fight their illnesses. This effect is apparent in indigenous cultures using shamanistic healing, which places healing power in objects and rituals. In fact, placebos are sometimes called sham treatments.

Placebos were used throughout the nineteenth century in blind assessments of medical treatments. These blind assessments were created to test controversial medical treatments of the time (e.g., mesmerism and **homeopathy**) and involved using a blindfold on or withholding information from patients so they were unaware of the exact nature of the treatment being studied. For example, in blind assessments of homeopathy conducted in 1834 in France, homeopathic remedies were replaced with an inert placebo substance without the patient's knowledge. These blind assessments were the forerunners to modern double-blind randomized controlled trials used in drug development and in the study of other therapeutic techniques.

According to some medical historians, from the early 1800s through as late as World War II, placebos (usually in the form of sugar pills or saline injections) were regularly prescribed for up to 80% of patients. Doctors used placebos to appease patients when no effective treatment for their symptoms was available or prescribed placebos to patients they perceived as difficult.

The first documented American clinical study using placebos was conducted in the late 1920s. In 1937 scientists at Cornell University Medical School published a study on an **angina** drug that used placebo and blind assessment techniques. They found that the patients who were given a placebo instead of the angina drug experienced an improvement of symptoms. This was the first published account in the United States that discussed the possible therapeutic value of the placebo effect.

Benefits

The placebo effect is usually positive by its nature because it indicates that a patient believes in the therapy and that the therapy has some sort of a beneficial effect. The placebo effect has been documented in a wide variety of diseases and disorders. Certain conditions such as headaches, arthritis, and **hot flashes** are especially responsive to placebos, as are some individuals.

Description

Every available medical treatment is subject to the placebo effect. If patients believe the therapy will benefit them, it usually will to some degree. Even if the placebo does not improve the symptoms directly, the peace of mind patients may feel after taking a treatment they believe will help them is often enough to encourage a sense of improved well-being. For this reason, controlled, scientific studies are so crucial to determining the actual clinical efficacy of medications and therapies.

The person prescribing the placebo treatment may also have an impact on the effect it has on the patient. For example, the doctor's enthusiasm about a new

treatment may heighten its placebo effect for the patient. In addition, if a healthcare provider is perceived as a trusted, well-respected figure by the patient, the patient may experience benefits from any treatments the provider prescribes.

Placebos are often used in scientific trials of new medications and treatments to determine their efficacy. A randomly selected group of study subjects known as the control group is given placebo medication (usually a sugar or water-based substance) or treatment while the rest of the subjects are administered the actual therapy. The patients do not know which group they are in during the study, and the researchers and study authors do not know which subjects are in which group (hence the term double-blind). This system helps researchers to determine if new treatments work because they are clinically effective or because the subjects believe they will work.

Some authorities have estimated that the average placebo effect is 33%, though it can range lower and higher. Therefore, to demonstrate that a treatment, procedure, or medication is effective, a trial has to show that it does significantly better than the placebo given to a control group. For example, a study of single-remedy homeopathy was conducted with a group of 487 patients with an influenza-like syndrome. Patients treated with a single, non-individualized remedy were 70% more likely to have recovered within 48 hours than those receiving the placebo. Mathematical analysis allows a researcher to determine whether this effect is statistically significant or not.

Preparations

Placebos have therapeutic value only if the patient believes they will work. If the healthcare provider elicits trust and respect and engenders comfort, the patient is likely to find the prescribed treatments beneficial, whether they are clinically effective or unproven.

The use of a placebo in scientific studies requires informed consent of the entire population of subjects. The study subjects must know that they have a 50/50 chance of receiving a placebo treatment instead of the treatment under investigation.

Precautions

Using placebos with patients presents ethical issues if the healthcare provider knows there is no therapeutic value to the treatment and other available treatments could possibly benefit the patient. For patients with progressive or life-threatening illnesses, taking a medication or therapy with no clinical value other than its placebo effect can be harmful if it causes them to ignore proven treatments that could improve their condition.

Some clinical trials of surgical procedures require the placebo or control subjects to undergo what is essentially unnecessary surgery, involving incisions and other invasive procedures while the final therapeutic portion of the procedure is withheld (the placebo). Although as of 2008 this is standard scientific procedure recommended by the U.S. Food and Drug Administration (FDA) for the approval of new medical procedures and devices, it is also commonly accepted knowledge that unnecessary surgery is never beneficial to a patient and can result in serious complications such as infection, hemorrhaging, and possible death.

Side effects

The placebo effect can have a negative influence also, a nocebo. If a placebo is given that patients believe to be harmful to their health in some way, the patients may develop symptoms appropriate to this belief. A toxic or negative placebo suggests the great degree to which attitudes and expectations can affect one's state of health or course of an illness. People who believe they have been cursed or are the victim of voodoo have been known to die.

Research and general acceptance

The placebo effect is a well-known phenomenon in the scientific community, and clinical trials and other scientific studies are built around it. Ethical concerns can arise when there is a risk that patients are not getting the potentially life-saving treatments they need. In some cases, the placebo effect is enough to compensate for this lack. For example, a study published in the *Archives of General Psychiatry* found that in 45 controlled trials of antidepressants, subjects in the control group experienced a significant positive therapeutic effect with the placebo only. In cases of treatments involving potentially fatal diseases such as **cancer** and **AIDS**, the ethical implications of placebo use may not be as clear-cut.

Surgical placebo procedures, which are a relatively new type of clinical study, are not as universally accepted as placebo drug trials. A heated debate in the medical community concerns the value of such studies. However, the use of placebo surgery for controlled clinical trials is endorsed by the National Institutes of Health, the medical research arm of the U.S. Department of Health and Human Services.

KEY TERMS

Double-blind randomized controlled trial—A study that uses two groups of subjects. One group (the experimental group) receives the treatment being tested, while the other group (the control group) receives a placebo. Double-blind means that neither the subjects nor the researchers know which subjects are in which group.

Homeopathy—A practice of medicine based on the theory that certain substances that produce a specific symptom will cure those same symptoms if administered in small, extremely diluted doses.

Plantain

Description

Plantain, *Plantago major*, was considered to be one of the nine sacred herbs by the ancient Saxon people, and has been celebrated in Anglo-Saxon poetry as the "mother of herbs." There are more than 200 species of plantain and nearly as many recorded uses for this humble herb. Plantain is native to northern and central Asia and Europe. Early colonists brought plantain to North America as one of their favored healing remedies. Native Americans called this persistent herb "white man's foot" as it is often found growing along well-trodden foot paths. The Latin generic name means "sole of the foot." The indigenous Americas adopted many of the traditional European uses for this beneficial herb. They also used the plant to draw out the poison of rattlesnake bite, to soothe rheumatic **pain**, as a poultice to treat battle **wounds**, and as an eyewash. They used the fresh young leaves and seeds in their diet.

Plantains. *(© foodfolio / Alamy)*

Plantain is a member of the Plantaginaceae family. Some of the familiar species, naturalized throughout North America, are: *Plantago major*, commonly known as common plantain, dooryard plantain, broad-leaved plantain, greater plantain, round-leafed plantain, way bread, devil's shoestring, bird seed, snakeweed, and white man's foot; *Plantago media L.*, known as hoary plantain; and *Plantago lanceolata L.*,

also known as English plantain, lance-leaf plantain, buckhorn, chimney-sweeps, headsman, ribgrass, ribwort, ripplegrass, hen plant, snake plantain, fire weed, and soldier's herb. Two species of plantain, valued medicinally primarily for the seed, are *Plantago psyllium L.* and *Plantago indica*, also known as flea seed and plantago. The dried, ripe seeds of these species, generally called **psyllium**, is high in mucilage and is widely used as a bulk-forming laxative.

Plantain is a hardy and prolific perennial found in fields, lawns, roadsides, footpaths, and marginal areas throughout the temperate regions of the world. It thrives even in poor, compacted soil. The sturdy leaves and flower stalks grow in a basal rosette directly from the mass of light-brown rootlets. Depending on the species, the leaves are broadly ovate or narrow and lance-like. The dark-green leaves have distinct, parallel ribs along their length and are slightly bitter to the taste. The yellow-green stamens and the rust-colored sepals of the tiny flowers encircle the wand-like spikes at the end of each stalk. Plantain's flower spikes resemble tiny cattail spikes. The yellow-green stamens are more prominent in *P. lanceolata L.*, encircling the flower spike like a delicate wreath. The tapered flower spikes in this species are longer than those of *P. major* stretching up well beyond the height of the basal leaves. Plantain flowers from June through September. Blossoms are followed by flea-size, light-brown seeds. The plant may reach to 2 ft (0.6 m) in height, and self-seeds freely.

General use

The leaves and seeds of plantain are most often used medicinally. The fresh leaves, crushed and applied to wounds, sores, insect **bites**, bee and wasp **stings**, **eczema**, and sunburn are healing to tissue because of the high allantoin content. Plantain is an ancient remedy used widely for relieving coughs, **bronchitis** , **tuberculosis**, **sore throat**, **laryngitis**, urinary **infections**, and digestive problems. The infusion has been used as a blood purifying tonic, a mild expectorant, and a diuretic. The juice from crushed leaves may also stem the flow of blood from **cuts**, and soothe the itch of poison ivy or the sting of **nettle** (*Urtica dioica*). The root of the herb has been used to relieve **toothache**. The juice may relieve **earache**. A decoction of plantain has been used in douche preparations to relieve leucorrhea, and the juice or infusion can ease the pain of ulcers and inflammation of the intestines. All plantains contain high amounts of mucilage and tannin, and have similar medicinal properties. Plantain is high in minerals and vitamins C and K.

KEY TERMS

Astringent—Any preparation or medication that causes the soft tissues of the body to contract or tighten.

Demulcent—A soothing substance or medicine, often containing mucilage, used to calm irritated mucous membranes.

Diuretic—A herbal preparation or medication given to increase urinary output.

Expectorant—A drug given to help bring up mucus or phlegm from the respiratory tract.

Mucilage—A gummy or gel-like substance present in plants.

Plantain is used throughout the world. It is an effective treatment for chronic **colitis**, acute **gastritis**, enteritis, and enterocolitis according to the Russian Ministry of Health. The German Commission E, an advisory panel on herbal medicines for that country, lists plantain as a safe and effective herb with demulcent, astringent and antibacterial properties. A poultice (salve prepared from the leaf) or an infusion used as a skin wash, have been shown to reduce pain, **itching**, and bleeding from **hemorrhoids**. Studies in Italy and Russia have confirmed plantain's usefulness as a weight-loss remedy. In Chinese medicine plantain is considered a remedy for male **impotence**. The species *P. major* and *P. lanceolata* contain mucilage, the iridoid glycosides cubin and catapol, flavonoids, tannins, and **silica**.

Plantain seeds, particularly those of the species *P. psyllium* and *P. ovata* soaked in water and ingested, are widely used as a gentle and safe bulk laxative and antidiarrheal. Plantago seeds from these two species are listed in *The United States Pharmacopoeia XXII* as an official laxative herb. Psyllium is found in numerous commercial laxative preparations. Psyllium seed has also been proven beneficial in reducing high levels of blood **cholesterol**. Psyllium seeds contain a high mucilage content in addition to other phytochemicals including monoterpene alkaloids, glycosides, sugars, triterpenes, fixed oil, fatty acids, and tannins. The entire plant may be used with an alum mordant to dye wool a bronze-gold color. A newer use of plantain starch is in the manufacture of pharmaceuticals; like corn starch, plantain starch can be used as an inert ingredient to mix with drugs in order to form tablets containing consistent measured doses of the drugs.

Preparations

Harvest plantain leaves throughout the spring and summer, before the herb is in full blossom. Fresh young leaves may be eaten in salads or cooked as a potherb. The juice of fresh, bruised leaves has an antibacterial effect. However this property is lost when the herb is infused with boiling water. Harvest seeds when they can be easily removed from the flower spikes. Dry the leaves quickly to avoid discoloration and store in clearly labeled, dark glass containers.

Leaf infusion: Place 2–4 tbsp of fresh plantain leaf, half if dried, in a warmed glass container. Bring 2-1/2 c of fresh, non-chlorinated water to the boiling point, add it to the herbs. Cover. Steep five to seven minutes. No need to decoct plantain leaves. Drink warm or cold throughout the day, up to three cups per day. The prepared tea will store for about two days in the refrigerator in a sealed jar.

Tincture: Combine 4 oz of finely-cut, fresh plantain leaf, or 2 oz dry, powdered herb with one pint of brandy, gin, or vodka, in a glass container. Cover and store the mixture away from light for about two weeks, shaking several times each day. Strain and store in a tightly capped, clearly labeled, dark glass bottle. A standard dose is 10–30 drops of the tincture in water, up to three times a day.

Precautions

Pregnant women should not use plantain, particularly the laxative psyllium preparations. Nursing mothers should consult a qualified herbalist before using psyllium or treating young children with the herb. Avoid inhaling psyllium seed powder as it may induce **asthma** attacks. Ingesting seeds without first soaking them in water may cause gastrointestinal problems. It is critical to drink large amounts of water when using psyllium, as the seeds absorb water in the intestine.

Persons who are interested in using herbal preparations as dietary supplements or to treat minor health conditions should note that the United States Food and Drug Administration (FDA) does not subject herbal preparations to the same set of regulations applied to prescription drugs. It is up to the manufacturer to make sure that a dietary supplement is safe before it is marketed. The FDA's role is that of post-marketing surveillance. Since the mid-1990s, there have been reports of herbal products that were mislabeled. In 1997, a young woman with a heart condition purchased a product that was labeled as "plantain" and experienced an abnormally rapid heartbeat. It turned out that the product was contaminated with **digitalis**, a powerful heart stimulant derived from **foxglove**. It is best to purchase herbs or herbal preparations only from established and reliable manufacturers. Questions about the safety of a specific product or reports of adverse reactions to a herbal product should be sent to the FDA's Center for Food Safety and Applied **Nutrition**, listed under Resources below.

Side effects

Psyllium seed and plantain may cause allergic reactions in sensitive persons.

Interactions

Plantain has been reported to decrease the absorption of digoxin (a heart medication) and lithium from the intestine. Its **Vitamin K** content may interfere with blood-thinning medications (anticoagulants). Plantain should not be taken together with prescription diuretics as it increases the risk of **potassium** loss from the bloodstream (hypokalemia). Persons taking any of these prescription medications should consult a physician before taking plantain as a dietary supplement.

Pleurisy

Definition

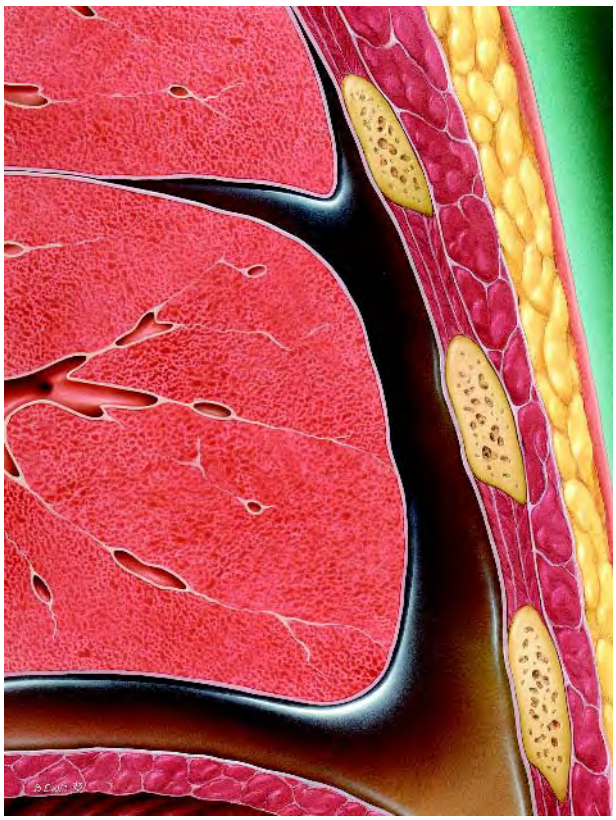
Pleurisy is an inflammation of the membrane that surrounds and protects the lungs (the pleura). Inflammation occurs when an infection or damaging agent irritates the pleural surface. Sharp chest pains are the primary symptom of pleurisy.

Description

Pleurisy, also called pleuritis, is a condition that generally stems from an existing respiratory infection, disease, or injury. In people who have otherwise good health, respiratory **infections** or **pneumonia** are the main causes of pleurisy. This condition used to be more common, but with the advent of antibiotics and modern disease therapies, pleurisy has become less prevalent.

The pleura is a double-layered structure made up of an inner membrane, which surrounds the lungs, and an outer membrane, which lines the chest cavity. The pleural membranes are very thin, close together, and have a fluid coating in the narrow space between them. This liquid acts as a lubricant, so that when the lungs inflate and deflate during breathing, the pleural surfaces can easily glide over one another.

Pleurisy occurs when the pleural surfaces rub against one another, due to irritation and inflammation. Infection within the pleural space is the most common irritant, although the abnormal presence of air, blood, or cells can also initiate pleurisy. These disturbances all act to displace the normal pleural fluid, which forces the membranes to rub, rather than glide, against one another. This rubbing irritates nerve endings in the outer membrane and causes **pain**.



Pleural effusion, the oozing of fluid from the blood or lymph into a pleural cavity, the space between the two layers of the pleura. *(Brian Evans / Photo Researchers, Inc.)*

Pleurisy also causes a chest noise that ranges from a faint squeak to a loud creak. This characteristic sound is called a "friction rub."

Pleurisy cases are classified either as having pleural effusion or as being "dry." Pleural effusion is more common and refers to an accumulation of fluid within the pleural space; dry pleurisy is inflammation without fluid build-up. Less pain occurs with pleural effusion because the fluid forces the membrane surfaces apart. However, pleural effusion causes additional complications because it places pressure on the lungs. This leads to respiratory distress and possible lung collapse.

Causes and symptoms

A variety of conditions can give rise to pleurisy. The following represent the most common sources of pleural inflammation:

- infections, including pneumonia, tuberculosis, and other bacterial or viral respiratory infections
- immune disorders, including systemic lupus erythematosus, rheumatoid arthritis, and sarcoidosis

KEY TERMS

Effusion—The accumulation of fluid within a cavity, such as the pleural space.

Empyema—An infection that causes pus to accumulate in the pleural space which may cause a tear in the pleural membrane and allow the infection to spread to other areas in the body.

Inflammation—An accumulation of fluid and cells within tissue that is often caused by infection and the resultant immune response.

Pneumonia—A condition caused by bacterial or viral infection that is characterized by inflammation of the lungs and fluid within the air passages.

Referred pain—The presence of pain in an area other than where it originates. In some pleurisy cases, referred pain occurs in the neck, shoulder, or abdomen.

- diseases, including cancer, pancreatitis, liver cirrhosis, and heart or kidney failure
- injury, from a rib fracture, collapsed lung, esophagus rupture, blood clot, or material such as asbestos
- drug reactions, from certain drugs used to treat tuberculosis (isoniazid), cancer (methotrexate, procarbazine), or the immune disorders mentioned above (hydralazine, procainamide, phenytoin, quinidine).

The hallmark symptom of pleurisy is sudden, intense chest pain that is usually located over the area of inflammation. Although the pain can be constant, it is usually most severe when the lungs move during breathing, coughing, **sneezing**, or even talking. The pain is usually described as shooting or stabbing, but in minor cases it resembles a mild cramp. When pleurisy occurs in certain locations, such as near the diaphragm, the pain may be felt in other areas such as the neck, shoulder, or abdomen (referred pain). Another indication of pleurisy is that holding one's breath or exerting pressure against the chest causes pain relief.

Pleurisy is also characterized by certain respiratory symptoms. In response to the pain, pleurisy patients commonly have a rapid, shallow breathing pattern. Pleural effusion can also cause shortness of breath, as excess fluid makes expanding the lungs difficult. If severe breathing difficulties persist, patients may experience a blue-colored complexion (cyanosis).

Diagnosis

The distinctive pain of pleurisy is normally the first clue physicians use for diagnosis. Doctors usually feel the chest to find the site of inflammation. A stethoscope is used to listen for abnormal chest sounds (such as the friction rub) as the patient breathes. Sometimes, a friction rub is masked by the presence of pleural effusion and further examination is needed for an accurate diagnosis.

To diagnose the illness that is causing pleurisy, doctors must evaluate the patient's history, additional symptoms, and laboratory test results. A chest x ray may also be taken to look for signs of accumulated fluid and other abnormalities. Computed tomography (CT) scan and ultrasound scans are more powerful diagnostic tools used to visualize the chest cavity.

The most helpful information in diagnosing the cause of pleurisy is a fluid analysis. Once the doctor knows the precise location of fluid accumulation, a sample is removed using a procedure called thoracentesis. In this technique, a fine needle is inserted into the chest to reach the pleural space and extract fluid. Several laboratory tests are performed to analyze the chemical components of the fluid and determine whether bacteria or viruses are present. Pleurisy associated with **rheumatoid arthritis** produces a distinctive pattern of tissue cells in the pleural fluid. Cancerous growths also shed cells into the tissue fluid. While most cases of pleurisy associated with **cancer** are secondary developments from a primary tumor, in some instances the pleurisy is the first indication of a malignancy.

In certain instances a biopsy of the pleura may be needed for microscopic analysis. A sample of pleural tissue can be obtained several ways: with a biopsy needle, by making a small incision in the chest wall, or by using a thoracoscope (a video-assisted instrument for viewing the pleural space and collecting samples).

Treatment

Alternative treatments can be used in conjunction with conventional treatment to help heal pleurisy. **Acupuncture** and botanical medicines are alternative approaches for alleviating pleural pain and breathing problems.

Herbal remedies

Poultices (crushed herbs applied directly to the skin) of respiratory herbs can assist in the healing process. An herbal remedy commonly recommended is pleurisy root (*Asclepias tuberosa*), so named because

of its use by early American settlers who learned of this medicinal plant from Native Americans. Pleurisy root helps to ease pain, inflammation, and breathing difficulties brought on by pleurisy. This herb is often used in conjunction with **mullein** (*Verbascum thapsus*) or elecampane (*Inula helenium*), which serve as expectorants to clear excess mucus from the lungs. Other respiratory herbs that are used in the treatment of pleurisy include **boneset** (*Eupatorium perfoliatum*), **catnip** (*Nepata cataria*), and **feverfew** (*Chrysanthemum parthenium*).

Herbs thought to combat infection, such as **echinacea** (*Echinacea* species), are also included in herbal pleurisy remedies. Antiviral herbs, such as *Lomatium dissectum* and *Ligusticum porteri*, can be used if the pleurisy is of viral origin.

Chinese medicine

Traditional Chinese treatments are chosen based upon the specific symptoms of the patient. The treatment principles are to harmonize the collaterals, regulate the qi, and possibly to treat stagnation of phlegm and blood. Acupuncture, ear acupuncture, and herbal remedies are used to treat chest pains. The herb **ephedra** (*Ephedra sinica*) opens air passages and alleviates respiratory difficulties in pleurisy patients. One pill of Xue Fu Zhu Yu Wan (Blood Mansion Eliminating Stasis Pill) can be taken twice daily to treat stabbing chest pain. The basic herbal formula, to which additional herbs are added for specific symptoms, is:

- Chuan Lian Zi (*Fructus meliae toosendan*), 10 g
- Jiang Xiang (*Ligum dalbergiae odoriferae*), 3 g
- Jie Geng (*Radix platycodi*), 5 g
- Xiang Fu (*Rhizoma cyperi*), 10 g
- Xuan Fu Hua (*Flos inulae*), 6 g
- Yan Hu Suo (*Rhizoma corydalis*), 10 g
- Yu Jin (*Tuber curcumae*), 10 g
- Zhi Ke (*Fructus aurantii*) 5 g

Other remedies

Other alternative remedies for pleurisy include:

- Aromatherapy. Essential oils can be effective when used as massage oils or inhaled with steaming water. Rosemary relieves pain. Peppermint relieves pain and decreases inflammation. Eucalyptus eliminates infection.
- Diet. Dietary recommendations include eating fresh fruits and vegetables, and adequate protein. The patient should ingest omega–3 fatty acids, which are fats with anti-inflammatory activity found in salmon, mackerel, herring, and flaxseed oil.
- Homeopathy. Homeopathic treatment, chosen by a trained practitioner based on the pattern of symptoms experienced by the patient, can be effective in resolving pleurisy.
- Hydrotherapy. Contrast hydrotherapy applied to the chest and back, along with compresses (cloths soaked in an herbal solution), can assist in the healing process.
- Supplements. Taking certain nutritional supplements, especially large doses of vitamin C, may also provide health benefits to persons with pleurisy.

Allopathic treatment

The pain of pleurisy is usually treated with analgesic and anti-inflammatory drugs, such as acetaminophen, ibuprofen, and indomethacin. Sometimes, a painful **cough** will be controlled with codeine-based cough syrups. However, as the pain eases, a person with pleurisy should try to breathe deeply and cough to clear congestion, otherwise pneumonia may occur.

The treatment used to cure pleurisy is determined by the underlying cause. Pleurisy from a bacterial infection is treated with antibiotics. Specific therapies designed for more chronic illnesses can often cause pleurisy to subside. In some cases, excess fluid must be removed by thoracentesis or a chest tube. If left untreated, a more serious infection, called empyema, may develop.

Expected results

Prompt diagnosis, followed by appropriate treatment, ensures a good recovery for most pleurisy patients. Generally speaking, the prognosis for pleurisy is linked to the seriousness of its cause.

Prevention

Preventing pleurisy is often a matter of providing early medical attention to conditions that can cause pleural inflammation. Maintaining a healthy lifestyle and avoiding exposure to harmful substances (for example, asbestos) are more general preventative measures.

Pneumonia

Definition

Pneumonia is an infection of the lung that can be caused by nearly any class of organism known to cause human **infections**. These include bacteria, amoebae, viruses, fungi, and parasites.

Description

Anatomy of the lung

To better understand pneumonia, it is important to understand the basic anatomic features of the respiratory system. The human respiratory system begins at the nose and mouth, where air is breathed in (inspired) and out (expired). The air tube extending from the nose is called the nasopharynx. The tube carrying air breathed in through the mouth is called the oropharynx. The nasopharynx and the oropharynx merge into the larynx. The oropharynx also carries swallowed substances, including food, water, and salivary secretion that must pass into the esophagus and then into the stomach. The larynx is protected by a trap door called the epiglottis, which prevents substances that have been swallowed, as well as substances that have been regurgitated (thrown up), from heading down into the larynx toward the lungs.

A useful method of picturing the respiratory system is to imagine an upside-down tree. The larynx flows into the trachea, which is the tree trunk, and thus the broadest part of the respiratory tree. The trachea divides into two tree limbs, the right and left bronchi. Each one of these branches off into multiple smaller bronchi, which course through the tissue of the lung. Each bronchus divides into tubes of smaller and smaller diameter, finally ending in the terminal bronchioles. The air sacs of the lung, in which oxygen-carbon dioxide exchange actually takes place, are clustered at the ends of the bronchioles like the leaves of a tree. They are called alveoli.

The tissue of the lung that serves only a supportive role for the bronchi, bronchioles, and alveoli is called the lung parenchyma.

Function of the respiratory system

The main function of the respiratory system is to provide oxygen, the most important energy source, for the body's cells. Inspired air (the air taken in when a person breathes) contains oxygen and travels down the respiratory tree to the alveoli. The oxygen moves out of the alveoli and is sent into circulation throughout the body as part of the red blood cells. The oxygen in the inspired air is exchanged within the alveoli for the waste product of human metabolism, carbon dioxide. The air people breathe out contains carbon dioxide. This **gas** leaves the alveoli during expiration. To restate this exchange of gases simply, humans breathe in oxygen, and they breathe out carbon dioxide.

Respiratory system defenses

The healthy human lung is sterile. There are normally no resident bacteria or viruses (unlike the upper respiratory system and parts of the gastrointestinal system, where bacteria dwell even in a healthy state). There are multiple safeguards along the path of the respiratory system. These are designed to keep serious, pathogenic organisms from invading and leading to infection.

The first line of defense includes the hair in the nostrils, which serves as a filter for larger particles. The epiglottis is a trap door of sorts, designed to prevent food and other swallowed substances from entering the larynx and then trachea. **Sneezing** and coughing, both provoked by the presence of irritants within the

respiratory system, help to clear such irritants from the respiratory tract.

Mucus produced by the respiratory system also serves to trap dust and infectious organisms. Tiny hair-like projections (cilia) from cells lining the respiratory tract beat constantly. They move debris trapped by mucus upwards and out of the respiratory tract. This mechanism of protection is referred to as the mucociliary escalator.

Cells lining the respiratory tract produce several types of immune substances that protect against various organisms. Other cells (called macrophages) along the respiratory tract actually ingest and kill invading organisms.

The organisms that cause pneumonia, then, are usually carefully kept from entering the lungs by these host defenses. However, when an individual encounters a large number of organisms at once, the usual defenses may be overwhelmed. Infection may happen either by inhaling contaminated air droplets or by aspiration of organisms inhabiting the upper airways.

Demographics

In the United States, pneumonia, in combination with **influenza**, is the eighth most common disease leading to death. An estimated 2.3 million Americans develop pneumonia each year, and about 58,500 die from it, according to 2004 statistics published by the Centers for Disease Control and Prevention (CDC). In developing countries, pneumonia ties with **diarrhea** as the most common cause of death.

Pneumonia is the most common fatal infection acquired by already hospitalized patients. Even in nonfatal cases, pneumonia is a significant economic burden on the healthcare system. One study estimates that people in the U.S. workforce who develop pneumonia cost employers five times as much in health care as the average worker.

Causes and symptoms

Causes

The list of organisms that can cause pneumonia is very large and includes nearly every class of infectious organism: viruses, bacteria, bacteria-like organisms, fungi, and parasites (including certain **worms**). Different organisms are more frequently encountered by different age groups. Further, other characteristics of individuals may place them at greater risk for infection by particular types of organisms:

- Viruses cause the majority of pneumonia cases in young children (especially respiratory syncytial virus, parainfluenza and influenza viruses, and adenovirus).
- Adults are more frequently infected with bacteria (such as *Streptococcus pneumoniae, Haemophilus influenzae,* and *Staphylococcus aureus*).
- Pneumonia in older children and young adults is often caused by the bacteria-like *Mycoplasma pneumoniae* (the cause of what is often referred to as "walking" pneumonia).
- *Pneumocystis carinii* is an extremely important cause of pneumonia in patients with immune problems, such as patients being treated for cancer with chemotherapy or patients with AIDS. Classically considered a parasite, it appears to be more related to fungi.
- People who have reason to come into contact with bird droppings, such as poultry workers, are at risk for pneumonia caused by the organism *Chlamydia psittaci.*
- A very large, serious outbreak of pneumonia occurred in 1976, when many people attending an American Legion convention were infected by a previously unknown organism. Subsequently named *Legionella pneumophila,* it causes what is was later called "Legionnaire's disease." The organism was traced to air conditioning units in the convention's hotel.

CONDITIONS PREDISPOSING TO PNEUMONIA. In addition to exposure to sufficient quantities of causative organisms, certain conditions may make an individual more likely to become ill with pneumonia. Certainly, the lack of normal anatomical structure could result in an increased risk of pneumonia. For example, there are certain inherited defects of cilia which result in less effective protection. Cigarette smoke, inhaled directly by a smoker or secondhand by an innocent bystander, interferes significantly with ciliary function, as well as inhibiting macrophage function.

Stroke, seizures, alcohol, and various drugs interfere with the function of the epiglottis. A weak epiglottis leads to a leaky seal on the trap door, with possible contamination by swallowed substances and/or regurgitated stomach contents. Alcohol and drugs also interfere with the normal **cough** reflex. This interference further decreases the chance of clearing unwanted debris from the respiratory tract.

Viruses may interfere with ciliary function, allowing themselves or other microorganism invaders (such as bacteria) access to the lower respiratory tract. One of the most important viruses is HIV (Human Immunodeficiency Virus), the causative virus in **AIDS** (acquired immunodeficiency syndrome). Between the 1980s and early 2000s this virus resulted in a huge

increase in the incidence of pneumonia. Because AIDS results in a general decreased effectiveness of many aspects of the host's immune system, a person with AIDS is susceptible to all kinds of pneumonia, which includes some previously rare parasitic types that would be unable to cause illness in an individual with a normal immune system.

The elderly have an increased risk of developing pneumonia due to a less effective mucociliary escalator, as well as immune system changes that occur naturally with the **aging** process.

Various chronic conditions predispose a person to infection with pneumonia. These include **asthma**, cystic fibrosis, and neuromuscular diseases that may interfere with the seal of the epiglottis. Esophageal disorders may result in stomach contents passing upwards into the esophagus, which increases the risk of aspiration into the lungs of those stomach contents with their resident bacteria. Diabetes, **sickle cell anemia**, lymphoma, **leukemia**, and **emphysema** also predispose a person to pneumonia.

Genetic factors appear to be involved in susceptibility to pneumonia. Certain changes in DNA appear to affect some patients' risk of developing such complications of pneumonia as septic shock.

Pneumonia is also one of the most frequent infectious complications of all types of surgery. Many drugs used during and after surgery may increase the risk of aspiration, impair the cough reflex, and cause patients to underfill their lungs with air. **Pain** after surgery also discourages patients from breathing deeply enough and from coughing effectively.

Radiation treatment for **breast cancer** increases the risk of pneumonia in some patients by weakening lung tissue.

In addition, the use of mechanical ventilators to assist patients in breathing after surgery increases their risk of developing pneumonia. This condition, now referred to as ventilator-associated pneumonia, has a mortality exceeding 50%.

Symptoms

Pneumonia is suspected in any patient who has **fever**, cough, chest pain, shortness of breath, and increased respirations (number of breaths per minute). Fever with a shaking chill is even more suspicious. Many patients cough up clumps of sputum, commonly known as spit. These secretions are produced in the alveoli during an infection or other inflammatory condition. They may appear streaked with pus or blood. Severe pneumonia results in the signs of oxygen deprivation, which includes blue appearance of the nail beds or lips (cyanosis).

The invading organism causes symptoms, in part, by provoking an overly strong immune response in the lungs. In other words, the immune system that should help fight off infections, kicks into such high gear, that it damages the lung tissue and makes it more susceptible to infection. The small blood vessels in the lungs (capillaries) become leaky, and protein-rich fluid seeps into the alveoli, which results in less functional area for oxygen-carbon dioxide exchange. The patient becomes relatively oxygen deprived, while retaining potentially damaging carbon dioxide. The patient breathes faster and faster, in an effort to bring in more oxygen and blow off more carbon dioxide.

Mucus production is increased, and the leaky capillaries may tinge the mucus with blood. Mucus plugs actually further decrease the efficiency of gas exchange in the lung. The alveoli fill further with fluid and debris from the large number of white blood cells being produced to fight the infection.

Consolidation, a feature of bacterial pneumonia, occurs when the alveoli, which are normally hollow air spaces within the lung, instead become solid, due to quantities of fluid and debris.

Viral pneumonia and mycoplasma pneumonia do not result in consolidation. These types of pneumonia primarily infect the walls of the alveoli and the parenchyma of the lung.

Severe acute respiratory syndrome (SARS)

Severe acute respiratory syndrome (SARS) is a contagious and potentially fatal disease that first appeared in the form of a multi-country outbreak in early February 2003 in Asia, North America, and Europe. The CDC later worked with the World Health Organization (WHO) to investigate the cause(s) of SARS and to develop guidelines for infection control. SARS was described as an atypical pneumonia of unknown etiology and the disease agent was identified as a previously unknown coronavirus.

Early symptoms of SARS include a high fever with **chills**, **headache**, **muscle cramps**, and weakness. This early phase is followed by respiratory symptoms, usually a dry cough and painful or difficult breathing. About 10 to 20% of patients require mechanical ventilation due to insufficient blood oxygen levels. The median incubation period of SARS is four to five days. The primary mode of transmission is direct mucus membrane (eyes, nose, and mouth) contact with infectious respiratory droplets. If the patient is isolated and receives prompt treatment within the first five days

after the onset of symptoms, the risk of infecting other people is greatly reduced, particularly if the SARS-designated care facility adheres to strict airborne precautions, according to the WHO. Treatments include antibiotics known to be effective against bacterial pneumonia; ribavirin and other antiviral drugs; and steroids. The mortality of SARS is estimated at 7 to 9%.

Diagnosis

For the most part, diagnosis of pneumonia is based on the patient's report of symptoms, combined with examination of the chest. Listening with a stethoscope reveals abnormal sounds, and tapping on the patient's back (which should yield a resonant sound due to air filling the alveoli) may instead yield a dull thump if the alveoli are filled with fluid and debris.

Laboratory diagnosis can be made of some types of bacterial pneumonia by staining sputum with special chemicals and looking at it under a microscope. Identification of the specific type of bacteria may require culturing the sputum (using the sputum sample to grow greater numbers of the bacteria in a lab dish.).

X-ray examination of the chest may reveal certain abnormal changes associated with pneumonia. Localized shadows obscuring areas of the lung may indicate a bacterial pneumonia, while streaky or patchy appearing changes in the x-ray picture may indicate viral or mycoplasma pneumonia. These changes on x ray, however, are known to lag behind the patient's actual symptoms.

Treatment

Pneumonia is a potentially serious condition that requires prompt medical attention. Patients should contact their doctors for immediate diagnosis and treatment. Alternative treatment such as nutritional support, however, can help alleviate some of the symptoms associated with pneumonia and boost the body's immune function.

Diet and nutrition

The following nutritional changes are recommended:

- Avoid all potentially allergenic foods and determine allergenic foods with an elimination diet.
- Reduce intake of sugar and processed foods.
- Get plenty of rest.
- Get plenty of fluids to prevent dehydration and help loosen phlegm.
- Consume nutritional supplements such as vitamins C, bioflavonoids, vitamin A, beta-carotene, and zinc.

Herbal treatment

Over-the-counter herbal preparations such as glycerol guaiacolate can help clear the lungs of phlegm and speed up the recovery process. Antimicrobial herbs, such as **goldenseal** (*Hydrastis canadenis*) and Chinese herbs, which stimulate the immune system, may be taken for treatment.

Other treatment

Other treatments include **yoga**, help with breathing, movement, and **relaxation**. Also recommended are **meditation** and the use of **guided imagery**. Individuals can contact local practitioners to enroll in such therapies.

Allopathic treatment

Prior to the discovery of penicillin antibiotics, bacterial pneumonia was almost always fatal. In the late 2000s, antibiotics, especially given early in the course of the disease, are very effective against bacterial causes of pneumonia. Erythromycin and tetracycline improve recovery time for symptoms of mycoplasma pneumonia. They do not, however, eradicate the organisms. Amantadine and acyclovir may be helpful against certain types of viral pneumonia.

Another antibiotic linezolid (Zyvox) was being used to treat penicillin-resistant organisms that cause pneumonia in the late 2000s. Linezolid is the first of a line of antibiotics known as oxazolidinones. Another drug known as ertapenem (Invanz) was reported to be effective in treating bacterial pneumonia.

Expected results

Rate of recovery varies according to the type of organism causing the infection. Recovery following pneumonia with *Mycoplasma pneumoniae* is nearly 100%. *Staphylococcus pneumoniae* has a death rate of 30 to 40%. Similarly, infections with a number of gram negative bacteria (such as those in the gastrointestinal tract which can cause infection following aspiration) have a high death rate of 25 to 50%. *Streptococcus pneumoniae,* the most common organism causing pneumonia, produces a death rate of about 5%. More complications occur in very young or very old individuals who have multiple areas of the lung infected simultaneously. Individuals with other chronic illnesses (including **cirrhosis** of the liver, congestive heart failure, individuals without a functioning spleen, and individuals who have other diseases that

KEY TERMS

Alveoli—The little air sacs clustered at the ends of the bronchioles, in which oxygen-carbon dioxide exchange takes place.

Aspiration—An action during which solids or liquids that should be swallowed into the stomach are instead breathed into the respiratory system.

Cilia—Hair-like projections from certain types of cells.

Consolidation—A condition in which lung tissue becomes firm and solid rather than elastic and air-filled because it has accumulated fluids and tissue debris.

Coronavirus—One of a family of RNA-containing viruses known to cause severe respiratory illnesses. In March 2003, a previously unknown coronavirus was identified as the causative agent of severe acute respiratory syndrome (SARS).

Cyanosis—A bluish tinge to the skin that can occur when the blood oxygen level drops too low.

Parenchyma—The supportive tissue surrounding a particular structure. An example is that tissue that surrounds and supports the actually functional lung tissue.

Sputum—Material produced within the alveoli in response to an infectious or inflammatory process.

result in a weakened immune system) experience complications. Patients with immune disorders, various types of **cancer**, transplant patients, and AIDS patients also experience complications.

Prevention

Because many types of bacterial pneumonia occur in patients who are first infected with the influenza virus, yearly vaccination against influenza can decrease the risk of pneumonia for the elderly and people with chronic diseases such as asthma, cystic fibrosis, diabetes, kidney disease, and cancer.

Maintaining a healthy diet that includes whole foods and **vitamin C** and B-complex vitamins aids in prevention. Also helpful in terms of both good health and prevention of pneumonia is developing a regular **exercise** regimen, as well as reducing **stress**.

A specific vaccine against *Streptococcus pneumoniae* is very protective and should also be administered to patients with chronic illnesses.

Patients who have decreased immune resistance are at higher risk for infection with *Pneumocystis carinii*. They are frequently put on a regular drug regimen of Trimethoprim sulfa and/or inhaled pentamidine to avoid Pneumocystis pneumonia.

Polarity therapy

Definition

Polarity therapy is a holistic, energy-based system that includes bodywork, diet, **exercise**, and lifestyle counseling for the purpose of restoring and maintaining proper energy flows throughout the body. The underlying concept of polarity therapy is that all energy within the human body is based in electromagnetic force and that disease results from improperly dissipated energy.

Origins

Austrian-American chiropractor, osteopath, and naturopath Randolph Stone (1888–1981) developed polarity therapy as an integration of Eastern and Western principles and techniques of healing. Stone discovered the ancient principles of the Ayurvedic philosophy in the course of his travels during a sojourn in India. On a life-long quest to learn the fundamentals of human vitality, he also studied **reflexology** and **traditional Chinese medicine**.

Stone became committed to the principles of **Ayurvedic medicine**, which he interpreted in conjunction with his scientific and medical knowledge to define polarity therapy. According to the philosophy of Ayurved, which is based in a set of principles called the tridosha—the energy of the human body is centered in five organs or regions (the brain; the cardiopulmonary [heart and lungs] region, the diaphragm, the smaller intestine, and the larger intestine). One of five airs or energy forms controls each respective region: prana in the brain, vyana in the heart and lungs, udana in the diaphragm, samana in the smaller intestine, and apana in the larger intestine. The five airs control all directional motion in the body, with each air in command of a different type of movement. Stone established further that the prana, centered in the brain, ultimately controlled the combined forces of the body. Any impediment or restriction to the flow of prana in turn affects the health of the entire body. The prana force is nurtured through the flow of food and air into the body as well as through our interactions with other living beings and through the intake of the five sensory organs.

Stone devoted much of his life to defining an elaborately detailed cause and effect relationship between the human anatomy and illness, based in the energy flow of the prana. He further attributed electromagnetic energy as the basis of the energy forces. He used the medical symbol of the Caduceus to define the patterns of the flow and described the energy movement in detail in charts of the human body. Polarity therapy is based in charted energy flows. The primary energy pattern is defined in a spiral motion that radiates from the umbilicus and defines the original energy flow of the fetus in the womb.

Benefits

Polarity therapy unblocks and recharges the flow of life energy and realigns unbalanced energy as a means of eliminating disease. Patients learn to release tension by addressing the source of the **stress** and by maintaining a healthy demeanor accordingly.

This treatment may be effective to promote health and healing to anyone willing to embrace the appropriate lifestyle. Polarity therapy is reportedly effective for anyone who has been exposed to toxic poisons. Likewise HIV-positive individuals may find comfort in polarity therapy. Additionally this is an appropriate therapy for relieving general stress, back **pain**, stomach cramps, and other recurring maladies and conditions.

Description

After determining the exact source of a patient's energy imbalance, the therapist begins the first of a series of bodywork sessions designed to rechannel and release the patient's misdirected prana. This therapy, akin to massage, is based in energetic pressure and involves circulating motions. In performing the regimen, the therapist pays strict attention to the pressure exerted at each location—even to which finger is used to apply pressure at any given point of the patient's anatomy. This technique, which comprises the central regimen or focal point of polarity therapy is very gentle and is unique to polarity therapy. It typically involves subtle rocking movements and cranial holds to stimulate body energy. Although firm, deep pushing touches are employed in conjunction with the massage technique, the polarity therapist never exerts a particularly forceful contact.

To support the bodywork, the therapist often prescribes a diet for the patient, to encourage cleansing and eliminate waste. The precepts of polarity therapy take into consideration specific interactions between different foods and the human energy fields.

Likewise, a series of exercises is frequently prescribed. These exercises, called polarity **yoga** include squats, stretches, rhythmic movements, deep breathing, and expression of sounds. They can be both energizing

KEY TERMS

Apana—life sustaining energy centered in the larger intestine; the fifth of the five airs of Ayurvedic philosophy; the life force governing expulsion activity.

Ayurveda—(Sanskrit, *Ayur,* life, and *veda,* knowledge) is translated as "knowledge of life" or "science of longevity." It became established as the traditional Hindu system of medicine.

Caduceus— the ancient and universal symbol of medicine consisting of the winged staff of Mercury and two intertwining serpents.

Prana—life sustaining energy centered in the human brain; the first of the five airs of Ayurvedic philosophy; the life force governing inspiration and the conscious intellect.

Primary energy pattern—a spiral motion that radiates from the umbilicus; the energy pattern associated with a child in the womb.

QV—quantum vacuum, a theory coined by physicists, which defines the interactions of energy that combine to form reality.

Reflexology—Belief that reflex areas in the feet correspond to every part of the body, including organs and glands, and that stimulating the correct reflex area can affect the body part.

Samana—life sustaining energy of the smaller intestine; the fourth of the five airs of Ayurvedic philosophy; the life force governing side-to-side motion.

Tridosha—the combination of three basic principles of energy, or biological humor, that comprise life, according to Ayurvedic philosophy.

Udana—life sustaining energy of the diaphragm, the third of the five airs of Ayurvedic philosophy, the life force governing upward motion.

Vyana—life sustaining energy of the heart and lungs; the second of the five airs of Ayurvedic philosophy; the life force governing circular motion.

and relaxing. Counseling may be included whenever appropriate as a part of a patient's highly individual therapy regimen to promote balance.

Preparations

Therapists take a comprehensive case history from every patient prior to beginning treatment. This preliminary verbal examination often monopolizes the first therapy session. Depending upon circumstances a therapist might have a need to assess the patient's physical structural balance through observation and physical examination.

Precautions

Polarity therapy is safe for virtually anyone, even the elderly and the most frail patients, because of the intrinsic gentleness of the **massage therapy**.

Side effects

Highly emotional releases of energy (laughter, tears, or a combination of both) are associated with this therapy.

Research and general acceptance

This is a complementary therapy of holistic, spiritually based treatment, which may be used in conjunction with a medical approach. Polarity therapy is practiced worldwide, but the majority of practitioners are based in the United States. Modern physicists employ concepts similar to Stone's basic theories of polarity in defining the quantum vacuum (QV) as a foundation of all reality. Still, by 2000, this holistic regimen had not achieved the widespread acceptance anticipated by Stone before his death in 1981.

When St. Paul Fire and Marine insurers offered a liability insurance package to therapy providers, the company recognized polarity therapy as an alternative medical treatment along with **acupuncture**, **biofeedback**, **homeopathy**, reflexology, and others.

Training and certification

The American Polarity Therapy Association (APTA) sanctions two levels of training. The Associate Polarity Practitioner (APP) is the preliminary level, based on a minimum level of excellence in this field. Registered Polarity Practitioner (RPP) is bestowed upon the graduates of an approved training curriculum. Post-graduate and specialty training is available in a variety of fields, and APTA certifies practitioners accordingly.

RANDOLF STONE (1890-1981)

Randolf Stone was born Rudolph Bautsch in 1890 in Austria. He immigrated with his family to the United States in 1898. As he grew, Stone started studying many medical practices and soon was experienced in the healing arts of naturopathy, osteopathy, and chiropractic. He changed his name to Randolf Stone in the 1920s.

Stone's quest for knowledge continued to grow. He soon turned to the study of physics, including quantum physics and the study of energy fields, in search of a more effective healing art. In pursuit of greater knowledge in these areas, he traveled throughout the United States. Additionally he returned to Europe and traveled to India to investigate the esoteric arts of different cultures.

Through his travels, Stone grew to believe in energy fields that surround people. When these fields are weak or disrupted, it results in sickness and disease. Stone developed polarity therapy. This is the manipulation of these human energy fields through nutrition, touch, and environmental factors. Stone based his theories of polarity therapy extensively on the precepts that he learned throughout the course of his travels, most fundamentally on the Ayurveda system of five energies that he learned in India. He also drew from his knowledge of chiropractic, naturopathy, and osteopathy medical treatments.

In 1947, Stone published his first book, *Energy,* discussing his views on the energy fields. He followed up this work with six other books, all expanding on polarity therapy. His writing, *The Physical Anatomy of Man,* became the foundation for all healing arts in the United States.

Polycystic ovary syndrome

Definition

Polycystic Ovary Syndrome (PCOS) is a collection of hormonal and metabolic imbalances marked by virilization, anovulation and polycystic ovaries.

Description

The condition known as PCOS was first defined by Drs. Stein and Leventhal in 1935, who observed that female patients with multiple **ovarian cysts** often had other distinct physical symptoms including excessive male-pattern hair growth, menstrual cycle disturbances leading to **infertility**, and **obesity**. In 2004, the American Society of Reproductive Medicine and European Society of Human Reproduction and Embryology redefined diagnostic criteria to include two out of three of the following: anovulation, hyperandrogenism, and polycystic ovaries.

Demographics

PCOS is the most common hormonal disorder of premenopausal women, affecting 5-7% of women of childbearing age. Symptoms typically begin to occur shortly after the onset of menses, however the syndrome may remain undiagnosed until later in life. There can be many different clinical presentations that fall under the category of PCOS. It has been suggested that PCOS may actually have several subcategories based on the variety of symptoms. The most common symptoms are excessive hair growth, menstrual irregularities and obesity. It is estimated that 95% of women with this collection of symptoms have PCOS.

Causes and Symptoms

The cause of PCOS is not fully understood. Several different mechanisms have been identified as contributing to PCOS: dysfunction of the central nervous system, ovarian disorders, and **insulin resistance**. Additionally, there appears to be a genetic component.

The central nervous system regulates autonomic processes of the body, and is in communication with

the endocrine system via the hypothalamus. The hypothalamus is responsible for regulating aspects of the autonomic nervous system and communicating with the pituitary gland via neuroendocrine agents. The hypothalamic hormone regulating reproduction, Gonadotropin-releasing hormone (GnRH), influences the pituitary gland to secrete follicle-stimulating hormone (FSH) and leutinizing hormone (LH). In PCOS, GnRH secretion is disrupted, resulting in elevated LH. The effect of LH on the ovary is to increase androgen production.

Alteration of ovarian function is another component of PCOS. Typically, there is a failure of the follicle to fully mature and ovulate. As a result, the ovaries may be quite enlarged by multiple unreleased follicles, now fluid-filled follicular cysts. Androgen production by the ovaries is enhanced, including testosterone and dehydroepiandrosterone (**DHEA**).

Metabolic alterations involving insulin likely play a role in PCOS. Between 40-80% of women with PCOS experience some degree of insulin resistance or dysglycemia, and about 40% will go on to develop Type II diabetes. Insulin resistance is the decreased sensitivity of insulin receptors of skeletal muscle. Decreased sensitivity to insulin leads to a need for more insulin to be released, resulting in chronically elevated levels of both insulin and glucose. Dysglycemia is certainly present in the general population and is not unique to PCOS, but there is a correlation between the two for many women. It has been proposed that the insulin resistance of PCOS is qualitatively different from that which occurs independently, and involves a problem with the signaling pathway of insulin. Insulin interferes with ovulation and the normal menstrual cycle.

In addition to the local effects of excess insulin, there are many systemic effects. About 40-60% of women with anovulatory menstrual cycles and PCOS are obese. The weight distribution tends to be abdominal, with an increased waist-to-hip ratio. This abdominal obesity is known to contribute to elevated risk of diabetes, **hypertension**, hyperlipidemia, and cardiovascular disease. Obesity further contributes to the abnormal hormone profile in women with PCOS by promoting estrogen conversion in adipose tissue.

Obesity is also linked with a decrease in sex-hormone-binding globulin (SHBG), a transport protein that binds to and carries estrogen and testosterone, which in their unbound form are metabolically active. The effect of estrogen on the ovary is to stimulate androgen production and increase ovarian receptors to LH, amplifying the androgen effect. Elevated testosterone produced by the ovary and unbound from SHBG is responsible for the symptoms of virilization that often occur with PCOS. These symptoms include excess hair growth, loss of hair from the head, and **acne**.

Testosterone is normally produced in small amounts by the ovaries and adrenal glands, as are weaker androgens **androstenedione**, dehydroepiandrosterone (DHEA) and dehydroepiandrosterone sulfate (DHEA-S). These can be converted to the highly active hormone dihydroxytestosterone (DHT) by the enzyme 5-a-reductase. Testosterone acts on receptors on hair follicles to promote hair growth, also known as hirsutism, on the chest, back, abdomen and face.

Hirsutism doesn't necessarily correlate with testosterone levels measured in the blood, as androgens may be elevated enough to cause hair growth and still be within normal limits on testing. The number of androgen receptors in the hair follicle determines the degree of hirsutism, and this has great genetic and ethnic variation.

Other skin changes may occur as part of the polycystic ovary syndrome. Acne is a fairly common symptom and presents as a result of an increase in circulating androgens. Skin discoloration at the neck and under the breasts, called *acanthosis nigricans*, is a unique symptom that is caused by elevated insulin. Skin tags, thickening of the skin (*hyperkeratosis*) and **infections** of hair follicles called *hydradenitis suppurativa* are also caused by hyperinsulinemia and may occur in PCOS.

Diagnosis

PCOS is considered a diagnosis of exclusion, made after a full workup to rule out other endocrine disorders. The first part of evaluation is a clinical assessment of medical history, family history and a physical examination. Signs and symptoms looked for on the physical exam include:

- hair loss on head
- facial hair growth: cheeks, chin, upper lip, sideburns
- acne
- thyroid enlargement
- skin discoloration
- skin tags
- body hair on chest, back, abdomen, between umbilicus and pubic area, thighs
- enlarged or tender ovaries
- weight, body mass index (BMI), waist-hip ratio

Next, the physician will order laboratory evaluation and ultrasound of the pelvis. A diagnosis of PCOS

can be made if the patient has clinical symptoms, laboratory abnormalities or multiple cysts on ultrasound. Often a woman will have all of these, but all two of the three must be present to make a diagnosis.

There are numerous laboratory tests that may be helpful for the diagnosis and management of PCOS. Many of these tests evaluate hormone levels:

- thyroid-stimulating hormone (TSH)
- prolactin
- LH and FSH
- testosterone, androstenedione, DHEA
- estrogen
- SHBG

Further tests to evaluate glucose regulation are indicated and include **fasting** glucose, insulin, and hemoglobin A1C (HgbA1C). HgbA1C measures glycosylated hemoglobin, a marker of the effects of prolonged elevated glucose. A glucose tolerance test (GTT) could also be performed, in which a series of serum samples are drawn after the patient consumes a standardized bolus of glucose. Fasting glucose and HgbA1C may be used to monitor treatment of insulin resistance.

Women with PCOS are at increased risk of cardiovascular disease, a problem associated with dysglycemia. Additional screening tests may be ordered:

- Lipid panel - includes total cholesterol, high-density and low-density lipoproteins (HDL and LDL), and triglycerides
- Homocysteine - a predictor of coronary, cerebral and peripheral vascular disease associated with vitamin B12 or folate deficiency
- C-Reactive protein (CRP) - a marker of inflammation and an independent risk factor for cardiovascular disease

Treatment

Conventional treatment for PCOS typically centers around drug therapy for dysglycemia. The most widely used drug is metformin (Glucophage), a non-sulfonylurea which increases cell receptor response to insulin, decreases intestinal absorption of glucose, and decreases production of glucose by the liver. Several studies have evidenced that metformin both decreases hyperinsulinemia and promotes ovulation in women with anovulatory cycles. It may also help with weight loss in overweight patients with PCOS.

Another pharmaceutical strategy for treating PCOS is suppressing ovarian function with oral contraceptive pills (OCPs). Treatment with OCPs will often initiate regular menses in women with **amenorrhea** or oligomenorrhea. The birth control pill decreases androgen levels, regulates menses and protects against uterine hyperplasia. However, there is conflicting evidence regarding the effect of OCPs on metabolic issues, some studies suggesting that oral contraceptive use promotes dysglycemia and leads to frank diabetes. Another obvious disadvantage of the oral contraceptive pill in PCOS is the problem of infertility.

Conventional treatment with PCOS seeking fertility is often metformin, clomifene, or a combination of the two. Clomifene (Clomid) acts on the ovaries to induce ovulation, and increases the rate of ovulation with use of metformin alone from 46% to 76%.

Women struggling with the often disruptive symptoms of PCOS may be seeking treatment for the virilizing effects of testosterone. One such treatment is spironolactone, a diuretic drug with antiandrogenic effects.

Nutrition/dietetic concerns

Of primary importance are lifestyle factors that can be modified to improve overall health and manage hyperinsulinemia. A high fiber diet rich in complex carbohydrates such as whole grains and vegetables, and avoidant of refined carbohydrates like pasta, breads, pastries and sweets, is crucial for glucose regulation. Developing dietary habits of eating small, frequent meals and snacks will help regulate glucose and insulin. Lean proteins consumed with every meal and snack make for slow-burning sources of fuel. Lastly, decreasing overall calorie consumption may be part of a holistic nutritional plan if weight loss is a goal of treatment. In overweight women, a loss of 10% body weight will reduce insulin resistance and often the weight loss alone can restore ovulation.

Regular **exercise** also reduces insulin resistance and promotes weight loss. Exercising five to seven days per week for thirty minutes is optimal. Walking or other movement after meals is another way to utilize excess circulating glucose, as active skeletal muscle is not dependent on insulin for its uptake.

Therapy

There are many complementary and alternative treatments for PCOS, often using similar strategies as pharmaceutical therapy to address insulin resistance, anovulation, infertility and hyperandrogenism. The goals of natural remedies for PCOS are to:

- increase insulin sensitivity, lower blood glucose and insulin levels
- induce ovulation and restore fertility

KEY TERMS

Adipose—Fat tissue, which can act as an endocrine organ by converting androgens to estrogen via the enzyme aromatase.

Adrenal glands—Composed of an outer cortex and inner medulla, the adrenal glands sit above both kidneys. The adrenal cortex produces several hormones including cortisol, DHEA, estrogen and progesterone, and aldosterone.

Amenorrhea—The absence of menses in women of childbearing age in the absence of pregnancy.

Androgen—Precursors to male hormones testosterone and androsterone.

Dysglycemia—Disrupted glucose regulation resulting in periods of hypoglycemia, hyperglycemia, elevated insulin and insulin resistance.

Hirsutism— Male-pattern growth of increased coarse hair in females.

Insulin—A protein produced by the pancreas, insulin regulates glucose uptake for use by cells.

Oligomenorrhea—Irregular, infrequent menses.

Virilization—Male sexual characteristics such as deepening voice, male-pattern hair growth and balding in women.

- lower estrogen and adrogens by increasing SHBG
- inhibit 5-alpha reductase to reduce conversion of androgens to dihydrotestosterone

Several nutrients are important cofactors needed for glucose metabolism. **Chromium**, often referred to as "glucose-tolerance factor," has been shown in several studies to lower blood glucose, insulin and Hgb A1C. Additionally, the botanical agents **fenugreek**, momordica, **gymnema** and cinnamon are used for lowering glucose and insulin.

The hyperandrogenism of PCOS can be improved by increasing SHBG and by inhibiting 5-a-reductase from converting androgens to dihydrotestosterone. **Saw palmetto** has traditionally been used in men with benign prostatic hypertrophy (BPH), and is anti-androgenic through its inhibition of 5-a-reductase. **Green tea**, soy and flax seeds have been found to increase SHBG, also acting to inhibit testosterone activity.

Menstrual irregularities including amenorrhea and anovulation often improve with management of insulin. Further treatments for hormone regulation include **acupuncture** and **botanical medicine**. Acupuncture has been shown to improve fertility when used in conjunction with conventional therapies. Western botanicals that may be helpful in PCOS include **black cohosh**, which may decrease elevated levels of LH.

Prognosis

The hormonal and metabolic imbalances of PCOS can usually be well managed with diet, exercise and medical or natural therapies.

Prevention

Because PCOS has an unclear etiology and includes a genetic component, it is difficult to determine how to prevent its onset. Maintaining a healthy weight and eating a nutritious diet low in refined carbohydrates are crucial in managing PCOS, and may help prevent some symptoms from developing.

Postpartum depression

Definition

Postpartum **depression** is a mood disorder that begins after **childbirth** and usually lasts at least six weeks.

Description

Postpartum depression, or PPD, affects approximately 15% of all childbearing women. The onset of postpartum depression tends to be gradual and may persist for many months or develop into a second bout following a subsequent **pregnancy**. Mild to moderate cases are sometimes unrecognized by women themselves. Many women feel ashamed and may conceal their difficulties. This is a serious problem that disrupts women's lives and can have effects on the baby, other children, partners, and other relationships. Levels of depression for fathers can also increase significantly.

Postpartum depression is often divided into two types: early onset and late onset. Early-onset PPD most often seems like the "blues," a mild brief experience during the first days or weeks after birth. During the first week after the birth, up to 80% of mothers experience the "baby blues." This period is usually a time of extra sensitivity; symptoms include tearfulness, irritability, **anxiety**, and mood changes, which tend to peak between three to five days after childbirth. The symptoms normally disappear within two weeks without requiring specific treatment apart from understanding, support, skills, and practice. In short, some depression, **fatigue**, and anxiety may fall within the "normal" range of reactions to giving birth.

Late-onset PPD appears several weeks after birth. It involves slowly growing feelings of sadness, depression, lack of energy, chronic fatigue, inability to sleep, change in appetite, significant weight loss or gain, and difficulty caring for the baby.

Causes and symptoms

Experts cannot always say what causes postpartum depression. Most likely, it is caused by a combination of factors that vary from person to person. Some researchers think that women are vulnerable to depression at all major turning points in their reproductive cycle, childbirth being only one of these markers. Factors before the baby's birth that are associated with a higher risk of PPD include severe **vomiting** (hyperemesis), premature labor contractions, and psychiatric disorders in the mother. In addition, new mothers commonly experience some degree of depression during the first weeks after birth. Pregnancy and birth are accompanied by sudden hormonal changes that affect emotions. Additionally, the 24-hour responsibility for a newborn infant represents a major psychological and lifestyle adjustment for most mothers, even after the first child. These physical and emotional stresses are usually accompanied by inadequate rest until the baby's routine stabilizes, so fatigue and depression are not unusual.

In addition to hormonal changes and disrupted sleep, certain cultural expectations appear to place women from those cultures at increased risk of postpartum depression. For example, women who bear daughters in societies with a strong preference for sons (such as Communist China) are at increased risk of postpartum depression. In other cultures, a strained relationship with the husband's family is a risk factor. In Western countries, domestic violence is associated with a higher rate of PPD.

Experiences of PPD vary considerably but usually include several symptoms.

Feelings:

- persistent low mood
- inadequacy, failure, hopelessness, helplessness

- exhaustion, emptiness, sadness, tearfulness
- guilt, shame, worthlessness
- confusion, anxiety, and panic
- fear for the baby and of the baby
- fear of being alone or going out

Behaviors:

- lack of interest or pleasure in usual activities
- insomnia or excessive sleep, nightmares
- not eating or overeating
- decreased energy and motivation
- withdrawal from social contact
- poor self-care
- inability to cope with routine tasks

Thoughts:

- inability to think clearly and make decisions
- lack of concentration and poor memory
- running away from everything
- fear of being rejected by the partner
- worry about harm or death to partner or baby
- ideas about suicide

Some symptoms may not indicate a severe problem. However, persistent low mood or loss of interest or pleasure in activities, along with four other symptoms occurring together for a period of at least two weeks, indicate clinical depression and require adequate treatment.

There are several important risk factors for postpartum depression, including the following:

- stress
- lack of sleep
- poor nutrition
- lack of support from one's partner, family, or friends
- family history of depression
- labor/delivery complications for mother or baby
- premature or postmature delivery
- problems with the baby's health
- separation of mother and baby
- a difficult baby (temperament, feeding, sleeping problems)
- pre-existing neurosis or psychosis

Diagnosis

Diagnosis of postpartum depression can be made through a clinical interview with the patient to assess symptoms.

Treatment

Postpartum depression can be effectively alleviated through counseling and support groups, so that the mother does not feel she is alone in her feelings. **Acupuncture**, **traditional Chinese medicine**, **yoga**, **meditation**, and herbs can all help the mother suffering from postpartum depression return to a state of balance.

Recommended herbal remedies to ease depressive episodes may include **damiana** (*Turnera diffusa*), ginseng (*Panax ginseng*), lady's slipper (*Cypripedium calceolus*), **lavender** (*Lavandula angustifolia*), oats (*Avena sativa*), **rosemary** (*Rosmarinus officinalis*), **skullcap** (*Scutellaria laterifolia*), St. John's wort (*Hypericum perforatum*), and vervain (*Verbena officinalis*). Women who are breastfeeding or are suffering from a chronic medical condition should consult a healthcare professional before taking any herbal remedies.

Some strategies that may help new mothers cope with the **stress** of becoming a parent include:

- Valuing her role as a mother and trusting her own judgment.
- Making each day as simple as possible.
- Avoiding extra pressures or unnecessary tasks.
- Trying to involve her partner more in the care of the baby from the beginning.
- Discussing with her partner how both can share the household chores and responsibilities.
- Scheduling frequent outings, such as walks and short visits with friends.
- Sharing her feelings with her partner or a friend who is a good listener.
- Talking with other mothers to help keep problems in perspective.
- Trying to sleep or rest when the baby is sleeping.
- Taking care of her health and well being.

Allopathic treatment

Several treatment options exist, including medication, **psychotherapy**, counseling, and group treatment and support strategies, depending on the woman's needs. One effective treatment combines antidepressant medication and psychotherapy. These types of medication are often effective when used for three to four weeks. Any medication use must be carefully considered if the woman is breastfeeding, but with some medications, continuing breastfeeding is safe. There are many classes of antidepression medications. Two of the most commonly prescribed for PPD are selective serotonin reuptake inhibitors (SSRIs) such as citalopram (Celexa),

KEY TERMS

Hyperemesis—Severe vomiting during pregnancy. Hyperemesis appears to increase a woman's risk of postpartum depression.

Postpartum—Following childbirth.

escitalopram (Lexapro), fluoxetine (Prozac), paroxetine (Paxil, Pexeva), and sertraline (Zoloft), and tricyclids, such as amitriptyline (Elavil), desipramine (Norpramin), imipramine (Tofranil), and nortriptyline (Aventyl, Pamelor). Nevertheless, medication alone is never sufficient and should always be accompanied by counseling or other support services. Also, many women with postpartum depression feel isolated. It is important for these women to know that they are not alone in their feelings. There are various postpartum depression support groups available in local communities, often sponsored by non-profit organizations or hospitals. Also, support information is available by calling the PPD helpline. Women can find a local support group by calling the Kristin Brooks Hope Center helpline at (800) 442-4673. For women who have thoughts of suicide, it is imperative to immediately call the toll-free 24-hour suicide hotline at (800) 784-2433.

Expected results

When a woman has supportive friends and family, mild postpartum depression usually disappears quickly. If depression becomes severe, a mother cannot care for herself and the baby, and in rare cases, hospitalization may be necessary. However, medication, counseling, and support from others usually work to cure even severe depression in three to six months.

Prevention

Exercise, including yoga, can help enhance a new mother's emotional wellbeing. New mothers should also try to cultivate good sleeping habits and learn to rest when they feel physically or emotionally tired. It is important for a woman to learn to recognize her own warning signs of fatigue and respond to them by taking a break.

Post-traumatic stress disorder

Definition

Post-traumatic **stress** disorder (PTSD) is a debilitating psychological condition trigged by a traumatic event, such as rape, war, a terrorist act, sudden or violent death of a loved one, natural disaster, or catastrophic accident. It is marked by recurring memories or thoughts of the event, "blunting" of emotions, increased arousal, and sometimes severe personality changes.

Description

Officially termed post-traumatic stress disorder since 1980, descriptions of post-traumatic stress were

Common characteristics that increase the risk of developing PTSD

Female

Middle-aged (40 to 60 years old)

No experience coping with traumatic events

Ethnic minority

Lower socioeconomic status

Children in the home

Having family members with PTSD

Pre-existing psychiatric condition

Primary exposure to the trauma

Living in traumatized community

Lacking a good support system (close family and friends)

(Illustration by Corey Light. Cengage Learning, Gale)

documented as early as the Civil War and in nineteenth century train crash victims. In the period between World War I and II, a condition known as "shell shock" or "battle fatigue" was recognized. Initially, it was thought that shrapnel entered the brain during battle explosions and caused small brain hemorrhages. When symptoms occurred in war veterans who had not been exposed to explosions, it was then often viewed as a character flaw.

In the 1970s, during and after the Vietnam War, post-traumatic stress received more serious research and documentation. In 1989, the National Center for Post-traumatic Stress Disorder was established in the U.S. Department of Veterans Affairs. Another benchmark was its addition to the third edition of the Diagnostic and Statistical Manual of Mental Disorders (DSM-III) published by the American Psychiatric Association. In the past 20 years, those who have been diagnosed with PTSD have been rape victims, victims of violent crimes, and survivors of natural disasters, terrorist attacks, and random shootings in schools and the workplace.

Although people of all ages, cultures, and socioeconomic backgrounds can develop PTSD if exposed to a life-threatening event, statistics gathered from past events indicate that the risk of PTSD increases in order of the following factors:

- female gender
- middle-aged (40 to 60 years old)
- little or no experience coping with traumatic events
- ethnic minority
- lower socioeconomic status
- children in the home
- women with spouses exhibiting PTSD symptoms
- pre-existing psychiatric conditions
- primary exposure to the event including injury, life-threatening situation, and loss
- living in a traumatized community

For example, over a third of the survivors of the 1995 Murrah Federal Building bombing in Oklahoma City developed PTSD and over half showed signs of **anxiety**, **depression**, and alcohol abuse. More than a year later, Oklahomans in general had an increased use of alcohol and tobacco products, as well as PTSD symptoms.

Children are also susceptible to PTSD and their risk is increased exponentially as their exposure to the event increases. Children experiencing abuse, the death of a parent, or those located in a community suffering a traumatic event can develop PTSD. Two years after the Oklahoma City bombing, 16% of children in a 100-mile radius of Oklahoma City with no direct exposure to the bombing had increased symptoms of PTSD. Weak parental response to the event, having a parent suffering from PTSD, and increased exposure to the event via the media all increase the possibility of the child developing PTSD symptoms.

Causes and symptoms

Specific causes for the onset of post-traumatic stress disorder are not clearly defined, although experts suspect it may be influenced both by the severity of the event, by the person's personality and genetic make-up, and by whether or not the event was expected. First response emergency personnel and those directly involved in the event or families who have lost loved ones in the event are most like to experience PTSD.

People exposed to mass destruction or death, toxic contamination, the sudden or violent death of a loved one, or the loss of home or community, are also at high risk for PTSD. Victims of human-caused trauma have a higher incidence of PTSD than those of natural disasters. Among rape and Holocaust survivors, the rate of PTSD is 50%.

A sampling of the types of traumatic events and the percentage of those exposed to them who develop PTSD includes:

- natural disaster, 4–5%
- mass shooting, 28%
- plane crash into hotel, 29%
- bombing, 34%

For men, events most likely to trigger PTSD are rape, combat exposure, childhood neglect, and childhood physical abuse. For women, these events are rape, sexual molestation, physical attack, threat with a weapon, and childhood physical abuse.

A related condition, Acute Stress Disorder (ASD), which occurs two days to four weeks after a traumatic event, is thought to be an indicator of the occurrence of PTSD. This is especially true if the following factors are present:

- lack of emotional and social support
- the presence of other stressors such as fatigue, cold, hunger, fear, uncertainty, and loss
- continued difficulties at the scene of the event
- lack of information about the event
- lack of self-determination
- treatment given in an authoritarian or impersonal manner
- lack of follow-up

PTSD symptoms are distinct and prolonged stress reactions that naturally occur during a highly stressful event. Common symptoms are:

- hyperalertness
- fear and anxiety
- nightmares and flashbacks
- sight, sound, and smell recollection
- avoidance of recall situations
- anger and irritability
- guilt
- depression
- increased substance abuse
- negative world view
- decreased sexual activity

Symptoms usually begin within three months of the trauma, although sometimes PTSD does not develop until years after the initial trauma occurred. Once the symptoms begin, they may fade away again within six months. Others suffer with the symptoms for far longer and in some cases, the problem may become chronic.

Among the most troubling symptoms of PTSD are flashbacks, which can be triggered by sounds, smells, feelings, or images. During a flashback, the person relives the traumatic event and may completely lose touch with reality, suffering through the trauma for minutes or hours at a time, believing that the traumatizing event is actually happening all over again.

Research conducted in the late 20th century suggests that PTSD sufferers undergo neurological and physiological changes stemming from altered brain activity. A decrease in size of the hippocampus (one of two seahorse-shaped parts of the brain generally believed by scientists to pay an essential role in formation of new memories) may affect the processing and integration of memory while abnormal activation of the amygdala (almond-shaped parts of the brain believed to have strong connections to mental and physical reactions) may be tied to fear response. This altered brain activity can lead to hyper-arousal of the sympathetic nervous system, increased sensitivity of the startle reflex, and sleep abnormalities.

The hormone levels of PTSD patients may also show abnormalities: for example, high levels of thyroid, epinephrine, and natural opiates coupled with low levels of cortisol. Blunted, or depressed, responses to a trauma may be the result of the body's increased production of opiates (narcotic-like hormones that induce mental lethargy), which masks the emotional **pain**.

People with post traumatic stress disorder are also like to suffer from other psychiatric disorders. Eighty-eight percent of men and 79% of women with PTSD meet the diagnostic criteria for other disorders. Physical ailments such as headaches, gastrointestinal ailments, immune system weaknesses, **dizziness**, chest pain, and general body discomfort are also common in PTSD sufferers.

Diagnosis

Consultation with a mental health professional for diagnosis and a plan of treatment is always advised. Many of the responses to trauma, such as shock, terror, irritability, blame, guilt, grief, sadness, emotional numbing, and feelings of helplessness, are natural reactions. For most people, resilience is an overriding factor and trauma effects diminish within six to sixteen months. It is when these responses continue or become debilitating that PTSD is often diagnosed.The third edition of the Diagnostic and Statistical Manual of Mental Disorders (DSM-III) outlined three forms of the disorder:

- Acute: onset within six months of the event and lasting less than six months
- Chronic: symptoms lasting six months or more
- Delayed: onset at least six months after the event

As outlined in DSM-IV, the exposure to a traumatic stressor means that an individual experienced, witnessed or was confronted by an event or events involving death or threat of death, serious injury or the threat of bodily harm to oneself or others. The individual's response must involve intense fear, helplessness, or horror. A two-pronged approach to evaluation is considered the best way to make a valid diagnosis because it can gauge under-reporting or over-reporting of symptoms. The two primary forms are structured interviews and self-report questionnaires. Spouses, partners and other family members may be interviewed. Because the evaluation may involve subtle reminders of the trauma in order to gauge a patient's reactions, individuals should ask for a full description of the evaluation process beforehand. Asking what results can be expected from the evaluation is also advised.

A number of structured interview forms have been devised to facilitate the diagnosis of post traumatic stress disorder:

- The Clinician Administered PTSD Scale (CAPS) developed by the National Center for PTSD
- The Structured Clinical Interview for DSM (SCID)
- Anxiety Disorders Interview Schedule-Revised (ADIS)
- PTSD-Interview
- Structured Interview for PTSD (SI-PTSD)
- PTSD Symptom Scale Interview (PSS-I)

Self-reporting checklists provide scores to represent the level of stress experienced. Some of the most commonly used checklists are:

- The PTSD Checklist (PCL), which has one list for civilians and one for military personnel and veterans
- Impact of Event Scale-Revised (IES-R)
- Keane PTSD Scale of the MMPI-2
- The Mississippi Scale for Combat Related PTSD and the Mississippi Scale for Civilians
- The Post Traumatic Diagnostic Scale (PDS)
- The Penn Inventory for Post-Traumatic Stress
- Los Angeles Symptom Checklist (LASC)

Treatment

A definitive treatment does not yet exist for PTSD nor is there a known cure. However, a number of therapies such as cognitive-behavior therapy, group therapy, and exposure therapy are showing promise. Cognitive-behavioral therapy focuses on changing specific actions and thoughts with the help of **relaxation** training and breathing techniques. In exposure therapy, the person relives the traumatic event repeatedly in a controlled environment and then works through the trauma.

A treatment technique known as eye movement desensitization and reprocessing (EMDR) has been employed with some success to treat PTSD. EMDR involves desensitizing the patient to his or her traumatic memories by associating a series of eye movements with both negative and positive events and emotions. The specific eye movements associated with the negative memories are thought to help the brain process the event and come to terms with the trauma. EDMR should only be performed by a healthcare practitioner, usually a clinical psychologist, certified in the technique.

Relaxation training, which is sometimes called anxiety management training, includes breathing exercises and similar techniques intended to help the patient prevent hyperventilation and relieve the muscle tension associated with the fight-or-flight reaction of anxiety. **Yoga**, aikido, t'ai chi, and **dance therapy** help patients work with the physical as well as the emotional tensions that either promote anxiety or are created by the anxiety.

Other alternative or complementary therapies are based on physiological and/or energetic understanding of how the trauma is imprinted in the body. These therapies affect a release of stored emotions and resolution of them by working with the body rather than merely talking through the experience. One example of such a therapy is Somatic Experiencing (SE), developed by Dr. Peter Levine. SE is a short-term, biological, body-oriented approach to PTSD or other trauma. This approach heals by emphasizing physiological and emotional responses, without re-traumatizing the person, without placing the person on medication, and without the long hours of conventional therapy.

When used in conjunction with therapies that address the underlying cause of PTSD, relaxation therapies such as **hydrotherapy**, **massage therapy**, and **aromatherapy** are useful to some patients in easing PTSD symptoms. **Essential oils** of lavender, chamomile, neroli, sweet marjoram, and ylang-ylang are commonly recommended by aromatherapists for stress relief and anxietyreduction.

Research into the prevention of PTSD is also undergoing intensive research. The National Mental Health Association provides RAPID grants that allow

researchers to visit disaster scenes to study acute effects and the effectiveness of early intervention. Rapid disaster relief and positive community response appear to be key. Not identifying individual survivors as "victims" also seems to help. Debriefing survivors as quickly as possible after the event can stem the development of PTSD symptoms.

Allopathic treatment

As of mid-2004, allopathic (medical practice that combats disease with remedies to produce effects different from those produced by the disease) treatment consists of a combination of medication along with supportive and cognitive-behavioral therapies. Effective medications include anxiety-reducing medications and antidepressants, especially the selective serotonin reuptake inhibitors (SSRIs) such as fluoxetine (Prozac) and sertraline (Zoloft). In 2001, the U.S. Food and Drug Administration (FDA) approved Zoloft as a long-term treatment for PTSD. In a controlled study, Zoloft was effective in safely improving symptoms of PTSD over a period of 28 weeks and reducing the risk of relapse. Sleep problems can be lessened by brief treatment with an anti-anxiety drug such as a benzodiazepine like alprazolam (Xanax). However, long-tem use of these drugs can lead to disturbing side effects, such as increased anger. The new research into the biological changes manifested in PTSD patients is leading to additional research on drugs used to monitor hormone levels and brain activity.

Expected results

With appropriate medication, emotional support, and counseling, most people show significant improvement. Behavior therapies can help reduce negative thought patterns and self talk. The patient typically moves back and forth through three recovery phases:

- Phase One, Safety: the elimination and/or management of dangerous behaviors and/or relationships. Becoming less fearful of thoughts, feelings, and dissociative (separated from the main stream of consciousness) episodes
- Phase Two: resolution of traumatic memory processing. Developing a narrative account of the trauma without becoming re-traumatized
- Phase Three: personality re-integration and rehabilitation

Successful treatment depends in part on whether or not the trauma was unexpected, the severity of the trauma, if the trauma was chronic (such as for victims of sexual abuse), and the person's inherent personality and genetic makeup. However, prolonged exposure to severe trauma such as experienced by victims of prolonged physical or sexual abuse and survivors of the Holocaust may cause permanent psychological scars.

Potassium

Description

Potassium is one of the electrolytes essential to the smooth running of the human body; in fact, just about all bodily functions depend on it to some extent. It is also one of the most abundant minerals in the body, constituting 70% of the positive ions inside cells; the rest are a mixture of **sodium**, **magnesium**, **calcium**, **arginine**, and others. Potassium is distributed to the cells by a process of passive diffusion and is regulated by an enzyme called adenosinetriphosphatase together with the level of sodium concentration inside the cell. Potassium and sodium are antagonistic, which means that an imbalance of one will automatically cause an imbalance of the other; normally potassium should predominate inside the cell.

General use

Potassium is necessary for normal cell respiration. A deficiency can cause decreased levels of oxygen, which will reduce the efficiency of cell function. Adequate supplies of potassium are also required to regulate heartbeat, facilitate normal muscle contraction, regulate the transfer of nutrients to cells, and regulate kidney function and stomach juice secretion, among other functions. One of the most important uses of potassium in the body is in the process of nerve transmission, as it is a cofactor catalyst for the activation of several enzyme systems, but since only minute amounts are required for these processes, deficiency in this respect is unlikely.

Potassium is thought to be therapeutically useful in many ways, including assisting in the treatment of **alcoholism** and **acne**, alleviating **allergies**, promoting the healing of **burns**, and preventing high blood pressure. It can also help with such problems as congestive heart failure, **chronic fatigue syndrome**, or **kidney stones**. People suffering from any of the above conditions should consider increasing their intake of potassium after talking to a professional.

Symptoms of potassium deficiency

A deficiency of potassium in the blood is referred to as hypokalemia and manifests itself in many ways. Among the most serious symptoms are arthritis, high blood pressure, **heart disease**, **stroke**, **cancer**, and even **infertility**, as potassium constitutes a vital element of seminal fluid.

Potassium deficiency will increase acid levels in the body, lowering the natural pH, which will have far reaching effects. Lack of potassium can also aggravate problems caused by lack of protein. If potassium levels are down, the liver cannot operate normally, particularly regarding transformation of glucose to glycogen. A healthy liver should have about twice as much potassium as sodium.

Potassium deficiency can cause problems with the formation of connective tissue and can render normally strong body tissue vulnerable to all kinds of problems. The collagen of a healthy person is approximately as strong as steel, and the strength of bone tissue can be likened to that of cast **iron**. Lack of potassium may create a susceptibility to **fractures**, skin lesions that do not heal, or other connective tissue problems. So important is potassium for the protection of collagen that many natural health gurus claim that along with other vital nutrients, it constitutes an essential element of protection against premature **aging**. In the 1920s, German physician Max Gerson became the first person ever to cure lupus lesions with a diet entirely raw fruit and vegetables designed to reduce abnormally high sodium levels and raise potassium levels to normal.

Potassium is essential to the efficient processing of foods in the body; without it they cannot be broken down into the proper compounds. This condition can lead to rheumatism, and is one reason why adequate potassium prevents rheumatism.

Potassium requirements

In the past potassium was more plentiful in the diet than salt, but gradually, the situation has been reversed. The widespread lack of potassium in modern **diets** is largely due to modern processing and high levels of salt added to most processed foods. Cooking and processing remove potassium, and added salt further robs the body of vital potassium. This departure from traditional cooking of fresh homegrown fruit and vegetables is likely the cause of many health problems faced by modern society.

Who needs potassium supplements?

Those who may need to take potassium supplements include women who take oral contraceptives, abusers of alcohol or drugs, smokers, athletes, workers whose job involves physical exertion, patients who have had their gastrointestinal tract surgically removed, anyone suffering from any degree of malabsorption syndrome, and vegetarians. People who have eating disorders, especially bulimia and anorexia, are particularly at risk of damage due to low potassium levels. Also, individuals who have been ill, anyone who has undergone surgery, and those who are taking cortisone or **digitalis** preparations, and those suffering from high levels of **stress** will probably have low potassium levels.

The U.S. Food and Drug Administration (FDA) has established a Daily Reference Value (recommended daily intake) of potassium as 3,500 mg. The actual average daily intake of potassium for Americans ranges significantly from a low of about 1,200 mg/day to as high as 4,000 mg/day. However, in general, nutritionists recommend reducing salt intake and ensuring adequate supply by increasing the amount of fresh fruit and vegetables in the diet.

If individuals feel that they may be suffering from a potassium deficiency but would like to make sure before taking supplements, there are a variety of laboratory tests that can be conducted. These include serum-potassium determinations (although these may be unreliable unless levels are very low), serum creatinine, electrocardiograms, serum-pH determinations, whole blood, sublingual cell smears, and red blood cell potassium level determinations.

Preparations

The best sources of potassium are fresh natural foods. Supplements may have side effects and large doses must be taken to approach the levels of potassium that can be obtained from food; the average tablet contains about 90 mg, for example, and a medium banana contains 500 mg. Vegetables containing the highest levels of potassium are generally those containing the lowest levels of starch. Seaweed has amazingly high potassium content, containing roughly ten times as much as leafy vegetables, but it also contains a large amount of mineral salt. Green coconut milk is another good source of potassium.

Plentiful sources of potassium

There is a great variety of natural foods that are an excellent source of potassium. These include avocados; bananas; chard; citrus fruits; juices such as grapefruit, tomato, and orange; dried lentils; green leafy vegetables; milk; molasses; nuts such as almonds, brazils, cashews, peanuts, pecans, and walnuts; parsnips; dried peaches; potatoes; raisins; sardines; spinach; and wholegrain cereals.

Cooking

Boiling food in water is a sure way to lose the potassium in it, unless it is to make soup. Baking and broiling are ways in which food can be cooked while at the same time preserving the potassium content; indeed, these methods preserve all the nutrients apart from **vitamin C** and some of the B vitamins, which are destroyed by heat. Broiling also oxidizes **essential fatty acids**. Stir-frying is also a good way of preserving nutrients. It is important to vary the intake of potassium rich foods in order to ensure adequate intake of other nutrients and to avoid the possibility of toxicity, as some vegetables contain elements that are toxic if they are eaten in large amounts (oxalic acid in rhubarb, for example). It is important to note that freezing also depletes potassium levels in foods.

RECIPE FOR POTASSIUM BROTH. Many variations of potassium broth can be found, and most natural health practitioners recommend one version or another, but the main constituents are the following vegetables, generally any vegetable of choice can be added to this base.

Ingredients

- 2 lb potatoes
- 1 lb carrots
- 1/2 lb peas
- bones for stock, or a vegetable bouillon cube
- 4 oz cracked wheat or pearl barley

First, in a stainless steel pan, boil the stock bones, if they are used. After about one hour, add the remaining ingredients and continue to simmer in plenty of water for about another hour. It is preferable to use the potatoes and carrots well scrubbed, but with their skins on, as this retains valuable nutrients. Keep any unused soup in the refrigerator.

Potassium supplements

Potassium supplements come in either tablet or liquid form, and anything over 390 mg requires a prescription in the United States. Enteric-coated tablets have been known to cause ulcers, as they do not dissolve until they reach the intestines and may prove too concentrated for the undefended intestinal wall. To be on the safe side, supplements should be taken with a glass of juice. Slow-release enteric-coated

supplements are available, which decrease the danger of ulcers. Potassium gluconate is the ideal supplement, as it more closely resembles the potassium found in plants. Small divided doses should be taken, as opposed to one large dose, when treating a potassium deficiency. Athletic drinks are an electrolyte replacement and as such contain potassium. Potassium supplements should be kept in a cool, dry place, out of direct light. They should not be frozen and should not be kept in the bathroom medicine cabinet as heat and moisture may reduce their effectiveness.

Precautions

In general, the multitude of nutrients that humans require in order to stay healthy are synergistic, which means they are interdependent. If one is depleted, it is highly likely others will be deficient. Many nutrients, for example, require the presence of either calcium or vitamin C for efficient use by the body, and if individuals have a deficiency of any of the B vitamins, they almost certainly will have a deficiency in the B vitamins in general, as these occur together in nature. Given the factor of synergy, it is very unwise to take large amounts of any one nutrient without making sure that the full spectrum of nutrients is plentifully available for the body to use, which can best be achieved by making sure that a large proportion of the daily diet consists of raw fruit and vegetables, whole grains, and unroasted nuts.

Of all the essential nutrients that are commonly taken as supplements, potassium is perhaps the most dangerous. Only 14 grams of potassium can cause death under certain circumstances, particularly when intake is low at other times. When potassium intake is restricted, somehow the mechanism for utilizing it is altered, so that large amounts cannot be processed.

Just the right amount of potassium is essential. Too much or too little can cause **muscle spasms and cramps** if a calcium deficiency also exists. Thus, it is important to ensure adequate intake of calcium and **vitamin D**, which will promote the uptake of calcium in the body.

Many sufferers of degenerative diseases such as **tuberculosis**, cancer, and arthritis, suffer from high serum potassium levels. This is not because they have too much serum, but because the disease affects body functions in such a way that it throws off this valuable nutrient instead of using it. In such cases, natural sources of potassium, such as fresh fruit or vegetable juice, can be more effective than supplements.

Potassium and heart disease

Potassium has been recommended for the treatment of heart disease since the 1930s, but some heart disease that is due to malnutrition does not respond to potassium. Indeed, because of the impaired ability of the body to take up potassium, it can be dangerous. Most heart disease patients of the Western world, however, can benefit from an increase in potassium levels.

Potassium and arthritis

Some individuals who begin to eat a well-balanced selection of fresh vegetables and fruits and eliminate a large proportion of processed, denatured foods begin to feel amazingly well very quickly, as the potassium/sodium balance in the body is restored. Tiredness and other symptoms, such as arthritis, are soon replaced with renewed energy and vigor, and the body is able to replenish itself and finds new strength. However, potassium is only partially successful at treating **osteoarthritis**.

Side effects

Those who are taking potassium-sparing diuretics, such as spironolactone, triamterene, or amiloride should not take potassium supplements. Anyone allergic to potassium supplements or those who have kidney disease should not take them either. Those suffering from Addison's disease, heart disease, intestinal blockage, stomach ulcers, those using medication for heart disease, or taking diuretics, or who are above the age of 55, should consult a doctor before taking potassium supplements. There are no contradictions for pregnant or breast feeding women, although they should not take mega-doses.

ECG and kidney function tests can be affected by potassium supplementation. A doctor should be informed if one is taking potassium supplements. However, supplementation will not affect blood tests, unless they are to measure serum-potassium levels.

Symptoms of potassium overdose

Overdose symptoms of potassium include listlessness, mental confusion, tingling of limbs, weakness, pallid complexion, low blood pressure, and an irregular or fast heartbeat. These symptoms can progress to a drop in blood pressure, convulsion, coma, and eventually cardiac arrest, and can also be triggered by any kind of shock to the system. If any of the above symptoms occur, or in cases of bloody stool (may appear black and tarry), or difficulty in breathing or **nausea**, medical help should be sought immediately.

KEY TERMS

Catalyst—A substance that increases the rate of a chemical reaction without undergoing change itself.

Collagen—Connective tissue fiber.

Electrolyte—An ionic substance that conducts an electrical current in solution and may be essential to normal bodily function.

Malabsorption—The inability of the digestive tract to absorb all the nutrients from food due to some malfunction or disability.

Mega-doses—Very high doses of vitamins intended to treat a variety of ailments, as recommended by orthomolecular practitioners.

Passive diffusion—A process whereby a liquid migrates from a solution of lower concentration to a solution of higher concentration, making the latter more dilute.

Positive ions—Ionic particles having a positive electrical charge.

Serum—Clear, fluid part of the blood.

High serum-potassium is the major problem with shock and is the major cause of death in cases of shock or injury. This is a life-threatening situation, and self treatment is not appropriate.

If such an emergency occurs and medical help is not available, a glass of water containing half a teaspoon of salt, a quarter of a teaspoon of bicarbonate soda and a little honey will help. Potassium supplements should be taken with extreme care in cases of dehydration, as this can be fatal. Adequate liquids, particularly juice, should always accompany the supplement.

Interactions

Care should be taken when taking potassium supplements in conjunction with diuretics. A practitioner should be consulted. A doctor should be informed when a patient is taking potassium supplements. In addition, the following are known to react with potassium:

- Amilorid: causes a dangerous rise in blood potassium
- Atropine: increases the possibility of intestinal ulcers, which may be caused by potassium supplements
- Belladonna: increases possibility of intestinal ulcers
- Calcium: increases likelihood of heartbeat irregularities
- Captopril: increases likelihood of potassium overdose
- Digitalis preparations: may cause irregular heartbeat
- Enalapril: increases chance of overdose
- Laxatives: may decrease effectiveness of potassium (due to the fact that they leach potassium from the body)
- Spironolactone: increases blood potassium
- Triamterene: increases blood potassium
- Vitamin B_{12}: slow release supplements may decrease the absorption of vitamin B_{12}, increasing requirements

Pranic healing

Definition

Pranic healing encompasses a broad array of therapeutic approaches, both ancient and modern, based on the notion that illnesses of body or mind involve an imbalance and/or blockage in the flow of vital life energy. In ancient India, this energy was known as

prana, as it still is in the contemporary practice of yoga and **Ayurvedic medicine**. Traditional Chinese medicine uses the term *qi* to describe this vital energy. Pranic healing seeks, by widely varying means, to strengthen and equalize the pranic flow. And, as the number of alternative therapies has mushroomed during the last several decades, the concept of prana/qi has become almost a common denominator among approaches that may otherwise seem wildly diverse.

Origins

The belief in a fundamental life force flowing through the human body (and, by extension, through all living things) is an ancient one, common to many healing systems worldwide. More recently, many Western therapies have incorporated a similar concept.

Prana

The concept of prana evolved thousands of years ago in India, apparently in connection with esoteric religious practices. A central concept in both yoga and Ayurveda (an ancient healing system), it is discussed in the earliest written sources for these disciplines—the *Yoga Sutras* of Patanjali and the ancient Hindu scriptures known as *vedas*.

Qi

As with prana, the origins of the concept of qi are lost in the distant past. **Acupuncture**, which uses needles inserted at specific points to stimulate the flow of qi, has been practiced extensively in China for thousands of years. Archaeologists have unearthed stone acupuncture needles dated to around 3000 B.C. The *Nei Jing* (or *Classic of Internal Medicine*), the oldest known text that discusses the theoretical basis of traditional Chinese medicine, is believed to have been written roughly 2,000 years ago. In addition to acupuncture, one type of Chinese massage is known as qi healing or healing with external qi.

Benefits

Because it is a general conceptual approach rather than a specific healing modality, pranic healing cannot be said to provide a specific list of benefits; although pranayama, or yogic breathing, is said to directly benefit the respiratory system. Some practitioners might argue that dealing with imbalances at such a fundamental level, rather than treating symptoms at a superficial level, benefits the patient by getting to the root of the problem and avoiding the risk of merely masking it by treating symptoms. Pranic healing also makes a good fit with the concept of wellness, as opposed to the mere absence of disease, that underlies many alternative therapies.

KEY TERMS

Kundalini—In yoga, energy that resides at the base of the spine and can be channeled upward for spiritual awakening.

Prana—The Indian word for vital life force or energy.

Pranayama—The yogic discipline of controlling the breath. It is sometimes used to refer to a form of yoga that emphasizes breathing exercises.

Qi—The Chinese word for life energy.

Description

The diverse array of therapies loosely described as pranic healing may be grouped under several subheads, depending on both their origins and the nature of the healing techniques they employ.

Traditional healing systems

Both Ayurveda and **traditional Chinese medicine** are ancient medicinal systems that view health and disease in terms of blockage and flow of vital energy. Both use various diagnostic techniques, herbs/diet, and other treatments (notably acupuncture, therapeutic **exercise**, and massage, in the case of TCM) to stimulate and balance energy flow.

Pranayama

Practitioners of pranayama, or yogic breathing, believe that prana is moving when the human breath, which is a manifestation of universal prana, is flowing freely. When the body's energy is blocked, this stagnation can lead to illness and disease. Because Ayurvedic medicine considers prana a kind of nutrient that one can take in through the breath, breathing exercises play an important role in health promotion in Ayurveda. Pranayama soothes the nervous system, induces **relaxation**, regulates respiration, and balances the hemispheres of the brain. The major technique of pranayama is alternate nostril breathing.

Bodywork

Over the last century or so, more especially in recent decades, a number of alternative therapies have emerged that manipulate the body and/or noninvasively stimulate specific points to promote wellness,

achieve healing, and strengthen the vital force. Among the many such modalities are reflexology, **polarity therapy**, breema, and **reiki**.

Nonphysical approaches

The many different schools of meditation generally involve some combination of breathing, chanting, special postures, and mental exercises to produce enhanced or altered states of being. The focus of different **meditation** techniques can range from simple relaxation to mainstream religious devotion to esoteric spiritual evolution.

Exercise systems

Various ancient systems—including **yoga**, qigong and t'ai chi—represent a blending of exercise, therapeutic benefits, and spiritual path. To the extent that these disciplines are viewed as healing modalities, they can be said to represent forms of pranic healing. Qigong, for example, literally means "energy cultivation." In each case, specific postures and/or movements—practiced daily, often in combination with breathing exercises—are said to encourage optimal energy flow.

Preparations

Preparations for the various types of pranic healing range from wearing comfortable non-binding clothing for bodywork to fasting and spiritual preparation for certain forms of meditation. Students of yoga are advised not to eat a full meal for two to three hours prior to a yoga class because some of the postures are uncomfortable on a full stomach.

Precautions

Despite the widespread adoption of the concept of prana by contemporary alternative therapies, it is not accepted in Western scientific circles. Although controlled studies have confirmed specific therapeutic benefits for both yoga and acupuncture—which, in different ways, are based on the idea of pranic healing—there is as yet no generally accepted scientific evidence for the theories that underlie these systems. Because so many different techniques and practitioners are said to employ some form of pranic healing, it can be difficult even to determine what, exactly, is meant by their respective uses of this terminology. And there is always the risk that a focus on maximizing pranic flow might interfere with more mainstream attempts to address tangible physiological problems.

Given the variety of practices and techniques that can be classified under pranic healing, persons who are interested in a specific form should find out beforehand what level of physical exercise is involved (if any) and what belief system (if any) underlies the practice. Some forms of bodywork may be too strenuous for people with heart disease, fragile bones, or other major health problems. In addition, some forms of pranic healing may produce physical or psychological phenomena that can startle those not expecting them. For example, a type of yoga known as kundalini yoga works with energy stored at the base of the spine that is activated by exercises. Some people who have experienced the movement of kundalini energy found it unsettling because they had not been prepared for it. It may be helpful to seek out an experienced guide or mentor who has practiced a specific form of pranic healing long enough to be aware of possible reactions.

Side effects

The side effects of pranic healing can range from headaches and muscular soreness or stiffness after bodywork sessions to edginess or nervousness resulting from energies released by meditation. These side effects are usually mild and disappear after further practice.

Research and general acceptance

Some forms of pranic healing, including yoga, Ayurveda, and traditional Chinese medicine, have been intensively studied. The Office of Alternative Medicine of the National Institutes of Health (NIH) funds research into various forms of pranic healing, including mind/body interventions. The NIH's National Center for Complementary and Alternative Medicine (NCCAM) maintains a clearinghouse of information about alternative therapies and clinical trials of their effectiveness.

Training and certification

The training and certification of practitioners of prana healing ranges from the equivalent of medical school and government licensing for practitioners of traditional Chinese medicine to various forms of certification conferred by other professions or groups. **Breema** and reiki have formal degrees or certification programs. The Shalem Institute in Washington, DC, has a program for training spiritual directors in the mainstream Christian churches. There are various yoga institutes in the United States that provide courses of instruction for teachers of yoga.

Prayer and spirituality

Definition

Prayer is an act of communication with God or the Absolute. The spiritual beliefs of the person praying influence how the Absolute is perceived. For some, the Absolute is known as the Great Goddess. Others experience the Absolute as God, Allah, the Tao, the Universal Mind, Brahma, the Void, or a myriad of other forms. Spiritual, or faith, healing is the relief of illness through some type of religious belief system held by the sick person or by someone praying for them.

Origins

Prayer in one form or another is a spiritual practice found in nearly every culture. The use of prayer for healing is a vital principle of Christianity, Judaism, and Islam. Even in a non-theistic religion such as Buddhism, prayer is important in healing. In the traditional medicine of Mexico, **curanderismo**, health is perceived as a gift from God. Disease is seen as a punishment for sins and God's help is necessary for a cure. Patients may pray or make a spiritual pilgrimage as part of their medical treatment.

Spiritual healing in the West dates back to Biblical times, when some of the Hebrew prophets and Jesus used the power of prayer to heal the sick and injured. In the Jewish and Christian religions, praying for healing and medical miracles has been common for 3,000 years. The Christian tradition of faith healing formally developed out of a first-century prayer ritual for healing. Among contemporary Christians belonging to liturgical churches (Roman Catholics, Eastern Orthodox, Episcopalians, and Lutherans), spiritual healing is related to the sacraments of the Eucharist and anointing the sick, especially in churches, shrines, or sites where miracles have taken place. In the United States, numerous spiritual healing or faith healing groups and movements have appeared since the early 1800s, such as the Emmanuel movement and the John Alexander Dowie movement.

Christian Science, a movement that grew out of the Association formed by Mary Baker Eddy in 1876, holds faith healing at the core of its principles. Christian Scientists believe that death and illness are illusions. Eddy claimed that the end result of knowledge gained through Christian Science is the power to heal. Eddy's beliefs stemmed from her claims that she was cured of various illnesses in 1862 through massage, positive reinforcement, and mental healing. In 1875, she published *Science and Health*, the founding text of Christian Science.

People have always prayed, especially when sick or facing death. Still, despite the scientific evidence pointing to the effectiveness of prayer, it is not generally accepted as a treatment method by the Western medical community. Hippocrates, the father of modern medicine, believed that the mind and body were separate, and this point of view is the foundation of modern Western medicine.

Beginning in the seventeenth century, with the philosophy of René Descartes, the West has increasingly focused on a material view of the world. In medicine this has meant that an almost exclusive concentration on the physical aspects of disease. The contribution of emotions, thoughts, relationships, and spirituality to disease and health were either ignored or discounted. Only since the 1960s has there been an increase in interest about the effectiveness of prayer, **meditation**, and other mind-body approaches to health and healing.

Benefits

Perhaps the two most obvious benefits of faith healing is that the cost is minimal or zero, and that it involves no medications or medical devices. The medical, scientific, and religious communities almost unanimously agree that the human mind has a tremendous amount of

untapped potential, including the power to heal physical and emotional ailments. A person's faith has a strong influence over his or her sense of well-being, ability to fight disease, and desire to get well, according to many researchers.

Prayer and other spiritual approaches can be particularly beneficial for people with stress-related disorders. Dr. Herbert Benson reports that meditative prayer can ease **anxiety**, mild **depression**, **substance abuse**, ulcers, **pain**, **nausea**, tension and migraine headaches, **infertility**, **premenstrual syndrome** (PMS), **insomnia**, and high blood pressure.

Prayer also plays an important role in helping people cope with difficult circumstances such as chronic illness and death. Prayer offers new meaning, purpose, hope, and a sense of guidance or control. These perceptions may help instill a fighting spirit, which has been reported to be an important factor in healing. Prayer can enrich the quality of one's life and also bring a feeling of peace and acceptance at the time of death. In addition, being part of a religious community can benefit patients by counteracting the social isolation that many sick people experience. Visits from friends or their spiritual leader are reminders that they are still part of a faith community and the larger human community.

More recently, researchers have recognized that prayer and spiritual practice are often related to people's connections with other creatures. Although the strength of the bond between humans and animals was first discussed in the context of people's grieving for dead pets, the human-animal connection and its role in spirituality is now being studied in its own right.

Description

Spiritual healing can involve a person praying alone by themselves for healing, one person praying for the healing of another person, or a group of persons praying for an ill person. It can involve formal ritual and the administration of the sacraments. Many Roman Catholic, Episcopal, and Lutheran congregations in the United States hold special Eucharists for healing; people can come for their own healing or in behalf of someone else.

Another common type of prayer is meditative prayer, which involves quieting the mind and focusing on an object, sound, movement, visualization, or simply the breath. Eastern types of meditative prayer may involve the repetition of a sound or phrase (mantra) or repeating the name of the Divine (japa). In India, there is a tradition of sacred temple dance as a form of meditative prayer. Western types of meditative prayer may focus on quieting the mind and opening the heart to listen to God, often repeating prayer-like mantras. Dr. Herbert Benson has studied the effects of meditative prayer and found many significant health benefits.

Many healers also use prayer as a form of spiritual healing. Healing utilizing prayer can be done at a distance or through the laying on of hands. Spiritual healing is often not distinguished from psychic and energy healing, although some researchers do make a distinction. A spiritual healer is primarily concerned with a way of being, while other types of healers are concerned with the sick person's body and try to heal the physical symptoms of the disease. A spiritual healer allows an infinite consciousness, intelligence, and love (known as God, or nonlocal mind) to express itself through the healer. Other types of healers direct their energy outward and concentrate on replenishing or changing the energy flow of the patient. Energy healers do this by using their hands or fingers. Examples of subtle energy healing include **reiki**, **therapeutic touch**, **qigong**, and **pranic healing**. Psychic healers are able to relieve symptoms from a distance with their minds.

Preparations

People can pray at any time at any place. There is no advance preparation needed. However, most of the major religious traditions have developed certain patterns or practices associated with prayer, such as the use of rosaries, prayer books, or prayer shawls, that are meaningful to members of those traditions and help them to focus their attention when they pray. There are many clergy and spiritual leaders in the major faith traditions in the United States who can explain the various practices associated with prayer and why they can be helpful preparation for praying.

Precautions

Prayer and spirituality are not a substitute for other medical care. It is a complementary practice. Patients with serious illnesses should not choose prayer over other medical therapies and delay seeking necessary treatment.

There is also potential for harm in prayer and spiritual practices. Studies have shown that the growth of microorganisms can be retarded or inhibited depending upon the intention of the healer. There is also evidence of negative prayer in many different cultures.

Side effects

There are no known side effects of positive prayer, although negative energy focused on an individual has been shown to produce negative results.

Research and general acceptance

A 1996 Gallup poll showed that nine out of 10 Americans pray and 75% pray every day. The most common prayers were for family well-being (98%), prayers of thanks (94%), prayers for strength or guidance (92%), and prayers for forgiveness (92%). Eighty-two percent of Americans prayed for health and healing. Prayer is one of the most common complementary practices to standard medical treatment.

As of 1993, one American researcher had compiled a list of over 130 English-language clinical studies that have documented the effectiveness of faith and prayer in healing. For example, a 1987 study at the University of California Medical School in San Francisco involving 393 patients with heart problems were divided into two groups. One group had people pray for them at a distance (intercessory prayer), and the other group did not. The prayed-for group had fewer deaths, medical interventions, and complications than the control (not prayed-for) group. Dr. Larry Dossey, who was co-chair of the Panel on Mind/Body Interventions in the Office of Alternative Medicine at the National Institutes of Health in 2000, has written several books on laboratory studies of prayer and the historical reluctance of the mainstream scientific community to examine the connections between prayer and healing.

A number of studies, also at Duke University, have shown that the combination of active involvement in a religious community and frequent prayer has powerful effects on blood pressure and **smoking**.

Over the past three decades approximately 200 studies have examined the ability of prayer to affect human beings, animals, plants, and even microorganisms. Evidence so far shows that there is no one best way to pray.

Acceptance of prayer and spiritual healing among medical professionals varies. Some feel quite strongly that medicine and spiritual practice should not be mixed and that doctors and nurses should refer patients to religious professionals for spiritual needs. Surveys have shown, however, that as of 2002 a majority (about 76%) of physicians and nurses in the United States feel comfortable praying with patients if asked to do so, and 96% would discuss spiritual or religious matters with patients confronting a life-threatening illness or end-of-life issues.

Some researchers have attempted in recent years to develop scales for measuring spiritual experiences, in order to have some basis for comparing findings from different studies. Two such measures are the Daily Spiritual Experience Scale (DSES), a 16-item questionnaire; and the Ironson-Woods Spirituality-Religion (SR) Index, which measures four factors—faith in God, sense of peace, religious behavior, and compassionate view of others. The Ironson-Woods Index has been used to study the effects of spirituality and religious practice on the long-term survival of **AIDS** patients.

Training and certification

Clergy and pastoral counselors in the mainstream religious bodies in the United States receive extensive training in the spiritual and mental health needs of patients. The American Association of Pastoral Counselors (AAPC) is a professional organization that certifies Christian clergy who have undergone advanced training in **psychotherapy** as well as theology. The AAPC supports about 100 counseling centers across the United States as well as certifying clergy who serve in hospital chaplaincies or mental health clinics. The corresponding certification body for Jewish rabbis and pastoral counselors is the National Association of Jewish Chaplains.

Spiritual healers in less structured traditions may be certified through a school of energy healing, recognized within a particular religious group for their healing aptitude, or initiated into healing by another means. Native American healers have formed the Indigenous Traditional Healing Council to provide certification for healers as well as to protect the integrity of Native American healing rituals. Many other healers develop their healing gifts on their own. Any caring person can develop a certain amount of healing ability through meditation, prayer, study with other experienced healers, and practice. There are many self-help books on prayer and meditation, but personal guidance is usually helpful to learn the subtleties of any approach to healing. Churches and other religious centers usually offer spiritual direction through prayer, meditation, or study.

Pregnancy

Definition

Pregnancy is the period from conception to birth. After an egg is fertilized by a sperm and implanted in the lining of the uterus, it develops into an embryo, and later into a fetus. Pregnancy usually lasts 40 weeks, beginning from the first day of the woman's last menstrual period. The condition is divided into trimesters, each lasting three months.

Recommended weight gain for pregnant women

If you are:	You should gain:
Underweight	About 27 to 40 pounds
Normal weight	About 25 to 35 pounds
Overweight	About 15 to 25 pounds
Obese	About 15 pounds or less

SOURCE: National Institute of Diabetes and Digestive and Kidney Diseases, National Institutes of Health, U.S. Department of Health and Human Services

General weight-gain recommendations for women who are expecting only one baby. *(Illustration by GGS Information Services. Cengage Learning, Gale)*

Description

Pregnancy is a state in which a woman carries a fertilized egg inside her body as it develops into a fetus and prepares to be born.

First month

At the end of the first month, the embryo is about 1/3 in long (.85 cm), and its head, trunk, and the beginnings of arms and legs have started to develop. The embryo gets nutrients and eliminates waste through the umbilical cord and placenta. By the end of the first month, the liver and digestive system begin to develop, and the heart starts to beat.

Second month

In this month, the heart starts to pump and the nervous system (including the brain and spinal cord) begins to develop. The 1 in (2.5 cm) long fetus has a complete cartilage skeleton, which is replaced by bone cells by month's end. Arms, legs, and all of the major organs begin to appear. Facial features begin to form.

Third month

By now, the fetus has grown to 4 in (10 cm) and weighs a little more than 1 oz (28 g). Now the major blood vessels and the roof of the mouth are almost completed. The face starts to take on a more recognizably human appearance. Fingers and toes appear. All the major organs are forming; the kidneys are now functional, and the four chambers of the heart are complete.

Fourth month

The fetus begins to kick and swallow, although most women still cannot feel fetal movement at this time. Now 4 oz (112 g) in weight, the fetus can hear and urinate and has established sleep-wake cycles. All organs are now fully formed, although they continue to grow for the next five months. The fetus has skin, eyebrows, and hair.

Fifth month

Now weighing up to 1 lb (454 g) and measuring 8 to 12 in (20–30 cm), the fetus experiences rapid growth as its internal organs continue to grow. At this point, the mother may feel fetal movement, and she can hear the heartbeat with a stethoscope.

Sixth month

Even though its lungs are not fully developed, some fetuses born during this month can survive with intensive care. Weighing 1 to 1.5 lbs (454–681 g), the fetus is red, wrinkly, and covered all over its body with fine hair. The fetus grows very rapidly during this month as its organs continue to develop.

Seventh month

There is a better chance that a fetus born during this month will survive. The fetus continues to grow rapidly and may weigh as much as 3 lbs (1.3 kg). Now the fetus can suck its thumb and look around its watery environment with open eyes.

Eighth month

Growth slows as the fetus begins to take up most of the space inside the uterus. Now weighing between 4 and 5 lbs (1.8–2.3 kg) and measuring 16 to 18 in (40–45 cm) in length, the fetus may at this time prepare for delivery next month by moving into the head-down position.

Ninth month

Adding 0.5 lb (227 g) each week as the due date approaches, the fetus drops lower into the mother's abdomen and prepares for the onset of labor, which may begin any time between the 37th and 42nd week of pregnancy. Most healthy babies weigh 6 to 9 lbs (2.7–4 kg) at birth and will be about 20 in (50 cm) long.

Causes and symptoms

Pregnancy is caused by a sperm fertilizing an egg. The first sign of pregnancy is usually a missed menstrual period, although some women bleed in the beginning. A woman's breasts swell and may become tender as the mammary glands prepare for eventual breastfeeding. Nipples begin to enlarge and the veins over the surface of the breasts become more noticeable.

Nausea and **vomiting** are common symptoms during the first three months of pregnancy. Since these symptoms are usually worse in the morning, this condition is known as **morning sickness**. Many women also feel extremely tired during the early weeks or pregnancy. Frequent urination is common, and there may be a creamy white discharge from the vagina. Some women crave certain foods, and an extreme sensitivity to odors may worsen the nausea. Maternal weight begins to increase.

In the second trimester (13–28 weeks) a woman begins to look noticeably pregnant and the enlarged uterus is easy to feel. The nipples get bigger and darker, the skin of Caucasians may darken, and some women may feel flushed and warm. Appetite may increase. By the twenty-second week, most women have felt the fetus move. During the second trimester, nausea and vomiting often diminish or disappear, and the pregnant woman often feels better and more energetic than in early pregnancy. Heart rate increases as does the volume of blood in the body.

By the third trimester (29–40 weeks), many women begin to experience a range of symptoms. Stretch marks (striae) may develop on the abdomen, breasts and thighs, and a dark line may appear from the navel to pubic hair. A thin fluid may be expressed from the nipples. Many women feel hot, sweat easily, and often find it hard to get comfortable. Kicks from an active fetus may cause sharp pains, and lower backaches are common. More rest is needed as the woman copes with the added **stress** of extra weight. Braxton Hicks contractions may get stronger.

At about the thirty-sixth week in a first pregnancy (later in repeat pregnancies), the fetus's head drops down low into the pelvis. This shift may relieve pressure on the upper abdomen and the lungs, allowing a woman to breathe more easily. The fetus's new position, however, places more pressure on the bladder.

The average woman gains 28 lb (12.7 kg) during pregnancy, 70% of it during the last 20 weeks. An average healthy full-term baby at birth weighs 7.5 lbs (3.4 kg), and the placenta and fluid together weigh another 3 lbs (1.3 kg). The remaining weight that a woman gains during pregnancy is mostly due to water retention and fat stores.

In addition to the typical symptoms of pregnancy, some women experience other problems that may be

annoying but usually disappear after delivery. **Constipation** may develop as a result of food passing more slowly through the intestine. **Hemorrhoids** and **heartburn** are fairly common during late pregnancy. Gums may become more sensitive and bleed more easily. Eyes may dry out, making contact lenses feel painful. Pica (a craving to eat substances other than food) may occur. Swollen ankles and **varicose veins** may be a problem in the second half of pregnancy, and chloasma (light brown spots) may appear on the face.

While the preceding symptoms are considered normal, there are some symptoms that may indicate more dangerous underlying problems. A pregnant woman experiencing any of the following should contact her doctor immediately:

- abdominal pain
- rupture of the amniotic sac or leaking of fluid from the vagina
- bleeding from the vagina
- no fetal movement for 24 hours (after the fifth month)
- continuous headaches
- marked sudden swelling of eyelids, hands, or face during the last three months
- dim or blurry vision during the last three months
- persistent vomiting

Diagnosis

Many women first discover they are pregnant after a positive home pregnancy test. Pregnancy urine tests check for the presence of human chorionic gonadotropin (hCG), which is produced by a placenta. Home tests can detect pregnancy as early as the first day of the missed menstrual period.

Home pregnancy tests are more than 97% accurate if the result is positive, and about 80% accurate if the result is negative. If the result is negative and there is no menstrual period within another week, the pregnancy test should be repeated. While home pregnancy tests are reliable, they are less accurate than a pregnancy test evaluated by a laboratory. For this reason, a woman may want to have a second pregnancy test conducted at her doctor's office to be sure of the accuracy of the result.

Blood tests to determine pregnancy are usually used only when a very early diagnosis of pregnancy is needed. This more expensive test, which also looks for hCG, can produce a result within nine to twelve days after conception.

Once pregnancy has been confirmed, there are a range of screening tests that can be done to screen for birth defects, which affect about 3% of unborn children. Two tests are recommended for all pregnant women: alpha-fetoprotein (AFP) and the triple marker test.

Other tests are recommended for women at higher risk for having a child with a birth defect. These groups include women over age 35 who have another child or a close relative with a birth defect or who have been exposed to certain drugs or high levels of radiation. Women with any of these risk factors may want to consider amniocentesis, chorionic villus sampling (CVS) or ultrasound.

Other prenatal tests

Other prenatal tests that are routinely performed include:

- pap test
- gestational diabetes screening test at 24–28 weeks
- tests for sexually transmitted diseases
- urinalysis
- blood tests for anemia or blood type
- screening for immunity to various diseases, such as German measles

Treatment

Alternative medicine offers a variety of treatments for conditions ranging from morning sickness to stretch marks. Before starting any treatment, a pregnant woman should consult with her doctor or healthcare practitioner. Note that except for **ginger**, the effectiveness of these herbs has not been proven to the satisfaction of conventional medical practitioners.

Prenatal care is vitally important for the health of the fetus. A pregnant woman should eat a balanced, nutritious diet of frequent small meals. Many physicians prescribe pregnancy vitamins, including **folic acid** and **iron** supplementation during pregnancy.

Herbal remedies

Numerous herbs are believed to remedy a range of conditions experienced by pregnant women. Many remedies can be taken as herbal teas, and packaged tea bags are sold at health food stores. The following herbs are recommended for pregnant women:

- Red raspberry leaf tea (*Rubus idaeus*) is regarded as an all-purpose remedy. It is said to be a good source of iron, to tone the uterus, protect against miscarriage,

and prevent infection, cramps, and anemia. Furthermore, red raspberry is believed to aid the birth process by stimulating contractions. The herb also is believed to prevent excessive bleeding during labor and afterwards.

- For morning sickness, several forms of ginger (*Zingiber officinale*) provide relief. A cup of ginger tea, ginger capsules, ginger ale, or ginger cookies can ease the queasiness.
- Lemon balm (*Melissa officinalis*) can be taken for nausea. It also aids digestion.
- Wild yam (*Dioscorea villosa*) and burdock root (*Arctium luppa*) are effective against morning sickness. Wild yam can be taken for pregnancy pain and cramping. The herb is taken to reduce the risk of miscarriage. Burdock root aids with water retention; it also protects against infant jaundice.
- Peppermint (*Mentha piperita*) can be taken after the first trimester to combat nausea. It helps with digestion, provides stomach relief, and serves as a body strengthener.
- Echinacea (various species) boosts the immune system to fight colds, flu, and infection.
- Chamomile (*Matricaria recutita*) provides soothing relaxation and can be used to help with sleep. It also helps with digestive problems and bowel difficulties.
- Yellow dock (*Rumex crispus*) thwarts infant jaundice. The herb helps with iron absorption.
- Bilberry (*Vaccinium myrtillus*) serves as a diuretic for bloating; it also strengthens vein and capillary support.
- Nettles (*Urtuca dioica*) and oat straw (*Avena sativa*) are sources of calcium. In addition, nettles and dandelion reportedly prevent high blood pressure and water retention. Nettles contain vitamin K and help to prevent excessive bleeding. Nettles can also be taken to avoid hemorrhoids and to enhance kidney function.
- Blue cohosh (*Caulophyllium thalictroides*) is taken during the last weeks of pregnancy to induce labor contractions and ease spasmodic pains.
- Lobelia (*Lobelia inflata*) works to relax the mother during delivery. The herb also aids with delivery of the placenta.

HERBS TO AVOID. Some herbs can cause complications to mother or fetus and should not be taken during pregnancy. Uterine contractions can be caused by **angelica** (*Angelica archangelica*, *A. atropurpurea*), lovage (*Levisticum vulgaris*), **mistletoe** (*Viscum album*), **mugwort** (*Artemesia vulgaris*), tansy (*Tanacetum vulgare*), wild ginger (*Asarum europaeum*), and **wormwood** (*Artemisia absinthium*). Other herbs to be avoided include cinchona (*Chinchona pubescens*), **eucalyptus** oil (*Eucalyptus globulus*), **juniper** (*Juniperus communis*), ma huang (**ephedra**) (*Ephedria sinica*), male fern (*Dryopteris filix-mas*), **pennyroyal** (*Mentha pulegium*), poke root (*Phytolacca americana*), rue (*Ruta graveolens*), shepherd's purse *Capsella bursa-pastoris*), and **yarrow** (*Achillea millefolium*).

Aromatherapy

Aromatherapy involves the use of **essential oils** as remedies. The application of combined oils to the skin is said to counteract stretch marks. An aromatherapist can recommend specific oil combinations.

Traditional Chinese medicine and acupuncture

In addition to using herbs for **infertility** problems, **traditional Chinese medicine** recommends herbal formulas for such problems associated with pregnancy as morning sickness, threatened miscarriage, and **postpartum depression**. One well-known formula, recommended to be taken three to six months before attempting conception, is called the Rock on Tai Mountain decoction. The formula is intended to build up both the woman's qi, or life energy, and her blood. In traditional Chinese medicine, it is thought that the mother's blood nourishes, the qi protects, and the qi in the kidneys holds the fetus.

Chinese practitioners use **acupuncture** to assist conception by clearing the stagnation of qi in the liver; to prevent miscarriage by conserving qi in the kidney; and to induce labor.

Traditional Chinese medicine recommends abstinence from intercourse during pregnancy in order to allow the placenta to develop normally and to prevent harm caused by sexual excess to the various organs and substances in the mother's body.

Hydrotherapy

Although pregnant women should avoid saunas and hot tubs, other forms of **hydrotherapy** can provide relief. To ease nausea, a warm compress is placed between the chest and abdomen 30 minutes before eating. The compress is a cloth soaked in hot water and wrung out. A foot bath can soothe swollen feet.

Homeopathy

Morning sickness can be treated by several homeopathic remedies. If a homeopathic remedy is a decimal potency, it is indicated by an "x". This indicates the number of times that one part of a remedy was

diluted in nine parts of a diluent. Distilled water is the preferred diluent.

Ipecacuanha 30x is recommended if the woman feels worse lying down, has **diarrhea**, and is salivating heavily. If morning sickness is accompanied by queasiness about eating, *Colchicum autumnale* 6x is recommended. ***Nux vomica*** 6x is the remedy when a woman vomits in the morning, but her condition improves after eating. *Phosphorus* 6x is taken when a woman vomits after drinking water. For nausea only, *Natrum phosporicum* 6x may provide relief.

Each remedy is taken every 15 minutes until the feeling of nausea lessens. However, no more than four doses should be taken in one day unless specified by a homeopath.

Flower remedies

Flower remedies are liquid concentrates made by soaking flowers in spring water. Also known as flower essences, 38 remedies were developed by homeopathic physician Edward Bach during the 1930s. Walnut, a Bach remedy for difficulty in adjusting to change, may be helpful to pregnant women. A thirty-ninth combination formula, the **rescue remedy**, is taken to relieve stress. A pregnant woman should, however, check with her doctor before beginning flower therapy. Flower essences, which contain alcohol, are taken in water and usually sipped.

Relaxation techniques

Relaxation techniques can be used to cope with such conditions as stress or morning sickness. Helpful techniques include **meditation**, deep breathing, and listening to relaxation tapes. Another useful technique is **guided imagery**. The mother does some deep breathing and then visualizes a positive image or affirmation.

Bodywork

Massaging sore areas of the body during pregnancy can reduce aches and stress. Another form of bodywork is the **Alexander technique**, developed by actor Frederick Matthias Alexander during the 1800s. An Alexander technique practitioner can show a woman how to release muscle tension, with emphasis on the neck. The technique focuses on posture and movement. It is said to reduce stress and relieve **pain** in such areas as the back.

Allopathic treatment

No medication (not even nonprescription drugs, herbal, or homeopathic remedices) should be taken except under medical supervision, since certain substances can pass from the mother through the placenta and into the developing fetus. Some drugs have been proven harmful to a fetus, but all drugs should be considered suspect and taken only with medical supervision. Drugs taken during the first three months of a pregnancy may interfere with the normal formation of the fetus's organs, leading to birth defects. Drugs taken later on in pregnancy may slow the fetus's growth rate, or they may damage specific fetal tissue (such as the developing teeth).

To have the best chance of having a healthy baby, a pregnant woman should avoid:

- smoking
- alcohol
- street drugs
- large amounts of caffeine
- artificial sweeteners.

Expected results

Pregnancy is a natural condition that usually causes little discomfort provided the woman takes care of herself and gets adequate prenatal care. **Childbirth** education classes for the woman and her partner help prepare the couple for labor and delivery.

Prevention

There are many ways to avoid pregnancy. A woman has a choice of many methods of contraception that will prevent pregnancy, including (in order of least to most effective):

- spermicide alone
- natural (rhythm) method
- diaphragm or cap alone
- condom alone
- diaphragm with spermicide
- condom with spermicide
- intrauterine device (IUD)
- contraceptive pill
- sterilization (either a man or woman)
- avoiding intercourse

KEY TERMS

Alpha-fetoprotein—A substance produced by a fetus's liver that can be found in the amniotic fluid and in the mother's blood. Abnormally high levels of this substance suggest there may be defects in the fetal neural tube, a structure that will include the brain and spinal cord when completely developed. Abnormally low levels suggest the possibility of Down syndrome.

Braxton Hicks contractions—Short, fairly painless uterine contractions during pregnancy that may be mistaken for labor pains. They allow the uterus to grow and help circulate blood through the uterine blood vessels.

Chloasma—A skin discoloration common during pregnancy, also known as the mask of pregnancy or melasma, with which blotches of pale brown skin appear on the face. The blotches may appear in the forehead, cheeks, and nose, and may merge into one dark mask. It usually fades gradually after pregnancy, but it may become permanent or recur with subsequent pregnancies.

Embryo—The result of fertilization of an egg by a sperm during the first eight weeks of development following conception. For the rest of pregnancy, the embryo is called a fetus.

Fetus—A developing unborn infant from the end of the eighth week after fertilization until birth.

Human chorionic gonadotropin (hCG)—A hormone produced by the placenta during pregnancy.

Placenta—The organ that develops in the uterus during pregnancy that links the blood supplies of the mother and fetus.

Rhythm method—The oldest method of contraception with a very high failure rate, in which partners refrain from having sex during ovulation. Ovulation is predicted on the basis of a woman's previous menstrual cycle.

Pregnancy massage

Definition

Pregnancy massage is the prenatal use of **massage therapy** to support the physiologic, structural, and emotional well-being of both mother and fetus. Various forms of massage therapy, including Swedish, deep tissue, neuromuscular, movement, and Oriental-based therapies, may be applied throughout pregnancy as well as during labor and the postpartum period.

Origins

Cultural and anthropological studies indicate that massage and movement during the childbearing experience were and continue to be a prominent part of many cultures' health care. Indian Ayurvedic medical manuals detail therapists' instructions for rubbing specially formulated oils into pregnant patients' stretched abdominal skin. Traditional sculptures depict Eskimo fathers supporting and lovingly stroking their laboring wives' backs. In certain Irish hospitals laboring women are held and touched by a doula (labor assistant) or midwife through most of their notably short, uncomplicated labors. For billions of women, over thousand of years, midwives' highly developed hands-on skills

Pregnancy massage increases blood flow, relaxes muscles, reduces water retention, and makes the skin more supple. It is particularly useful in relieving the back pain of late pregnancy. *((c) Photo Researchers, Inc. Reproduced by permission.)*

have provided loving support and eased childbearing discomforts. As massage therapy resumes its place within Western healthcare methods, pregnancy massage is becoming one of its fastest growing specialized applications.

Benefits

Profound physiologic, functional, emotional, relational, and lifestyle changes occur during gestation and labor, often creating high **stress** levels. Too much stress can negatively affect maternal and infant health, resulting in reduced uterine blood supply and higher incidence of miscarriage, prematurity, and other complications. Massage therapy can help a woman approach her due date with less **anxiety** as well as less physical discomfort. Even apart from easing specific aches, massage can act as an overall tonic and increase the expectant mother's body awareness.

KEY TERMS

Doula—A woman who assists an expectant mother with physical and emotional support during labor.

Edema—An abnormal accumulation of fluid in specific parts of the body, causing swelling of the area. Many women experience edema of the wrists and ankles during pregnancy.

Massage therapy can address the various physical challenges of pregnancy: **edema**; foot, leg, or hand discomforts; and **pain** in the lower back, pelvis, or hips. **Swedish massage** may facilitate gestation by supporting cardiac function, placental and mammary development, and increasing cellular respiration. It can also reduce edema and high blood pressure as well as contribute to sympathetic nervous system sedation. Deep tissue, trigger point, and both active and passive movements alleviate stress on weight-bearing joints, muscles, and fascial tissues to reduce neck and back pain caused by poor posture and strain on the uterine ligaments. During labor, women whose partners use basic massage strokes on their backs and legs have shorter, less complicated labors. After the baby's birth, massage therapy can gently facilitate the body's return to its pre-pregnancy state, alleviate pain, foster a renewed sense of body and self, and help maintain flexibility despite the physical stresses of infant care. For post-Caesarean mothers, specific therapeutic techniques can also reduce scar tissue formation and facilitate the healing of the incision and related soft tissue areas.

Description

When nestled with pillows or other specialty cushions into a side-lying or semi-reclining position, most women are more comfortable for the 30–60 minutes of a typical massage session. A pregnant woman can expect to enjoy many of the same techniques, draping, and professional demeanor offered all massage therapy clients. The lower back, hips, and neck benefit from sensitively applied deep tissue, neuromuscular, and **movement therapy**. Edema in the legs and arms may be relieved with the gliding and kneading strokes of Swedish or **lymphatic drainage** massage. Pregnant women should expect a thorough health and prenatal intake interview with their therapists. Cost, procedures, and insurance coverage are similar to those for other massage client populations.

Preparations

In addition to the preparations listed in the massage therapy entry, some expectant women will be asked to secure a release from their maternity healthcare provider, especially those with complications or high risk factors.

Precautions

In addition to those listed in the massage therapy entry, the following other precautions are prudent:

- The abdomen should be touched only superficially with a flat, gentle hand.
- Any pressure applied to the inner leg should also be superficial.
- Women who must be on bed rest for any complication are at higher risk of blood clots forming in their legs; therefore, most massage of the legs should be avoided.
- Massage is safest when a woman is either lying on the side or propped semi-sitting at a 45–70 degree angle rather than lying on her back or belly.
- Because there are many other specific body areas and types of techniques that must be avoided or modified according to an individual woman's health condition, advanced specialized training of the therapist and consultation with her physician or midwife are highly recommended. It is better to avoid massage if the woman has vaginal bleeding, abdominal pain, or diarrhea.

Side effects

There are no known side effects to receiving appropriate prenatal massage therapy.

Research and general acceptance

Current research on the benefits of touch is providing a contemporary basis for its reintroduction into maternity care. Scientists have found that rats restricted from cutaneous self-stimulation had poorly developed placentas and 50% less mammary gland development. Their litters were often ill, stillborn, or died shortly after birth due to poor mothering skills. Women who are nauseated and/or **vomiting** prenatally experienced a decrease in these discomforts when they applied finger pressure to a specific **acupuncture** point (**acupressure**) on their forearm several times each day. Pregnant women massaged twice weekly for five weeks experienced less anxiety, leg, and back pain. When compared with control groups who practiced **relaxation** exercises only, the women who had had massage reported better sleep and improved moods, and their labors had fewer complications, including fewer premature births. Studies show that when women receive nurturing touch during later pregnancy, they touch their babies more frequently and lovingly. During labor the presence of a doula, a woman providing physical and emotional support, including extensive touching and massage, reduces the length of labor and number of complications, interventions, medications, and Caesarean sections.

Training and certification

Some massage therapy schools include comprehensive courses in pregnancy massage therapy. More often, however, therapists receive only introductory guidance in maternity applications during their 500–1000 hours of basic training and then pursue specialization certification in pre- and perinatal massage therapy. Several nationwide programs offer such advanced training in 24–34 hour workshop programs.

Premenstrual syndrome

Definition

Premenstrual syndrome (PMS) refers to over 150 symptoms that occur between ovulation and the onset of **menstruation**. The symptoms include both physical

Symptoms of PMS

Physical	Emotional/behavioral
Weight gain	Moodiness/irritability
Fluid retention	Anxiety or tension
Breast tenderness	Depression
Headaches and body aches	Panic attacks
Acne	Suicidal thoughts
Hot flashes	Crying fits
Nausea	Aggressiveness
Cold sores and herpes outbreaks	Social withdrawal
Constipation or diarrhea	
Food cravings/Appetite changes	
Insomnia	
Fatigue

ones, such as breast tenderness, back **pain**, abdominal cramps, **headache**, and changes in appetite; behavioral symptoms such as clumsiness, poor concentration, and sleep problems; and psychological symptoms of **anxiety**, irritability, **depression**, and unrest. Severe forms of this syndrome are referred to as premenstrual dysphoric disorder (PMDD). These symptoms may be related to hormonal imbalances and emotional disorders.

Description

Between 40 and 75% of all menstruating women experience symptoms that occur before or during menstruation. PMS encompasses a wide range of symptoms, some as minor as appetite change or others so severe that they may interfere with daily life. Some women experience an increase in their sexual libido (sex drive). Only 3 to 7% of women experience the much more severe premenstrual dysphoric disorder (PMDD). These symptoms can last 4 to 10 days and can have a substantial impact on a woman.

The reason some women get severe PMS whereas others get little or none of the symptoms is not understood. PMS symptoms usually begin at puberty and last until **menopause**. Women more sensitive to hormonal change may experience PMS more than others. **Stress** also contributes and the relief of tension often lessens the other symptoms as well. Overall, however, it is difficult to predict who is most at risk for PMS.

Causes and symptoms

Because PMS is restricted to the second half of a woman's menstrual cycle, after ovulation, it is thought that hormones play a role. During a woman's monthly menstrual cycle, which lasts from 24 to 35 days, hormone levels change. The hormone estrogen gradually rises during the first half of a woman's cycle, the pre-ovulatory phase, and falls dramatically at ovulation. After ovulation, the post-ovulatory phase, progesterone levels gradually increase until menstruation occurs. Both estrogen and progesterone are secreted by the ovaries, which are responsible for producing the eggs. The main role of these hormones is to cause thickening of the lining of the uterus (endometrium).

However, estrogen and progesterone also affect other parts of the body, including the brain. In the brain and nervous system, estrogen can affect the levels of neurotransmitters, such as serotonin. Serotonin has long been known to have an effect on emotions and eating behavior. It is thought that when estrogen levels go down during the post-ovulatory phase of the menstrual cycle, decreases in serotonin levels follow. Whether these changes in estrogen, progesterone, and serotonin are responsible for the emotional aspects of PMS is not known with certainty. However, most researchers agree that the chemical transmission of signals in the brain and nervous system is in some way related to PMS. This position is supported by the fact that the times following **childbirth** and menopause are also associated with both depression and low estrogen levels.

Nutritional deficiencies, food **allergies**, and **hypoglycemia** (low blood sugar) have been linked with PMS. A diet deficient in **essential fatty acids**, **zinc**, **magnesium**, and vitamin B_6 may affect estrogen and progesterone production and their balance in the body.

Over 150 symptoms for PMS have been identified. These include physical, behavioral, and emotional aspects that range from mild to severe. The physical symptoms include bloating, headaches, food cravings, abdominal cramps, headaches, tension, **fatigue**, **acne**, muscle aches, and breast tenderness. Behavioral symptoms may include

Conceptual illustration of menstrual pain. *(© PHOTOTAKE Inc. / Alamy)*

insomnia, lack of concentration, and clumsiness. Emotional aspects include mood swings, irritability, and depression.

Diagnosis

The best way to diagnose PMS is to review a detailed diary of a woman's symptoms for several months. PMS is diagnosed by the presence of physical, psychological, and behavioral symptoms that are cyclic and occur in association with the premenstrual period of time. PMDD, which is far less common, was officially recognized as a disease in 1987. Its diagnosis depends on the presence of at least five symptoms related to mood that disappear within a few days of menstruation. These symptoms must interfere with normal functions and activities of the individual.

Treatment

There are many natural treatments for PMS and PMDD depending on the symptoms and their severity. **Hypnotherapy**, spiritual healing, **color therapy**, **reflexology**, **Ayurvedic medicine**, **traditional Chinese medicine**, **acupuncture**, **acupressure**, **aromatherapy**, herbal treatment, Naturopathic treatment, and **homeopathy** are all used to treat PMS.

Vitamins and minerals

Some women find relief with the use of vitamin and mineral supplements. Magnesium can reduce the fluid retention that causes bloating, whereas **calcium** may decrease both irritability and bloating. Magnesium and calcium also help relax smooth muscles, which may reduce cramping. Some studies indicate that calcium supplements can reduce premenstrual complaints by nearly half. **Vitamin E** reduces breast tenderness, nervous tension, fatigue, and insomnia. Vitamin B_6 decreases fluid retention, fatigue, irritability, and mood swings. Vitamin B_5 supports the adrenal glands and may help reduce fatigue.

Phytoestrogens and natural progesterone

The Mexican wild yam, *Dioscorea villosa*, contains a substance that may be converted to progesterone in the body. Because this substance is readily absorbed through the skin, it can be found as an ingredient in many skin creams. (Some products also have natural progesterone added to them.) Some herbalists believe that these products can have a progesterone-like effect on the body and decrease some of the symptoms of PMS.

The most important way to alter hormone levels may be by eating more phytoestrogens. These plant-derived compounds have an effect similar to estrogen in the body. One of the richest sources of phytoestrogens is soy products, such as tofu and soy milk. Additionally, many supplements contain **black cohosh** (*Cimicifuga racemosa*) or **dong quai** (*Angelica sinensis*), which are herbs high in phytoestrogens. **Red clover** (*Trifolium pratense*), **alfalfa** (*Medicago sativa*), **licorice** (*Glycyrrhiza glabra*), **hops** (*Humulus lupulus*), and legumes are also high in phytoestrogens. Increasing the consumption of phytoestrogens is also associated with decreased risks of **osteoporosis**, **cancer**, and **heart disease**.

Herbal treatment

Herbal treatment has been used to treat many symptoms of PMS. Herbs to alleviate cramps include **angelica** root, **cramp bark**, **kava kava**, red **raspberry**, **black haw**, and **rosemary**. Black cohosh, **peppermint**, strawberry leaf, and **valerian** root have been used to decrease mood swings. **Dandelion**, couch grass, and **hawthorn** are effective diuretic herbs used to reduce bloating and swelling. **Burdock root** and red clover are liver cleansing herbs that can be useful in eliminating excess estrogen from the system. Herbs to balance hormones include **blessed thistle**, dong quai, false unicorn root, **fennel** seed, sarsaparilla root, and squaw vine. **Feverfew** may be effective for migraine headaches.

Many herbs may be beneficial as a natural antidepressant. St. John's wort (*Hypericum perforatum*) has been shown in scientific trials to be an effective antidepressant. As with the standard antidepressants, however, it must be taken continuously and does not show an effect until used for four to six weeks. A preliminary study conducted at the University of Exeter in England indicated that St. John's wort may also be an effective treatment for the moods associated with PMS. For two menstrual cycles, each woman in the study took one 300 milligram tablet of St. John's wort daily and maintained a diary in which each woman rated her symptoms on a scale of zero to four. Of the 19 women who completed the study, symptom ratings improved by about 50%. Scores on tests of anxiety and depression also dropped significantly after the first month on St. John's wort. There are also herbs, such as **skullcap** (*Scutellaria lateriflora*) and kava kava (*Piper methysticum*), that can relieve the anxiety and irritability that often accompany depression. An advantage of these herbs is that they can be taken when symptoms occur rather than continually.

Chaste-berry tree (*Vitex agnus-castus*) in addition to helping rebalance estrogen and progesterone in the body also may relieve the anxiety and depression associated with PMS. It is also used to treat menstrual irregularities, painful menstruation, and breast pain in women with PMS. Two surveys of its effectiveness were done on 1,542 women who took a liquid extract (42 drops daily) for spans up to 16 years. The patients' doctors rated its effectiveness as very good, good, or satisfactory in 92% of cases. An article on the surveys was published in the February 2000 issue of *Let's Live* magazine.

Another natural PMS remedy is **evening primrose oil** (EPO) *Oenothera biennis*. EPO is derived from the plant's seeds and is valued for its oil-containing essential fatty acids. These include **linoleic acid** and **gamma-linoleic acid** (GLA). Women with PMS have been shown to have impaired conversion of linoleic acid to GLA. Because a deficiency of GLA might be a factor in PMS and because evening primrose oil contains significant amounts of GLA, researchers have studied EPO as a potential way to reduce PMS symptoms. In several double blind studies, EPO was found to be beneficial, whereas in other studies it was no more effective than a placebo. The studies were done in the 1980s and 1990s. Despite these conflicting results, many homeopathic health practitioners recommend EPO. The usual recommended dose is 3 to 4 grams per day. EPO seems to work best when used over several menstrual cycles and may be more helpful in women with PMS who also experience breast tenderness or **fibrocystic breast disease**.

Aromatherapy

Aromatherapy oils can be a useful adjunct treatment for PMS. **Lavender** oil reduces headaches, cramps, and painful breasts. **Chamomile** and sandalwood oils may be used to relieve stress and tension. Premenstrual fatigue may be remedied by geranium, bergamot, and rosemary oils.

Homeopathy

A number of homeopathic remedies may be applied in the treatment of PMS, depending upon the individual's symptoms. Natrum muriaticum may be the appropriate remedy when irritability, lack of self-confidence, depression, anxiety, and headaches are present. **Sepia** may be given when PMS is accompanied by stress, weepiness, and to calm nerves. Symptoms of indifference, panic attacks, anger, tension, **hair loss**, sugar cravings, and a reduced sex drive may indicate that Kali carbonicum may be the appropriate remedy.

Allopathic treatment

Allopathic treatments available include over-the-counter anti-inflammatory drugs such as ibuprofen or acetominophen, antidepressant drugs, hormone treatment, or (only in extreme cases) surgery to remove the ovaries. Anti-inflammatory drugs are useful in reducing headaches, muscle aches, and cramping. One recommendation is to begin taking the anti-inflammatory one to two days before the onset of cramps. Doing so will block the cramp-causing hormones, prostaglandins, and may prevent any **nausea**, **vomiting**, and **diarrhea** associated with PMS. Hormone treatment usually involves oral contraceptives. This treatment is used to prevent ovulation and the changes in hormones that accompany ovulation. Some studies, however, indicate that hormone treatment has little effect over placebo. In 2006, the U.S. Food and Drug Administration (FDA) approved Sarafem for the treatment of premenstrual dysphoric disorder (PMDD), a severe form of PMS. As of April 2008, it was the only prescription medication indicated for the treatment of this condition. Sarafem, however, is not a new drug. It is actually a new brand name for the antidepressant fluoxetine (Prozac), which has had some very serious allegations leveled against it. Opponents of the drug claim that it is a trigger for violent and/or suicidal behavior in certain susceptible individuals.

Antidepressants

Besides Prozac, other antidepressants prescribed for PMS include sertraline (Zoloft) and paroxetine (Paxil). They are termed selective serotonin reuptake inhibitors (SSRIs) and act by indirectly increasing the brain serotonin levels, thus stabilizing emotions. Some doctors prescribe antidepressant treatment for PMS throughout the cycle, while others direct patients to take the drug only during the latter half of the cycle. Antidepressants should be avoided by women wanting to become pregnant. Side effects of sertraline were found to include nausea, diarrhea, and decreased libido.

Expected results

The prognosis for women with both PMS and PMDD is good. Most women experience relief from symptoms when treated.

Prevention

Women who have PMS typically have very poor **diets**. Maintaining a good diet, one low in sugars, salt, fats, alcohol, and **caffeine**, and high in phytoestrogens and complex carbohydrates, may prevent some of the symptoms of PMS. Consumption of more complex carbohydrates may relieve PMS symptoms since carbohydrates drop serotonin levels as they raise insulin levels. For instance, two cups of cereal or a cup of pasta has enough carbohydrate to effectively increase serotonin levels. Carbohydrates also provide steady levels of blood sugar and act to stabilize one's mood. One recommendation is to eat 100 calories of complex carbohydrates every three hours beginning one week before menstruation. Complex carbohydrates include whole wheat bread and pasta, brown rice, and whole grain foods. Caution should be taken due to the fact that a high carbohydrate diet causes water retention, which in turn is a symptom of PMS. Also, excess caffeine consumption has been associated with breast tenderness and fibrocystic breasts. Because of the potential that PMS is caused by estrogen dominance, one might also consider steps that eliminate or reduce the consumption of xenoestrogens (estrogenic compounds from the hormones and pesticides in the food supply). A vegetarian diet or consumption of organically grown meats, eggs, fruits, vegetables, and dairy products are two ways one might reduce xenoestrogen exposure.

Women should try to **exercise** three times a week, keep in generally good health, and maintain a positive self image. Because PMS is often associated with stress, avoidance of stress or developing better means to deal with stress can be important. Chronic stress has two very important effects on the body related to PMS: it increases cortisol, a hormone produced by the adrenal glands, that keeps women going through times of stress and it increase production of prolactin. Cortisol competes for progesterone receptor sites. If it is chronically elevated, women end up with the symptoms of progesterone deficiency, even though their bodies may be producing enough for their needs. Further, cortisol can stimulate feelings of irritability, anger and rage, familiar symptoms for women with PMS. Stress reduction techniques such as **biofeedback** training, exercise, time management skills, **yoga**, and **meditation** may all be useful to women who are chronically stressed.

KEY TERMS

Antidepressant—A drug used to control depression.

Estrogen—A female hormone important in the menstrual cycle.

Neurotransmitter—A chemical messenger used to transmit an impulse from one nerve to the next.

Phytoestrogens—Compounds found in plants that can mimic the effects of estrogen in the body.

Progesterone—A female hormone important in the menstrual cycle.

Serotonin—A neurotransmitter important in regulating mood.

Prickly heat

Definition

Prickly heat is a common disorder of the sweat glands characterized by a red, **itching**, prickling rash following exposure to high environmental temperatures.

Description

Prickly heat is also known as heat rash, sweat retention syndrome, and miliaria rubra. This disorder occurs during the summer months or year-round in hot, humid climates, and is caused by blockage of the sweat glands. The skin contains two types of glands: one produces oil and the other produces sweat. The sweat glands are coil-shaped and extend deep into the skin. Blockage can occur at several different depths, producing four distinct skin rashes:

- Miliaria crystallina. This is the most superficial blockage and affects only the thin upper layer of skin, the epidermis. Sweat that cannot escape to the surface forms little blisters. A bad sunburn as it just starts to blister can look exactly like miliaria crystallina.
- Miliaria rubra. Blockage at a deeper layer causes sweat to seep into the living layers of skin, causing irritation and itching.
- Miliaria pustulosais. A complication of miliaria rubra in which the sweat is infected with pyogenic (pus-producing) bacteria and contains pus.
- Miliaria profunda. The deepest of all blockages causes dry skin and possibly goose bumps.

These four types of heat rash can cause complications because they prevent sweat from cooling the body, as normally occurs when the sweat evaporates from the skin surface. Sweating is the most important human cooling mechanism available in hot environments. If it does not work effectively, the body can rapidly become overheated, with severe and potentially fatal consequences.

Causes and symptoms

The best evidence to date suggests that bacteria form the plugs in the sweat glands. These bacteria are probably normal inhabitants of the skin, and why they suddenly interfere with the free flow of sweat is not understood.

Heat rash appears suddenly and has a hot, itching, prickling sensation. Infants are more likely to get miliaria rubra than adults. Obese persons are also more susceptible to heat rash. All the sweat retention **rashes** are also more likely to occur in hot, humid weather.

Failure to secrete sweat can cause the body to overheat. Before the patient suffers heat **stroke**, there will be a period of heat exhaustion symptoms (**dizziness**, thirst, weakness) when the body is still effectively maintaining its normal temperature. Then the patient's temperature rises, often rapidly, to 104 or 105° F (40° C) and beyond. Heat stroke is an emergency that requires immediate and rapid cooling. The best method of treatment is immersion in ice water.

Diagnosis

Prickly heat can be diagnosed and treated by a dermatologist (skin disease specialist). The symptoms of a rash and dry skin in hot weather are usually sufficient to diagnose these conditions.

KEY TERMS

Ambient—Surrounding.

Antipruritic—A type of medication applied to the skin to stop itching.

Pyogenic—Capable of generating pus. Streptococci, staphylococci, and bowel bacteria are the primary pyogenic organisms.

Syndrome—A collection of abnormalities that occur together often enough to suggest that they have a common cause.

Treatment

Naturopaths maintain that **essential fatty acids** can speed the clearing of the rash. The patient should eat fish rich in fatty acids (salmon, mackerel, or herring). Other sources include dark green leafy vegetables and **flaxseed** oil.

The homeopathic remedy for prickly heat is a dose of *apis* in 30c potency, taken when the itching or prickling sensation begins. *Apis* may be taken every 2 hours for up to 10 days.

An alkaline bath is the **hydrotherapy** treatment for prickly heat. The patient should soak for 30–60 minutes in a tub filled with lukewarm water containing 1 cup of baking soda.

Herbal treatments to relieve itching include sprinkling arrow root powder over the rash or rubbing a slice of fresh daikon radish or raw potato over the rash. A sponge bath with **ginger** will increase circulation. Fresh grated ginger is steeped in boiling-hot water, cooled, and then sponged over the rash. For widespread itching the patient can take cool baths with corn starch and/or oatmeal.

Chinese herbal medicines are used internally for widespread prickly heat or externally for small areas of rash. The medicines Zhi Yang Po Fen (Relieve Itching Powder), Jie Du Cha Ji (Resolve Toxin Smearing Liquid), and Qing Dai San Cha Ji (Natural Indigo Powder Smearing Liquid) can be applied to the rash. Fresh lotus leaf with a decoction of Jin Yin Hua (*Flos lonicerae*) can be taken as a tea. A decoction of the following herbs can be taken by mouth:

- Qing Hao (*Herba artemisiae annuae*): 5g
- Bo He (*Herba menthae*): 5 g
- Jin Yin Hua (*Flos lonicerae*): 10 g
- Dan Zhu Ye (*Herba lophatheri*): 10 g
- Lu Dou Yi (*Pericarpium phaseoli munginis*): 10 g
- Ju Hua (*Flos chrysanthemi*): 5 g
- fresh lotus leaf: one piece

Allopathic treatment

Heat rash may be treated with topical antipruritics (itch relievers) containing calamine, **aloe**, menthol, camphor, **eucalyptus** oil, and similar ingredients. Dermatologists can peel off the upper layers of skin using a special ultraviolet light. This treatment will remove the plugs and restore sweating, but is not necessary in most cases.

Expected results

With cooler temperatures, the rash disappears in a day, but the skin may not recover its ability to sweat for two weeks (the time needed to replace the top layers of skin with new growth from below).

Prevention

Because the body cannot cool itself adequately without sweating, careful monitoring for symptoms of heat exhaustion is important, especially in infants or the elderly. If the symptoms of heat exhaustion do appear, the person should move into the shade or take a cool bath or shower. Clinical studies have found that application of topical antiseptics like hexachlorophene almost completely prevented these rashes. General measures to prevent prickly heat include:

- wearing loose-fitting clothing
- removing sweat-soaked clothing
- taking a cool shower or bath after sweating
- limiting outdoor activities to the mornings and evenings during hot weather
- staying in an air-conditioned environment during hot weather.

Prickly pear cactus

Description

A member of the Cactaceae (or cactus) family, prickly pear cactus, also known as nopal, grows in the United States, Mexico, and South America. It also flourishes in Africa, Australia, and the Mediterranean.

Although prickly pear cactus can tolerate a wide range of temperature and moisture levels, it grows best in sunny, desert-like conditions. Over a dozen species of prickly pear cactus belong to the *Opuntia* genus, but all of them have flat, fleshy, green-colored pads that look like large leaves and are oval to round in shape. With a tendency to grow quickly and at odd angles, the pads are actually the stems of the plant. It is in the pads that the moisture is stored. In general, the pads range from 4 in (10 cm) to 18 in (46 cm) in length. Larger pads have been known to grow as wide as 9 in (23 cm) or more. The height of a prickly pear cactus can vary and be anywhere from less than a foot to 7 ft (2.1 m) tall.

Prickly pear cactus. *(© Chris Howes/Wild Places Photography / Alamy)*

KEY TERMS

Genus—With regard to botany, genus refers to a plant's classification. Plants within the same genus have one or more common characteristics.

Spines—These sharp needle-like protrusions serve the plant in three important ways. Not only do they conduct water and reduce water loss, but they also protect the plant from herbivores.

Like most cactus plants, the prickly pear cactus has long, sharp spines that protrude from the pads. In addition, harder-to-see tiny spines, called glochids, can be found at the base of the more predominant spines. Disguised in fuzzy-looking patches, the glochids appear harmless. However, they come off the pad easily and once they've gotten into a person's skin, they can be difficult to remove and cause irritation for days.

The pads and fruit of the prickly pear cactus are edible. The fruit can be peeled and eaten raw. However, many experts suggest that the fruit is best when it is made into candy, jelly, juice, or wine. It is also available dried or in extract form.

From early spring to summer, the cactus blossoms and sets fruit, which line the edges of the pads. Anytime thereafter, until late fall, the fruit ripens and is ready to be picked. The fruit should be harvested only when ripe and, according to Savio, "Those that are best for eating fresh ripen from September to November." Once picked, the fruit has a brief shelf life—typically under a week.

Most often, the flowers of the prickly pear cactus are red, yellow, or purple with each flower yielding one fruit. On average, the fruit grows to be about 2.5 in (7 cm) long and is cylindrical in shape. Although the fruit's flesh can be found in many different colors, such as white, green, yellow, red, or purple, most people in the United States are familiar with the reddish-purple or dark red variety; whereas in Mexico, the white-skinned varieties are most common.

In a 1998 paper presented in Santiago, Chile, at the International Symposium on Cactus Pear and Nopalitos Processing and Uses, Armida Rodriguez-Felix and Monica A. Villegas-Ochoa reported that the chemical composition of prickly pear cactus pads is not unlike most vegetables. High in **amino acids**

(building blocks of proteins and highly bioactive, generally), prickly pear cactus is said to be high in fiber, B vitamins, **magnesium**, and **iron**. Rodriguez-Felix and Villegas-Ochoa listed the following ingredients as well:

- water
- carbohydrates
- protein
- fat
- minerals
- vitamin C
- beta carotene

General use

Prickly pear cactus has been used for healing purposes and as food for centuries. Loaded with protein and vitamins, the cactus, also known as nopal, has been used to treat diabetes, stomach problems, **cuts** and **bruises**, **sunburn**, windburn, **constipation**, and cold symptoms. Folk remedies abound, such as the one that involves heating the pads and placing them on a cold sufferer's chest to relieve congestion.

In an article published in *The Hindu,* India's national newspaper, Ms. Margarita Barney de Cruz, president of the Group to Promote Education and Sustainable Development, was quoted as having said that nopal was even used in the sixteenth to eighteenth centuries for painting churches and convents. Apparently, according to Barney de Cruz, this practice originated in rural Mexico when it was discovered that prickly pear cactus could be used to make a highly effective waterproof paint for homes.

Rural residents, especially farmers, in Mexico and elsewhere have utilized the prickly pear cactus for years as an effective way to mark property lines, as well as a protective barrier against predators, both animal and human. In central Africa, the juice from the pads has long been considered an effective mosquito repellent.

An important part of the Mexican culture for centuries, prickly pear cactus is still being used there for medicinal and nutritional purposes. In *Worldwide Gourmet,* edited by Michele Serre, prickly pear cactus reportedly is one of the most important food crops collected by the native population and is widely eaten as both a fruit and vegetable. In northern Mexico, the pads are often fed to dairy cows in order to add a unique and sweet flavor to their milk. Not only is this feed inexpensive, but also the resulting dairy product is highly prized among local consumers.

Today, prickly pear cactus is still being used as a remedy for many of the same problems it was used for in the past. For example, it is still commonly used topically to treat cuts, insect **bites**, sunburn, and windburn. Over the past three decades, some interesting studies have been conducted on the healing properties of prickly pear cactus, with a primary research focus on its effectiveness in lowering blood sugar levels. Wholehealthmd.com reported that animal studies done in the 1990s indicate that extracts of the prickly pear at doses lower than traditionally used can reduce blood sugar levels. This is promising for the possible development of easy-to-use extracts that may some day be effective for use in treating diabetes in humans. With regard to the cactus pads themselves, not the extract, some interesting studies have indicated that the cooked pads do help reduce sugar levels, thereby validating traditional medicinal usage. According to the experts at wholehealthmd.com, one theory of the mechanism of blood sugar lowering is that the high fiber from the pad's gooey pectin absorbs sugar in the body, and then enables the body to very slowly release sugar through the course of the day.

Two 1988 studies, one published in *Diabetes Care* and the other in the *Archives of Investigative Medicine,* conducted by Frat-Munari and colleagues indicated that consuming 100 to 500 grams of cooked pads was beneficial in treating humans with diabetes. Results confirmed a drop of between 8 to 31% of blood glucose readings. The Frati-Munari studies involved three groups on three separate "treatments." One group took nopal, one group took a water placebo, the third took zucchini squash. The water group experienced no change in serum glucose levels, whereas a slight increase of serum glucose concentrations was measured in the zucchini squash group. Those taking nopal displayed improvements in elevated blood sugar.

In a similar study published by the *Texas Journal of Rural Health* in 1998, Keith Rayburn, M.D., and colleagues had an interestingly different outcome. In the study by Rayburn et al, although blood sugar readings also fell after consumption, the water ingestion group showed a declining glucose concentration, whereas in the studies by Frati-Munari that was not the case. Dr. Rayburn and colleagues compared their study to two studies with similar findings (one by Chen et al conducted in 1988 and another by Gannon et al conducted in 1989) and made three important assessments. One explanation for the different findings might have to do with the water control group. It may have had a declining glucose reading because its members were allowed to drink as much water as they liked, which could have had a blood-sugar-lowering effect. Secondly, although the use of nopal in folk culture is not limited to one species, Rayburn and

colleagues did point out that the nopal used in their study differed from the nopal used in the 1988 studies by Frati-Munari and colleagues. In fact, Rayburn and his colleagues specifically stated, "We cannot rule out the possibility that *O. streptacantha* might have more activity than other species." Finally, and perhaps most importantly, Rayburn and colleagues concluded, "Despite lacking an acute hypoglycemic effect in our subjects, it is possible that nopal has other important metabolic effects, such as lowering lipids or increasing insulin sensitivity, as suggested by Frati-Munari et al [in two studies published in 1991]."

In a literature review published in 2002 by the *Journal of American Pharmacists Association,* Drs. Shapiro and Gong investigated the uses of several products and conclude that based on the evidence, several natural products in common use can lower blood glucose in patients with diabetes.

Interesting research continues to be conducted to validate or discover new ways in which prickly pear cactus can be used medicinally. For example, in a 1998 study published in *Archives of Pharmaceutical Research* by Dr. E. H. Park and colleagues, it was suggested that prickly pear cactus pads could be used to reduce inflammation and help relieve stomach problems. Some evidence also exists that prickly pear cactus could be effective in reducing **cholesterol** levels, but more research needs to be conducted.

Preparations

Gloves should be worn when the pads and fruit are removed from the cactus. Even those varieties regarded as "spineless" have glochids, so beware. To avoid getting punctured by the spines, use a long, sharp knife to cut and tongs to lift the pads and fruit away from the plant. Place the cuttings in a bowl or basket with handles. Novices should continue to wear gloves until all the spines are removed. To remove the spines, simply scrape them off with a blunt knife, while holding the pad at its base. Another way to remove the spines is to burn them off by passing the pad over an open flame, but this should be done with great care and suitable utensils such as tongs with heat resistant handles. Many experts recommend cutting off the edges or peeling them entirely. Most experts agree that the young, bright green pads are the most tender and the best ones for culinary purposes.

If the pads are small, they can be sautéed in a covered pan with some olive oil and vegetables, such as mushrooms, peppers, onions, or tomatoes. The ingredients should be simmered over low heat until the pad is very tender. Some people also prefer to add ground pepper and herbs such as cilantro, basil, or **rosemary**. The nopales can also be sautéed until cooked. The pads can also be sliced thin to resemble green beans. As Savio states, "They can be eaten raw in salads, boiled and fried like eggplant, pickled with spices, or cooked with shellfish, pork, chilies, tomatoes, eggs, coriander, **garlic**, and onions." In an article published by *Wilderness Way,* Christopher Nyerges suggests that the cut slices be boiled in water, drained, and then boiled again to reduce the sliminess. The slices can then be seasoned with butter and garlic powder prior to serving them. Once dried, the peeled and sliced pads are known as leather britches, according to Nyerges. Much like string beans, the leather britches add texture and fiber to stews and soups.

Omelets containing prickly pear cactus are common in the southwestern United States. When a young cactus pad is cooked in a skillet for use in an omelet, its bright green color will change to "a dull green-almost tan-as it cooks," Nyerges explained.

An interesting suggestion regarding "the importance of a penny" can be found in the *Worldwide Gourmet*. In an article on prickly pear cactus, the reader is encouraged "to rub a **copper** penny with baking soda and lemon, heat it on the grill until it turns red, and then put it in the water used to cook the nopal. This allows the water to reach its boiling point more quickly and also neutralizes the viscous substance found in the cactus."

Often tasting similar to watermelon, the fruit can be eaten raw and is delicious chilled. It is filled with little seeds, which account for its grainy texture. The seeds are edible, too, but some people prefer to remove them. In the Native American culture, it is customary to dry and grind the seeds for later use in flour.

According to Nyerges, making juice is simple. Just "press the peeled fruit through a colander to remove the seeds and add an equal amount of water to the sweet, pulpy mass." When chilled, it's a refreshing summer beverage.

For soft, shiny hair, cut a peeled cactus pad into10 small pieces. Put them in a blender with two cups of water. Turn the blender on low for a few seconds, just enough to get the cactus juices into the water but not so long that the mixture turns to mush. Then strain the pieces out, leaving only the juicy water. The juicy water can then be used as a hair massage, which should be thoroughly rinsed out after one minute. If the mixture is allowed to thicken, it can still be used, although it will take more time to rinse out.

For minor cuts, the juice from the pads has been used traditionally much like **aloe** vera. Savio suggests to "simply cut off a portion of a [peeled] pad, crush it,

and squeeze the juice into the cut; the sap will soothe the wound." When an equal measure of prickly pear cactus and water are mixed, the juice can be somewhat jelly-like, making it an ideal salve for windburn.

Recommended dosages vary, but most experts agree that eating 100 to 500 grams of the prickly pear cactus daily is reasonable, provided that there are no contraindications for doing so. For those that prefer juice, 2 to 4 ounces a day are suggested. If in doubt, consult with a physician or registered dietician for an individual assessment.

Precautions

Even Opuntia cacti, regarded as spineless, have glochids, so beware.

Consuming prickly pear cactus is not recommended while pregnant or breast-feeding. In addition, it has not been established whether it is safe for young children or anyone with severe liver or kidney disease to consume nopal.

In general, prickly pear cactus is considered safe in food form, which has been consumed for centuries by native peoples. However, less is known about the extract form, which should be taken only after consulting a physician.

People taking drugs for diabetes should not consume nopal without first consulting with a physician, since insulin or diabetes medication dosage may be affected.

Because water causes dried nopal to swell, oral doses of dried nopal should be taken with at least 8 ounces of water to avoid potentially dangerous blockages of the esophagus or intestines.

Side effects

Adverse side effects such as mild bloating, **diarrhea**, **headache**, and **nausea** have been reported after consuming nopal.

The experts at wholehealthmd.com caution that it is possible to be allergic to prickly pear cactus, although it isn't common. Signs of an allergic reaction are those typically associated with other food **allergies**. They include skin rash, **hives**, swelling, chest **pain**, breathing problems such as tightness in the chest or throat, and digestive symptoms such as diarrhea or constipation. If any of these reactions occur, one should contact a physician immediately.

Although rare, **contact dermatitis** has been reported from touching the nopal plant or applying it to broken skin. People with sensitive skin should consult a physician before using nopal as a topical ointment. More common is skin irritation caused by coming in contact with the plant's spines during the collection and cleaning process, which is why gloves should be worn, especially during the collection process.

Interactions

Because some studies have shown that consuming nopal may cause lower blood sugar by increasing the body's ability to absorb insulin, people taking drugs for diabetes, such as Actos, Avandia, Glyset, and Prandin, to name a few, should consult with their physician before adding nopal to their **diets**.

In order to avoid **hypoglycemia**, which is blood sugar that is too low, nopal should not be used in conjunction with other blood sugar medication and herbs such as **bitter melon**, **chromium**, **kudzu**, panax ginseng, or high amounts of **ginger** without the guidance of a health professional. Symptoms of hypoglycemia include shakiness, confusion, distorted speech, and loss of muscle control. Hypoglycemia is potentially an emergency and even deadly problem, and requires immediate intervention (offering fruit juice or professional health care management).

In theory, because dried nopal becomes gel-like when combined with water, taking it within two hours of other medications (or even after meals) could alter the way food and medications are absorbed in the body. Always consult with a physician or pharmacist before adding dried nopal (or any form of nopal) to your health care regime. Be sure to make a complete list of any other herbal product being taken, as well as any prescribed or over-the-counter medicine, so that an informed decision can be made.

Prince's pine

Description

Prince's pine, the evergreen shrub *Chimaphila umbellate,* is closely related to the wintergreens and is sometimes confused with striped **wintergreen** (*C. maculata*). Other names for prince's pine are pipsissewa (the most common alternate name), king's curse, ground holly, love in winter, rheumatism weed, butter weed, winter green, and pyrola umbellata.

Prince's pine grows in deep or moderate shade and requires moist, well-drained soil. It is most often found growing under conifers (pines, firs) and along mountain streams to an altitude of about 7,700 ft (2,500 m). The plant is widely distributed in the northern hemisphere and can be found in northern Europe, Siberia, Canada, Alaska, and across most of the continental United States, except for a region stretching from Florida to Texas and north through Nebraska. Prince's pine is on the endangered species list in the state of Illinois, is a threatened species in Iowa and Ohio, and is listed as vulnerable in New York. In Germany it is a protected species.

Prince's pine grows slowly, reaching a mature height of 8–10 inches (10–25 cm). The leaves, shiny dark green on top and lighter green underneath, are 2 to 3 inches (5–8 cm) long and about .5 inches (1.2 cm) wide and tapered at both ends. The leaves remain green all year. Scented light purple to cream-colored flowers develop in July and August. The leaves are used in healing. In some cultures, the yellow rhizome (root-like part) is also ground and used medicinally.

General use

Prince's pine is used as a food additive as well as a healing herb. An extract of the leaves is used to flavor root beer and candy. In Mexico, prince's pine is used to flavor an alcoholic drink made from fermented sprouted corn. The plant is also used in the perfume industry because of its pleasant scent.

Prince's pine is thought to have diuretic, astringent, antibacterial, and tonic properties. A chemical analysis of the herb shows that, among other compounds, it contains hydroquinones, which are known to have antibacterial actions, and tannins, which are known astringents.

Historically, many different Native American tribes used prince's pine to treat urinary problems and to regulate **menstruation**. The herb was also used to induce sweating and treat fevers. Some Native American tribes made a tea of the ground rhizome and used it for treating **tuberculosis** and other lung **infections**. Other traditional uses are treatment of **gonorrhea** (a sexually transmitted disease), stomach **cancer**, and rheumatism. Externally the leaves were used to treat skin diseases.

Modern herbalists mainly use prince's pine to treat urinary tract infections and as a general tonic. Prince's pine is thought to have many of the same actions as uva-ursi (*Acrtostaphylos uva-ursi*), although less intense. In 1999, a United States patent was filed

for an herbal treatment for **chronic fatigue syndrome** that has prince's pine as one of its four ingredients. Prince's pine, under the name pipsissewa, was included in the *United States Pharmacopoeia* from 1820 to 1916.

Prince's pine is also used in homeopathic medicine. Homeopathic medicine operates on the principle that "like heals like," which means that a disease can be cured by treating the person with substances that produce the same symptoms as the disease, while also working in conjunction with the homeopathic law of infinitesimals. In opposition to traditional medicine, the law of infinitesimals states that the *lower* a dose of curative, the more effective it is. To achieve a low dose, the curative is diluted many, many times until only a tiny amount remains in a huge amount of the diluting liquid. In homeopathic medicine, prince's pine is used to treat disorders of the urinary tract, female reproductive system, and male prostate.

Preparations

The leaves of prince's pine are usually harvested from wild-growing plants in the summer when the plant is in flower. They are dried for future use but lose much of their fragrance when dried. Leaves are crushed or ground and prepared as a decoction, fluid extract, or syrup. Dosage varies depending on the preparation and condition being treated. Fresh leaves are often crushed and put directly on the skin to treat skin diseases, although an extract of prince's pine can also be used externally.

Precautions

No studies have been done on the safety of prince's pine, so pregnant and breastfeeding women would do well to avoid using this herb.

Side effects

No side effects from the internal use of prince's pine have been reported. Given that this herb is also used as a food additive, it is highly likely to be safe when used internally in moderate quantities. Fresh leaves placed directly on the skin can cause **blisters** in some sensitive individuals.

Interactions

No studies have been done on interactions between prince's pine and other herbs or traditional pharmaceuticals. Individuals who regularly take dietary supplements, herbs, or pharmaceutical drugs should discuss the use of prince's pine with their healthcare provider before beginning treatment.

KEY TERMS

Astringent—A substance that reduces secretions, dries and shrinks tissue, and helps control bleeding.

Decoction—A preparation made by boiling an herb, then straining the solid material out. The liquid is then taken internally as a drink.

Diuretic—A substance that removes water from the body by increasing urine production.

Pritikin diet

Definition

The Pritikin diet is a heart-healthy high-carbohydrate, low-fat, moderate-exercise lifestyle diet developed in the 1960s. It promotes eating whole grains, vegetables, and fruit instead of animal protein, eggs, processed grains, and sugar.

Origins

Nathan Pritikin, the originator of the Pritikin Diet, was diagnosed with **heart disease** at the age of 42. In the late 1950s when Pritikin was diagnosed,

about 40% of calories in the average American diet came from fats. Pritikin was given little medical guidance on how lifestyle changes might slow his heart disease. Although educated as an engineer, Pritikin worked to devise his own heart-healthy diet. He spent the next 20 years researching diet and **nutrition**, experimenting with a variety of **diets**, such as eating only meats or only lentils. He recorded the information and his reactions to the various diets along with blood and other medical tests. He finally concluded that a program combining moderate **exercise** with a diet low in fat and high in fiber was most beneficial, and credits it with reversing his own heart disease. Based on his experience, he opened the Pritikin Longevity Center in Florida in 1975. Here people could come and immerse themselves for one or more weeks in the Pritikin Eating Plan.

In 1976, he opened the Pritikin Longevity Center in Santa Barbara, California, which moved a few years later to Santa Monica, California. Pritikin detailed his program of diet and exercise in his 1979 book, *The Pritikin Program for Diet and Exercise*, which quickly became a bestseller. He and his son, Robert Pritikin, have published eight additional books on diet and exercise. Robert Pritikin took over management of the longevity center following the death of his father in 1985.

Pritikin's diet came to national attention when Pritikin and Florida cardiologist David Lehr appeared in the CBS program "60 Minutes" in 1977. The Pritikin Diet soon became the most popular diet of the 1970s. The Pritikin Program took on new credibility in 1984 when the National Institutes of Health published its landmark lipid study that said lowering **cholesterol** reduced the risk of heart disease. Since that time, many research studies have been done to evaluate the effectiveness of the Pritikin Plan, the results of which have been published in mainstream, refereed medical journals. More than 75,000 people have experience the Plan at what is now the upscale Pritikin Longevity Center & Spa at the Turnberry Isle Yacht Club in Aventura, Florida. Millions of others have bought Pritikin's books and tried the Plan.

Benefits

The consensus among health professionals is that a diet low in fat and high in fiber can help prevent a wide range of medical problems. It also provides significant health benefits to people who already have many different health conditions. Additionally, it can also be effective in weight loss and ideal weight maintenance.

Pritikin Diet emphasizes the following specific health benefits:

- lowered total cholesterol and LDL or "bad" cholesterol
- lowered blood pressure, so that people with high blood pressure may no longer need pressure-lowering drugs
- better control of insulin levels, so that people with type 2 diabetes can often control their disease through diet and without drugs
- decrease in the circulating levels of compounds that increases the risk of heart disease and blood vessel damage
- a substantially reduced risk of heart disease, hypertension, type 2 diabetes, and breast, colon, and prostate cancers.
- lifetime freedom from obesity and all of its associated health risks and lifestyle-limiting conditions

Description

The Pritikin diet is basically the opposite of another popular program, the **Atkins diet**. While the Atkins regimen is high in fat and protein and low in carbohydrates, the Pritikin program is low in fat and protein and high in whole-grain natural complex carbohydrates. Pritikin believed the reason a large number of Americans are overweight is because they do not eat enough complex carbohydrates, such as whole-grain corn, rice, and wheat.

The Pritikin diet is based on a wide variety of foods, including fruits, vegetables, beans, and low-fat dairy products. There are four levels to the Pritikin diet, each based on calories. Individuals pick the level they want based on how overweight they are, how much weight they want to lose, and how quickly they want to. In his book, "The Pritikin Permanent Weight-Loss Manual," Pritikin lists two weeks of sample menus for each level. The book also contains information on a free-form version of the diet, in which the dieter selects any food that has low calorie density.

The Pritikin Plan is based on eating a particular number of servings of each group of foods as follows:

- at least five 1/2-cup servings of whole grains such as wheat, oats, and brown rice or starchy vegetables such as potatoes, and dried beans and peas. Refined grain products (white flour, regular pasta, white rice) are limited to two servings daily, with complete elimination of refined grain products considered optimal.
- at least four 1-cup servings of raw vegetables or 1/2-cup servings of cooked vegetables. Dark green, leafy, and orange or yellow vegetables are preferred.

- at least three servings of fruit, one of which can be fruit juice.
- two servings of calcium-rich foods such as nonfat milk, nonfat yogurt or fortified and enriched soymilk.
- no more than one 3.5 ounce cooked serving of animal protein. Fish and shellfish are preferred. Lean poultry should optimally be limited to once a week and lean beef to once a month. This diet is easily adapted to vegetarians by replacing animal protein with protein from soy products, beans, or lentils.
- no more than one caffeinated drink daily. Instead drink water, low-sodium vegetable juices, grain-based coffee substitutes (e.g. Postum) or caffeine-free teas.
- no more than four alcoholic drinks per week for women and no more than seven for men, with red wine preferred over beer or distilled spirits.
- no more than seven egg whites per week
- no more than 2 ounces (about 1/4 cup) of nuts daily

Other foods such as unsaturated oils, refined sweeteners (e.g. concentrated fruit juice, corn syrup), high-sodium condiments (e.g. soy sauce), and artificial sweeteners (e.g. Splenda) are "caution" foods. They are not recommended, but if they are used, the Plan gives guidance in how to limit them to reasonable amounts. Animal fats, processed meat, dairy products not made with non-fat milk, egg yolks, salty snacks, cakes, cookies, fried foods and similar high-calorie choices are forbidden.

An important component of the Pritikin program is exercise. Pritikin encourages many types of exercise routines, but aerobic exercises like walking, jogging, swimming, and indoor machines that simulate these activities are recommended for optimum weight loss. The suggested routine should include 5-10 minutes of warm-up, 20-30 minutes of workout, and 5-10 minutes of cool-down.

Unlike the Atkins diet, the Pritikin program can be easily followed by vegetarians, including vegans.

Preparations

No advance preparation is required for the diet.

Precautions

As with any diet, overweight individuals and those with serious medical conditions such as heart disease or diabetes who are contemplating the Pritikin diet should first check with their doctor or health care practitioner. Individuals taking certain prescription drugs may find the need for these drugs will decrease and should be monitored by their physician during and following the weight loss period.

Side effects

The Pritikin diet is not believed to cause any adverse side effects.

Research and general acceptance

Unlike many diets, the Pritikin Plan has the respect of much of the medical community and has a thirty-year history of delivering on most of its health promises. Supporters of the diet point to many studies done by both Longevity Center doctors and outside investigators and published in highly respected journals such as the *Journal of the American Medical Association* and the *New England Journal of Medicine*. People do lose weight and keep it off, along with decreasing the risk of heart disease when following the plan.

Dietitians and nutritionists also like the fact that the diet teaches people how to eat well using ordinary foods rather than special pre-packaged foods. This keeps the cost of following the Plan low, especially since the Plan calls for dieters to eat only small quantities of meat. In addition, the Plan is designed to provide a balance of vitamins and minerals from food and does not rely on dietary supplements.

The biggest criticism of the Pritikin Plan is that it requires rigorous self-discipline to stay on for a lifetime. People who do well on the Pritikin Plan tend to be highly motivated and zealous about following the diet. Many healthcare professionals feel long-term success for most people is more likely to occur if the dieter follows a well-balanced but less rigorous diet.

Some nutritionists also take issue with whether the low fat component of the diet allows people to get enough beneficial fats such as **omega-3 fatty acids** and whether absorption of the fat-soluble vitamins A, D, E, and K is impaired. To date these criticisms have not been supported by research findings. However, critics were handed more ammunition by a long-term study of 49,000 American women ages 50–79 that found that a low-fat diet had no effect on the risk of developing heart disease or **cancer**. The study was published in February 2006 in the *Journal of the American Medical Association*. The findings are controversial, and go against much current medical thinking. This study will certainly stimulate additional research on low-fat diets.

Training and certification

The diet can be followed by nearly anyone and requires no special training or certification.

KEY TERMS

Carbohydrates—Neutral compounds of carbon, hydrogen, and oxygen found in sugar, starches, and cellulose.

Cholesterol—A steroid alcohol found in human cells and body fluids, implicated in the onset of heart disease.

Complex carbohydrates—A type of carbohydrate found mostly in green plants and vegetables.

Crohn's disease—A disease of the colon, characterized by diarrhea, cramps, and loss of appetite and weight.

Triglycerides— A blood fat lipid that increases the risk for heart disease.

Vegan—A strict vegetarian diet that does not allow meat or dairy products.

Probiotics

Definition

Probiotics, as defined by the Food and Agricultural Organization of the United Nations (FAO), are "live microorganisms administered in adequate amounts which confer a beneficial health effect on the host." The microorganisms referred to in this definition are non-pathogenic bacteria (small, single celled organisms which do not promote or cause disease), and one yeast, *Saccharomyces*. They are considered "friendly germs," due to benefits to the colon and the immune system. The word probiotic is a compound of a Latin and a Greek word; it means "favorable to life." Probiotics is also sometimes used to refer to a form of nutritional therapy based on eating probiotic foods and dietary supplements. Although probiotic supplements have also been used with farm animals, most are produced for human consumption in the form of dairy products containing two types of microbes—lactobacilli and bifidobacteria. As with the extended use of **royal jelly**, probiotics are now also being used in face creams and similar cosmetic products.

A new category called prebiotics now also appears in the literature. Prebiotics refer mainly to certain foods, and occasionally to certain food products, that support probiotic microorganism viability, enhancing their survivability. Included among prebiotics are foods such as Jerusalem and regular artichokes, oats, leeks, onions and whole grain breads or cereals. Examples of prebiotic food products are the **Fructooligosaccharides** (fructo-oligo-saccharides, or fruit derived, digestion resistant sugars) (FOS), also in honey, and the galactooligosaccharides (galacto-oligo-saccharides), sugars in galactose-containing foods like goats milk.

Origins

Although the term probiotics is relatively recent, as are science-based investigations, the use of probiotic-containing fermented foods in many cultures of the world predates the advent of refrigeration. The applied notion of improving health by supplementing the natural microflora of the human intestines with additional bacteria taken by mouth goes back to the late nineteenth century. At that time, some physicians attributed sickness and the **aging** process to a build up of waste products (or, putrefaction) in the colon (the lower part of the large intestine that empties into the rectum), and toxic materials leaking from the colon into the bloodstream. The process of leakage—

now referred to as gut permeability or leaky gut syndrome— and the poisoning that resulted from it, were called autointoxication. The autointoxication theory assumed that dietary changes aimed at reducing toxic decomposition in the colon would be beneficial to health. Some observers knew about the use of lactic acid bacteria in sausage-making to ferment the meat and protect it from spoilage. Because these bacteria are harmless to humans, it was thought that adding them to the diet by eating fermented foods would reduce the amount of toxins produced in the colon. The Lactobacilli group of bacteria, some of which are found in yogurt, was the first identified probiotic. In the 1920s and 1930s, many doctors recommended **acidophilus** milk, which contains the lactobaccili bacterium called *Lactobacillus acidophilus,* for the treatment of **constipation** and **diarrhea**. This treatment was effective for many patients.

The next phase in the development of probiotics came in the 1950s, when medical researchers began to study *L. acidophilus* as a possible answer to some of the digestive side effects of taking antibiotics. It was known that antibiotic medications upset the natural balance of the intestinal microflora by killing of the beneficial as well as the pathogenic bacteria. The researchers thought that taking oral preparations of *L. acidophilus* might offset the side effects of the antibiotics.

One of the chief difficulties in benefiting from probiotic supplementation has been assuring survivability of the bacteria as it passes through the acidity of the stomach and the digestive processes of the small intestine and successfully colonizing in the colon. Recently, a new probiotic with exceptional survivability and colonization characteristics, as demonstrated in studies, has emerged. This probiotic, screened from many **strains** of lactobacilli and named after its co-discoverers, Sherwood Gorbach and Barry Goldin, is known as Lactobacillus GG (LGG). LGG was demonstrated effective against psuedomembranous **colitis**, an infection of the colon by *Clostridium difficile* as a result of antibiotic overkill of beneficial bacteria, and against atopic **eczema** in children due to gut permeability. LGG was demonstrated to have positive results against Candida in mice, as well. Three patents have been awarded on LGG from June 1989 to May 1995. In 1987, a Finnish dairy cooperative, Valio, Ltd., was granted a license to conduct research. About 1992, Valio released a fermented milk product with LGG called Gefilus. In 1996, a division of an American corporation was formed, called CAG Functional Foods, which markets LGG as the product Culturelle. One source reported significant benefit from the use of Culturelle when cultured in milk. Culturelle is currently available only in capsules, but a yogurt product is anticipated to be marketed soon.

Much of the research and marketing of proven probiotics is conducted outside the United States. One such research proven probiotic strain is Lactobacillus plantarum 299v. It has been particularly valuable in **irritable bowel syndrome** (IBS) and recovery from surgery. Its colonization ability was proven using biopsy.

Two proven beneficial strains marketed in the United States are *Lactobacillus reuteri,* a Swedish product proven effective against diarrhea in children due to a rotavirus (a virus transmitted from feces), available in the Stoneyfield brand of yogurt, and *Saccharomyces boulardii*, a yeast product available in capsules effective against antibiotic associated diarrhea.

Benefits

Probiotic foods and dietary supplements have been recommended as treatments for a variety of diseases and disorders, ranging from problems confined to the digestive tract to general health issues.

Intestinal complaints

To summarize, probiotic organisms, in particular the LGG strain, have been shown to be helpful in managing the following intestinal disorders:

- Pseudomembranous colitis, a potentially life-threatening inflammation of the colon caused by an overgrowth of the bacterium *Clostridium difficile* as a result of the patient's having taken antibiotics that causes profuse watery diarrhea, cramps, and low-grade fever.
- so-called "traveler's diarrhea"
- acute nonbacterial diarrhea
- rotaviral diarrhea
- irritable bowel syndrome (IBS)
- bacterial overgrowth in the small bowel by organisms such as Helicobacter pylori, implicated in gastric ulcers (studies have demonstrated benefit but not cure)

Lifestyle-related disorders

Some supporters of probiotics go beyond applications limited to treatment of intestinal disorders. In keeping with the theory of autointoxication, they maintain that probiotics are effective in treating a wide range of chronic and acute illnesses thought to result from a condition called intestinal dysbiosis, or

poor intestinal health quality due to toxic buildup, putrefaction, and leaky gut syndrome. Intestinal dysbiosis is defined as an imbalance among the various microorganisms in the digestive tract. This imbalance is attributed to a combination of Western high-protein **diets**, **stress**, environmental pollution, and allopathic medications. Putrefaction is believed to result from a low fiber diet, chronic constipation or sluggish colon, and poor food combining leading to increased gut fermentation. Leaky gut syndrome is the term used to suggest that the effect of these toxins on the intestinal cell walls is damaging to intestinal integrity, and as a result, large molecules of relatively undigested food and toxins cross the intestinal membrane into the blood stream.

Some alternative practitioners maintain that the following diseases and disorders are directly related to intestinal dysbiosis or may also be beneficially treated with probiotics:

- mental health problems
- chronic fatigue syndrome
- muscular soreness and stiffness
- autoimmune disorders, including lupus, rheumatoid arthritis, ankylosing spondylitis, enteric arthritis, and Reiter's syndrome (by immune stimulation and repair of the leaking gut)
- lactose intolerance (by increasing the presence of lactase)
- infectious diseases
- high blood pressure (research has demonstrated a systolic blood pressure decrease of 10–20 mm Hg with the use of a fermented milk product
- high cholesterol (clinical studies have not been conclusive; as one source said, "evidence is not overwhelming")
- cancer (by decreasing exposure from gene altering substances)
- menopausal problems in women (by improving the liver's ability to detoxify and eliminate hormonal metabolites)
- vaginosis (once thought to be relatively benign, now implicated in easier transmission of sexual diseases, pelvic inflammatory disease, and pregnancy-related complications, improved by reducing vaginal pH which inhibits growth of unfavorable bacteria)
- allergies and asthma (a double-blind placebo-controlled study demonstrated a 50% drop in children followed up to two years of age)
- kidney stones, by inhibiting the absorption of oxalate from the intestines

More specifically, probiotic foods and dietary supplements are claimed to counteract intestinal dysbiosis in the following ways:

- production of vitamins. Friendly bacteria are said to manufacture vitamin B_3, vitamin B_6, and folic acid.
- anti-tumor and anti-cancer activity
- suppression of pathogenic microorganisms in favor of the non-pathogenic
- relief of anxiety symptoms through indirect detoxification
- protection against radiation and other environmental toxins
- support of the immune system, by reducing immune load
- recirculation of female hormones in the bloodstream by a cleaner liver and cleaner blood, thus maintaining higher levels of estrogen in menopausal women
- maintenance of smooth bowel functioning

Description

Products

Probiotics is a nutrition-based therapy and relies primarily on the addition of foods or supplements containing friendly bacteria to the diet. Some recommended foods are ordinary grocery store items that involve fermentation in their production; these include miso, pickles, sauerkraut and fermented dairy products such as yogurt and kefir. As mentioned, other food or food products called prebiotics, such as Jerusalem artichokes and FOS, are thought to support the growth of the beneficial bacteria in the intestines. Most users and recommenders of probiotics, however, encourage the use of loose powdered, refrigerated dietary supplements of friendly bacteria or LGG capsules. Some of these products are milk-based, while others are milk-free. Probiotic dietary supplements are over-the-counter (OTC) preparations that can be easily purchased at grocery or health food stores, or from European manufacturers over the Internet. The types of bacteria most often recommended are *Lactobacillus GG*, *Lactobacillus acidophilus*, *Lactobacillus bulgaricus*, and, especially for children *Bifidobacterium bifidum*. Breast milk is reported to contain nutrients that support bifidobacterium growth.

Dosage and administration

Some practitioners distinguish between a therapeutic dose of probiotic products, which is given for 10 days, and a maintenance dose, which is used afterward. One source gives 2–5 level tsp (5–10 g) of powdered supplement as the daily therapeutic dose if the patient is taking *L. acidophilus* or *B. bifidum*, 1–3 tsp

(3–6 g) if the patient is using *L. bulgaricus*. The maintenance dose of *L. acidophilus* is given as 0.5 tsp (1 g) daily; of *B. bifidum*, 2 tsp (4 g) daily; of *L. bulgaricus*, 0.5 tsp (1 g) with each meal. The recommended dose of LGG capsules is once daily. A dose two or three times daily may also be used initially to overcome acute symptoms.

Patients are advised to take these supplements with spring water, but not with juice or broth. These fluids are thought to stimulate the secretion of stomach acids that will destroy the friendly bacteria.

Preparation

The fact that probiotic products include some ordinary dairy and grocery items means that most people who use them do not think of them as medications and see no need to consult a health professional. Persons who are taking prescription medications and persons with compromised immune status, however, are advised to consult their doctors before using probiotic dietary supplements. These products often influence the bulk and frequency of bowel movements, thus increasing the elimination rate of some medications and necessitating a dose adjustment.

Some practitioners of nutritional therapies recommend cleansing the lower digestive tract with an enema or colonic treatment before beginning a course of probiotic supplements. Conversely, use of probiotics may be particularly recommended following colonic therapy as it is following antibiotic therapy.

Precautions

Although the bacteria in probiotic supplements are human-friendly, some persons may have food **allergies** or a digestive tract that is sensitive to miso, other fermented foods, or the milk powder that may be in some products. Vegetarians or persons who cannot digest milk-based products may prefer probiotic supplements with a rice base.

Product reliability is a concern because probiotic dietary supplements are not regulated by the Food and Drug Administration (FDA) and because study after study demonstrates the difficulty of maintaining a live probiotic culture, in or out of the body. One study of the microorganisms in 25 dairy products and 30 powdered products found that more than one third of these products contained no living microorganisms, and only 13% of the products contained all of the bacteria types listed on the label. One practitioner suggests the following guidelines for evaluating the effectiveness of probiotic products:

- Number of viable organisms. A number lower than 1 billion organisms per gram is considered inadequate for a therapeutic dosage.
- Type of organism. Single-strain products are considered more useful than multi-strain products on the grounds that the different bacteria in multi-strain products may compete with each other.
- Processing method. Products that have been put through a centrifuge or ultra-filtration system are thought to have fewer viable bacteria.
- Additives. Products that do not have hormones or other chemicals added to stimulate the growth of the bacteria are considered more effective.
- Form. Powdered supplements are considered preferable to liquids. Encapsulated powders are second-best, except in the case of LGG capsules.
- Storage. Probiotic products that are not refrigerated are thought to lose much of their effectiveness.

Side effects

The side effects of treatment with probiotics may include a condition called excessive drainage syndrome, which includes **headache**, diarrhea, bloating, or constipation. Another commonly reported side effect is intestinal **gas**. These side effects are attributed to the cleansing of toxins from the body and may last for some days. Practitioners recommend lowering the supplement dosage to reduce the side effects, or pretreating with colonic therapy, or stool softeners and fiber as tolerated or advised by a healthcare professional.

Research and general acceptance

More studies of probiotics have been done in Europe than in the United States, which is reflected in the fact that the leading manufacturers of probiotic supplements are presently based in Europe. Some mainstream researchers in Europe as well as in the United States are skeptical of some of the claims made for probiotics. Their reasons include the following considerations:

- The studies done in support of probiotics are mostly anecdotal or heavily reliant on test-tube experimentation rather than on clinical trials in human subjects. As of 2000, relatively few strains of probiotic bacteria have been shown to have clinical value. These strains are helpful in treating milk allergy and irritable bowel syndrome in humans, and in improving resistance to a yeast called *Candida* in immunocompromised mice.
- The basic concept of probiotics is based on a misunderstanding of the role of microflora in the human digestive tract.

KEY TERMS

Autointoxication—Self-poisoning by toxic products formed within the body during intestinal digestion. This term was coined around 1885 as part of a theory that regarded intestinal function as a central aspect of health.

Colon—The part of the large intestine that lies between the cecum and the rectum, and is divided by name into three parts, the ascending, transverse and descending colon. In a healthy person, the ascending colon rises upward intra-abdominally from above the right leg toward the right hip, the transverse colon crosses over to the left hip, and the descending colon segment joins the rectum intra-abdominally, near the top of the left leg. An unhealthy colon may droop, drape, or twist, and be enlarged or otherwise irregularly shaped.

Intestinal dysbiosis—An imbalance among the various microorganisms that live in the digestive tract.

Intestinal microflora—The bacteria and other microorganisms that live in the human gastrointestinal tract.

Miso—A fermented paste made from soybeans, salt, and rice or barley, used to flavor soups and sauces in Oriental cooking.

Pseudomembranous colitis—A potentially life-threatening inflammation of the colon, caused by a toxin released by the Clostridium difficile bacterium that multiplies rapidly following antibiotic treatment.

Traveler's diarrhea—Diarrhea caused by ingesting local bacteria to which one's digestive system has not yet adapted.

- It is difficult to see how bacteria taken by mouth can survive the process of human digestion. At present, only two species of lactobacilli, *L. GG* and *L. plantarum 299v*, have been shown to be able to colonize the human gut.
- Supporters of probiotics emphasize two types of bacteria, the lactobacilli and the bifidobacteria, and virtually ignore the hundreds of other species that live in the intestines.

More clinical studies examining the effects of probiotics on specific conditions are being conducted. One such study in the making will examine the effect of probiotics on hepatic steatosis, or fatty degeneration of the liver. An inclusion criteria was biopsy diagnosis of non-alcoholic fatty liver disease. The study is expected to be completed in October 2004.

Training and certification

As of 2000, there are no training or certification programs specifically for probiotics. Most practitioners who recommend probiotics have been trained as nutritionists or naturopathic physicians.

Prolotherapy

Definition

Prolotherapy is the treatment of soft-tissue damage through the use of injections. The injections lead to inflammation in the area, and the body reacts by increasing the blood supply and sending more nutrients to the area, resulting in tissue repair. The term prolotherapy is derived from the word *prolo*, short for proliferation, as the therapy is intended to proliferate tissue growth in the damaged area.

Origins

The idea behind this therapy dates back more than 2000 years to Hippocrates, who used it to treat soldiers with injured shoulders. Instead of injections Hippocrates used a hot poker, which he speared into the shoulder joint, causing inflammation and stimulating the body to repair itself. Prolotherapy using injections was derived from a treatment developed by H.I. Biegeleisen called sclerotherapy, used to treat **varicose veins**. In the 1950s, George Hackett, often called a pioneer of prolotherapy, was experimenting with and touting the benefits of the procedure.

Benefits

Prolotherapy has been used to treat chronic neck and back **pain**, joint pain from arthritis, headaches, **fibromyalgia**, sports injuries, **carpal tunnel syndrome**, and partially torn tendons, ligaments, and cartilage.

The benefit of prolotherapy is that it is a nonsurgical procedure that can be administered in a clinic, saving patients from undergoing anesthesia and surgery followed by a long recovery period. It's also cheaper than surgery. The average back or neck surgery costs about $40,000, while a single prolotherapy treatment runs anywhere from $90–$200, though patients may need several treatments. Furthermore, with prolotherapy there is no loss of mobility as there is with back surgery, when doctors fuse together the vertebrae in an effort to create stability in the spine.

Another benefit is that prolotherapy takes patients off drugs. Patients escape the cost of pain killers and their side effects.

Description

In prolotherapy, a doctor injects a sugar water or salt water-based solution into the damaged ligament or tendon at the point where it attaches to the bone. The injection produces an inflammation, which increases blood flow, swelling, and pain. The body then launches a course of repair and healing. The inflammation tricks the body into thinking another injury has occurred, so it sends in macrophages, which are cells that ingest and destroy the irritant solution. These cells clean up the area. The body then sends in fibroblasts, which are cells that help build fibrous tissue. The fibroblasts excrete collagen, a protein that makes the ligaments denser and stronger. The stronger ligaments provide more support for the joints, often alleviating the pain.

The length of treatment sessions varies and depends on the area being treated. For example, treatment of an injured elbow involves injections only in one site, whereas treatment of larger areas, like the neck and back, involves more injections. Treating an elbow may take only a few injections, whereas the back may involve up to 50 injections for one treatment. The more injections, the longer the treatment.

The treatment generally involves several sessions, usually three to six, which are separated by two or three-week intervals. Some practitioners space treatments four or six weeks apart.

Though doctors have practiced prolotherapy for more than a half-century, it is still considered an alternative treatment; therefore most insurance policies don't cover it.

Preparations

Analgesics and sedatives may be given before treatment to reduce discomfort. Many patients, however, forgo sedation because they cannot drive home

KEY TERMS

Analgesics—Referring to a class of medicines that relieves pain, including aspirin and Tylenol.

Fibroblasts—Found in connective tissue, these fat, oval cells help build fibrous tissue.

Ligaments—The rubbery band of tough tissue that connects one bone to another bone in a joint.

Macrophages—Often called the garbage collectors of the body, these cells, found in connective tissue, lymphatic tissue, and bone marrow, destroy other cells, microorganisms, and foreign matter found in the blood and tissues.

Tendons—Refers to the tough, fibrous connective tissue that connects muscles to bones.

afterward. Many doctors use topical freeze sprays, ice packs, or anaesthetic cream to reduce skin sensation.

It is recommended that patients drink plenty of water in the hours before the procedure because it helps with cell hydration.

Precautions

As with all procedures, there are risks. Patients are asked to sign a consent and waiver. Since the treatment involves inserting a needle into the body, there is a chance of puncture to arteries, nerves, or even lung tissue, depending on the area to be treated. Some patients may have allergic reactions to the substance injected.

Side effects

The most common side effects include pain during the injections and soreness and stiffness afterward. Patients are reminded not to take any anti-inflammatory drugs, such as ibuprofen, because these will impede the healing process prolotherapy aims to set in place.

Research and general acceptance

According to the Alternative Medicine Network, studies show prolotherapy relieves 92% of those treated; however, the therapy is relatively untested.

Opponents wonder how prolotherapists decide where to make their injections since areas of ligament weakening won't show up on an x ray. Others fear nervous system damage should the substance be injected too close to the nerves. Prolotherapy received a bad name in the 1950s when the *Lancet* reported three cases of paralysis and two deaths after treatment. It did not resurface for a number of years. As of 2000, there were only 400–500 U.S. doctors administering the treatment.

In the April 1997 issue of *Headache,* Dr. Irwin Abraham of Rochester, New York, reported preliminary findings of a study on prolotherapy to cure chronic headaches with **neck pain**. Of 17 patients, 11 said their symptoms were improved or relieved after treatment. At a two-year follow-up, nine reported complete relief, one had partial relief, and one's symptoms had relapsed.

Training and certification

Abraham stated in *Headache* that prolotherapy is a "safe, simple, and long-lasting treatment that any primary care physician can perform in the office setting." Doctors can learn prolotherapy through observation and instruction by a skilled prolotherapist.

The American Association of Orthopedic Medicine offers courses and workshops to train physicians and works to increase the number of physicians using the therapy.

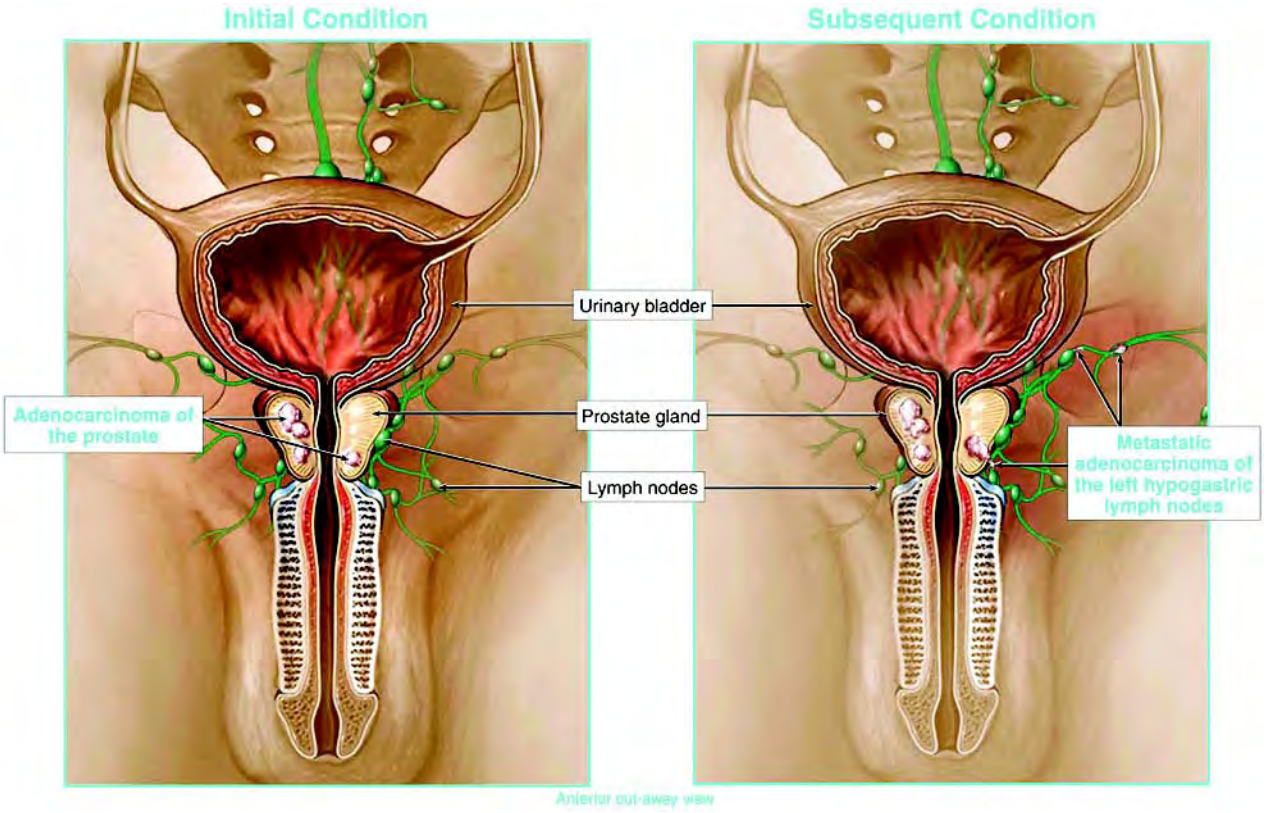
Prostate cancer

Definition

In prostate **cancer** cells of the prostate become abnormal and start to grow uncontrollably, forming tumors. Tumors that can spread to other parts of the body are called malignant tumors or cancers. Tumors incapable of spreading are said to be benign.

Description

As of 2007, prostate cancer was the most commonly diagnosed malignancy among adult males in Western countries. Although prostate cancer is often very slow growing, it can be aggressive, especially in younger men. Given its slow growing nature, many men with the disease die of other causes rather than from the cancer itself. In 2007, there were more than 218,000 new cases of prostate cancer and more than 27,000 deaths from the disease in the United States. More than 2 million men in the United States who have been diagnosed with prostate cancer at some



Progression of prostate cancer. *(© Nucleus Medical Art, Inc. / Alamy)*

point were still alive as of 2007, according to the American Cancer Society (ACS). The Canadian Cancer Society reported about 22,000 new cases of prostate cancer and 4,300 deaths in 2007. It is the number one cancer among Canadian men accounting for 27% of all cancers in males. Although prostate cancer may be very slow-growing, it is a heterogeneous disease and can be quite aggressive, especially in younger men. When the disease is slow-growing, it may often go undetected. Because it may take years for the cancer to develop, many men with the disease will probably die of other causes, rather than from the cancer itself.

Prostate cancer affects African American men twice as often as it does Caucasian men, and the mortality rate among African Americans is also two times higher. African Americans have the highest rate of prostate cancer in the world, whereas the rate in Asians is one of the lowest. However, although the rate of prostate cancer in native Japanese is low, the rate in Japanese Americans is closer to that of white American men. This pattern suggests that environmental factors and diet also play a role in prostate cancer.

The prostate, testicles, and seminal vesicles are the major male sex glands. These three glands together secrete the fluid that makes up semen. The prostate is about the size of a walnut and lies just behind the urinary bladder. A tumor in the prostate interferes with proper control of the bladder and normal sexual functions. Often, the first symptom of prostate cancer is difficulty in urinating. However, because the same symptom can be caused by a common, noncancerous condition of the prostate (benign prostatic hyperplasia), this symptom is insufficient in determining if prostate cancer is present.

As the prostate cancer grows, some of the cells break off and spread to other parts of the body through the lymph or the blood. The most common sites to which it spreads are the lymph nodes, the lungs, and various bones around the hips and the pelvic region.

Causes and symptoms

As of the late 2000s the cause of prostate cancer was not known; however, the disease is found mainly in men over the age of 55. The average age at diagnosis is 72. In fact, 80% of the prostate cancer cases occur in men over the age of 65. While only 1 in 100,000 men

gets prostate cancer under the age of 40, the frequency rises to 1,326 cases per 100,000 for men between the ages of 70 and 74. Hence, age appears to be a risk factor for prostate cancer.

Some studies have shown that a family history of prostate cancer puts a man at higher risk for developing this disease. In addition, there is some evidence that a diet high in fat increases the risk of prostate cancer. Workers in the electroplating and welding industries who are exposed to the metal cadmium and rubber industry workers appear to have a higher than average risk of getting this disease. Research has indicated that men with high plasma testosterone levels also may be at an increased risk.

Frequently, prostate cancer has no symptoms, and the disease is diagnosed when the patient goes for a routine screening examination. However, occasionally, when the tumor becomes large or the cancer has spread to the nearby tissues, the following symptoms may be seen:

- weak or interrupted flow of the urine
- frequent urination (especially at night)
- difficulty starting urination
- inability to urinate
- pain or burning sensation when urinating
- blood in the urine
- persistent pain in lower back, hips, or thighs (bone pain)
- painful ejaculation

Diagnosis

Prostate cancer is curable when detected early. However, because the early stages of prostate cancer may not have any visible symptoms, it often goes undetected until the patient goes for a routine physical examination. Diagnosis of the disease is made using some or all of the following tests.

Digital rectal examination (DRE)

In order to perform this test, the doctor puts a gloved, lubricated finger into the rectum to feel for any lumps in the prostate. The rectum lies just behind the prostate gland, and a majority of prostate tumors begin in the posterior region of the prostate. If the doctor does detect an abnormality, then more tests are ordered to confirm the diagnosis.

BLOOD TESTS. Blood tests are used to measure the amounts of certain protein markers, such as the prostate-specific antigen (PSA), found circulating in the blood. The cells lining the prostate generally make this protein and a small amount can be detected in the bloodstream. However, prostate cancers produce a lot of this protein, and it can be easily detected in the blood. Hence, when PSA is found in the blood in higher than normal amounts for the patient's particular age group, cancer may be present.

TRANSRECTAL ULTRASOUND. A small probe is placed in the rectum, and sound waves are released from the probe. These sound waves bounce off the prostate tissue and an image is created. Since normal prostate tissue and prostate tumors reflect the sound waves differently, the test can be used quite efficiently to detect tumors. Though the insertion of the probe into the rectum may be slightly uncomfortable, the procedure is generally painless and takes only 20 minutes.

PROSTATE BIOPSY. If cancer is suspected from the results of any of the above tests, the doctor removes a small piece of prostate tissue with a hollow needle. This sample is then checked under the microscope for the presence of cancerous cells. Prostate biopsy is the most definitive diagnostic tool for prostate cancer.

If cancer is detected during the microscopic examination of the prostate tissue, the pathologist grades the tumor using the Gleason system, which means the pathologist scores the tumor on a scale of 1 to 10 to indicate how aggressive the tumor is. Tumors with a lower score are less likely to grow and spread than are tumors with higher scores. The Gleason system is different from staging the cancer. When doctors stage a cancer, they give it a number that indicates whether it has spread, as well as the extent of its spread. In Stage I, the cancer is localized, whereas in the last stage, Stage IV, the cancer cells have spread to other parts of the body.

X RAYS AND IMAGING TECHNIQUES. A chest x ray may be ordered to determine whether the cancer has spread to the lungs. Imaging techniques (such as computed tomography scans and magnetic resonance imaging), in which a computer is used to generate a detailed picture of the prostate and areas nearby, may be used to get a clearer view of the internal organs. A bone scan also may be used to check whether the cancer has spread to the bone.

Treatment

The doctor and the patient decide on the treatment mode after considering many factors. Such factors include the patient's age, the stage of the tumor, his general health, and the presence of any other illnesses. In addition, the patient's personal preferences

and the risks and benefits of each treatment protocol are taken into account before any decision is made.

Various natural remedies used to treat noncancerous prostate problems can be implemented with the approval of a medical doctor along with the recommended medical care. **Prostate enlargement** is a precursor to prostate cancer, and many alternative treatments are available to alleviate benign prostate enlargement. Among these is the herb **saw palmetto**, which has shown to be highly effective in the treatment of prostate enlargement. In addition, treatments that focus on strengthening the immune system of the cancer patient can be helpful, using physiological and psychological therapies.

Lycopene, the antioxidant found in tomatoes and tomato products, has long been thought to help prevent prostate cancer. In the first clinical intervention trial of prostate cancer patients in 2001, lycopene supplementation slowed the progression of prostate cancer.

Visualization of a healthy, cancer-free body, and of cancer cells as weak and confused is believed to constitute healing imagery. Numerous studies affirm the power of a positive mental attitude in assisting conventional medical treatment to be more effective, while at the same time, minimizing undesirable side effects of chemotherapy or radiation.

Compounds contained in **maitake** mushrooms are believed to enhance the immune response and slow the growth of tumors. One study by a homeopathic physician, Abram Ber of Phoenix, Arizona, found that patients with prostate cancer treated with maitake mushroom tablets reported a decrease in the urge to urinate, along with improvement in the flow of urine.

Watchful waiting

Watchful waiting means no immediate treatment is recommended, but doctors keep the patient under careful observation. This option is generally used in older patients when the tumor is not very aggressive and the patients have other, more life-threatening illnesses. Prostate cancer in older men tends to be slow-growing. Therefore, the risk of the patient dying from prostate cancer, rather than from other causes, is relatively small.

Allopathic treatment

Surgery

For early stage prostate cancer, surgery is the best option and the most common one. Radical prostatectomy involves complete removal of the prostate. During the surgery, a sample of the lymph nodes near the prostate is removed to determine whether the cancer has spread beyond the prostate gland. Because the seminal vesicles (the glands where sperm is made) are removed along with the prostate, **infertility** is a side effect of this surgery. In order to minimize the risk of **impotence** (inability to have an erection) and incontinence (inability to control urine flow), a procedure known as nerve-sparing prostatectomy is used.

In a different surgical method, known as the transurethral resection procedure (TURP), only the cancerous portion of the prostate is removed, by using a small wire loop that is introduced into the prostate through the urethra. This technique is most often used in men who cannot have a radical prostatectomy due to age or other illness, and it is rarely recommended.

RADIATION THERAPY. Radiation therapy involves the use of high-energy x rays to kill cancer cells or to shrink tumors. It can be used instead of surgery for early stages of cancer. The radiation can either be administered from a machine outside the body (external beam radiation), or small radioactive pellets can be implanted in the prostate gland in the area surrounding the tumor.

HORMONE THERAPY. Hormone therapy is commonly used when the cancer is in an advanced stage and has spread to other parts of the body. Prostate cells need the male hormone testosterone to grow. Decreasing the levels of this hormone, or inhibiting its activity, causes the cancer to shrink. Hormone levels can be decreased in several ways. Orchiectomy is a surgical procedure that involves complete removal of the testicles, leading to a decrease in the levels of testosterone. Alternatively, drugs (such as LHRH agonists or anti-androgens) that bind to the male hormone testosterone and block its activity can be given. Another method tricks the body by administering the female hormone estrogen. When this is given, the body senses the presence of a sex hormone and stops producing testosterone. However, there are some unpleasant side effects to hormone therapy. Depending on the doses of estrogen, men may have **hot flashes** (such as those symptomatic of **menopause**), enlargement and tenderness of the breasts, erectile dysfunction (ED) or loss of sexual desire, as well as a risk of **blood clots**, heart attacks, and strokes.

CHEMOTHERAPY. Chemotherapy is the use of drugs to treat a disease. The drugs can either be taken as a pill or injected into the body through a needle that is inserted into a blood vessel. This type of treatment is called systemic treatment because the

drug enters the blood stream, travels through the whole body, and kills the cancer cells that are outside the prostate. Chemotherapy is sometimes used to treat prostate cancer that has recurred after other treatment. As of 2008, research was ongoing to find more drugs that are effective for the treatment of prostate cancer.

CRYOTHERAPY. Cryotherapy was still in the experimental stages in the United States as of early 2008. Cryosurgery destroys the cancer by freezing it and is under study as an alternative to surgery and radiation therapy. To avoid damaging healthy tissue, the doctor places a cryoprobe in direct contact with the tumor to freeze it. It is likely to be at least several years before cryotherapy is ready for general use in the United States. However, cryotherapy is in use in India as a primary treatment for localized or locally advanced prostate cancer.

Expected results

According to the American Cancer Society, the survival rate for all stages of prostate cancer combined increased from 50 to 87% between 1975 and 2005. Due to early detection and better screening methods, nearly 60% of the tumors are diagnosed while they are still confined to the prostate gland. The five-year survival rate for early stage cancers is almost 99%. Sixty three percent of the patients survive 10 years, and 51% survive 15 years after initial diagnosis.

Prevention

Because the cause of the cancer is not known, there is no definite way to prevent prostate cancer. However, the American Cancer Society recommends that all men over age 40 have an annual rectal exam and that men have an annual PSA test beginning at age 50. Those who have a higher than average risk, including African American men and men with a family history of prostate cancer, should begin annual PSA testing even earlier, starting at age 45.

Some evidence suggests that a diet high in fat increases the risk of prostate cancer. A diet high in fruits and vegetables may decrease the risk. Studies also suggest that nutrients such as soy isoflavones, **vitamin E**, **selenium**, **vitamin D**, and **carotenoids** (including lycopene, the red color agent in tomatoes and beets) may decrease prostate cancer risk. Further studies to find out whether men can reduce their risk of prostate cancer by taking certain dietary supplements were underway as of early 2008, according to the National Cancer Institute.

KEY TERMS

Anti-androgen drugs—Drugs that block the activity of the male hormone.

Benign—Not spreading, cancerous, or life-threatening.

Benign prostatic hyperplasia (BPH)—A noncancerous condition of the prostate that causes growth of the prostate tissue, thus enlarging the prostate and obstructing urination.

Biopsy—Surgical removal and microscopic examination of living tissue for diagnostic purposes.

Chemotherapy—Chemical (drug) treatment of disease; in cancer treatment, the use of synthetic drugs to destroy a tumor either by inhibiting the growth of the cancerous cells or by killing the cancer cells.

Estrogen—A female sex hormone.

Hormone therapy—In prostate cancer, treatment that involves reducing the levels of the male hormone testosterone, so that the growth of the prostate cancer cells is inhibited.

Lymph nodes—Small bean-shaped structures that are scattered along the lymphatic vessels. These nodes serve as filters and retain any bacteria or cancer cells that are traveling through the system.

Malignant—Capable of spreading, cancerous, and potentially life-threatening.

Prostatectomy—Surgical removal of the prostate gland.

Radiation therapy—Treatment using high energy radiation from x-ray machines, cobalt, radium, or other sources.

Rectum—The last 5 to 6 in (13-16 cm) of the intestine that leads to the anus.

Semen—A whitish, opaque fluid containing sperm released at ejaculation.

Seminal vesicles—The pouches above the prostate that store semen.

Testicles—Two egg-shaped glands that produce sperm and sex hormones.

Testosterone—A male sex hormone produced mainly by the testicles.

Trans-rectal ultrasound—A procedure in which a probe is placed in the rectum. High-frequency sound waves that cannot be heard by humans are sent out from the probe and reflected by the prostate. These sound waves produce a pattern of echoes which are then used by the computer to create sonograms, or pictures of areas inside the body.

Various research initiatives were underway as of early 2008 to discover new ways to treat and possibly prevent prostate cancer. Researchers were studying changes in genes that may increase the risk for developing prostate cancer. Some studies were looking at the genes of men who were diagnosed with prostate cancer at a relatively young age, such as less than 55 years old, and the genes of families who have several members with the disease. Other studies were trying to identify which genes, or combination of genes, are most likely to lead to prostate cancer. Much more work was needed, however, before scientists could say exactly how genetic changes relate to prostate cancer.

Scientists were also looking at ways to stop prostate cancer from returning in men who have already been treated for the disease. These approaches use drugs such as finasteride, flutamide, nilutamide, and LH-RH agonists that manipulate hormone levels. One study found that the combination of nilutamide and an experimental cancer vaccine was effective in reducing recurrence of prostate cancer. The experimental vaccine was designed to strengthen the body's natural defenses against prostate cancer. The experimental prostate cancer vaccine, called Provenge, was denied approval by the U.S. Food and Drug Administration (FDA) in 2007 because it failed to shrink prostate tumors during a trial in 127 men. The safety and effectiveness of a drug or vaccine are key measurements the FDA uses in approving or disapproving it. However, the study reported men who received the Provenge vaccine lived 4.5 months longer than men on conventional treatments. In 2007, an FDA advisory panel recommended approval of Provenge, finding that it was both safe and effective. In a rare move, the FDA rejected the advisory panel's approval recommendation, saying it wanted another study done. This study was expected to be completed in late 2008.

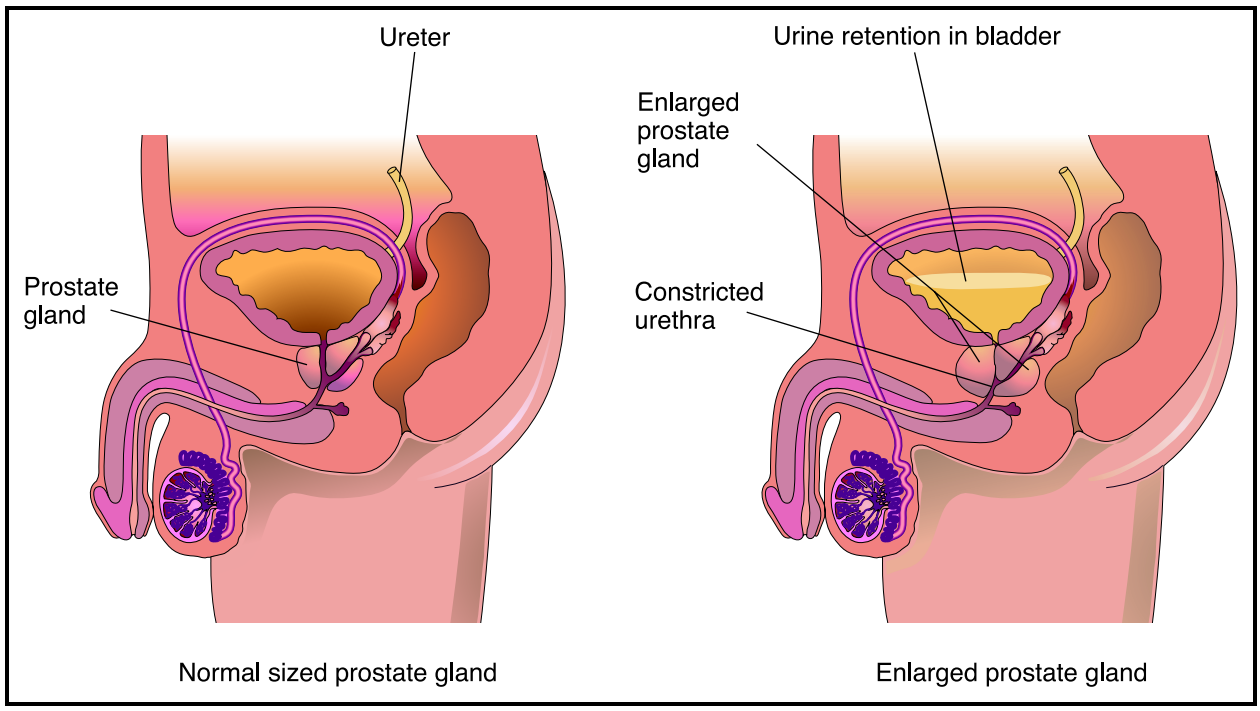
Prostate enlargement

Definition

A non-cancerous condition that affects many men past 50 years of age, enlarged prostate makes eliminating urine more difficult by narrowing the urethra, a tube running from the bladder through the prostate gland. It can effectively be treated by surgery and, in the 2000s, by certain drugs.

Description

The common term for enlarged prostate is BPH, which stands for benign (non-cancerous) prostatic hyperplasia or hypertrophy. Hyperplasia means that the prostate cells are dividing too rapidly, increasing the total number of cells and therefore the size of the organ itself. Hypertrophy simply means enlargement. BPH is often part of the **aging** process. The actual changes in the prostate may start as early as the 30s but



An enlarged prostate is a non-cancerous condition in which the narrowing of the urethra makes the elimination of urine more difficult. It most often occurs in men over age 50. *(Iustration by Electronic Illustrators Group. Cengage Learning, Gale)*

take place very gradually, so that significant enlargement and symptoms usually do not appear until after age 50. Past this age the chances of the prostate enlarging and causing urinary symptoms become progressively greater. More than 40% of men in their 70s have an enlarged prostate. Symptoms generally appear between the ages of 55 and 75. About 10% of all men eventually require treatment for BPH.

BPH has been viewed as a rare condition in blacks, but this finding may partly be due to the fact that black patients may have less access to medical care. The condition also seems to be uncommon among the Chinese and other Asian peoples, for reasons that in the 2000s are not clear.

Causes and symptoms

The cause of BPH is a mystery, but age-related changes in the levels of hormones circulating in the blood may be a factor. Whatever the cause, an enlarging prostate gradually narrows the urethra and obstructs the flow of urine. Even though the muscle in the bladder wall becomes stronger in an attempt to push urine through the smaller urethra, in time, the bladder fails to empty completely at each urination. The urine that collects in the bladder can become infected and lead to stone formation. The kidneys themselves may be damaged by infection or by urine constantly backing up.

When the enlarging prostate gland narrows the urethra, a man will have increasing trouble starting the urine stream. Because some urine remains behind in the bladder, he will have to urinate more often, perhaps two or three times at night (nocturia). The need to urinate can become very urgent and, in time, urine may seep out. Other symptoms of BPH are a weak and sometimes a split stream and general aching or **pain** in the perineum (the area between the scrotum and anus). Some men may have considerable enlargement of the prostate before even mild symptoms develop.

If a man must strain to urinate, small veins in the bladder wall and urethra may rupture, causing blood to appear in the urine. If the urinary stream becomes totally blocked, the urine collecting in the bladder may cause severe discomfort, a condition called acute urinary retention. Urine that stagnates in the bladder can easily become infected. A burning feeling during urination and **fever** are clues that infection may have developed. Finally, if urine backs up long enough it may increase pressure in the kidneys, though this rarely causes permanent kidney damage.

Diagnosis

When a man's symptoms point to BPH, the physician first performs a digital rectal examination, inserting a finger into the anus to feel whether—and how

much—the prostate is enlarged. A smooth prostate surface suggests BPH, whereas a distinct lump in the gland might mean **prostate cancer**. The next procedure is a blood test for a substance called prostate-specific antigen (PSA). Between 30–50% of men with BPH have an elevated PSA level. In fact, some studies indicate that the PSA level can be used as a predictor of a man's long-term risk of developing BPH. A high BPH level does not indicate **cancer** by any means, but other measures are needed to make sure that the prostate enlargement is benign.

An ultrasound examination of the prostate, which is entirely safe and delivers no radiation, can show whether the prostate is enlarged and may indicate if cancer is present.

If digital or ultrasound examination of the prostate raises the suspicion of cancer, most urologists recommend that a prostatic tissue biopsy be performed. This procedure is usually performed with a lance-like instrument that is inserted into the rectum. It pierces the rectal wall and, guided by the physician's finger, obtains six to eight pieces of prostatic tissue that are sent to the laboratory for microscopic examination.

A catheter placed through the urethra and into the bladder can show how much urine remains in the bladder after the patient urinates—a measure of how severe the obstruction is. Another and very simple test for obstruction is to have the man urinate into a uroflowmeter that measures the rate of urine flow. A very certain—though invasive—way of confirming obstruction from an enlarged prostate is to pass a special viewing instrument called a cystoscope into the bladder, but this is not often necessary.

It is routine to check a urine sample for an increased number of white blood cells, which may mean there is infection of the bladder or kidneys. The same sample may be cultured to show what type of bacterium is causing the infection and which antibiotics will work best. The state of the kidneys may be checked in two ways: imaging by either ultrasound or injecting a dye (the intravenous urogram, or pyelogram); or a blood test for creatinine, which collects in the blood when the kidneys cannot.

Treatment

An extract of the **saw palmetto** (*Serenoa repens* or *S. serrulata*) has been shown to stop or decrease the hyperplasia of the prostate. The herb is believed to inhibit the enzyme that converts one type of testosterone to another (significant in both prostate enlargement and prostate cancer), offering the same positive effects as the prescription drug Proscar or Propecia (finasteride) without the negative side effects. Symptoms of BPH will improve after taking the herb for one to two months but continued use is recommended.

In 2006, researchers in San Francisco reported that a year-long study of saw palmetto to treat BPH showed it was no more effective than a placebo in controlling symptoms. The study of 225 men taking 160 mg of saw palmetto twice a day concluded that there clearly was no benefit of using saw palmetto to treat BPH. The researchers said that previous studies that showed saw palmetto effective in treating BPH involved a small number of participants and had a short duration. However, researchers said their study was not conclusive and urged further research. They also noted that other health practitioners believe a higher dose of saw palmetto is needed for it to be effective.

Zinc is also effective in shrinking an enlarged prostate. A 15–30 mg zinc supplement, or inclusion of pumpkin or sunflower seeds in the daily diet, can produce the desired effect. Prevention of prostate inflammation and swelling is thought to be aided by an increase in **essential fatty acids**. One source of these fatty acids is **flaxseed** oil, available in capsule or liquid form at most health food stores.

The increase in circulation to the groin achieved by certain **yoga** poses and exercises can ease prostate problems. The knee squeeze and the seated sun poses should become a part of the daily routine. The stomach lock **exercise**, performed in a supine position, involves taking a deep breath and then breathing out slowly as the buttocks, groin, and stomach muscles are pulled in. Experts believe this exercise can both prevent prostate problems and treat flare ups; however, this exercise is not recommended for those with **hypertension**, **heart disease**, **hiatal hernia**, or ulcers.

Imagery that involves picturing the prostate shrinking to normal size and sensing an even flow of urine, practiced twice a day, can be helpful. A **reflexology** session to relax the entire body, with special attention to the prostate and endocrine reflexes in the hands and feet, may help the body heal itself.

Allopathic treatment

A class of drugs called alpha blockers relaxes the muscle tissue surrounding the bladder outlet and lining the wall of the urethra to permit urine to flow more freely. These drugs improve obstructive symptoms but do not keep the prostate from enlarging. Examples of alpha-blockers include terazosin (Hytrin), doxazosin (Cardura), prazosin (Minipress), tamsulosin (Flomax), and alfuzosin (Uroxatral). Another class of

drugs, called 5 alpha-reductase inhibitors, does shrink the prostate and may delay the need for surgery. Symptoms may not, however, improve until the drug has been used for three months or longer. One 5 alpha-reductase inhibitor, finasteride (Proscar and Propecia), has been shown to reduce the risk of developing prostate cancer by as much as 25%. Side effects occur in less than 10% of men using these drugs and include sexual problems such as a decrease in ejaculate volume, loss of sex drive, and erectile dysfunction. Another 5 alpha-reductase inhibitor is dutasteride (Avodart). Antibiotic drugs are given promptly whenever infection is diagnosed. Some medications, including antihistamines and some decongestants, can make the symptoms of BPH suddenly worse and even cause acute urinary retention and, therefore, should be avoided.

When drugs have failed to control symptoms of BPH but the physician does not believe that conventional surgery is yet needed, a procedure called transurethral needle ablation (TUNA) may be tried. The patient is given local anesthesia, and a needle is inserted into the prostate and radio frequency energy is applied to destroy the tissue that is obstructing urine flow. Another approach is microwave **hyperthermia**, using a device called the Prostatron to deliver microwave energy to the prostate through a catheter. This procedure is done at an outpatient surgery center.

For many years the standard operation for BPH has been transurethral resection (TUR) of the prostate. Under general or spinal anesthesia, a cystoscope is passed through the urethra and prostate tissue surrounding the urethra is removed using either a cutting instrument or a heated wire loop. The small pieces of prostate tissue are washed out through the scope. No incision is needed for TUR. There normally is some blood in the urine for a few days following the procedure. In a few men—less than 5% of all those having TUR—urine will continue to escape unintentionally. Other uncommon complications include a temporary rise in blood pressure with mental confusion, which is treated with salt solution. Erectile dysfunction—the inability to achieve lasting penile erections—does occur, but probably in fewer than 10% of patients. A narrowing or stricture rarely develops in the urethra, but this can be treated fairly easily.

Studies of men who undergo transurethral resection after acute urinary retention indicate that the general public remains not well informed about BPH. A majority of the men who were diagnosed with acute urinary retention said that they had had their symptoms for over a year. When asked why they did not seek treatment earlier, 35% said they were afraid of surgery, but 41% thought their symptoms were only a normal part of aging.

As of late 2007, a number of new treatments for BPH were being investigated, ranging from newly developed drugs to existing drugs used to treat other conditions. One of these new drugs, NX-1207, was undergoing clinical trials in the United States. Initial results showed the drug was extremely effective in treating BPH with minimal side effects and no sexual side effects, according to researchers at the Johns Hopkins University School of Medicine. Further studies were underway as of late 2007, and there was no estimated date when the drug might be ready to submit to the U.S. Food and Drug Administration for approval. Existing drugs that were being looked at as treatments for BPH include the anti-wrinkle drug botulinum toxin A (Botox), the over-the-counter pain relievers aspirin and ibuprofen, and the erectile dysfunction medications sildenafil (Viagra), vardenafil (Levitra), and tadalafil (Cialis).

Expected results

In several studies, 160 mg dose of saw palmetto given twice daily for 45 days achieved positive results in approximately 80% of the patients studied. That percentage increased when results were obtained after 90 days. People taking saw palmetto should use only standardized extracts that contain 85–95% fatty acids and sterols. Dosages vary depending on the type of saw palmetto used. A typical dose is 320 mg per day of standardized extract or 1–2 g per day of ground, dried, whole berries. It may take up to four weeks of use before beneficial effects are seen.

When BPH is treated by conventional TUR, there is a risk of complications but, in the great majority of men, urinary symptoms are relieved and the quality of life is much enhanced. It was anticipated that less invasive forms of surgical treatment would be increasingly used to achieve results as good as those of the standard operation.

Prevention

Whether BPH is caused by hormonal changes in aging men, there is no known way of preventing the condition as of early 2008. Once it does develop and symptoms are present that interfere seriously with the patient's life, timely medical or surgical treatment reliably prevents symptoms from getting worse. Also, if the condition is treated before the prostate has become grossly enlarged, the risk of complications is minimal. A potentially serious complication of BPH is urinary infection (and possible infection of the kidneys), which

KEY TERMS

Catheter—A rubber or plastic tube placed through the urethra into the bladder to remove excess urine when the flow of urine is cut off or to prevent urinary infection.

Creatinine—One of the waste substances normally excreted by the kidneys into the urine. When urine flow is slowed, creatinine may collect in the blood and cause toxic effects.

Hyperplasia—A condition in which cells, such as those making up the prostate gland, divide abnormally rapidly and cause the organ to become enlarged.

Hypertrophy—A term for enlargement, as in BPH (benign prostatic hypertrophy).

Urethra—The tube that conducts urine from the bladder outside the body; in male, the urethra extends from the bladder to the tip of the penis. When the urethra is narrowed by an enlarging prostate, symptoms of BPH develop.

Urinary retention—The result of progressive obstruction of the urethra by an enlarging prostate, causing urine to remain in the bladder even after urination.

can be prevented by using a catheter to drain excess urine out of the bladder so that it does not collect, stagnate, and become infected. There is no scientific evidence that diet or **nutrition** plays a direct role in the development of an enlarged prostate. However, a 2006 study reported that obese men were up to 3.5 times more likely to have an enlarged prostate than men with a normal weight.

Psoralea seeds

Description

Psoralea seed comes from the plant *Psoralea corylifolia*. *Psoralea corylifolia* grows in warm climates from the Middle East to China. This herb requires direct sunlight and moist, well-drained soil. In some parts of its habitat, it is considered a weed that competes with food crops. In other areas, especially in India, it is cultivated as a medicinal crop.

Psoralea corylifolia is an erect annual herb that grows to a height of about 20 to 40 inches (.6–1.2 m). It has broad, elliptical, slightly serrated leaves. The plant flowers from August to December and produces an elongated seed pod containing a single large, smooth, black seed. *Psoralea corylifolia* is a member of the bean family. Unlike some members of this family, the seeds have a bitter, unpleasant taste and are not used for food. They are, however, used extensively in healing. Occasionally the roots, leaves, and fruit (seed pod and seed) of the herb are also used medicinally.

Psoralea corylifolia is widely used in India, China, and Tibet and has more than a dozen different names. In **traditional Chinese medicine** (TCM) it is called bu gu zhi. In India some of its more common names are

bakuchi, babachi, bawchi, bukchi, bemchi, barachi, bavachi, hakuch, latakasturi, and bodi. In English, it is sometimes called Malay tea or scruf pea.

General use

Psoralea seed is commonly used both internally and externally in Ayurvedic and traditional Chinese medicine. In both systems of healing, psoralea seed is used to treat similar conditions. An essential oil, when extracted from the seed, can be taken internally or applied to the skin. Seeds also can be ground into a powder and taken internally or mixed into a paste and used externally.

Psoralea seeds are most often used in the treatment of skin diseases, especially leucoderma and vitiligo. These are conditions in which the skin loses pigmentation. White patches begin as small spots, then merge into larger patches. Although rare in the United States, the condition is thought to affect between 1% and 2% of people in India. Leucoderma is treated both with the essential oil taken internally and a paste applied to the skin. It is thought to stimulate the production of new skin pigment. Other skin diseases such as **psoriasis**, alopecia (**hair loss**), **eczema**, and a variety of inflammatory skin diseases are also treated with psoralea seed. The herb is also used to treat leprosy, scorpion sting, and snake bite.

There is some scientific basis for the use of psoralea seed in treating skin disease. The seeds contain the compound psoralen. In traditional Western medicine, a compound containing psoralen is applied to the skin, and then the skin is exposed to ultraviolet (UV) light as a treatment for psoriasis and eczema. Research has also shown that psoralea seed extract has antibiotic and antifungal properties and is effective against some types of internal parasites.

In addition to treating skin diseases, psoralea seed oil or powder is used in TCM and **Ayurvedic medicine** to treat disorders of the urinary and male reproductive system, including **bedwetting**, frequent urination, premature ejaculation, low sex drive, and **impotence**. In TCM, psoralea is considered a general yang tonic.

Occasionally other parts of the plant are used besides the seed. Chewing the root is said to help control dental caries (cavities). The leaves are used to treat **diarrhea**, and the seed pod is used as a diuretic. Other claims for this herb are that it helps prevent **osteoporosis**, has anticancer properties, and can treat **tuberculosis**. There is little scientific evidence to support these uses, although much research was being done on this herb as of 2008 in China and India.

KEY TERMS

Ayurvedic medicine—A 5,000-year old system of holistic medicine developed in India. Ayurvedic medicine is based on the idea that illness results from a personal imbalance or lack of physical, spiritual, social, or mental harmony.

Diuretic—A substance that removes water from the body by increasing urine production.

Eczema—A disease in which the skin becomes dry, red, itchy, and thickened.

Osteoporosis—A condition found in older individuals in which bones decrease in density, become fragile, and are likely to break. It can be caused by lack of vitamin D and/or calcium in the diet.

Psoriasis—A disease in which the skin develops itchy, dry, scaly red patches.

Traditional Chinese medicine (TCM)—An ancient system of medicine based on maintaining a balance in vital energy or qi that controls emotions, spiritual, and physical wellbeing. Diseases and disorders result from imbalances in qi (the life force), and treatments such as massage, exercise, acupuncture, and nutritional and herbal therapy are designed to restore balance and harmony to the body.

Yang aspects—Qualities such as warmth, activity, and light.

Preparations

The traditional method of extracting the essential oil from psoralea seed was quite complicated and involved burying the seeds in a pottery crock and then building a fire over the crock to extract the oil. As of 2008, factories in India produce a standardized essential oil from the seeds by modern extraction methods. A powder for internal use is also available in capsule form. A paste for external use can be made in the proportions of 1 part alcoholic extract of psoralea seed, 2 parts chaulmugra oil, and 2 parts lanoline.

Precautions

No studies have been done on the safety of psoralea seed, so pregnant and breastfeeding women should avoid using this herb.

Side effects

The psoralen found in psoralea seed sensitizes the skin to sunlight. In about 5% of people, psoralea seed

oil or paste applied externally causes skin irritation and blistering. Internal use of psoralea seed may cause mild stomach upset.

Interactions

No studies have been done as of 2008 on interactions between psoralea seed and other herbs or traditional pharmaceuticals. Individuals who regularly take dietary supplements, herbs, or pharmaceutical drugs should discuses the use of psoralea seed with their healthcare provider before beginning treatment.

Tish Davidson, A. M.

Psoriasis

Definition

Psoriasis is a chronic, non-contagious disease characterized by inflamed hyperproliferative lesions covered with silvery-white scabs of dead skin.

Description

Psoriasis, which affects at least four million Americans, is slightly more common in women than in men. Although the disease can develop at any time, 10–15% of all cases are diagnosed in children under 10, and the average age at onset of symptoms is 28 years of age.

Hand with severe Psoriasis. *(© Medical-on-Line / Alamy)*

Psoriasis is most common in fair-skinned people and relatively rare in dark-skinned individuals, although the rate among African Americans appeared as of 2008 to be slowly rising.

Normal skin cells mature and replace dead skin every 28–30 days. Psoriasis causes skin cells to mature in less than a week. Because the body cannot shed the old skin as rapidly as new cells are rising to the surface, raised patches of dead skin develop on the arms, back, chest, elbows, legs, nails, folds between the buttocks, and scalp.

Psoriasis is considered mild if it affects less than 5% of the surface of the body, moderate if 5–30% of the skin is involved, and severe if the disease affects more than 30% of the body surface.

Types of psoriasis

Dermatologists distinguish different forms of psoriasis according to what part of the body is affected, how severe symptoms are, how long they last, and the pattern formed by the scales.

PLAQUE PSORIASIS. Plaque psoriasis (psoriasis vulgaris), the most common form of the disease, is characterized by small, red bumps that enlarge, become inflamed, and form scales. The top scales flake off easily and often, but those beneath the surface of the skin clump together. Removing these scales exposes tender skin, which bleeds and causes the plaques (inflamed patches) to grow.

Plaque psoriasis can develop on any part of the body, but most often occurs on the elbows, knees, scalp, and trunk.

SCALP PSORIASIS. At least 50 of every 100 people who have any form of psoriasis have scalp psoriasis. This form of the disease is characterized by scale-capped plaques on the surface of the skull.

NAIL PSORIASIS. The first sign of nail psoriasis is usually pitting of the fingernails or toenails. Size, shape, and depth of the marks vary, and affected nails may thicken, yellow, or crumble. The skin around an affected nail is sometimes inflamed, and the nail may peel away from the nail bed.

GUTTATE PSORIASIS. Named for the Latin word *gutta,* which means "a drop," guttate psoriasis is characterized by small, red, drop-like dots that enlarge rapidly and may be somewhat scaly. Often found on the arms, legs, and trunk and sometimes in the scalp, guttate psoriasis can clear up without treatment or disappear and resurface in the form of plaque psoriasis.

PUSTULAR PSORIASIS. Pustular psoriasis usually occurs in adults. It is characterized by blister-like lesions filled with non-infectious pus and surrounded by reddened skin. Pustular psoriasis, which can be limited to one part of the body (localized) or can be widespread, may be the first symptom of psoriasis or develop in a patient with chronic plaque psoriasis.

Generalized pustular psoriasis is also known as Von Zumbusch pustular psoriasis. Widespread, acutely painful patches of inflamed skin develop suddenly. Pustules appear within a few hours, then dry and peel within two days.

Generalized pustular psoriasis can make life-threatening demands on the heart and kidneys.

Palomar-plantar pustulosis (PPP) generally appears between the ages of 20 and 60. PPP causes large pustules to form at the base of the thumb or on the sides of the heel. In time, the pustules turn brown and peel. The disease usually becomes much less active for a while after peeling.

Acrodermatitis continua of Hallopeau is a form of PPP characterized by painful, often disabling, lesions on the fingertips or the tips of the toes. The nails may become deformed, and the disease can damage bone in the affected area.

INVERSE PSORIASIS. Inverse psoriasis occurs in the armpits and groin, under the breasts, and in other areas where skin flexes or folds. This disease is characterized by smooth, inflamed lesions and can be debilitating.

ERYTHRODERMIC PSORIASIS. Characterized by severe scaling, **itching**, and **pain** that affects most of the body, erythrodermic psoriasis disrupts the body's chemical balance and can cause severe illness. This particularly inflammatory form of psoriasis can be the first sign of the disease, but often it develops in patients with a history of plaque psoriasis.

PSORIATIC ARTHRITIS. About 10% of patients with psoriasis develop a complication called psoriatic arthritis. This type of arthritis can be slow to develop and mild, or it can develop rapidly. Symptoms of psoriatic arthritis include:

- joint discomfort, swelling, stiffness, or throbbing
- swelling in the toes and ankles
- pain in the digits, lower back, wrists, knees, and ankles
- eye inflammation

Causes and symptoms

The cause of psoriasis is unknown, but research related to the Human Genome Project was mapping the genetic component of the disease in the 2000s. In 2003, researchers at Washington University in St. Louis announced that three genes on chromosome 17 appear to be implicated in the development of psoriasis. Markers (indicators) for psoriasis have also been found on 10 other chromosomes, although specific genes for the diseases have not yet been discovered. Researchers believe that psoriasis is a multifactorial disorder, which means that it is the end result of a number of different factors. It appears to be caused by the combined action of multiple disease genes in a single individual that are triggered by irritants in the environment. Factors that increase the risk of developing psoriasis include:

- blood relatives with psoriasis
- stress
- exposure to cold temperatures
- injury, illness, or infection
- steroids and other medications
- mechanical stress (leaning on knees or skin exposure to chemicals, for example)

Trauma and certain bacteria may trigger psoriatic arthritis in patients with psoriasis.

Diagnosis

A medical history and physical examination is the basis for a diagnosis of psoriasis. In some cases, a microscopic examination of skin cells is also performed.

Blood tests can distinguish psoriatic arthritis from other types of arthritis.

Treatment

Psoriasis treatments include:

- Soaking in warm water and German chamomile (*Matricaria recutita*) or bathing in warm salt water

- Drinking as many as three cups a day of hot tea made with one or a combination of the following herbs: burdock root (*Arctium lappa*), dandelion (*Taraxacum mongolicum*) root, Oregon grape root (*Mahonia aquifolium*), sarsaparilla (*Smilax officinalis*), and balsam pear (*Momardica charantia*)
- Taking two 500–mg capsules of evening primrose oil (*Oenothera biennis*) a day. Pregnant women should not use evening primrose oil, and patients with liver disease or high cholesterol should use it only under a doctor's supervision.
- Eating a diet that includes plenty of fish, turkey, celery (for cleansing the kidneys), parsley, lettuce, lemons (for cleansing the liver), limes, fiber, and fruit and vegetable juices
- Eating a diet that eliminates animal products high in saturated and unsaturated fats, such as fried foods, dairy products, and fatty meats, that promote inflammation
- Drinking plenty of water (at least eight glasses) each day
- Regularly imagining clear, healthy skin

Other helpful alternative approaches include identifying and eliminating food allergens from the diet; enhancing liver function; augmenting the supply of hydrochloric acid in the stomach; and completing a **detoxification** program. Constitutional homeopathic treatment, if properly prescribed, can sometimes help resolve psoriasis.

Allopathic treatment

Age, general health, lifestyle, and the severity and location of symptoms influence the type of treatment used to reduce inflammation and decrease the rate at which new skin cells are produced. Because the course of this disease varies with each individual, doctors must experiment with or combine different treatments to find the most effective therapy for a particular patient.

Mild-moderate psoriasis

Steroid creams and ointments are commonly used to treat mild or moderate psoriasis, and steroids are sometimes injected into the skin of patients with a limited number of lesions. Two drugs, calcipotriene (Dovonex) and tazarotene (Tazorac) have been approved by the U.S. Food and Drug Administration (FDA) for the treatment of mile-to-moderate psoriasis.

Brief daily doses of natural sunlight can significantly relieve symptoms. **Sunburn**, however, has the opposite effect.

Certain moisturizers and bath oils can loosen scales, soften skin, and may eliminate the itch. (Often petroleum-based, coal tar-based, or other greasy ointments are used.) Adding a cup of oatmeal to a tub of bath water or using Aveeno in the bath can soothe the itch. Dilute, topical salicylic acid (an ingredient in aspirin) can be used to remove dead skin or increase the effectiveness of other therapies.

Moderate psoriasis

Administered under medical supervision, ultraviolet light B (UVB) is used to control psoriasis that covers many areas of the body or that has not responded to other treatment. Doctors combine UVB treatments with topical medications to treat some patients and sometimes prescribe home phototherapy, in which the patient administers his own UVB treatments.

Photochemotherapy (PUVA) is a medically supervised procedure that combines medication with exposure to ultraviolet light (UVA) to treat localized or widespread psoriasis. An individual with wide-spread psoriasis that has not responded to treatment may enroll in one of the day treatment programs conducted at special facilities throughout the United States. Psoriasis patients who participate in these intensive sessions are exposed to UVB and given other treatments for six to eight hours a day for two to four weeks.

Another form of treatment that has several advantages over standard phototherapy is therapy with an excimer laser system. Laser treatment for psoriasis uses a carefully focused beam of ultraviolet light that not only relieves symptoms quickly but also minimizes exposure of healthy skin to the ultraviolet rays.

Severe psoriasis

Methotrexate (MTX) can be given as a pill or as an injection to alleviate symptoms of severe psoriasis or psoriatic arthritis. Patients who take MTX must be carefully monitored by a doctor who checks blood liver enzymes to prevent liver damage. In the early years of its use, methotrexate was responsible for the death of a number of patients whose liver function had not been properly monitored.

Psoriatic arthritis can also be treated with nonsteroidal anti-inflammatory drugs (NSAIDs), such as acetaminophen (Tylenol) or aspirin. Hot compresses and warm water soaks may also provide some relief for painful joints.

Another medication used to treat severe psoriasis is etrentinate (Tegison), whose chemical properties are similar to those of **vitamin A**. Most effective in treating pustular or erythrodermic psoriasis, etrentinate also relieves some symptoms of plaque psoriasis. Etrentinate can enhance the effectiveness of UVB or

PUVA treatments and reduce the amount of exposure necessary.

Some doctors also use other systemic drugs that have not been approved specifically for the treatment of psoriasis. Among these so-called off-label drugs are isotretinoin (Accutane), hydroxyurea (Hydrea), mycophenolate mofetil, sulfasalazine, and 6-thioguanine. Accutane is a less effective psoriasis treatment than Tegison, but it can cause many of the same side effects, including **nosebleeds**, inflammation of the eyes and lips, **bone spurs**, **hair loss**, and birth defects. Tegison is stored in the body for an unknown length of time and should not be taken by a woman who is pregnant or planning to become pregnant. A woman should use reliable birth control while taking Accutane and for at least one month before and after her course of treatment.

Cyclosporin emulsion (Neoral) is used to treat stubborn cases of severe psoriasis. Cyclosporin is also used to prevent rejection of transplanted organs, and Neoral should be particularly beneficial to psoriasis patients who are young children or African Americans, or those who have diabetes. The drawback to cyclosporin, however, is that it has been implicated in an increased risk of **skin cancer** for psoriasis patients.

As of 2008, the latest drug approved by the FDA for use with psoriasis was a recombinant DNA (genetically engineered) product called alefacept (Amevive). Alefacept targets the T-cells that cause psoriasis without suppressing the patient's immune system. Not only does the new drug relieve the symptoms of psoriasis more rapidly than current treatments, but patients also remain symptom-free longer.

Other conventional treatments for psoriasis include:

- Capsaicin (*Capsicum frutecens*), an ointment that can stop production of the chemical that causes the skin to become inflamed and halts the runaway production of new skin cells. Capsaicin is available without a prescription but should be used under a doctor's supervision to prevent burns and skin damage.
- Hydrocortisone creams, topical ointments containing a form of vitamin D called calcitriol, and coal-tar shampoos and ointments can relieve symptoms but may cause such side effects as folliculitis (inflammation of hair follicles) and heightened risk of skin cancer.

Expected results

Most cases of psoriasis can be managed. However, some people who have psoriasis are so self-conscious and embarrassed about their appearance that they become depressed and withdrawn. The Social Security Administration grants disability benefits to about 400 psoriasis patients each year.

KEY TERMS

Arthritis—An inflammation of the joints.

Cyclosporin—A drug that suppresses the immune system and has been used to treat severe psoriasis. Some research indicates that cyclosporin may increase the risk of skin cancer for psoriasis patients.

Plaque—An area or patch of inflamed skin. The most common form of psoriasis is plaque psoriasis.

Prevention

A doctor should be notified if any of the following occurs:

- Psoriasis symptoms appear or reappear after treatment.
- Pustules erupt on the skin and the patient experiences fatigue, muscle aches, and fever.
- Unfamiliar, unexplained symptoms appear.

Psychic healing *see* **Cayce systems**

Psychoneuroimmunology

Definition

Psychoneuroimmunology (PNI), is a relatively recent branch of science that enforces beliefs that physicians have held for many centuries, perhaps well before the times of the ancient Greeks. The premise is that a patient's mental state influences diseases and healing. Specifically, PNI studies the connection between the brain and the immune system.

Origins

The term psychoneuroimmunology was coined by Robert Ader, a researcher in the Department of Psychiatry at the University of Rochester Medical Center in Rochester, New York. In the 1970s, studies by Ader and other researchers opened up new understandings of how experiences such as **stress** and **anxiety** can affect a person's immune system.

In the 1970s, Ader performed experiments on lab rats, which showed that environmental factors could impact the immune system. Ader's work went against accepted scientific knowledge, which held that the immune system was not related to other bodily systems, and had no way to physically interact with the nervous system. However, other studies confirmed Ader's findings. The field of PNI blossomed, and hundreds of studies explored various interactions between the immune system and other mental and physical processes.

Many PNI studies have focused on how stress, hostility, and **depression** impact the immune system. Many conditions such as **heart disease**, **osteoporosis**, arthritis, delayed wound healing, and premature **aging**, are related to stress and negative emotions. Fewer studies have been aimed at showing the benefits of happiness, or positive emotions, on health (perhaps because this is more difficult to test).

KEY TERMS

Cytokine—An immunoregulatory substance secreted by cells of the immune system. Cytokines act as signals between cells.

Many doctors have noted that a patient's desire to get well is related to the outcome of a disease. Clinical anecdotes recount cases of miraculous healing for no demonstrable reason, or cases where a terminally ill patient held on for months longer than expected to make it to a daughter's wedding or other important occasion. Faith in the physician (or shaman or other healer) has also long been thought to influence healing. The ancient Greek physician Galen wrote, "He cures most successfully in whom the people have the most confidence."

The **placebo effect** is also a curious aspect of healing. A placebo is a sugar pill or other non-active prescription, which might be given so that the patient thinks he or she is being treated medically. The actual incidence of the placebo effect is difficult to measure, but some researchers believe that as many as one-third of all patients will improve on a placebo.

Benefits

More than a particular therapy, PNI is a field of research. However, PNI has explored the benefits of many nontraditional or holistic approaches to healing. These include **psychotherapy** and counseling for people with **cancer**, and **biofeedback** and **relaxation** therapies to reduce stress. It is possible that PNI studies will lead to the discovery of new ways to enhance the immune system, just as it has already shown new ways the immune system can be suppressed. PNI gives credibility to many long-held folk beliefs about the effect of the mind on disease and healing. By demonstrating the physical means by which the mind influences the body, and vice versa, PNI provides a measure of validity to holistic approaches to healing.

Description

Psychoneuroimmunology provides a scientific framework for researchers to investigate the aspects of healing that go beyond standard clinical therapy. PNI researchers look for the physical links that allow the immune system to respond to psychological factors, such as the will to live to a certain date. They look

at the ways that mental states, such as hopelessness, can signal the immune system to lower the body's defenses.

Research and general acceptance

Though many scientists were at first skeptical of the findings of PNI, by the start of the twenty-first century the field gained wider credibility. A great deal of new research is being carried out, and there are several academic journals devoted to PNI. Researchers emphasize that they are not simply providing scientific backing for beliefs that happy people live longer, or that people who hold in their anger give themselves cancer. Instead, they are discovering how the immune system communicates with the neurological and endocrine systems.

Some studies focus on the function of cytokines, which are substances secreted by cells of the immune system. The two main classes of cytokines are pro-inflammatory (producing inflammation) and anti-inflammatory (fighting inflammation). Studies of cytokines show that psychological factors such as stress depress the immune system, but that deviations in the immune system can also trigger psychological and behavioral changes. The communication goes both ways. A person, who is fighting infection, perhaps from a cold, undergoes behavioral changes like **fatigue**, irritability, and loss of appetite. PNI maps complex interactions among the body's systems. Factors studied include mood, illness, immune response, susceptibility to disease, and maintenance of health.

In the early years of the twenty-first century, the United States Public Health Service funded hundreds of research grants in the field of PNI. PNI has been particularly enlightening for researchers and caregivers who deal with people who have cancer, as well as depression.

Psychophysical integration *see* **Trager psychophysical integration**

Psychophysiology

Definition

Psychophysiology is the branch of physiology that is concerned with the relationship between mental (psyche) and physical (physiological) processes; it is the scientific study of the interaction between mind and body. The field of psychophysiology draws upon the work of physicians, psychologists, biochemists, neurologists, engineers, and other scientists.

A psychophysiological disorder is characterized by physical symptoms that are partly induced by emotional factors. Some of the more common emotional states responsible in forming illness include **anxiety**, **stress**, and fear. Common psychosomatic ailments include migraine headaches, attention deficit hyperactivity disorder (ADHD), arthritis, ulcerative **colitis**, and **heart disease**.

Origins

Historically, there has been a large chasm between the allopathic (mainstream) and alternative medical worlds with regard to views on psychophysiology. While the allopathic medical field continues to follow the Cartesian model of health, in which mind and body are seen as separate, the alternative medical field stands firmly on the notion that the mind and body are intricately connected. In general, treatment in the mainstream medical system is oriented toward fixing or curing isolated symptoms in the body. Alternative health providers strive to look at the symptoms, as well as the underlying pathology, or cause. While the first focuses on isolated parts of a whole system, the latter group strives to address the whole being, mind and body, emotions, and physical symptoms.

They believe that mental processes intricately affect bodily ones, and vice versa.

With a more holistic mentality, the population is experiencing an ever-progressing paradigm shift in which the body and mind are no longer viewed as separate, but rather as intricately interrelated. Medically, as well as culturally, Western society has reached the point at which the focus is increasingly on integrative mind/body healthcare. More patients and physicians are choosing to utilize therapies built upon the holistic models in which psyche (mind) and soma (physical body) are seen as one, or intimately related. They are utilizing such modalities as **meditation**, **yoga**, bodywork, and visualization techniques in efforts to relieve overall stress and to heal various psychosomatic illnesses.

KEY TERMS

Paradigm shift—A philosophical or spiritual change in the pattern or model by which one lives and views the world.

Rolfing—Form of therapeutic bodywork that seeks to heal the mind by improving the physical structure of the body.

Ulcerative colitis—Autoimmune disease of the colon, classified as a psychosomatic disorder.

Visualization techniques—A form of meditation, contemplation, and imagination that seeks to alter physical processes and directions of behavior or outcomes by focused mental awareness on specific images.

Benefits

The field of psychophysiology is leading the way to an ongoing investigation into the intricacies of the mind/body relationship. Applied psychophysiology focuses on the effects of emotional states on the central nervous system, by observing and recording data on such physiological processes as sleep rhythms, heart rate, gastrointestinal functioning, immune response, and brain function. Techniques used to measure such factors include electroencephalograms (EEGs), magnetic resonance imaging (MRI), and computerized axial tomography (CAT) scans. In an effort to quantify the effectiveness of different treatment techniques, the science of psychophysiology is being applied to many areas of alternative medicine, from **psychotherapy** and hypnosis to bodywork and meditation. Studies of the effects of emotional states on various physiological processes abound. For instance, it has been shown that there is a relation between loneliness and heart disease, as well as a connection between post traumatic stress disorder, **irritable bowel syndrome**, and **fibromyalgia**. By documenting the effects of emotions on health, this field hopes to improve the healing capacities of treatments. Many of the studies done by psychophysiologists occur in research institutions and universities.

There are several interpretations of what a healthy psychophysiology may look like. However, there are common characteristics that speak of mind/body health. Ultimately, such a holistic state exists when internal and mental awareness becomes strong enough to create a sense of embodiment, balance, and presence in an individual's body. Disease may be present in such a state, yet with this underlying, holistic understanding there exists more fighting power by which to heal. Science is proving this fact. Therapies that integrate mind/body processes have been shown to aid the healing processes for numerous diseases.

When stresses, traumas, or debilitating emotional states are present, individuals may experience physiological unrest. For example,if an individual with a known allergy to bee **stings** receives such a sting, the natural reaction could be panic. As a result of this psychological response, blood pressure and heart rate increase, digestive functions decrease, and the person becomes dizzy. If emotional stresses or traumas of this kind remain in the body/mind for extended periods of time, an imbalance in the healthy system may eventually manifest, as when individuals under chronic stress succumb to illness or disease. The field of psychophysiology is showing that the most effective treatments are those that address the emotional states of disease as well as the physical aspects.

Treatments

Treatments for psychosomatic illnesses are being synthesized from both the allopathic and alternative medical worlds. Methods vary from drug therapy and **biofeedback** to the use of meditation, yoga, and **massage therapy**. Many treatments have been shown to be effective; individuals have the freedom and responsiblity to discover for themselves the treatments that have the most personal benefit. What is effective for one person may not work for another. Consumers of mind/body treatments are encouraged to evaluate options, practitioners, and their individual needs. The field of psychophysiology conducts research to improve the information available to consumers.

In general, treatments are selected if they complement and strengthen an individual's awareness of the body/mind relationship. Such practices are most effective in achieving overall states of health when addressing the mind to affect the body, and vice versa. For example, two disciplines that have proven effective in establishing this awareness are meditation, a mind-centered activity, and **Rolfing**, a form of therapeutic bodywork. Treatments that simultaneously work with both the physiology and the psychology are highly beneficial. This thorough approach may be achieved by pairing modalities that complement one another. Examples include combining psychotherapy with bodywork, and certain drug therapies with meditation, visualization, and yoga.

Mind/Body

Meditation is an age-old process that has great potential in quieting the mind, calming the emotions, and balancing the physiology. For centuries, Eastern peoples and their traditions have focused on the art of meditation. Meditative techniques vary from bringing one's attention to the breath, to chanting a mantra (a specifically pre-established word or phrase), or to focusing one's gaze on a specific, unchanging image (a visualization technique). Focusing awareness inward to bodily sensations may interrupt unhealthy thought patterns, thereby reducing or preventing the effects of stress on the physiology. Studies as well as experiential phenomena have shown that meditation decreases blood pressure, muscle **pain**, and **cholesterol**, while improving digestion, relieving anxiety and **depression**, improving immunity, and boosting energy levels. Ultimately, meditation may lead to knowing one's self, both psychologically and physiologically. It is out of this state of embodied presence and attention that healing occurs.

Body/Mind

Certain forms of bodywork have been successful in affecting the mind by working through the body. Emotions, thoughts, and feelings may reside in the body, just as much as they do in the mind. For example, a depressed person's body may reflect the emotional state by hunched shoulders, sad facial expressions, and slow movements. Psychology has shown that by adopting positive physical expressions such as a smile or improved posture, a person will experience corresponding and measurable effects in the mind. These relationships, through the science of psychophysiology, are being experimentally validated.

By manipulating the structure of the body during bodywork, a healer may directly or indirectly affect both physiological and psychological health. Benefits from this type of therapy come from both the new changes in the physiology, as well as the changes in the consciousness and awareness of physically existing patterns. By becoming aware of such body/mind relations, healer and client break up old patterns in the physical tissue, the mind, and the emotions. An overall body/mind freedom is enhanced, bringing with it a greater chance for a holistic state of health.

Research and general acceptance

Interest in the mind/body relationship is as ancient as it is vast, and the field of psychophysiology is researching and validating this connection. The allopathic medical world has achieved great breakthroughs in human health, particularly with regard to the treatment of traumatic and life-threatening injuries and diseases. Medically, socially, and environmentally, a more holistic and preventive approach to healthcare is being sought, one that integrates and balances the mind/body relationship. Much work is being done to develop new knowledge; the field of psychophysiology is a major contributor to the exploration.

Training and certification

A variety of health professionals, such as physicians and psychologists, incorporate the principles of psychophysiology into their work. One of the objectives of the Association for Applied Psychophysiology and Biofeedback (AAPB) is to promote professional standards of practice, ethics, and education for its members. Certifications exist for professionals such as massage therapists and others who perform specialized techniques that incorporate psychophysiology principles.

Douglas Dupler

Psychosomatic medicine

Definition

Psychosomatic medicine is the study, diagnosis, and treatment of physical health conditions that stem from emotional problems. It emphasizes the unity of the mind and body in health and medicine. Many physicians believe understanding the psychological causes of illnesses is a key in understanding and treating the physical symptoms of the illnesses themselves.

Origins

Throughout recorded history, people are said to have been cured of diseases by various mystical practices, such as incantation, **prayer**, the laying on of hands, and other rituals. It is unclear exactly when medical practitioners made a connection between the mind and certain diseases, although records show that it dates back to at least the 1700s.

In 1774, German physician Franz Anton Mesmer (1734–1815) applied a scientific basis for mysticism when he waved magnets over some patients to cure them. He later discovered the magnets were not needed and he could get the same results by passing his hands over some patients. He called his technique "animal magnetism," and said it was based on the principle that illnesses occur when the body's flow of natural electromagnetic energy becomes blocked. He opened a practice in Vienna, Austria, and later went to Paris, where he lived and worked for six years, using magnetism and hypnosis to treat illnesses. He was eventually driven out of both cities and labeled a "quack" since his techniques did not always work.

Mesmer's work was studied by American scientist and statesman Benjamin Franklin (1706–1790) and French chemist Antoine Lavoisier (1743–1794), who became famous for isolating oxygen. Both spent years duplicating Mesmer's work, but with no successful results. However, the research led Franklin to conclude that the mind does have an influence over physical ailments; that in some patients, the belief that they will be cured actually cures them.

Further research into psychosomatic medicine was conducted by Austrian psychologist Sigmund Freud (1856–1939) in the late 1800s. Research continued, and by the 1960s the field had gained respect by the general medical community. Today, **biofeedback**, hypnosis, prayer, and humor are considered legitimate facets of psychosomatic medicine.

KEY TERMS

Biofeedback—The use of monitoring devices that display information about body functions, such as heart rate or blood pressure, to help patients learn to consciously control the functions.

Cholesterol—A compound found in animal tissue and blood of which high levels in the blood are linked to clogged arteries, heart disease, and gallstones.

Electromagnetic energy—Energy created by electromagnetism, the forces of electricity and magnetism.

Hypnosis—A sleeplike condition that can be artificially induced in people, in which they are susceptible to suggestions from the hypnotist.

Lipids—A group of organic compounds consisting of fats, oils, and related substances that, along with proteins and carbohydrates, are the structural components of living cells.

Meditation—Emptying the mind of thoughts, or concentrating on just one thing to help in relaxation.

Prostate—A gland in males that secretes a fluid into the semen that improves the movement and viability of sperm.

Psychoanalysis—A psychological theory and therapeutic method based on the idea that the mind works on conscious and unconscious levels and that childhood events have a psychological influence on people throughout their lives.

Psychosocial—Relating to both the psychological and the social aspects of a person.

Transendental Meditation—A focusing of the mind based in part on Hindu meditation techniques in which each person is given a word or phrase to meditate upon.

Benefits

The primary benefit of psychosomatic medicine is that it does not involve drugs, surgery, or other invasive treatments. It is also greatly beneficial in conditions created by the mind rather than a physical condition. In addition, in psychosomatic medicine, the patient has the greatest ability to control the healing process through various positive thinking techniques.

Description

In tne April 2002 issue of *Managed Healthcare Executive*, Dr. David Sobel, director of Patient Education and Health Promotions for Kaiser Permanente's

Northern California region, explained that one of the first things he noticed when he started practicing medicine is that a large number of his patients had problems that could not be explained by conventional medical and diagnostic techniques. He said that, "Up to 20% possess diagnosable psychiatric disorders but even more impressive is that upwards of 80% of the patients will be suffering significant levels of psychosocial distress." He went on to say "distress often expresses itself through physical or bodily symptoms...if not causing the symptoms, then certainly exacerbating them." He calls the condition a deficiency of mind-body regulation.

To address this, Kaiser Permanente developed a mind-body core program that includes teaching patients how to relax, manage **stress**, communicate more effectively, and think more positively.

Preparation

There is no preparation needed to undergo psychosomatic treatment, other than a willingness to believe it may be effective.

Precautions

Patients should be wary of psychosomatic practitioners who do not have degrees in medicine or psychology, or specialized training in either field. Some patients may also need conventional medical care or a combination of conventional and psychosomatic therapies.

Side effects

There are no known serious side effects of psychosomatic treatment in patients deemed suitable for the treatment by a qualified medical practitioner.

Research and general acceptance

A study published in 2002 by researchers at the Carnegie Mellon University Department of Psychology found that people with positive emotions were less likely to catch the **common cold**. A study by the University of California at San Francisco, published in 2002, reported that people with **AIDS** who had a positive attitude had a lower death rate from AIDS-related complications.

A Canadian study published in 2002 showed that people with breast or **prostate cancer**, who meditated and practiced **yoga** regularly, had an enhanced quality of life and reduced stress regarding their illness. A study published in 2000 by the Center for Health and **Aging** Studies at Maharishi University of Management in Fairfield, Iowa, showed that people who practiced Transcendental **Meditation** significantly reduced their **cholesterol** levels. Meditation also improved brain and immune system functions of patients in a study by several universities, which was published in 2003.

Training and certification

Many colleges and universities have psychosomatic medicine departments or training programs for certification. Practitioners usually are certified physicians or psychiatrists, but can also be other medical professionals, such as psychologists and nurses. However, practitioners can also include those with no medical training, such as hypnotists, counselors, ministers, and yoga and meditation instructors.

Psychotherapy

Definition

Psychotherapy can be defined as a means of treating psychological or emotional problems such as neurosis or personality disorder through verbal and nonverbal communication. It is the treatment of psychological distress through talking with a specially trained therapist and learning new ways to cope rather than merely using medication to alleviate the distress. It is done with the immediate goal of aiding the person in increasing self-knowledge and awareness of relationships with others. Psychotherapy is carried out to assist people in becoming more conscious of their unconscious thoughts, feelings, and motives.

Psychotherapy's longer-term goal is making it possible for people to exchange destructive patterns of behavior for healthier, more successful ones.

Different approaches to psychotherapy

The psychodynamic approach was derived from principles and methods of psychoanalysis, and it encompasses psychoanalysis, Jungian analysis, Gestalt therapy, client-centered therapy, and somatic or body therapies, among other forms of psychotherapy. Psychoanalysis is therapy based upon the work of Austrian physician Sigmund Freud (1856–1939), and those who followed, Carl Jung, Alfred Adler, Erich Fromm, Karen Horney, and Erik Erikson. The basis of psychoanalytic therapy is the belief that behavior and personality develop in relation to unconscious wishes and conflicts from childhood. Gestalt therapy, developed by Frederick (Fritz) Perls, emphasizes the principles of self-centered awareness and accepting responsibility of one's own behavior. Client-centered therapy was formulated by Carl Rogers, and it introduced the idea that individuals have the resources within themselves for self-understanding and for change. Part of this concept is that the therapist exposes his or her own true feelings and does not adopt a professional posture, keeping personal feelings unclear. Somatic or body therapies include: dance therapy, holotropic breathwork, and Reichian therapy.

The behavioral approach encompasses various behavior modification techniques and theories, including assertiveness training/social skills training, operant conditioning, hypnosis/hypnotherapy, sex therapy, systematic desensitization, and others. Systematic desensitization was pioneered by Joseph Wolpe, after he became frustrated with psychoanalysis. This therapy is a combination of deep muscular **relaxation** and emotive imagery exercises, in which the client relaxes and the therapist verbally sets scenes for the client to imagine. These scenes include elements of the client's fears, building from the smallest fear toward the largest fear, and the therapist monitors the client and introduces the scenes, working to maintain the client's relaxed state.

The cognitive approach stresses the role that thoughts play in influencing behavior. Rational-emotive therapy and reality therapy are both examples of the cognitive approach. Rational-emotive therapy was pioneered by Albert Ellis in the mid-1950s. This therapy is based on the belief that events in and of themselves don't upset people, but people get upset about events because of their attitudes towards the events. Ellis's therapy set out to change people's attitudes about events through objective, firm direction from the therapist and talk therapy. Reality therapy, developed by William Glasser, is based upon the idea that humans seek to satisfy their complex needs, and the behaviors they adopt are to accomplish that satisfaction. In Glasser's theory, some people usually fulfill themselves and are generally happy, while others are unable to fulfill themselves and get angry or depressed.

The family systems approach includes family therapy in several forms and is the attempt to modify relationships within the family. Family therapy views behaviors and problems as the result of family interactions, rather than as belonging to a family member. One theory, developed by Murray Bowen, has become its own integrated system with eight basic concepts,

Types of psychotherapy

Type	Description	Disciplines	Proponents
Psychodynamic	Based on psychoanalysis, the psychodynamic approach believes behavior and personality stem from the unconscious wishes and conflicts from childhood.	Psychoanalysis, Jungian analysis, Gestalt therapy, Client-centered therapy, and somatic or body therapies.	Sigmund Freud, Carl Jung, Alfred Adler, Erich Fromm, Karen Horney, Erik Erikson, and Frederick (Fritz) Perls
Behavioral	Encompasses various behavior modification techniques and theories, but often includes the use of positive reinforcement in order to change attitudes and increase self-efficacy.	Assertiveness training/social skills training, operant conditioning, hypnosis/ hypnotherapy, sex therapy, systematic desensitization, biofeedback, and stress management.	Joseph Wolpe
Cognitive	Focuses on the influence thoughts have on behavior.	Rational-emotive therapy and reality therapy	Albert Ellis, William Glasser
Family systems	Believes behavior is influenced by family dynamics and attempts to modify relationships within the family.	Family therapy	Murray Bowen

(Illustration by Corey Light. Cengage Learning, Gale)

including differentiation of self and sibling position. This system attempts to help an individual become differentiated from the family, while remaining in touch with the family system.

In the practical application of these approaches, psychotherapy can take many forms. Some of the most commonly practiced forms include:

- Counseling, the provision of both advice and psychological support, is the most elemental form of psychotherapy. Counseling can be short-term therapy done to assist a person in dealing with an immediate problem such as marital problems or family planning, substance abuse, bereavement, or terminal illness. Or it can be longer-term, more extensive treatment that addresses feelings and attitudes that impair success.
- Group psychotherapy requires less therapist time, and is thus less expensive. In fact, the interactions that occur between members of the group are expected to provide the change and healing each member receives. The therapist functions as a facilitator, or one who encourages and controls the group interchanges. Group therapy provides each member with the additional benefit of sharing and feedback from others experiencing similar emotional problems. This sharing and feedback has been found to be therapeutic, and the group can actually function as a trial social setting, allowing people to try out newly-learned behaviors.
- Family therapy began in the 1930s, when Freudian analyst Alfred Adler used it in working with his patients' entire families. Since the 1950s, it has been a widely used and highly respected means of therapy based upon the belief that the relationships and interactions within a family have a profound impact upon the patient's mental difficulties. Family therapy generally does not deal with internal conflicts, but rather encourages positive interactions between the various family members.

KEY TERMS

Behavioral therapy—A collection of techniques for treating mental disorders based upon changing abnormal behavior rather than attempting to analyze its fundamental basis. It is particularly used in phobic or obsessional disorders, and seeks to eliminate symptoms rather than treating the underlying psychological cause.

Magnetism—(Animal magnetism) A discredited theory put forth by Viennese physician Franz Anton Mesmer stating that all persons possess magnetic forces that can be used to influence magnetic fluid in other people and therefore effect healing. Mesmer opened a clinic in Paris in 1878, and appeared to cure people apparently suffering from hysterical conditions, such as emotionally caused paralysis.

Neurosis —A term commonly used to describe a range of relatively mild psychiatric disorders in which the sufferer remains in touch with reality. Neurotic disorders include mild depression, anxiety disorders (including phobias and obsessive compulsive disorders), somatization disorders, dissociative disorders, and psychosexual disorders.

Personality disorder—A group of conditions characterized by a general failure to learn from experience or adapt appropriately to changes, resulting in personal distress and impairment of social functioning.

All forms of psychotherapy require an atmosphere of absolute mutual trust and confidentiality. Without this total safety, no form of therapy will be successful.

Origins

Psychotherapy had its beginnings in the ministrations of some of the earliest psychologists, priests, magicians, and shamans of the ancient world. They attempted to determine the causes of the person's emotional distress by talking, counseling, and educating, and interpreting both behavior and dreams. Many of these practices became suspect as the work of charlatans, and fell into disrepute over the centuries. There was little change or progress in the treatment of mental illness over the centuries that followed.

Austrian physician Franz Anton Mesmer (1734–1815) began using what he termed *magnetism* and both the power of suggestion and hypnosis in 1772. Mesmer's treatments, too, fell into disrepute after his theories were rejected by a medical board of inquiry in 1784. Then, nearly a century later, Mesmer's ideas were rediscovered by French neurologist Jean-Martin Charcot (1825–1893). Dr. Charcot used suggestion and hypnosis for treating psychological difficulties at Salpêtrière Hospital in Paris in the late nineteenth century. Mesmer is now known as the Father of Hypnosis.

In the late nineteenth and early twentieth century, Austrian physician Sigmund Freud studied Charcot's work, and came to believe that hypnosis was less a treatment for mental illness than a means of determining its underlying cause. Freud used hypnosis as one means of uncovering the often traumatic, not consciously recalled memories of his neurotic patients just as he used their dreams to evaluate their mental conflicts. He later abandoned hypnosis because he did not induce successful trances in his neurology patients. His *The Interpretation of Dreams*, published in 1899, made the point that a person's dreams were actually a window into the inner, unknown mind—the royal road to the unconscious. He used the information he obtained not only to help his patients, but also to collect data that eventually helped verify some of his psychodynamic assumptions.

Sigmund Freud theorized that the human personality is composed of three basic parts, the *id*, the *ego*, and the *superego*. The id is defined as the most elemental part, the one that unconsciously motivates people toward fulfilling instinctive urges. The ego is more related to intellect and judgement. It arbitrates between the internal, usually unrecognized desires all human beings have and the reality of the external world. The superego, unconscious controls dictated by moral or social standards outside of ourselves, is probably most easily described as another name for the conscience.

Freud believed that mental illness was the result of people being unable to resolve conflict, or inadequate settlement of disharmony among the ego, superego, and id. To deal with these internal psychic conflicts, people develop defense mechanisms, which is normally a healthy response. The defense mechanisms become harmful to mental health when overused, or used inappropriately. Freud further postulated that childhood psychic development is primarily based upon sexuality; he divided the first eighteen months of life into three sex-based phases: oral, anal, and genital.

Freud's earliest students, including Carl Jung and Alfred Adler, came to believe that Freud had overestimated the influence sexuality had on psychic development, and found other influences that helped to shape the personality. In the late 1800s and into the twentieth century, 1904 Nobel Prize winner Ivan

Petrovich Pavlov pioneered the research that would later result in behavioral therapies, such as the work of American behaviorist Burrhus Frederic Skinner. And in the 1930s, American psychologist Carl Ransom Rogers began his school of psychology that emphasized the importance of the relationship between the patient (or client, according to Rogers) and the therapist in bringing about positive psychic change.

Primal therapy, developed by Arthur Janov in the 1960s, is based upon the assumption that people must relive early life experiences with all the acuity of feeling that was somehow suppressed at the time in order to free themselves of compulsive or neurotic behavior. Primal therapy was a cathartic approach that many therapists now believe can impede progress because a person can become addicted to the release (even "high") associated with the catharsis and seek to keep repeating it for the momentary satisfaction. Transactional analysis, based on Eric Berne's work, came into favor in the 1970s, and supposes that all people function as either parent or child at various times, and teaches the person to identify which role he or she is filling at any given time and to evaluate whether this role is appropriate.

Benefits

The generally accepted aims of psychotherapy are:

- Increased insight or improved understanding of one's own mental state. This can range from simply knowing one's strengths and weaknesses to understanding that symptoms are signs of a mental illness and to deep awareness and acceptance of inner feelings.
- The resolution of disabling conflicts, or working to create a peaceful and positive settlement of emotional struggles that stop a person from living a reasonably happy and productive life.
- Increasing acceptance of self by developing a more realistic and positive appraisal of the person's strengths and abilities.
- Development of improved and more efficient and successful means of dealing with problems so that the patient can find solutions or means of coping with them.
- An overall strengthening of ego structure, or sense of self, so that normal, healthy means of coping with life situations can be called upon and used as needed.

Though there are no definitive studies proving that all five of these goals are consistently realized, psychotherapy in one form or other is a component of nearly all of both in-patient and community based psychiatric treatment programs.

Description

Classic Freudian psychotherapy is usually carried out in 50-minute sessions three to five times per week. The patient lies on a couch while he or she talks with the therapist. Freudian therapy characteristically requires ongoing treatment for several years, though in Freud's era it did not. Most other forms of individual psychotherapy, including Jungian, counseling, humanistic, Gestalt, or behavioral therapies, are carried out on a weekly basis (or more frequently, if necessary), in which the person meets with his or her therapist in the therapist's office, and may or may not continue for longer than a year.

Group therapy is held in a variety of settings. A trained group therapist chooses the people that presumably would benefit and learn from interactions with each other. The size of a group is usually five to 10 people, plus a specially trained therapist who guides the group discussion and provides examination of issues and concerns raised.

Child psychotherapy is done for the same reasons as adult psychotherapy—to treat emotional problems through communication. The obvious difference is that child psychotherapy must acknowledge the child's stage of development. This means that the therapist may use different techniques, including play, rather than only talking to the patient.

A newer direction in the treatment of mental disorders is the use of brief psychotherapy sessions, often combined with medication, to treat neurotic conditions. Another short-term psychotherapy is often termed crisis intervention, and is used to aid people in dealing with specific crises in their lives, such as the death of a loved one.

Research and general acceptance

Psychotherapy, in its many forms, has been accepted and used throughout the world for over one hundred years. It is normally covered as a valid treatment of mental disorder by both public and private health insurers. Because the various types of psychotherapy have different aims, and mental illnesses usually do not have absolute measurable signs of recovery, evaluating psychotherapy's effectiveness is difficult. As a general rule, the majority of people who undergo treatment with psychotherapy can expect to make appreciable gains. Studies have revealed, however, that not everyone who goes into therapy will be

helped, or helped as much as others, and some will even be harmed.

Training and certification

Though the actual clinical practice of psychotherapy is very much the same among disciplines, therapists come from a variety of different fields, including medicine, psychology, social work, and nursing.

Psychiatrists are required to complete four years of medical school and one year of internship, followed by a three-year residency in psychiatry. In order to be a psychoanalyst, a minimum of three years further training at a psychoanalytic institute is necessary, along with personal ongoing analysis.

Psychologists earn a Ph.D. in clinical psychology followed by a year of supervised practice, and additionally may take specialized training at a specific psychotherapeutic school, including therapy for themselves.

Social workers who specialize in mental health must earn a master's degree or doctorate before being allowed to practice.

Psychiatric nurses generally earn a master's degree and practice in hospitals or community mental health centers.

Most states in the United States require a license to practice as a psychotherapist, and by law in the majority of the states, they are accountable only to the other members of their profession.

Psyllium

Description

Psyllium is a seed used for medicinal purposes taken from the common fleawort, *Plantago psyllium* and related species. There are about 250 species of the genus *Plantago* found worldwide. The most common species producing seed for medicinal use, in addition to *P. psyllium,* are *P. afra*, *P. isphagula*, *P. ovata*, and *P. indica*.

Psyllium is extensively cultivated in many parts of the world. Shrubby perennial plants with narrow green leaves put up spikes of small flowers that mature into seedpods. The seeds and husks are harvested and used in healing. The seeds are small (1.5–2 cm) and brown or reddish-brown.

Psyllium has been used in **Ayurvedic medicine** in India and in **traditional Chinese medicine** for thousands of years. It has also been used in Europe for

Psyllium plants. *(©PlantaPhile, Germany. Reproduced by permission.)*

many years, but it became common in North American healing in the second half of the twentieth century. However, by 21st century, psyllium was widely accepted by both alternative and traditional healthcare professionals.

General use

Psyllium has three major uses that have been well documented by modern scientific research. These include the treatment of **diarrhea**, the relief of **constipation**, and the lowering of serum **cholesterol** levels. Psyllium has other traditional uses that not been rigorously scientifically documented.

Psyllium seed is high in dietary fiber, making it a good bulk laxative for treating chronic constipation. It is also used to soften stools and ease bowel movements after operations involving the anus and rectum, when **hemorrhoids** or anal fissures are present, or during **pregnancy** to lessen the strain of bowel movements.

Psyllium seeds are coated with a substance called mucilage that swells or "bulks up" when exposed to water. This extra volume stimulates the movement of material through the bowel. In addition, the moist, gummy mucilage lubricates the lining of the intestine. Both United States health authorities and the German Federal Health Agency's Commission E, established in 1978 to independently review and evaluate scientific literature and case studies pertaining to herb and plant medications, approve the use of psyllium to treat constipation. Psyllium is the main ingredient in over-the-counter bulk laxatives such as Metamucil, Regulan, and Serutan.

Although it may at first seem contradictory, psyllium is also used to treat diarrhea and bouts of **irritable bowel syndrome**, a condition in which periods of diarrhea alternate with periods of constipation. As psyllium passes through the intestines, it absorbs water. This reduces the amount of fluid in the bowel and helps to control diarrhea. Both United States health authorities and the German Commission E have approved the use of psyllium to treat diarrhea.

German health authorities approved the use of psyllium to reduce serum cholesterol levels in the early 1990s, while the U. S. Food and Drug Administration (FDA) did not permit health claims to be made for psyllium content in foods until 1997. In that year, the FDA reviewed several scientific studies indicating that a daily intake of 10.2 grams of psyllium seed husk, combined with a diet low in saturated fats, consistently lowered blood cholesterol levels. Additional studies have confirmed the FDA's daily intake recommendation. Moreover, an improvement in the ratio of high-density lipoproteins (HDL, or "good" cholesterol) to low-density lipoproteins (LDL, or "bad" cholesterol) occurs when psyllium is used on a daily basis. The beneficial effects of psyllium on blood cholesterol levels, however, are somewhat affected by sex and age. Other surveys have found that wellness programs in which psyllium intake is one component of personalized behavioral change recommendations are more effective in lowering blood cholesterol than simply taking psyllium by itself. The FDA allows psyllium to be added to foods such as cereals (e.g., Bran Buds, Heartwise). The FDA permits foods containing psyllium to make the health claim that as part of a diet low in saturated fat and cholesterol, psyllium may help to prevent coronary **heart disease**).

In addition to these approved therapeutic uses, psyllium is used in traditional Chinese medicine to treat stomach and intestinal ulcers, **heartburn**, and to help manage non-insulin dependent (type 2) diabetes. Studies done by traditional medical parishioners have shown that psyllium taken before meals may reduced the rise in blood glucose (blood sugar) that occurred after eating, suggesting a valid role for psyllium in diabetes management. Additional studies are being undertaken.

Psyllium is also used to help control appetite in individuals who are dieting. The idea behind this is that psyllium slows stomach emptying and makes the individual feel fuller sooner and longer.

Some early studies suggested that psyllium might protect against **colorectal cancer**. Larger, better-designed studies have found only a minimal association between dietary fiber intake (including psyllium) and decreased rates of colorectal **cancer**. As of 2008, the role of psyllium in cancer prevention was still being investigated.

In Ayurvedic medicine, psyllium is used to cleanse the body by absorbing toxins in the large intestine so that they can be eliminated from the body. Some herbalists believe this action helps reduce the risk of colon cancer. Psyllium is also used by Ayurvedic practitioners to treat urethritis.

Preparations

Psyllium is available in a large number of over-the-counter (OTC) formulations. In the United States, it is sold in mainstream pharmacies and supermarkets under a variety of brand names including Metamucil, Fiberall, and Naturacil. Many other common laxatives include psyllium as an ingredient. Psyllium is also added to some breakfast cereals to increase their fiber content. In health food stores, psyllium can be obtained as powdered husks or seeds. A common dosage for

constipation is 2 tsp of psyllium (7 g) taken with at least one glass (8 oz) of water up to three times a day. The dose for diarrhea can be even higher—up to 40 grams per day.

Precautions

Psyllium is one of the safest laxatives available for long-term use. It is widely considered by the traditional medical community as very safe and effective when used in recommended doses for constipation and diarrhea.

People who are suspected of having an intestinal blockage or who suffer from narrowing of the esophagus or any other part of the intestinal tract should not use psyllium. People with diabetes, and children under age six should use psyllium only after talking to their doctor. Psyllium is generally accepted as safe to use throughout pregnancy and while breastfeeding. In rare cases psyllium can cause a severe allergic reaction. Allergic reaction is most common in people who have long-term workplace exposure to psyllium.

Although such accidents are unusual, cases have been reported of patients suffocating when a mass of psyllium blocked the upper airway. Although these incidents are most common in elderly patients or those with neurological disorders, anyone taking a psyllium preparation on a regular basis should drink a large glass of water or other liquid immediately following each dose.

Side effects

The use of psyllium may cause increased abdominal **gas**, stomach rumbling, and a feeling of bloating. A few patients may experience **nausea** and **vomiting**, but these side effects are rare.

Interactions

Psyllium slows the absorption from the intestine of some nutrients and may change the rate of absorption of some medications. Some nutrients that may be absorbed more slowly include **zinc**, **calcium**, **iron**, and vitamin B12. Carbohydrates are absorbed more slowly, which may make it necessary for insulin-dependent diabetics to adjust their insulin dose. Psyllium may also slow down or decrease the absorption of certain medications, including antibiotics, digoxin, lithium, tricyclic antidepressants, carbemazepine, and anti-diabetic medicines such as glyburide and metformin. Individuals taking any of these drugs should talk to their healthcare provider before beginning psyllium. Absorption problems can usually be avoided by taking psyllium an hour after taking other medications. Apart from affecting speed of absorption, as of 2008, psyllium is not known to interact with any standard pharmaceuticals.

KEY TERMS

Mucilage—A gummy, gelatinous substance that coats psyllium seeds and helps them absorb water.

Urethritis—An infection of the urethra or tube that drains the bladder.

Pulsatilla

Description

Pulsatilla nigricans, commonly known as pulsatilla, is a remedy derived from the plant commonly known as wind flower, pasque flower, or meadow anemone. The perennial plant is a member of the Ranunculaceae family and is native to central and northern Europe and southern England. This wild plant grows in sunny meadows, pastures, and fields.

A crown of leaves forms on the ground, from which a single flower grows in May and August. The stem reaches a height of about 6 in (15 cm) and has downy hairs that grow on it. The flower is colored dark violet-brown.

The plant was used medicinally during ancient times for eye ailments. During the 19th century, the eclectic physicians and contemporaries of Samuel Hahnemann, the father of **homeopathy**, noted pulsatilla's use in the treatment of melancholy, swelling of the knees, and nervous system disorders. In ancient times it was used as an external remedy for ulcers and eye inflammation.

The plant contains lactones, saponins, anemone camphor, tannins, and a volatile oil. It is antispasmodic and antibacterial and acts on the nervous system. When chewed, a caustic substance contained in the plant **burns** the tongue and throat. When applied topically, it may cause **blisters** on the skin. Though not used as widely as it was in the 19th century, pulsatilla may be used to treat painful periods, **insomnia**, headaches, **boils**, ovarian **pain**, and **asthma**.

The pulsatilla plant contains lactones, saponins, anemone camphor, tannins, and a volatile oil. It is antispasmodic and antibacterial and acts on the nervous system. *(Chris Gomersall / Alamy)*

KEY TERMS

Conjunctivitis—An inflammation of the mucous membranes that cover the outer eyeball and line the eyelids. The eye appears red or pink and is itchy or sore.

Infusion—An herbal tea created by steeping herbs in hot water (1 tsp herb to 1 cup water). Generally, leaves and flowers are used in infusions.

Perennial—A plant that persists for several years.

Succussion—A process integral to the creation of a homeopathic remedy in which a homeopathic solution is repeatedly struck against a firm surface. This is performed to thoroughly mix the substance and magnify its healing properties.

General use

Traditional Chinese medicine

Chinese anemone root (*Pulsatilla chinensis*) is a related herb used in **traditional Chinese medicine**. Bai tou weng, as it is referred to in Mandarin, is prescribed by Chinese medicine practitioners to clear heat and detoxify fire poison. It is used in damp heat conditions of the stomach and large intestine in dysentery. Dysentery is a disease marked by frequent watery stools and often accompanied by stomach pain, **fever** or dehydration. The herb has a bitter taste and is antimicrobial. The plant has also been used to treat **diarrhea**, **wounds**, and trauma.

Homeopathy

Homeopaths prescribe pulsatilla for acute ailments that are caused by grief, anger, fright, shock, consumption of rich foods, loss of vital fluids, exposure to the sun, suppression of **menstruation**, and mental strain. This herb is often called the queen of homeopathic remedies, as it is indicated in so many conditions. These conditions include arthritis, **bronchitis**, **chickenpox** with **cough** and low fever, colds, coughs, digestive troubles, eye and ear **infections**, fevers, headaches, **measles** with a cough and cold, **mumps** with swollen and painful glands, and menstrual difficulties.

Physical symptoms include thirstlessness, one-sided complaints, weakness, slow digestion, chilliness, and thick, yellow bodily discharges. The pains are cutting, stitching, or burning, and they wander from body part to body part. The lymph glands are often swollen, and the sweat and breath smell repugnant. The lips and mouth are dry, and a white or yellow-

coated tongue is often present. The patient may crave butter, but dislikes bread, hot food and drinks, fats, rich food, and meat. These foods cause **indigestion** and **nausea**. The patient is chilly, often with cold hands and feet, but dislikes heat.

Pulsatilla is generally chosen because it acts so well on ailments that are of an emotional nature. The remedy is typically suited for mild, gentle, and timid women and children with blonde hair and blue eyes. Pulsatilla patients are generally emaciated persons who are sympathetic, sad, weepy, sensitive, easily offended, jealous, depressed, shy, introspective, and anxious. The patient desires affection and the company of others, and is often fearful of being alone, of the dark, or in a crowd. She may be filled with remorse or despair and may be suicidal. She cries easily and is not afraid to show her emotions.

A typical indication of the pulsatilla patient lies in her erratic emotional and physical behavior. Her moods are always changing: one minute she may be happy, the next may find her crying. Ailments are one-sided or change location. For instance, arthritic pain may stop in one joint and appear in another. Pulsatilla is a useful remedy for teething babies who are weepy, whiny, and want to be carried.

Symptoms are worse in the morning, in the evening before midnight, in cold air, when the feet are wet, and while standing or lying down. They are also aggravated by warmth, while lying on the painless side, during and after eating, eating warm foods, after sleep, by rapid motion, and before, during, and after menstruation. Conditions that improve the symptoms include fresh air, lying on the painful side, pressure, gentle motion, cold, and cold applications.

SPECIFIC INDICATIONS. Arthritic inflammations have little swelling or redness. The pains are pulling, sore, and bruised, and shift from joint to joint. They are relieved by the cold, fresh air, and slow movement. Symptoms are worse from heat, wet weather, upon beginning to move, or after the **common cold**. The patient often has a **dry mouth**, fever, and lacks thirst.

Back pains occur in the lower back or small of the back. The back feels tired and weak, like it was sprained, and the pains are aching and pressing. The pains are worse when bending down or rising after long periods of sitting, but are relieved from gentle motion and walking slowly. The backache often occurs before and during the menstrual period.

Bronchitis accompanied by a dry cough that is worse in the evening or when lying down is indicative of this remedy. The cough is loose in the morning and the mucous expelled is bitter or salty. The cough is better when sitting up or in cool air and worse after eating.

Pulsatilla is a useful remedy for breastfeeding mothers with an overabundant supply of milk. It is often indicated in postnatal **depression** accompanied by crying.

The cold indicative of pulsatilla is accompanied by **sneezing**, **chills**, fever, and sometimes **nosebleeds**. The patient catches cold easily. The nose is stuffed in a warm room and in the evening, and is watery in fresh air. The discharge is thick and yellow or green. The sense of smell and taste is lost. Symptoms are relieved by fresh air.

Conjunctivitis with redness and swelling of the eyelids is accompanied by a thick, yellow discharge that oozes from the eyes. In the morning the eyes are often stuck shut. The eyes are typically itchy and burning. The symptoms are better from cold applications or cold air.

Constipation with ineffective urging and a backache occurs with this remedy. When the patient does defecate, the stools are large and hard.

The cough typical of this remedy is an exhausting cough that occurs in fits. The cough is dry at night and loose in the morning. There is a loud rattling in the chest that often wakes the patient. A sticky, yellow or green mucus is present, but may be difficult to expel. The throat may become raw, sore, and painful from the cough. The cough is better from fresh air and sitting up, and worse from exertion, lying down, heat, or a stuffy room.

The diarrhea is a greenish-yellow color and is slimy and watery. There is a rumbling in the abdomen before it is expelled. The pains in the abdomen are cutting. The diarrhea is worse at night, after eating, after eating starchy or rich food, when overheated, or in a stuffy room.

Digestive disturbances are caused by eating rich or fatty foods, pork, ice cream, fruit, or cold foods. The patient lacks appetite or thirst and often suffers from nausea and **vomiting**. He may have a dry mouth and may feel as if a lump was behind the sternum. Indigestion is accompanied by bitter-tasting belches, stomach pains, and **heartburn**. Diarrhea may also be present. Symptoms are worse after eating or drinking and at night.

Pulsatilla types do not fare well in hot weather and often suffer from exhaustion. They are worse from the sun, a stuffy room, or mental exertion.

Pulsatilla is indicated in fevers in which the patient is not thirsty and has a dry mouth. The fever is hot and burning and is typically one-sided, i.e. the body may be hotter on one side than the other. The sweat

produced may occur on one side of the body or be localized to one area. The patient may weep and moan while feverish. The fever is worse in heat, at night, under warm covers, in a stuffy room, or after washing. Intermittent fevers are worse between 2:00 p.m. and 3:00 p.m. These fevers are worse from heat and covering.

The **headache** pains occur in the front of the head or at the temples. The pains are throbbing, pressing, one-sided pains that are worse from movement, excessive sun, eating rich foods, hot drinks, bending over, standing, running, or blowing the nose.

Insomnia is caused by anxious dreams, a restless sleep, too much thinking, and a repetition of thoughts. When the feet become hot, the patient sticks them out of the bed. Then the patient is awakened because his feet are cold.

Menstrual difficulties are also indicative of this remedy and often occur as a result of suppressed menstruation. Menstruation is accompanied by vomiting, nausea, skin affections, sadness, weeping, and pain in the abdomen, liver, and back. The period is generally late. The flow may start and stop or be present only during the day. The pains are aching, dull, and wandering. They are better when the patient is doubled over. Symptoms are aggravated by wetting the feet.

Varicose veins are sore and stinging. They are worse while standing and better from walking and cold applications. They are also worse during **pregnancy** and when circulation in the limbs is poor.

Preparations

Pulsatilla nigricans is available in dried bulk form, and as a tincture. Pharmacies, health food stores, and Chinese herbal stores carry the various preparations. They are also available as prescribed by a herbalist, homeopathic doctor, and Chinese medicine practitioner.

The homeopathic preparation of pulsatilla is created in the following manner. The plant is collected when the flowers are in full bloom and pounded to a pulp. This pulp is soaked in alcohol, then strained and diluted. The final homeopathic remedy is created after the diluted mixture is succussed repeatedly. The remedy is available at health food and drug stores in various potencies in the form of tinctures, tablets, and pellets.

The dried plant combines well with **cramp bark** as a treatment for painful periods. For skin conditions it is combined with **echinacea**.

An infusion is made by pouring one cup of boiling water over 1/2 tsp of the dried plant. The mixture steeps for 10-15 minutes then should be strained. Pulsatilla can be drunk up to three times daily.

For use in traditional Chinese medicine, the herb should be soaked for one hour in warm water, then simmered for 30-120 minutes. It is usually used in combination with other herbs.

The tincture dosage is 1-2 ml three times daily.

Precautions

If symptoms do not improve after the recommended time period, a homeopath or health care practitioner should be consulted.

The recommended dose should not be exceeded.

Those seeking this remedy should not use the fresh plant.

Side effects

There are no known side effects.

Interactions

When taking any homeopathic remedy, use of **peppermint** products, coffee, or alcohol is discouraged. These products will cause the remedy to be ineffective.

Pulsatilla chinensis is contraindicated in chronic dysentery with a deficiency of Spleen and Stomach. It is only used for acute dysentery.

Pulse diagnosis

Definition

Pulse diagnosis is a diagnostic technique used in several healing systems to determine the health conditions and course of treatment for patients.

KEY TERMS

Acupuncture—Healing technique in traditional Chinese medicine utilizing the insertion of thin needles and other methods.

Ayurvedic medicine—Traditional healing system developed in ancient India and practiced around the world.

Diagnosis—Means of determining health problems and general condition in a patient.

Traditional Chinese medicine—Healing system developed in ancient China utilizing acupuncture, acupressure massage, herbal remedies, and other healing techniques.

Origins

As used in **Ayurvedic medicine** and **traditional Chinese medicine** (TCM), the techniques of pulse diagnosis have been developed over thousands of years, as these two systems of medicine are the world's oldest. **Acupuncture**, a branch of TCM, has long relied on pulse diagnosis as a main tool to determine the course of treatment. In Western medicine, every time a doctor checks the pulse of a patient and listens to the heartbeat with a stethoscope, the doctor is practicing a form of pulse diagnosis.

Benefits

Pulse diagnosis is a quick, inexpensive, and non-invasive diagnostic tool. When performed by trained professionals, it can be an effective means for determining the health conditions of patients.

Description

In conventional Western medicine, doctors check the pulse of patients by placing their hands on the wrist and by listening to the pulse at various points on the body with a stethoscope. Doctors check for abnormalities in rhythm and rate that may indicate heart problems, internal bleeding, and **fever**. Measuring blood pressure is essentially another pulse diagnosis, which indicates **hypertension**, circulatory conditions, and other problems.

In older healing systems, such as Ayurveda and TCM, doctors check the pulse just as Western doctors do, but they use a very intricate system of pulse measurements, and they rely on careful observations instead of diagnostic tools. Pulse diagnosis is considered as much an art as a science, and it takes physicians many years of training to become experts. Doctors skilled in pulse diagnosis can often find health problems with a quick touch. Some published observations have documented the effectiveness of pulse diagnosis by trained experts, comparing their diagnoses with the diagnoses with modern technology.

In Ayurvedic medicine, pulse diagnosis is called *nadi parkiksha*. The principle measurement of pulse is taken at the radial artery, a blood vessel that is located on the inside of the wrist. Ayurvedic doctors use three fingers to feel the pulse, and particular conditions are indicated depending on the pulse characteristics that each finger feels. Doctors note heart rate, counting how many beats occur per minute and per breathing cycle of the patient. Doctors also take deep and shallow readings of the pulse, pressing hard or gently on the artery. Ayurvedic doctors believe that the pulse can indicate how *prana*, or life energy, is flowing through a patient's system, and can indicate the condition of internal organs. Doctors check the pulse on both wrists, because each side of the body gives different indications.

Ayurvedic doctors may take pulse readings at other points on the body as well. These points include the brachial artery on the inside of the arm above the elbow, the carotid artery at the base of the neck, the femoral artery that travels down the inside of the leg, and pulse points at the temples, at the ankles, and on the top of the feet. Ayurvedic physicians use other diagnostic tools in conjunction with pulse analysis, including interviewing the patient and closely observing the physical characteristics of the tongue, voice, skin, eyes, appearance, urine, and stool, in addition to utilizing conventional diagnostic methods.

Pulse diagnosis in traditional Chinese medicine (including acupuncture) shares some similarities with Ayurvedic medicine. In TCM, pulse diagnosis is used to check the condition of the blood and of *qi* (chi), which is the invisible life energy that travels in channels (meridians) throughout the body. Using pulse diagnosis, physicians determine the condition of the internal organs, and describe conditions according to yin and yang (cold or hot, empty or full, weak or strong, etc.). Pulse diagnosis tells acupuncturists where there are problems with the flow of energy in the body.

In TCM, there are several pulse diagnosis techniques, but the one most commonly used is checking the radial arteries on each wrist. Each wrist has six positions that are checked, and the 12 positions on both wrists correspond to the 12 internal organs. At each position, there are three depths that are checked.

LI SHIZ-HEN (1518-1593)

Li Shiz hen was born in 1518 in the town of Kin Zhou (var. Qizhou) along the Yangtze River in the Hubei prov ince of China. His family was renowned for its medical expertise. At age 14, Shiz hen elected to study the family arts of medicine and pharmacology. As a medical student he distinguished himself with his scholarly writings.

Shiz hen served as a pharmacist for the Ming Dynasty. His reputation was such that he was assigned to an official position at the Imperial Academy of Medicine in Peking. There he earned the respect of the prince of China. Between 1552 and 1578, with the express permission of the Imperial family, Shiz hen engaged himself in studying the priceless ancient Chinese writings on medicinals, after which he undertook the massive task of reorganizing and classifying all of the information that was at his disposal. Shiz hen incorporated information that he learned from his own family along with the knowledge from the treasured ancient writings collected by the Chinese monarchs for centuries. The result of his decades long project was a massive encyclopedic text, called the *Bencao gangmu.* Shiz hen's work comprised 52 volumes, including all existing knowledge of botanicals and medicine that was available at the time. The books contained thousands of medical prescriptions and information on over 1,000 herbs. He presented the manuscript to the scholar Wang Shiz hen, who wrote an introduction for the book.

Shiz hen's voluminous work, also known as the *Great Herbal,* was the greatest written contribution from the Far East during the sixteenth century. In 1596, three years after Shiz hen's death, the Emperor Shen Tsun declared the book to be the official medical reference of China.

In all, the pulse can have 36 different qualities. Some of the observations noted during pulse diagnosis include the position of the artery, whether it is deep or shallow, the hardness or softness of the artery, the diameter of the blood vessel, the rate and strength of the pulse, and the rhythm of the heartbeat. TCM practitioners may take the pulse at other points on the body, frequently including the carotid artery at the base of the neck.

In TCM and acupuncture, pulse diagnosis is used in conjunction with other diagnostic techniques. TCM doctors closely interview patients, and pay attention to seeing, hearing, and smelling the patient. TCM practitioners also observe the tongue, and palpate (touch) parts of the body to check for swelling, **pain**, temperature, moisture, and other characteristics. TCM practitioners may also use conventional diagnostic techniques such as blood tests, scans, and others.

Preparation

Pulse diagnosis should be performed on patients under normal conditions to insure accuracy. The pulse should not be diagnosed after **exercise**, physical exertion, bathing, massage, sex, eating or drinking, while the patient is very hungry, or in a room where the temperature is very hot or cold.

Precautions

Pulse diagnosis can be a quick and inexpensive means of diagnosis, but it should be performed by a trained specialist to be most effective. Pulse diagnosis is best used in conjunction with other diagnostic techniques, including conventional ones. For patients with severe, chronic, or undetermined conditions, getting more than one diagnosis or opinion is recommended.

Training and certification

Pulse diagnosis is a technique that requires careful training by specialists. Pulse diagnosis is taught at schools that teach Ayurvedic medicine, traditional Chinese medicine, and acupuncture.

Pyridoxine

Description

Pyridoxine, or vitamin B_6, is a member of the water-soluble family of B vitamins. It is necessary in the metabolism of proteins, fats, and carbohydrates; to make hormones and neurotransmitters; and to support the immune system. It also plays a role in the production of normal, healthy red blood cells and some of the neurotransmitters needed for proper nervous system function. In conjunction with **folic acid** and cobalamin, it acts to reduce homocysteine levels, thus lowering the risk of developing **heart disease**.

General use

Mild deficiencies of pyridoxine are common, despite the low daily requirements. The Recommended Daily Allowance (RDA) for babies under six months of age is 0.1 milligram (mg), and for babies six months to one year old, it is 0.3 mg. The daily requirement is 0.5 mg for children one to three years old, 0.6 mg for those four to eight years old, and 1 mg for nine- to 13-year-olds. Males aged 14–18 years need 1 mg, and those 19 years and older need 1.3 mg. The RDA for females aged 14–18 years is 1.2 mg for females, and for females over the age of 19, 1.3 mg. Requirements are somewhat increased during **pregnancy** (1.9 mg) and lactation (2 mg).

Pyridoxine has numerous therapeutic uses apart from treating deficiency. It has a calming effect on the nervous system and may alleviate **insomnia** by increasing serotonin levels in the brain. Because of the calming effects of pyridoxine, it has been tried as a possible adjunctive treatment for **schizophrenia**. As of 2008, however, the findings were inconclusive although additional studies on the use of pyridoxine for dealing with mental illness were under way.

Evidence suggests that pyridoxine reduces **nausea** for about a third of pregnant women who experience **morning sickness**. In addition, pyridoxine does not have any harmful effects on the fetus. It is also used to decrease the risk of heart disease by lowering homocysteine levels. Taken in conjunction with **magnesium** supplements, pyridoxine has been found to have beneficial effects on some people with **autism**. The vitamin B_6 and magnesium combination can also help to prevent the recurrence of **calcium** oxalate **kidney stones** in susceptible people. Those who are affected by **depression** or gestational diabetes may benefit from a moderate addition of it, as well. One type of hereditary **anemia** and several metabolic diseases are effectively treated with high doses of pyridoxine. A few chemotherapeutic agents, including vincristine, can be taken with fewer side effects when pyridoxine is added to the patient's regimen. The data are equivocal on whether **asthma** is improved by vitamin B_6 supplementation, but high doses—50 mg, taken twice daily—were used in the studies performed, creating a risk of nerve injury. There is some question as to the benefit to taking it for PMS, **carpal tunnel syndrome**, or diabetic neuropathy, although there is no harm in a trial of additional B_6 at a modest level. Taking B_6 has some benefit for those suffering from **osteoporosis** and **epilepsy**. Nevertheless, the advice of a healthcare professional should be sought before undertaking this, and any, supplemental treatment.

Preparations

Natural sources

Meats are the best food source of pyridoxine, followed by dairy and eggs. Although some grains contain B vitamins, they are generally lost in processing. Bananas, potatoes, mangoes, and avocados have the highest vitamin B_6 value among vegetarian foods. Fresh foods should be used because freezing destroys much of this vitamin. Minimizing the amount of water used in cooking prevents pyridoxine and other water soluble vitamins from leaching into it.

Supplemental sources

Pyridoxine supplements are available in both oral and injectable forms. Pyridoxine is also added to many processed grain products. Individuals may consider taking a balanced B complex supplement rather than high doses of an individual vitamin unless given instructions by a medical doctor to do so. Supplements ought to be stored in a cool, dry place, away from light, and out of the reach of children.

Deficiency

Symptoms of pyridoxine deficiency are nonspecific but may include nervousness, irritability, muscle twitches, insomnia, confusion, weakness, loss of coordination, and anemia. Frequent **infections** are likely as well due to the importance of vitamin B_6 to the immune system.

Risk factors for deficiency

Since meats are the best source of pyridoxine, followed by dairy and eggs, vegans are one of the groups at risk for deficiency. A balanced B vitamin supplement is adequate to prevent deficiency. People with malabsorption syndromes, chronic illnesses, or

hyperthyroidism may require somewhat larger amounts of vitamin B_6. Those who take birth control pills are more likely to have abnormally low levels and may benefit from a supplement of 25–50 mg per day. Elderly people are more likely to have a poor diet, and deficient pyridoxine will both increase their susceptibility to illness and prolong recovery. Alcoholics, smokers, and people who take certain medications, including estrogen, theophylline (for asthma), hydralazine (for **hypertension**), penicillamine (for **rheumatoid arthritis**), and isoniazid (for **tuberculosis**) are more likely to need extra pyridoxine. For asthmatics on theophylline, the side effects of this medication can also be reduced by the additional vitamin B_6. A healthcare professional ought to be consulted before individuals begin a program of supplementation.

Precautions

Allergic reactions to oral or injected pyridoxine are known to occur but are rare. It is possible to have toxic effects from large doses. At 2,000 mg daily, nerve damage may occur, causing numbness or tingling of the extremities and loss of coordination. These symptoms are usually, but not always, reversible. At 500 mg for daily dosages, there is possible toxicity if chronically taken many months or years. Finally, at 150 mg taken daily, there is rare, but possible, toxicity with long-term use. Thus, it is best to take no more than 50 mg a day unless under medical supervision to avoid the potential for toxicity. Chronic large doses may also cause photosensitivity. Pregnant women who take megadoses may create dependence in the newborn, who would be at risk for seizures. Nursing infants can also suffer adverse effects from large doses ingested in breast milk.

Side effects

High doses of pyridoxine may cause a rash in addition to the more serious complications listed under precautions.

Interactions

Optimal levels of **riboflavin**, **vitamin C**, magnesium, and **selenium** improve pyridoxine absorption. The effectiveness of levodopa is reduced by pyridoxine. Anyone taking levodopa, most commonly used to treat **Parkinson's disease**, should not take supplemental vitamin B_6. Other combination forms of medication for Parkinson's disease may not be affected. Phenytoin and phenobarbital, two medications sometimes used to control epilepsy, may also become less effective in the presence of extra vitamin B_6. Pyridoxine requirements are increased by the medications hydralazine, penicillamine, isoniazid, and some immunosuppressive agents. Both theophylline and estrogen containing medications, including birth control pills, block the metabolism of pyridoxine.

KEY TERMS

Chemotherapeutic agent—A medication used to treat disease, usually cancer.

Homocysteine—An amino acid produced from the metabolism of other amino acids. High levels are an independent risk factor for heart disease.

Neurotransmitter—One of a group of chemicals used by the nervous system to transmit messages between two neurons (nerve cells).

Serotonin—A neurotransmitter in the brain that helps to regulate moods, emotions, sleep, and appetite.

Vegan—A person who does not eat any animal products, including dairy and eggs.

Q

Qigong

Definition

Qigong (pronounced "chee-gung," also spelled *chi kung*) is translated from the Chinese to mean "energy cultivation" or "working with the life energy." Qigong is an ancient Chinese system of postures, exercises, breathing techniques, and meditations. Its techniques are designed to improve and enhance the body's *qi*. According to traditional Chinese philosophy, qi is the fundamental life energy responsible for health and vitality.

Origins

Qigong originated before recorded history. Scholars estimate qigong to be as old as 5,000–7,000 years. Tracing the exact historical development of qigong is difficult, because it was passed down in secrecy among monks and teachers for many generations. Qigong survived through many years before paper was invented, and it also survived the Cultural Revolutions in China of the 1960s and 1970s, which banned many traditional practices.

Qigong has influenced and been influenced by many of the major strands of Chinese philosophy. The Taoist philosophy states that the universe operates within laws of balance and harmony, and that people must live within the rhythms of nature—ideas that pervade qigong. When Buddhism was brought from India to China around the seventh century A.D., **yoga** techniques and concepts of mental and spiritual awareness were introduced to qigong masters. The Confucian school was concerned with how people should live their daily lives, a concern of qigong as well. The **martial arts** were highly influenced by qigong, and many of them, such as **t'ai chi** and kung fu, developed directly from it. **Traditional Chinese medicine** also shares many of the central concepts of qigong, such as the patterns of energy flow in the body. **Acupuncture** and **acupressure** use the same points on the body that qigong seeks to stimulate. In China, qigong masters have been renowned physicians and healers. Qigong is often prescribed by Chinese physicians as part of the treatment.

Due to the political isolation of China, many Chinese concepts have been shrouded from the Western world. Acupuncture was only "discovered" by American doctors in the 1970s, although it had been in use for thousands of years. With an increased exchange of information, more Americans have gained access to the once-secret teachings of qigong. In 1988, the First World Conference for Academic Exchange of Medical Qigong was held in Beijing, China, where many studies were presented to attendees from around the world. In 1990, Berkeley, California hosted the First International Congress of Qigong. In the past decade, more Americans have begun to discover the beneficial effects of qigong, which motivate an estimated 60 million Chinese to practice it every day.

Benefits

Qigong may be used as a daily routine to increase overall health and well-being, as well as for disease prevention and longevity. It can be used to increase energy and reduce **stress**. In China, qigong is used in conjunction with other medical therapies for many chronic conditions, including **asthma**, **allergies**, **AIDS**, **cancer**, headaches, **hypertension**, **depression**, mental illness, strokes, **heart disease**, and **obesity**.

Qigong is presently being used in Hong Kong to relieve depression and improve the overall psychological and social well-being of elderly people with chronic physical illnesses.

Description

Basic concepts

In Chinese thought, qi, or chi, is the fundamental life energy of the universe. It is invisible but present in

Beijing, woman in Ritan park using Qigong breathing exercise. *(© diyiming / Alamy)*

KEY TERMS

Martial arts—Group of diverse activities originating from the ancient fighting techniques of the Orient.

Meridians—Channels or conduits through which Qi travels in the body.

Qi—Basic life energy, according to traditional Chinese medicine.

Yin/Yang—Universal characteristics used to describe aspects of the natural world.

the air, water, food, and sunlight. In the body, qi is the unseen vital force that sustains life. We are all born with inherited amounts of qi, and we also get acquired qi from the food we eat and the air we breathe. In qigong, the breath is believed to account for the largest quantity of acquired qi, because the body uses air more than any other substance. The balance of our physical, mental, and emotional levels also affect qi levels in the body.

Qi travels through the body along channels called meridians. There are 12 main meridians, corresponding to the 12 principal organs as defined by the traditional Chinese system: the lung, large intestines, stomach, spleen, heart, small intestine, urinary bladder, kidney, liver, gallbladder, pericardium, and the "triple warmer," which represents the entire torso region. Each organ has qi associated with it, and each organ interacts with particular emotions on the mental level. Qigong techniques are designed to improve the balance and flow of energy throughout the meridians, and to increase the overall quantity and volume of qi. In qigong philosophy, mind and body are not separated as they often are in Western medicine. In qigong, the mind is present in all parts of the body, and the mind can be used to move qi throughout the body.

Yin and yang are also important concepts in qigong. The universe and the body can be described by these two separate but complementary principles, which are always interacting, opposing, and influencing each other. One goal of qigong is to balance yin and yang within the body. Strong movements or techniques are balanced by soft ones, leftward movements by rightward, internal techniques by external ones, and so on.

Practicing qigong

There are thousands of qigong exercises. The specific ones used may vary depending on the teacher, school, and objective of the practitioner. Qigong is used for physical fitness, as a martial art, and most frequently for health and healing. Internal qigong is performed by those wishing to increase their own energy and health. Some qigong masters are renowned for being able to perform external qigong, by which the energy from one person is passed on to another for healing. This transfer may sound suspect to Western logic, but in the world of qigong there are some amazing accounts of healing and extraordinary capabilities demonstrated by qigong masters. Qigong masters generally have deep knowledge of the concepts of Chinese medicine and healing. In China, there are hospitals that use medical qigong to heal patients, along with herbs, acupuncture, and other techniques. In these hospitals, qigong healers use external qigong and also design specific internal qigong exercises for patients' problems.

There are basic components of internal qigong sessions. All sessions require warm-up and concluding exercises. Qigong consists of postures, movements, breathing techniques, and mental exercises. Postures may involve standing, sitting, or lying down. Movements include stretches, slow motions, quick thrusts, jumping, and bending. Postures and movements are designed to strengthen, stretch, and tone the body to improve the flow of energy. One sequence of postures and movements is known as the "Eight Figures for Every Day." This sequence is designed to quickly and effectively work the entire body, and is commonly performed daily by millions in China.

Breathing techniques include deep abdominal breathing, chest breathing, relaxed breathing, and holding breaths. One breathing technique is called the "Six Healing Sounds." This technique uses particular breathing sounds for each of six major organs. These sounds are believed to stimulate and heal the organs.

Meditations and mind exercises are used to enhance the mind and move qi throughout the body. These exercises are often visualizations that focus on different body parts, words, ideas, objects, or energy flowing along the meridians. One mental **exercise** is called the "Inner Smile," during which the practitioner visualizes joyful, healing energy being sent sequentially to each organ in the body. Another mental exercise is called the "Microscopic Orbit Meditation," in which the practitioner intently meditates on increasing and connecting the flow of qi throughout major channels.

Discipline is an important dimension of qigong. Exercises are meant to be performed every morning and evening. Sessions can take from 15 minutes to hours. Beginners are recommended to practice between 15–30 minutes twice a day. Beginners may take classes once or twice per week, with practice outside of class. Classes generally cost between $10–$20 per session.

Preparations

Qigong should be practiced in a clean, pleasant environment, preferably outdoors in fresh air. Loose and comfortable clothing is recommended. Jewelry should be removed. Practitioners can prepare for success at qigong by practicing at regular hours each day to promote discipline. Qigong teachers also recommend that students prepare by adopting lifestyles that promote balance, moderation, proper rest, and healthy **diets**, all of which are facets of qigong practice.

Precautions

Beginners should learn from an experienced teacher, as performing qigong exercises in the wrong manner may cause harm. Practitioners should not perform qigong on either full or completely empty stomachs. Qigong should not be performed during extreme weather, which may have negative effects on the body's energy systems. Menstruating and pregnant women should perform only certain exercises.

Side effects

Side effects may occur during or after qigong exercises for beginners, or for those performing exercises incorrectly. Side effects may include **dizziness**, **dry mouth**, **fatigue**, headaches, **insomnia**, rapid heartbeat, shortness of breath, heaviness or numbness in areas of the body, emotional instability, **anxiety**, or decreased concentration. Side effects generally clear up with rest and instruction from a knowledgeable teacher.

Research and general acceptance

Western medicine generally does not endorse any of the traditional Chinese healing systems that utilize the concept of energy flow in the body, largely because this energy has yet to be isolated and measured scientifically. New research is being conducted using sophisticated equipment that may verify the existence of energy channels as defined by the Chinese system. Despite the lack of scientific validation, the results of energy techniques including qigong and acupuncture have gained widespread interest and respect. One California group of qigong practitioners now conducts twice-yearly retreats to improve their skills and energy level. Furthermore, qigong masters have demonstrated to Western observers astounding control over many physical functions, and some have even shown the ability to increase electrical voltage measured on their skin's surface. Most of the research and documentation of qigong's effectiveness for medical conditions has been conducted in China, and is slowly becoming more available to English readers. Papers from the World Conferences for Academic Exchange of Medical Qigong are available in English, and address many medical studies and uses of qigong. A video is now available that presents the basic concepts of medical qigong as well as specific exercise prescriptions for the treatment of **breast cancer**. The exercise prescriptions consist of movements, postures, visualizations, and positive affirmations.

In terms of mainstream research in the United States, the first ongoing long-term study of qigong began in 1999 at the Center for Alternative and Complementary Medicine Research in Heart Disease at the University of Michigan; it focuses on the speed of

healing of graft **wounds** in patients undergoing coronary bypass surgery. The National Center for Complementary and Alternative Medicine (NCCAM) has been funding studies of qigong since 2000. The first such study was conducted by a researcher in Arizona with patients using heart devices (pacemakers, etc.).

The breathing techniques of qigong are being studied intensively by Western physicians as of 2003 as a form of therapy for anxiety-related problems and for disorders involving the vocal cords. Qigong is also being used in the rehabilitation of patients with severe asthma or chronic obstructive pulmonary disease (COPD).

Training and certification

In China, qigong has been subject to much government regulation, from banning to increased requirements for teachers. In the United States at this time, qigong has not been regulated. Different schools may provide teacher training, but there are no generally accepted training standards. Qigong teachings may vary, depending on the founder of the school, who is often an acknowledged Chinese master. The organizations listed below can provide further information to consumers.

Quan yin

Definition

Quan yin is the English transliteration of the Chinese name for a Buddhist divine figure whose Sanskrit name is Avalokitesvara. The meaning of this name is usually given as "the lord who hears and sees all," or "the lord who is seen within [the believer's soul]." The Chinese name Quan yin is sometimes translated as "the one who hears prayers." Quan yin is also known in China as Guanshiyin; in Japan as Kannon, Kanzeon, or Kwannon; in southeastern Asia as Quon Am; in Bali as Kanin; and in Tibet as Chen-resigs or Spyan-ras-gzigs. Although some English-language sources refer to Quan yin as a "goddess" or "saint," these terms are somewhat misleading because of their association with Western religions. Peter Matthiessen's phrase, "mythical embodiment of Buddhahood," or bodhisattva, is a more accurate description. A bodhisattva is a spirit or person who has earned the right, through renunciation of passions and cravings, to escape from the cycle of reincarnation and enter nirvana, but chooses to postpone their own bliss until they have helped others to achieve enlightenment.

Devotion to Quan yin as the bodhisattva of infinite mercy and compassion is widespread in the Buddhist world, and can be dated as far back as the first centuries of the Christian era. *(Beaconstox / Alamy)*

Origins

Devotion to Quan yin as the bodhisattva of infinite mercy and compassion is widespread in the Buddhist world, and can be dated as far back as the first centuries of the Christian era. It is important to note, however, that the notion of deity in Buddhism is quite different from Jewish and Christian concepts of God as creator and ruler of the universe. In classical Buddhist teachings, there are three forms or bodies of Buddhahood: the body of essence (Buddha as disembodied and impersonal absolute truth or reality; nirvana); the body of bliss (Buddha as a formless spirit with the power to save humans); and the body of emanation or transformation (Buddha assuming a human form to guide people to enlightenment). Avalokitesvara (Quan yin) is regarded as the embodiment of Buddha who guards the world between the appearance of Sakyamuni, the historical Siddhartha Gautama (born in India about 500 B.C.), and Maitreya, the Buddha of the future.

Avalokitesvara was originally portrayed as a male among Indian Buddhists, because a female bodhisattva is impossible according to the oldest Buddhist texts. Devotion to Avalokitesvara in the form of Quan yin was introduced into China as early as the first century A.D., and into Japan in the sixth or seventh century. Prior to the twelfth century A.D., Quan yin was always portrayed as a male in Chinese and Japanese art. The reason for later artistic representations of her as a female is not completely understood. Some scholars attribute the change to the popularity of a passage in the Lotus Sutra that speaks of Avalokitesvara as having the power to grant children to childless women, and to assume a human body of either sex in order to guide others to nirvana. By the eighth century, the Lotus Sutra was honored in China and Japan above all other Buddhist sacred texts because it was understood to mean that women could also attain enlightenment.

Other scholars think that a Chinese legend about Quan yin may have also played a part in popular devotion to this bodhisattva as a woman. According to the legend, Quan yin was born into this world as the daughter of a king of the Chou Dynasty (1050–256 B.C.), who was sentenced to death by her father for refusing to marry. When the executioner tried to behead her, his sword shattered before he could touch her. The legend helps to explain why Quan yin has been regarded in some parts of Asia as a protector of women who offers life as a Buddhist nun as an alternative to marriage. In Japan, the princess Chujo-Hime (753–781 A.D.), who was persecuted by her stepmother and became a Buddhist nun at the age of seventeen, was thought to be a living incarnation of Kannon. A memorial service is held each year in Japan on May 14 for Chujo-Hime at the Tokushoji Temple.

In Japan, the Pure Land sect of Buddhism honored Kannon or Kanzeon as one of the principal attendants of Amida, the Buddha of the Western Paradise. Japanese religious art often portrays the so-called Amida Raigo triad, which depicts Amida himself; Kannon, who represents the Buddha's mercy; and the Seishi Bosatsu, a bodhisattva who represents the Buddha's strength and power. The three are often shown as descending on a cloud at the moment of a Buddhist's death to lead him or her to the Western Paradise.

Popular modern Buddhist art portrays Quan yin as a barefoot woman dressed in a long flowing white

KEY TERMS

Avalokitesvara—The Sanskrit name of Quan yin.

Bodhisattva—A Buddhist holy person who has attained enlightenment, but postpones nirvana in order to help others become enlightened.

Lotus sutra—One of the most sacred texts of Buddhism, regarded as a summary of the supreme Buddhist teaching that leads one directly to enlightenment.

Nirvana—In Buddhism, release from the cycle of reincarnation through conquering one's hatreds, passions, and delusions.

robe, often pouring a stream of water from a small vase. The water represents peace and healing. She may also be shown holding a lotus, which represents purity; pearls, which symbolize illumination; or a bowl of rice seed, which represents fertility. Some statues also show her with several pairs of arms, each holding a different cosmic symbol, which symbolize the universal embrace of Buddha's compassion. She is also depicted standing on a fish, which represents her role as the special protector of fishermen and travelers.

Benefits

The benefits of devotion to Quan yin, like those of Western religious practice, include inner peace, a feeling of love leading to acts of compassion for others, and a stronger sense that one's existence has meaning. According to the National Center for Complementary and Alternative Medicine (NCCAM), religious and spiritual practices that emphasize positive beliefs and attitudes help the human immune system, lower the impact of emotional **stress** on the body, and lower the risk of developing **anxiety** disorders and **depression**.

According to a Buddhist nun who claims to have been taught the Quan Yin Method for attaining enlightenment by a Himalayan master, those who practice this method will "gain a happy and more relaxed life, liberate [themselves from the cycle of reincarnation], and save five generations of [their] family."

Description

Devotion to Quan yin or Kannon is fairly informal in most parts of eastern Asia. Devotees may meditate on the bodhisattva's qualities of mercy and compassion, and strive to put these qualities into action through service or acts of kindness toward others. In China, women sometimes offer small pieces of jade carved with images on Quan yin in her temples, or place them in domestic shrines. Other Buddhists may wear amulets with images of Quan yin or prayers of devotion. Peter Matthiessen tells of wearing an amulet made from a plum pit that was given to him by his Japanese spiritual teacher. The plum pit was inscribed with a ten-phrase **prayer** to Kanzeon in tiny Japanese characters. Some phrases from the prayer include: "Kanzeon! Devotion to Buddha! We are one with Buddha .... Our true Bodhisattva nature is eternal, joyful, selfless, pure. So let us chant each morning Kanzeon, with mindfulness! Every evening Kanzeon, with mindfulness!"

Some devotees go on pilgrimages to holy places associated with Quan yin. These include the mountainous island of Pu Tuo Shan off the coast of Shanghai, China, where Quan yin is said to have lived for nine years. At one time there were over a hundred shrines to Quan yin on the island, as well as a community of a thousand Buddhist monks. Japanese Buddhists may make the Bando Pilgrimage, which makes a circuit of 33 sites in eastern Japan sacred to Kannon. Visiting the shrines in the proper order is said to preserve the believer from hell and open the gate to the Western Paradise.

The Quan Yin Method for attaining nirvana requires 2-1/2 hours of **meditation** per day in addition to the following five precepts:

- Refraining from taking the life of any sentient beings. This precept requires strict adherence to a vegan or lactovegetarian diet.
- Refraining from speaking what is not true.
- Refraining from taking what is not offered.
- Refraining from sexual misconduct.
- Refraining from the use of intoxicants, which include gambling, pornography, and violent films or literature as well as alcohol, tobacco, and recreational drugs.

Preparations and precautions

There are no specific preparations necessary for devotion to Quan yin. Western readers, however, should obtain information about this bodhisattva from reliable histories of Buddhism or Asian religion rather than from popular New Age sources.

Research and general acceptance

No studies have been done as of 2004 comparing devotion to Quan yin to other forms of religious or spiritual practice. In the West, devotion to Quan yin is

more common among women who have left mainstream Jewish or Christian groups than it is among men. Some of these women identify Quan yin with such mother goddesses as Isis or with such Christian saints as the Virgin Mary. Scholars of religion, however, regard these comparisons as misleading and historically inaccurate.

Training and certification

Although there are Buddhist monasteries and study centers in the United States, they do not offer certification for teachers comparable to ordination for Christian or Jewish clergy. Readers who are interested in learning more about Quan yin or Buddhism in general may contact the monastery listed under Resources below.

Quercetin

Description

Quercetin is a widespread plant chemical, or phytochemical. Many food items contain quercetin. These include **garlic** and onions; broccoli, cauliflower, brussels sprouts, cabbage, and other brassica vegetables; leafy, green vegetables; apples, berries, and many other fruits; green and black tea; and red wine. This plant chemical is also found in commonly used medicinal herbal supplements such as St. John's wort (*Hypericum perforatum*) and *Ginkgo biloba*.

Quercetin is a particular type of phytochemical known as a flavonoid or bioflavonoid; more specifically, it is a member of a certain class of flavonoids called flavonols. Quercetin appears to have significant anti-inflammatory and antioxidant properties. **Antioxidants** act on free radicals, which are highly reactive molecules that initiate damaging chain reactions in the body. The body produces its own antioxidants that counter free radicals, but free radicals can still build up as a result of **stress**, age, pollution, cigarette smoke, or other causes. It is believed that the antioxidants found in fresh fruits and vegetables, sometimes by way of quercetin, may provide a protective effect. Practitioners of traditional medicine have long espoused the use of quercetin-containing plants to treat numerous medical conditions, including arthritis, **allergies**, **heart disease**, **cataracts**, cold sores, and **gout**, among others. Some practitioners also recommend quercetin supplements to treat **cancer**.

General use

For centuries, practitioners of traditional medicine in many different cultures have prescribed the intake of quercetin-containing plants to treat various illnesses. It was not until the 1930s, however, that Hungarian physiologist Albert Szent-Györgyi (1893–1986) first isolated flavonoids. His work introduced the scientific community to these phytochemicals.

At one point, scientists were concerned about quercetin because research had shown that it caused mutations in the DNA within bacteria and suggested that it might have a role in causing cancer in humans. Those concerns were allayed by subsequent studies in humans, as well as some in animals, that indicated quercetin instead may actually have a protective effect against cancer.

Cell-culture studies have indicated that quercetin both slows the growth of and encourages the programmed cell death (called apoptosis) of cancer cells.

The latter is especially important because cancer cells often do not undergo the programmed cell death that occurs in normal cells. In the late 2000s, the American Cancer Society, however, remained cautious with regard to quercetin because many of the studies of it had been performed on cell cultures or animals.

In addition to the cell-culture research, animal studies have also shown that quercetin may be effective in protecting against various cancers. In 2007, for instance, a research team published results from a small clinical trial that looked at quercetin's effects against colon cancer. Their results indicated that a combined treatment of quercetin and **curcumin**, a compound in curry, also worked against colon cancer in humans. In the study, published in *Clinical Gastroenterology & Hepatology*, the researchers provided the quercetin-containing supplement to five individuals who had a rare genetic condition, called familial adenomatous polyposis, which causes precancerous polyps to grow in their intestines and eventually leads to colon cancer. Over the course of the experiment, the researchers measured a 60% reduction in the number of polyps and a 50% decrease in the polyps' size. Another much larger study published in a 2006 issue of the *American Journal of Epidemiology*, however, showed no correlation between higher intakes of quercetin and other flavonols and a lower risk for colon cancer. This study reviewed self-reported dietary information as well as cancer incidence among 107,401 individuals. The researchers concluded that their results provided "little support for the hypothesis of an association between flavonoid intake and **colorectal cancer** risk, at least within the ranges of intakes consumed in the populations studied."

Another large cancer-related study published in a 2007 issue of the *American Journal of Epidemiology* indicated that quercetin seemed to have a preventive effect on pancreatic cancer, especially among smokers. This study's researchers estimated the intake of quercetin along with two other flavonols from self-reported dietary information collected from 183,518 individuals and then followed the participants for eight years to determine the incidence of pancreatic cancer. The researchers found that all three flavonols—the other two were kaempferol and myricetin—were associated with a significantly reduced risk of pancreatic cancer among current smokers, who have a comparatively high propensity for the disease.

Like the prostate-cancer study, many other studies have focused on fruit- and vegetable-rich **diets**, but not exclusively on quercetin. While such diets may be high in quercetin, the fact that they also contain many additional compounds makes it difficult for scientists to pinpoint the specific effects of quercetin.

The effects of quercetin on the cardiovascular system have also been studied. Animal studies have shown that quercetin prevents **hypertension** and cardiac hypertrophy (thickening of the heart muscle) in rats. In addition, numerous epidemiological studies point to a connection between quercetin and the prevention of **stroke** and cardiovascular disease, and a study in the November 2007 issue of the *Journal of Nutrition* reported that quercetin was able to reduce blood pressure in people who had hypertension.

Practitioners of traditional medicine may prescribe quercetin for various ailments, including **hay fever** and other allergies. It is thought that quercetin may reduce the amount of histamines that the body produces and releases in response to allergens, and this in turn may lessen the severity of allergy-related symptoms such as runny nose, watery eyes, and **hives**. This suspicion has also led to its use in treating insect **bites**. Quercetin is sometimes prescribed to treat arthritis, which is an inflammation of the joints, and to prevent **atherosclerosis** (sometimes called hardening of the arteries). It is also used treat or prevent cataracts and **macular degeneration**, which are thought to perhaps be related to the action of free radicals. Quercetin is also believed to lessen the burning **pain** associated with chronic prostatitis, which is an inflammation of the prostate, and to treat ulcers. Some users of quercetin assert that it helps **wounds** heal more quickly. In addition, practitioners may prescribe quercetin to help lower **cholesterol** levels, although research supporting this effect was lacking as of 2008.

Quercetin has potential implications in treatments for pain. According to a study in a 2003 issue of *Drug Development Research*, quercetin may alleviate some of the adverse effects that often occur with the use of morphine and other opioid drugs to treat moderate to severe pain. These adverse effects include drug tolerance, in which the effectiveness of the dose lessens over time, and drug dependence. The study, done on mice, showed that quercetin reversed the development of both morphine tolerance and dependence.

Various studies have shown that quercetin has antiviral properties. A study in a 2003 issue of the *Journal of Antimicrobial Chemotherapy*, for instance, reported that quercetin is a potential treatment for infection with the herpesvirus known as HSV-1. Indeed, some people use quercetin to treat cold sores, which are caused by HSV-1. The study also showed that quercetin counteracted a type of adenovirus. Adenoviruses infect numerous membranes in the body and are common causes of respiratory **infections**.

KEY TERMS

Bromelain—One or more enzymes found in pineapples and sometimes added to supplements to boost their effectiveness.

Flavonoids—Naturally occurring chemicals found in many fruits and vegetables that have potential beneficial effects on human health.

Phytochemicals—Plant chemicals.

Preparations

To help prevent cancer, the American Cancer Society recommends a daily diet that contains five or more servings of fruits and vegetables, but it does not have specific recommendations for any specific compound, including quercetin, that is contained within those fruits and vegetables.

Besides ingesting quercetin in foods, quercetin supplements are available in many health food stores as a powder and in capsule form. Quercetin supplements are sometimes combined with **bromelain**, which is an enzyme found in pineapple. This enzyme is thought to have anti-inflammatory properties, to fight allergies, and to heighten the activity of quercetin. Recommended dosages of quercetin can vary from 200–750 mg per day, often taken in several doses. Practitioners may also recommend that an individual increase his or her intake of the compound by taking various quercetin-containing extracts, such as *Ginkgo biloba*, or by consuming **green tea**, which is also high in quercetin.

Precautions

Major problems were unknown as of 2008, although some individuals may experience **nausea** from high doses of quercetin supplements.

Interactions

Persons taking quercetin supplements, particularly those containing bromelain, should consult their physician if they are taking other medications because possible drug interactions can occur. In addition, individuals who are undergoing chemotherapy should discuss this supplement with their doctors before taking it.

Rabies

Definition

Rabies is a viral illness that can affect any mammal but is most common in carnivores (flesh-eaters). It is sometimes referred to as a zoonosis, or disease of animals that can be communicated to humans. Rabies is usually transmitted in the saliva through a bite wound. The virus attacks the central nervous system, and is fatal once symptoms begin, with very rare exceptions.

Description

Rabies, also known as hydrophobia, belongs to the rhabdovirus family. Fewer than 10% of animal cases reported in the United States in 1998 were in domestic animals. Raccoons accounted for the largest number of cases in wild animals. Cases of rabies in humans are very infrequent in the United States, averaging one or two a year (down from over 100 cases annually in 1900), but the worldwide incidence is estimated to be between 30,000 and 50,000 cases each year. These figures are based on data collected by the World Health Organization (WHO) in 1997 and updated in 2002. Rabies is most common in developing countries in Africa, Latin America, and Asia, particularly India. Dog **bites** are the major origin of infection for humans in developing countries, but other important host animals may include the wolf, mongoose, and bat. Most deaths from rabies in the United States result from bat bites; the most recent victim was a man in Iowa who died in September 2002.

People whose work frequently brings them in contact with animals are considered to be at higher risk than the general population. This would include those in the fields of veterinary medicine, animal control, wildlife work, and laboratory work involving live rabies virus. People in these occupations and residents of or travelers to areas where rabies is a widespread problem should consider being immunized.

In late 2002, rabies re-emerged as an important public health issue. Dr. Charles E. Rupprecht, director of the World Health Organization (WHO) Collaborating Center for Rabies Reference and Research, has listed several factors responsible for the increase in the number of rabies cases worldwide:

- Rapid evolution of the rabies virus. Bats in the United States have developed a particularly infectious form of the virus.
- Increased diversity of animal hosts for the disease.
- Changes in the environment that are bringing people and domestic pets into closer contact with infected wildlife.
- Increased movement of people and animals across international borders. In one recent case, a man who had contracted rabies in the Philippines was not diagnosed until he began to feel ill in the United Kingdom.
- Lack of advocacy about rabies.

Causes and symptoms

The most common way to contract rabies is from the bite of an infected animal. Although bats are the most frequent source of human infection in the United States, dogs are the primary vector of rabies in most parts of the world. The disease may also be transmitted by tissues and body fluids other than saliva. Rare cases have occurred as a result of infection through corneal transplantation.

Rabies travels from the site of the bite along the peripheral nerves to the brain. The average incubation period in humans is 30–50 days, although it varies from 10 days to over a year. The initial symptoms are flu-like and nonspecific. They may include **fever**, **headache**, muscle **pain**, **sore throat**, **fatigue**, **nausea**, and **vomiting**. Altered sensation and muscle twitching in the area of the bite are signs that are more suspicious of rabies. When the virus reaches the brain, signs related to encephalitis (local or general inflammation of brain tissue)

KEY TERMS

Biopsy—The removal of a small sample of tissue for diagnostic purposes.

Direct fluorescent antibody test (dFA test)—A test in which a fluorescent dye is linked to an antibody for diagnostic purposes.

Encephalitis—Inflammation of the brain.

Rhabdovirus—A type of virus named for its rod- or bullet-like shape.

Vector—An animal or insect that carries a disease-producing organism.

Zoonosis (plural, zoonoses)—Any disease of animals that can be transmitted to humans. Rabies is an example of a zoonosis.

appear. This typically involves agitation, progressing to confusion, combativeness, seizures, and localized areas of paralysis. There may also be hypersensitivity to light, sound, and touch. The patient may be coherent at times, but less so as the disease progresses. Many viruses causing encephalitis may produce similar signs. The next stage is dysfunction of the brainstem. The well-known phenomenon of foaming at the mouth is caused by excessive saliva production combined with difficulty swallowing. Many patients will refuse liquids at this point due to the painful muscle contractions caused by swallowing. This is how rabies came to be known as hydrophobia, which means "fear of water." Coma ensues soon after brainstem involvement, and death occurs when the respiratory center is affected. The course of the disease is four to 20 days after symptoms appear, unless life support is used.

Diagnosis

Early in its course, and without a known history of an animal bite, rabies can be difficult to diagnose. Symptoms of the early encephalitic (brain tissue inflammation) phase are similar to those of most viral types of encephalitis. When signs of brainstem dysfunction appear shortly after this time, rabies becomes a more likely possibility. Several tests are available for rabies diagnosis, but none are extremely reliable in the living patient. Part of the challenge is that rabies is so limited to nerve tissue until the late phases of the disease. The examination of brain tissue reveals a characteristic known as a Negri body, which is diagnostic. Direct fluorescent antibody (dFA) staining of saliva, skin biopsy, and corneal impressions may also yield a diagnosis.

Treatment

Local wound cleansing is important. Anyone who has experienced an animal bite should wash it thoroughly with soap and water. Rabies is a fatal illness, so a bite that breaks the skin warrants a call to a health care provider for evaluation of whether post-exposure prophylaxis (PEP) is necessary. Alternative treatments are recommended as a complementary therapy to conventional treatment in the case of rabies. Observation of the animal for signs of rabies is recommended whenever possible.

Allopathic treatment

If a person is bitten by a domestic animal and the owner is known, vaccination status should be checked. People bitten by healthy, immunized animals are unlikely to need post-exposure prophylaxis (PEP). The animal can be confined for 10 days. If it is healthy at the end of that time, it is presumed not to have been capable of transmitting rabies at the time of the bite, so PEP for the person bitten is not necessary.

Wild animals that have bitten can be captured, destroyed, and tested for rabies. Postexposure vaccine and specific immune globulin can be given if deemed necessary. In the United States, if the person who was bitten has not had prophylactic immunization and has a high-risk bite, generally five rabies vaccinations and one injection of human rabies immune globulin are given. There have been no cases in this country of people contracting rabies after receiving correctly administered PEP.

Bites from mice, rats, or squirrels rarely require rabies prevention because these rodents are typically killed by any encounter with a larger, rabid animal, and would therefore be less likely to be carriers. Bites from raccoons, bats, or unvaccinated dogs or cats are more suspect. Anyone bitten by a bat in the United States should receive PEP unless the bat is captured and proven not to be rabid.

If a pet is bitten by an animal suspected to have rabies, its owner should contact a veterinarian immediately and notify the local animal control authorities. Domestic pets with current vaccinations should be revaccinated immediately; unvaccinated dogs, cats, or ferrets are usually euthanized (put to sleep). Further information about domestic pets and rabies is available on the American Veterinary Medical Association (AVMA) web site.

Expected results

Survival of rabies after the appearance of symptoms is exceedingly rare.

Prevention

The following precautions should be observed in environments where humans and animals may likely come into contact. Domesticated animals, including household pets, should be vaccinated against rabies. Booster shots, given according to the manufacturer's recommendations, are required to maintain immunity. Wild animals should not be touched or petted, no matter how friendly an animal may appear. It is also important not to touch an animal that appears ill or passive, or whose behavior seems odd, such as failing to show the normal fear of humans. These are all possible signs of rabies. Many animals, such as raccoons and skunks, are nocturnal and their activity during the day should be regarded as suspicious. People should not interfere with fights between animals. Because rabies is transmitted through saliva, a person should wear rubber gloves when handling a pet that has had an encounter with a wild animal. Windows and doors should be screened. Some victims of rabies have been attacked by infected animals, particularly bats, that entered through unprotected openings. Finally, garbage or pet food should not be left outside because it may attract wild or stray animals.

Members of the high-risk occupations mentioned above should consider prophylactic immunization. Those who receive this pre-exposure vaccine still require PEP in the event of a potentially infective episode, but they have several advantages. One is that they require fewer post-exposure vaccines. A second advantage is that the timing of the PEP may be less critical for people who are in remote areas, or don't have ready access to vaccine for other reasons. Last, some people may be exposed without being aware of it, and the prophylactic vaccine might protect them.

Radiation injuries

Definition

Radiation injuries are caused by ionizing radiation emitted by such sources as the sun, x-ray and other diagnostic machines, tanning beds, and radioactive elements released in nuclear power plant accidents and detonation of nuclear weapons during war and as terrorist acts.

Description

Ionizing radiation is made up of unstable atoms that contain an excess amount of energy. In an attempt to stabilize, the atoms emit the excess energy into the atmosphere, creating radiation. Radiation can either be electromagnetic or particulate.

Radiation sources

Natural sources	
Radon gas	55%
Inside the body	11%
Rocks, soil, and groundwater	8%
Cosmic rays	8%
Artificial sources	
Medical x-rays	11%
Nuclear medicine	4%
Consumer products (such as tobacco, televisions, and smoke detectors)	3%
Miscellaneous (including occupational exposure, nuclear fallout, and the production of nuclear materials for energy and weaponry)	<1%

(Illustration by Corey Light. Cengage Learning, Gale)

KEY TERMS

Bone marrow suppression—Decrease in production of blood components, including red blood cells, white blood cells, and platelets. This can result in anemia, increased susceptibility to infections, and excessive bleeding.

Cosmic radiation—Radiation of high penetrating power originating in outer space. It consists partly of high-energy atomic nuclei.

Dirty bomb—A bomb made with conventional explosives that also contains radioactive isotopes. When the bomb explodes, the radioactive material spreads contamination over a wide area.

DNA—Deoxyribonucleic acid. The chemical of chromosomes and hence the vehicle of heredity.

Esophagitis—Inflammation of the esophagus.

Isotope—An unstable form of an element that gives off radiation to become stable. Elements are characterized by the number of electrons around each atom. One electron's negative charge balances the positive charge of each proton in the nucleus. To keep all those positive charges in the nucleus from repelling each other (like the same poles of magnets), neutrons are added. Only certain numbers of neutrons work. Other numbers cannot hold the nucleus together, so it splits apart, giving off ionizing radiation. Sometimes one of the split products is not stable either, so another split takes place. The process is called radioactivity.

Melanoma—A highly malignant form of skin cancer associated with overexposure to ultraviolet radiation from sunlight.

Pneumonitis—Inflammation of the lungs.

The energy of electromagnetic radiation is a direct function of its frequency. The high energy, high frequency waves that can penetrate solids to various depths cause damage by separating molecules into electrically charged pieces, a process known as ionization. X rays are a type of electromagnetic radiation. Atomic particles come from radioactive isotopes as they decay to stable elements. Electrons are called beta particles when they radiate. Alpha particles are the nuclei of helium atoms—two protons and two neutrons—without the surrounding electrons. Alpha particles are too large to penetrate a piece of paper unless they are greatly accelerated in electric and magnetic fields. Both beta and alpha particles are types of particulate radiation. When over-exposure to ionizing radiation occurs, there is chromosomal damage in deoxyribonucleic acid (DNA). DNA is very good at repairing itself; both strands of the double helix must be broken to produce genetic damage.

Because radiation is energy, it can be measured. There are a number of units used to quantify radiation energy. Some refer to effects on air, others to effects on living tissue. The roentgen, named after Wilhelm Conrad Roentgen, who discovered x rays in 1895, measures ionizing energy in air. A rad expresses the energy transferred to tissue. The rem measures tissue response. A roentgen generates about a rad of effect and produces about a rem of response. The gray and the sievert are international units equivalent to 100 rads and rems, respectively. A curie, named after French physicists who experimented with radiation, is a measure of actual radioactivity given off by a radioactive element, not a measure of its effect. The average annual human exposure to natural background radiation is roughly 3 milliSieverts (mSv).

Any amount of ionizing radiation will produce some damage; however, there is radiation everywhere, from the sun (cosmic rays) and from traces of radioactive elements in the air (radon) and the ground (uranium, radium, carbon-14, potassium-40 and

many others). Earth's atmosphere protects us from most of the sun's radiation. Living at 5,000 feet altitude in Denver, Colorado, doubles exposure to radiation, and flight in a commercial airliner increases it 150-fold by lifting us above 80% of that atmosphere. Because no amount of radiation is perfectly safe and because radiation is ever present, arbitrary limits have been established to provide some measure of safety for those exposed to unusual amounts. Less than 1% of them reach the current annual permissible maximum of 20 mSv.

A 2001 ruling by the Federal Court of Australia indicated that two soldiers died from **cancer** caused by minimal exposure to radiation while occupying Hiroshima in 1945. The soldiers were exposed to less than 5 mSv of radiation. The international recommendation for workers is safety level of up to 20 mSv. The ruling and its support by many international agencies suggests that even extremely low doses of radiation can be potentially harmful.

Ultraviolet (UV) radiation exposure from the sun and tanning beds

UV radiation from the sun and tanning beds and lamps can cause skin damage, premature **aging**, and skin cancers. Malignant melanoma is the most dangerous of skin cancers and there is a definite link between type UVA exposure used in tanning beds and its occurrence. UVB type UV radiation is associated with **sunburn**, and while not as penetrating as UVA, it still damages the skin with over exposure. Skin damage accumulates over time, and effects do not often manifest until individuals reach middle age. Light-skinned people who most often burn rather than tan are at a greater risk of skin damage than darker-skinned individuals that almost never burn. The U.S. Food and Drug Administration (FDA) and the Centers for Disease Control (CDC) discourage the use of tanning beds and sun lamps and encourage the use of sunscreen with at least an SPF of 15 or greater. In addition, the rising incidence of melanoma in the United States has led the Environmental Protection Agency (EPA) to develop a sun safety education program for school-age children in order to begin changing public attitudes toward tanning.

Overexposure during medical procedures

Ionizing radiation has many uses in medicine, both in diagnosis and in treatment. X rays, CT scanners, and fluoroscopes use it to form images of the body's insides. Nuclear medicine uses radioactive isotopes to diagnose and to treat medical conditions. In the body, radioactive elements localize to specific tissues and give off tiny amounts of radiation. Detecting that radiation provides information on both anatomy and function. During the past 10 years, skin injuries caused by too much exposure during a medical procedure have been documented. In 1995, the FDA issued a recommendation to physicians and medical institutions to record and monitor the dosage of radiation used during medical procedures on patients in order to minimize the amount of skin injuries. The FDA suggested doses of radiation not exceed 1 Grey (Gy). (A Grey is roughly equivalent to a sievert.) As of 2001, the FDA was preparing further guidelines for fluoroscopy, the procedure most often associated with medical-related radiation skin injuries such as **rashes** and more serious **burns** and tissue death. Injuries occurred most often during angioplasty procedures using fluoroscopy.

CT scans of children have also been problematic. Oftentimes the dosage of radiation used for an adult isn't decreased for a child, leading to radiation overexposure. Children are more sensitive to radiation; a February 2001 study indicates 1,500 out of 1.6 million children under 15 years of age receiving CT scans annually will develop cancer. Studies show that decreasing the radiation by half for CT scans of children will effectively decrease the possibility of overexposure while still providing an effective diagnostic image. The benefits to receiving the medical treatment utilizing radiation is still greater than the risks involved; however, more stringent control over the amount of radiation used during the procedures will go far to minimize the risk of radiation injury to the patient.

Recent evidence suggests that some ethnic groups may be more vulnerable than others to radiation damage. A study done at New York University found that Jews are more likely to develop **ovarian cancer** as a delayed side effect of diagnostic x-rays of the abdomen than non-Jews. These findings require confirmation by further research, but they do indicate that ethnicity and other genetic factors are involved in susceptibility to radiation damage.

Side effects from radiation therapy to treat cancer

As many as half of all cancer patients receive some form of radiation therapy as a component of treatment. The therapy can be delivered from either an external or an internal source, although the former is more common. The machines used for external radiation have become more specialized to deliver the appropriate dose to either a superficial or a deep location on the body. Depending on the type and site of cancer being treated, internal sources of radiation can be injected, swallowed, or placed within the body in

sealed containers. These are implanted into or near the tumor, either temporarily or permanently.

Some types of tumors may be eliminated by radiation therapy, if the patient is able to withstand the necessary dose. In other cases, radiation is used in conjunction with other methods of treatment. It may be given before surgery, to shrink a tumor to an operable size, or after surgery, to try to destroy any cancerous cells that may remain. Radiation can be used to make patients with incurable disease more comfortable by decreasing the bulk of tumors to reduce **pain** or pressure. Treatment that is given as a comfort measure only is known as palliation, or palliative therapy.

Occupational radiation exposure

Specialists in industrial and occupational health are increasingly aware of the rising number of injuries related to on-the-job radiation exposure. One study of Swedish workers exposed to high levels of low-frequency magnetic fields found an increased incidence of kidney, liver, and pituitary gland tumors among the men, and a higher rate of **leukemia** and brain tumors among the women.

Sadly, the delayed effects of occupational radiation exposure have also delayed the adoption of necessary protection for workers at risk. A study of the high rate of **lung cancer** among Navajo Indians who worked in uranium mines during World War II did not bring about even partial protection for the miners until 1962. It was not until 1990 that Congress passed the Radiation Exposure Compensation Act to provide care for the injured miners.

The effects of cosmic radiation on human beings are also being investigated because of concern for the safety of air crew. Although findings are still inconclusive as of 2002, recent reports of an increased incidence of cancer among airline pilots and cabin crew members have led epidemiologists to study the long-term effects of cosmic radiation at the altitudes of modern aircraft flight.

Radiation exposure from nuclear accidents, weaponry, and terrorist acts

Between 1945 and 1987, there were 285 nuclear reactor accidents, injuring over 1,550 people and killing 64. The most striking example was the meltdown of the graphite core nuclear reactor at Chernobyl in 1986, which spread a cloud of radioactive particles across the entire continent of Europe. Information about radiation effects is still being gathered from that disaster, however 31 people were killed in the immediate accident and 1,800 children have thus far been diagnosed with thyroid cancer. In a study published in May 2001 by the British Royal Society, children born to individuals involved in the cleanup of Chernobyl and born after the accident are 600% more likely to have genetic mutations than children born before the accident. These findings indicate that exposure to low doses of radiation can cause inheritable effects.

Since the terrorist attack on the World Trade Center and the Pentagon on September 11, 2001, the possibility of terrorist-caused nuclear accidents has been a growing concern. All 103 active nuclear power plants in the United States are on full alert, but they are still vulnerable to sabotage such as bombing or attack from the air. A no-fly zone of 12 miles below 18,000 feet has been established around nuclear power plants by the Federal Aviation Administration (FAA). There is also growing concern over the security of spent nuclear fuel—more than 40,000 tons of spent fuel is housed in buildings at closed plants around the country. Unlike the active nuclear reactors that are enclosed in concrete-reinforced buildings, the spent fuel is stored in non-reinforced buildings. Housed in cooling pools, the spent fuel could emit dangerous levels of radioactive material if exploded or used in makeshift weaponry. Radioactive medical and industrial waste could also be used to make "dirty bombs." Since 1993, the Nuclear Regulatory Commission (NRC) has reported 376 cases of stolen radioactive materials.

One response on the part of health care workers has been stepped-up training in radiation disaster management. Emergency department personnel are being trained as of 2002 to use radiologic monitoring and other specialized equipment for treating victims of a terrorist attack involving radiation.

Causes and symptoms

Radiation can damage every tissue in the body. The particular manifestation will depend upon the amount of radiation, the time over which it is absorbed, and the susceptibility of the tissue. The fastest growing tissues are the most vulnerable, because radiation as much as triples its effects during the growth phase. Bone marrow cells that make blood are the fastest growing cells in the body. A fetus in the womb is equally sensitive. The germinal cells in the testes and ovaries are only slightly less sensitive. Both can be rendered useless with very small doses of radiation. More resistant are the lining cells of the body—skin and intestines. Most resistant are the brain cells, because they grow the slowest.

The length of exposure makes a big difference in what happens. Over time the accumulating damage, if

not enough to kill cells outright, distorts their growth and causes scarring and/or cancers. In addition to leukemias, cancers of the thyroid, brain, bone, breast, skin, stomach, and lung all arise after radiation. Damage depends, too, on the ability of the tissue to repair itself. Some tissues and some types of damage produce much greater consequences than others.

There are three types of radiation injuries.

- External irradiation: as with x-ray exposure, all or part of the body is exposed to radiation that either is absorbed or passes through the body.
- Contamination: as with a nuclear accident, the environment and its inhabitants are exposed to radiation. People are affected internally, externally, or with both internal and external exposure.
- Incorporation: dependent on contamination, the bodies of individuals affected incorporate the radiation chemicals within cells, organs, and tissues and the radiation is dispersed throughout the body.

Immediately after sudden irradiation, the fate of those affected depends mostly on the total dose absorbed. This information comes mostly from survivors of the atomic bomb blasts over Japan in 1945.

- Massive doses incinerate immediately and are not distinguishable from the heat of the source.
- A sudden whole-body dose over 50 Sv produces such profound neurological, heart, and circulatory damage that patients die within the first two days.
- Doses in the 10–20 Sv range affect the intestines, stripping their lining and leading to death within three months from vomiting, diarrhea, starvation, and infection.
- Victims receiving 6–10 Sv all at once usually escape an intestinal death, facing instead bone marrow failure and death within two months from loss of blood coagulation factors and the protection against infection provided by white blood cells.
- Between 2–6 Sv gives the person a fighting chance for survival if he or she is supported with blood transfusions and antibiotics.
- One or two Sv produces a brief nonlethal sickness with vomiting, loss of appetite, and generalized discomfort.

Side effects of radiation therapy

Damage caused to normal cells can show up either in the time frame shortly following radiation treatment, or as long as years after radiation has been completed. Symptoms that frequently occur soon after treatment include loss of appetite, **fatigue**, and skin changes. Less commonly, patients have **headache**, **nausea**, **vomiting**, **hair loss**, and weakness. In more severe cases, dehydration, seizures, and shock-type reactions can occur. The severity and type of effects will depend on the region of the body receiving treatment, the type of radiation used during the course of treatment, and the dose. There is also individual variation in the response. Skin rashes are common. They may take the form of redness, burn, dryness, **itching**, or soreness. Organs that were in the path of the beam may show changes, including scarring, functional changes (such as decrease in elasticity), and loss of cells. Tissues that have a rapid turnover of cells may be most severely affected, including the skin and lining of the gastrointestinal tract. More severe injuries may include long-term bone marrow suppression, and occasionally even other cancers, particularly sarcomas.

People who receive radiation in the region of the head and neck are likely to experience a dry and sore mouth to some degree. The skin may become dry, and the area under the chin may droop. Sense of taste can be altered or lost. Some may experience hair loss, earaches, or difficulty swallowing due to inflammation of the esophagus.

Radiation treatments given for or around the breast, chest, or lung can also cause esophagitis and accompanying trouble swallowing. Changes in the lung tissue may lead to pneumonitis or pulmonary fibrosis. The patient may develop a **cough**. Breast treatments may cause pain and swelling. Blood counts can decrease.

Side effects from treatment of the stomach and abdominal area can induce nausea and **diarrhea**. In the pelvic region, radiation may result in difficulties with urination, and **infertility** in both males and females. Women may also have symptoms of dryness, itching, or burning of the vagina.

Diagnosis

The various effects of radiation on the body are well recognized. Patients who are scheduled to undergo radioactive treatments should be informed of the potential side effects they will encounter based on the area being treated and the dose of radiation being used. Advice for coping with minor injuries should be given, as well as descriptions of what symptoms should prompt a call or a visit to the treating physician.

Treatment

It is clearly important to have some idea of the dose received as early as possible, so that attention can be directed to those victims in the 2-10 Sv range that

might survive with treatment. Blood transfusions, protection from infection in damaged organs, and possibly the use of newer stimulants to blood formation can save many victims in this category.

Local radiation exposures usually damage the skin and require careful wound care, removal of dead tissue, and skin grafting if the area is large. Again infection control is imperative.

One of the best known, and perhaps even mainstream, treatments of radiation injury is the use of *Aloe vera* preparations on damaged areas of skin. It has demonstrated remarkable healing properties even for chronic ulcerations resulting from radiation treatment. Another topical herb that may be effective against skin inflammation following radiation therapy is **chamomile** cream. Studies support the benefits of chamomile for skin inflammation and wound healing. Additional topical herbs that may be helpful are **calendula** and **St. John's wort**. These therapies can prove very helpful since skin reaction is one of the most common side effects of radiation therapy.

Guided imagery is a method that may be used following radiation treatment, especially to help ease pain. Several nutritional supplements help with healing **wounds**. These include **essential fatty acids** (Omega 3 and 6), **vitamin A**, vitamin B, and magnesium/zinc.

If the tumor being treated is determined to be sensitive to radiation, there are a few herbs that are said to reduce the adverse effects of radiation exposure. Ginseng is one that research suggests may have this benefit. Other nutrients thought to have some protective effects are coenzyme Q10, **kelp**, **pantothenic acid**, and **glutathione** with L-cysteine and L-methionine. **Garlic** and **vitamin C** support immune function. **Grape seed extract** is a powerful antioxidant that protects against cell damage by free radicals. Any nutritional measures to support optimum health before treatment are beneficial.

Allopathic treatment

The type of treatment used depends on the area and severity of the injury. Something as serious as bone marrow suppression would require more intensive therapy, whereas more minor conditions are treated symptomatically. Radiation-induced esophagitis may necessitate intravenous or gastrostomy feeding for a time until the injury is healed. If a perforation or a stricture develops, surgery may be necessary. Products are available to keep the eyes (drops with vitamin A) and oral mucosa moist, as the cells producing mucus and tears are often damaged.

Expected results

Tissue damage resulting from radiation exposure tends to be chronic in nature, and may even be progressive. For the lesser and more common types of problems, long-term treatment of symptoms should be anticipated.

Prevention

Part of preventing radiation injury involves doing research on the condition being treated. It is a good idea to be certain that radiation is the best available treatment for a particular cancer type before embarking on a course of therapy.

Information on preventing or minimizing damage from radiation produced by terrorist devices or other nuclear emergencies is available in a series of fact sheets that can be downloaded from the Centers for Disease Control (CDC) web site. The fact sheets cover such topics as basic radiation facts, acute radiation sickness (ARS), dirty bombs, effects of radiation on health, possible effects of radiation on unborn children, and protective measures in the case of a nuclear event.

Radiesthesia

Definition

Radiesthesia is also commonly known as dowsing. It is regarded principally as a mystic art that has many facets and applications. Basically, it is the process of locating the presence of an object, or assessing the energy given off by a subject, with an implement known as a dowsing rod, which is a Y-shaped hazel, beech, or alder branch or a **copper** rod. Dowsers may also use a pendulum, which is often weighted with a crystal or some other heavy weight. It is said that the important factor is the length of the line to which the weight is attached.

Origins

The concept of radiesthesia was known to the ancient Egyptians and Chinese; their artwork bears witness to this fact. Some estimate that dowsing may date as far back as 7,000 years.

The British Society of Dowsers was formed in the 1930s. The art was given the name radiesthesia by French priest Alex Bouly, derived from the Latin words radiation and perception. However, to many people it is still called dowsing. Modern practitioners of radiesthesia claim that their art uses a "sense" that was once commonly acknowledged, but that has been lost with time. **Radionics** is the process of dowsing using specially designed electrical equipment.

Benefits

While some may call its usefulness to question, the least that can be said is that radiesthesia does no harm.

KEY TERMS

Divining—The act of locating an object using a special sense or instinct.

Geopathic stress—Any variation in normal energy patterns which some believe can cause illness.

Rates—The subtle emanations of energy which may be detected with radionic equipment.

It does not employ radiation, it does not involve the administration of chemicals, and it is noninvasive. Some radiesthesia practitioners claim that they can not only diagnose illness and potential illness, but that they can also cure the patient by altering their energy patterns.

Description

Many different types of objects have traditionally been found with the aid of radiesthesia. Perhaps water wells most readily spring to mind. However, the list is long and includes minerals, lost objects, and people, including bodies, animals, and plants.

Practitioners specializing in this field list several uses of radiesthesia for health purposes. They claim that, in addition to locating areas and causes of disease, dowsing can indicate energy levels before and after healing sessions.

Radiesthesia is used by some who follow a holistic way of life to detect how fresh fruit and vegetables are before they buy them, claiming that the freshest produce gives off more energy than that which is not so fresh. It can also be used to assess the quality of soil and indicate steps to improve soil quality, they say.

The basic concept of radiesthesia is that there is some kind of interaction between the mind of the dowser and the object or information being sought. Practitioners refer to this interaction as the use of a kind of sixth sense, or extra sensory perception. It has also been described as a particular kind of instinct. Some who practice radiesthesia say that as many as 80% of people have the ability to dowse but many are unaware of it.

Some practice radiesthesia without even a prosthesis (a divining rod or pendulum), they just instinctively sense things. When used, a diving rod or pendulum is described as an implement that will help the dowser to focus on the object at hand.

To measure a human energy field, it should first be ascertained that the subject is not wearing any jewelry

or crystals. Then the therapist should stand three paces away, facing the patient. L-rods (divining rods) should be held parallel to the ground and pointing towards the patient. The dowser's mind should be focused and a conscious decision must be taken to measure the energy field of the patient's body.

Radiesthesia is also used to pick a location to build a house for example, so as to avoid certain situations such as groundwater, geopathic **stress**, or any other factor that is believed to be detrimental to health. In times gone by, important buildings such as churches, hospitals, palaces, castles and homes, were commonly built after consultation with a dowser regarding the best location.

Usually, when consulting with a radiesthesia practitioner, the patient will first be asked to provide a full case history prior to radiesthesia analysis. If radionic equipment is used, a detector pad will measure energy emanations, which are known as rates, and will be used in the analysis. These rates are said to correspond to organs, diseases, psychological condition, the elements, and even to indicate which alternative therapy would be best to treat the patient.

Preparations

The special equipment necessary for radiesthesia is the dowser's chosen divining implement, which may include specially designed electronic equipment. However, patients will be advised to remove jewelry and any crystals, and possibly anything metal attached to their clothes.

Precautions

Those who are seeking treatment for serious disease are advised to consult an alternative practitioner with regard to a radiesthesia consultation and to mention this to their allopathic physician.

Side effects

There are no known side effects associated with radiesthesia.

Research and general acceptance

Although there are many unexplained accounts of the successful use of radiesthesia, or dowsing, the practice is still the target of much ridicule and even contempt from some areas of the allopathic medical profession.

Training and certification

Since radiesthesia is considered an art, it is an acquired art more than a discipline that can be learned. However, the Radionics Institute, which was founded in 1988, offers various courses in addition to their world-wide training forum.

Radionics

Definition

Radionics is a highly controversial field that claims to detect and modulate life force using electronic devices. Patients can be diagnosed and treated without even meeting the practitioner, who uses a radionic "black box" to tune into "vibrational frequencies" from a sample of hair or blood. The device is then used to "broadcast" healing frequencies back to the patient, who may be hundreds of miles away.

Origins

The seeds of radionics can be found in **radiesthesia**, a diagnostic technique employing pendulums or dowsing rods developed by three French priests during the early 1900s. The founding father of radionics was Albert Abrams, an American neurologist (1864–1924) who believed that his machines could, from a sample of blood, hair, or even handwriting, determine a patient's sex, race, financial status, religion, and underlying causes of illness. His therapeutic machines were hermetically sealed and were not sold, only leased on the condition that they never be opened. Investigators who examined the devices around the time of Abrams' death found nothing inside to which they could attribute potential medical benefit. The principles of distance healing were

developed by a U.S. chiropractor, Ruth Drown, during the 1930s. Drown also maintained that her devices could produce x-ray-like images of a patient's condition, based solely on a blood sample. A scientific committee that examined these images in 1950 detected no recognizable anatomic structures in them, and concluded they were simply "fog patterns."

Benefits

For legal reasons, most radionics practitioners and manufacturers of radionics equipment are cautious of making public pronouncements about specific health benefits. However, a journal published by radionics founder Albert Abrams claimed the technology was effective against diseases as serious as **cancer**, **tuberculosis**, and **syphilis**. Court testimony has indicated that similar claims are made by present-day practitioners.

Description

Radionics advocates believe that underlying causes of diseases emit radio-like frequencies that can be detected by their equipment. A bundle of hair or a card containing a few dried drops of blood is placed into a receptacle in the machine. This "witness" is then analyzed using either a moving pendulum or a detector pad on which changes in surface tension are noted. In this way, areas of "resonance" are detected. Treatment may employ both appropriate frequencies generated by the machine, as well as the extra-sensory abilities of the healer. During the 1990s, computerized "adaptive biofeedback-type" devices were developed, allegedly capable of monitoring and responding "every 200 millionths of a second" to changes in the patient's body. Radionic treatment may be supplemented by homeopathic remedies, **color therapy**, and herbal extracts.

Precautions

Patients need to understand that the claims of radionics are highly controversial and, in some cases, grandiose. One radionics organization based in Canada not only offers certification in 18 healing-related fields, but also advertises its willingness to advise on such diverse subjects as gambling, animal breeding, management consulting, gardening, financial investments, engineering, prospecting, and archeology. This institute claims that radionics has been proven "in hundreds of controlled studies over the past 80 years," but refuses to divulge the names of its graduates "given the controversial nature of radionics." Furthermore, this group will not correspond with any potential client until an initial fee of at least $300 has been paid in U.S. currency. Another manufacturer of radionics-type equipment claims the ability "to enter the mind of any person on this planet" and to "compel them to do your will." It is particularly important to carefully read the literature offered by radionics practitioners, which often contains revealing disclaimers. A medical opinion should be sought in all cases of serious illness.

KEY TERMS

Placebo effect—The ability of substances possessing no medicinal value to nonetheless achieve health benefits through the patient's belief and consequent optimism.

Side effects

Radionic therapy is non-invasive and has no known side effects.

Research and general acceptance

Most physicians dismiss radionics as quackery, arguing that any observed benefits are caused only by **placebo effect**. In the United States, medical devices must be approved by the federal Food and Drug Administration (FDA), and a 1998 district court decision in Minnesota determined that the sale of an unapproved radionics "black box" device violated state laws against deceptive trade practices and consumer fraud. The sale of such equipment to terminally ill patients constituted "health quackery at its worst," said Hubert Humphrey III, the state's attorney general. "This deplorable conduct aimed at vulnerable, desperate consumers is health fraud in its darkest form and will not be tolerated in Minnesota," Humphrey said. Radionics advocates, on the other hand, say they suffer from systematic government oppression.

Training and certification

Home-study courses and/or certification in radionics are offered by institutions in the United States, Canada, and the United Kingdom. In some cases these institutes also market radionics equipment.

Rashes

Definition

Rash is a popular term for a group of spots or an area of red, inflamed skin. A rash is usually a symptom of an underlying condition or disorder. Often only temporary, a rash is rarely a sign of a serious problem.

Description

A rash may occur on only one area of the skin, or it can cover almost all of the body. A rash may or may not itch. Depending on how it looks, a rash may be described as:

- blistering (raised oval or round collections of fluid within or beneath the outer layer of skin)
- macular (flat spots)
- nodular (small, firm, knotty rounded masses)
- papular (small, solid, slightly raised areas)
- pustular (pus-containing skin blisters)

Causes and symptoms

There are many theories as to why skin rashes occur. Sometimes the cause can be determined, and sometimes it cannot. Generally, a skin rash is an intermittent symptom, fading and reappearing. Rashes may accompany a range of disorders and conditions.

- Infectious illnesses. A rash is a symptom of many different infectious illnesses or conditions caused by bacteria, viruses, fungi, and other organisms. These include chickenpox, scarlet fever, Rocky Mountain spotted fever, ringworm, herpes, shingles, measles, scabies, and Lyme disease.
- Shared cosmetics and similar personal care items. It is not unusual for people to develop rashes from sharing face powder, mascara, and similar items with other family members or friends.
- Allergic reactions. One of the most common symptoms of an allergic reaction is an itchy rash. Contact dermatitis is a rash that appears after the skin is exposed to an allergen, such as metal, rubber, some cosmetics or lotions, or some types of plants (such as poison ivy, oak, or sumac). Drug reactions are another common allergic cause of rash. In this case, a rash is only one of a variety of possible symptoms, including fever, seizures, nausea and vomiting, diarrhea, heartbeat irregularities, and breathing problems. This rash usually appears soon after the first dose of the medicine is taken, although allergic reactions may be delayed for several days. Common culprits include such drugs as nevirapine, a medication used to treat HIV infection, and minocycline, a drug used to treat acne.
- Autoimmune disorders. Conditions in which the immune system attacks the body (like with systemic lupus erythematosus or purpura) often have a characteristic rash.
- Nutritional disorders. Scurvy, for example, is a disease caused by a deficiency of vitamin C and produces a rash as one of its symptoms.
- Cancer. A few types of cancer, such as chronic lymphocytic leukemia, can be the underlying cause of a rash.

Young girl with poison ivy rash on her face, which she is treating with calamine lotion. *(© Scott Camazine / Alamy)*

Rashes in infants

Rashes are extremely common in infancy, are not usually serious, and can be treated at home most of the time.

Diaper rash is caused by prolonged skin contact with bacteria and the baby's waste products in a damp diaper. This rash has red, spotty sores and there may

KEY TERMS

Atopic dermatitis—An intensely itchy inflammation often found on the face of people prone to allergies. In infants and early childhood, it's called infantile eczema.

Dermatitis (dermatoses)—A general term for inflammation of the skin.

Eczema—A superficial type of inflammation of the skin that may be very itchy and weeping in the early stages; later, the affected skin becomes crusted, scaly, and thick. There is no known cause.

Psoriasis—A common chronic skin disorder that causes red patches anywhere on the body.

Purpura—A group of disorders characterized by purple, red, or brown areas of discoloration visible through the skin.

Scabies—A contagious parasitic skin disease characterized by intense itching.

Systemic lupus erythematosus—A chronic immune disorder that attacks multiple parts of the body, including skin, blood vessels, kidneys, and connective tissue. Patients sometimes have a butterfly rash.

be an ammonia smell. In most cases, the rash will respond to drying efforts within three days. A diaper rash that does not improve in this time may be a **yeast infection** requiring prescription medication. A doctor should be consulted if the rash is solid, bright red, and is associated with a **fever**, or if the skin develops **blisters**, **boils**, or pus.

Infants can also get a rash on their cheeks and chin caused by contact with food, saliva, and stomach contents. This rash will come and go, but usually responds to a good cleaning after meals. About one-third of all infants develop **acne**, usually after the third week of life, in response to their mothers' hormones before birth. This rash will disappear in a few weeks to a few months. Heat rash is a mass of tiny pink bumps on the back of the neck and upper back caused by blocked sweat glands. The rash usually appears during hot, humid weather, although a baby with a fever can also develop the rash.

A baby should been seen by a doctor immediately if a rash:

- appears suddenly and is purple or blood colored
- looks like a burn
- appears while the infant seems to be sick

Diagnosis

A family doctor, naturopathic doctor, or dermatologist (skin disease specialist) can diagnose and treat rashes. Diagnosis can be made based on the patient's medical history, the appearance of the rash, the location of the rash, and any other accompanying symptoms. In some cases, the doctor may take a biopsy (skin sample) of the rash to assist in the diagnosis.

Treatment

Alternative treatments for rashes focus on relieving symptoms, clearing the rash, and rejuvenating the skin. There are many forms of alternative medicine that have remedies for rashes.

Herbals

Herbal remedies are very common in the treatment of different types of rashes. **Shingles** may be relieved by taking 30–50 drops of **St. John's wort** tincture in water three to six times a day. A variety of different herbals can be applied to different kinds of rashes.

- agrimony (*Agrimonia eupatoria*) tea spray: hives and moist rashes
- aloe (*Aloe vera*) gel: weeping rash, shingles, burns, sunburn
- amaranth (*Amaranthus hypochondriacus*) tea wash: hives
- beech (*Fagus grandifolia*) tea wash: diaper rash and poison ivy or oak rash
- black walnut (*Juglans nigra*) leaf tea: rashes, rashes caused by parasites, scabies
- burdock (*Articum lappa*) decoction: hives, eczema
- calendula (*Calendula officinalis*) infusion: hives, burns, sunburn; calendula lotion: plant-contact dermatitis
- cattail (*Typha latifolia*) paste: poison ivy rash
- chamomile tea wash: poison ivy, oak, or sumac rash
- chickweed (*Stellaria media*) salve: severe rashes, hives
- comfrey (*Symphytum officinale*) ointment, cream, or lotion: inflamed rash; cold tea compress from comfrey root: plant-contact dermatitis
- heartsease (*Viola tricolor*) infusion: hives
- goldenseal (*Hydrastis canadensis*) wash: poison ivy rash, rash caused by infection, diaper rash
- jewelweed (*Impatiens pallida*) rub: poison ivy or oak rash and skin irritation caused by briars, brambles, or nettles
- nettle (*Urtica dioca*) infusion: hives

- oak bark (*Querus alba*) tea: rashes
- oatmeal bath: plant-contact dermatitis
- pennyroyal (*Hedeoma pulegiodes*) tea wash: hives, shingles, measles, scabies, mumps, chickenpox, diaper rash, and poison ivy or oak rash
- pine (*Pinus* species) ashes: measles, chickenpox, and mumps rash
- plantain (*Plantago major*) poultice: poison ivy rash
- poplar (*Populus candicans*) tea wash: rashes
- sage (*Salvia officinalis*) tea wash: poison ivy or oak rash, and moist, weepy rashes
- sassafras (*Sassafras albidum*) root tea: rashes, shingles
- slippery elm (*Ulmus fulva*) bark paste: rashes
- solomon's seal (*Polygonatum multiflorum*) mashed root: poison ivy or oak rash
- St. John's wort (*Hypericum perforatum*) oil: shingles, and dry, itchy rashes
- sumac (*Rhus glabra*) tea wash: poison ivy rash
- thyme (*Thymus vulgaris*) salve: rashes
- witch hazel (*Hamamelis virginiana*) tincture: poison ivy or oak rash, diaper rash, and weeping rash
- yellow dock (*Rumex crispus*) decoction: hives

It is a good idea, however, to be careful in using herbal remedies. Cases have been reported of patients developing body rashes from **allergies** to such herbs as **feverfew**.

Homeopathy

Homeopathic remedies are individually prescribed for each patient. Some possible homeopathic remedies include:

- calcium sulfide (*Hepar sulphuris*) for rash with pus
- graphite (*Graphites*) for dry, red, cracked, itchy rash in the skin folds
- honeybee (*Apis*) for swelling and hives from bee stings
- nosode (*Medorrhinum*) for sharply defined red, possibly shiny, rash suggesting yeast infection
- poison ivy (*Rhus toxicodendron*) for plant contact dermatitis, itching hives, and restlessness
- stinging nettle (*Urtica urens*) for stinging hives with little inflammation
- sulfur for dry, red, cracked, itchy rash anywhere, including around the anus.

Other treatments

Other rash remedies include:

- Aromatherapy. The essential oils thyme, lavender, jasmine, and German chamomile may relieve allergy-induced eczema.
- Ayurveda. Rashes and hives are treated by drinking fresh cilantro juice and applying the pulp onto the rash. Fresh coconut water, melon rind, or a paste of turmeric (one part) and sandalwood (two parts) in goat's milk can be applied to the affected area. Hot milk (1 cup) containing coriander (1 teaspoon), cumin (1/2 teaspoon), and raw sugar (1 teaspoon) can be ingested once or twice daily to heal rashes and hives and restore skin health.
- Chinese medicine. Hives are treated with herbal preparations, acupuncture, ear acupuncture, and cupping. Preparations applied to the skin to relieve the itching associated with hives include Jie Du Cha Ji (Resolve Toxin Smearing Liquid), Zhi Yang Po Fen (Relieve Itching Powder), and Zhi Yang Xi Ji (Relieve Itching Washing Preparation). Contact dermatitis and drug dermatitis are treated with herbal formulas comprised of herbs chosen specifically for the patient's symptoms.
- Diet. An increased intake of mackerel, salmon, and herring provides essential fatty acids that may decrease itching and inflammation.
- Hydrotherapy. Hives can be relieved by rubbing the affected area with an ice cube, taking a cool bath, or using a cold compress.
- Hypnosis. Emotional stress can trigger many different dermatoses including certain rashes. Hypnosis has been helpful in treating atopic dermatitis, herpes, itching, psoriasis, hives, and other dermatoses.
- Juice therapy. Red rashes are treated with fresh apple, dark grape, papaya, or pineapple juices drunk at room temperature between meals.
- Supplements. Rashes may be treated with skin-repairing vitamins A, C, B complex, and zinc. Vitamin E can reduce skin dryness (decreasing the itch).

Allopathic treatment

Treatment of rashes focuses on providing relief of the **itching** that often accompanies them. Soothing lotions, topical corticosteroids (such as hydrocortisone), or oral antihistamines (Benadryl) can provide some relief. Topical antibiotics may be administered if the patient, particularly a child, has caused an infection by scratching.

For diaper rash, the infant's skin should be exposed to the air as much as possible. Ointments are not needed unless the skin is dry and cracked. Experts also recommend switching to cloth diapers and cleaning affected skin with plain water.

Expected results

Most rashes that have an acute cause (such as an infection or an allergic reaction) will disappear as soon

as the infection or irritant is removed from the system. Rashes that are caused by chronic conditions (such as autoimmune disorders) may remain indefinitely or may fade and then return periodically.

Prevention

Some rashes can be prevented, depending on the cause. A person known to be allergic to certain drugs or substances should avoid those things in order to prevent a rash. It is also a good idea to avoid sharing cosmetics and personal care items (including lip balms) with other family members or friends. Diaper rash can be prevented by using cloth diapers, keeping the diaper area very clean, breast-feeding, and changing diapers often. A person should launder clothing and rinse his or her skin first with rubbing alcohol and then with water after contact with a plant that can cause **contact dermatitis**.

Raspberry

Description

Raspberry (*Rubus ideaeus*) is a deciduous bush from the Rosaceae family that grows up to 6 ft (2 m) high, with erect and thorny stems, a thin spine and perennial roots. The bush is well-known for its fruit, a red spherical berry that grows continuously on the branches. Cymes (clusters) of white flowers bloom in late spring to early summer. Raspberries can be grown in many temperate countries, in either dry or moist wooded areas.

General use

Raspberry leaves are used as an astringent and stimulant. High concentrations of tannin found in the plant are the source of its astringent effects. It also contains flavonoids, pectin, citric and malic acids, and a crystallizable fruit sugar and water. Raspberries are high in minerals, especially **iron**, **magnesium**, and **calcium**. Raspberry is well regarded as a women's herb. The leaves are brewed into a tea that is used during **pregnancy** as well as to increase breast milk after the baby is born. Some women use tea made from raspberry leaves to regulate their menstrual cycles and to decrease heavy menstrual flow. It is also used for gastrointestinal disorders, respiratory illness, the cardiovascular system and for sores in the mouth and throat. The fruit has been found be anticarcinogenic.

Pregnancy

Raspberry leaves have been used for centuries by women during pregnancy. But it wasn't until a 1941

Raspberry. *(© blickwinkel / Alamy)*

KEY TERMS

Cyme—A flower cluster whose main branch ends in a flower that blooms before the others at its side or base.

Ellagic acid—A yellow crystalline compound derived from tannins and used to prevent bleeding. It is found in raspberries and is thought to help prevent cancer.

study in the British medical journal *Lancet* that raspberry leaves were scientifically confirmed to contain a complex biochemical that is a uterine relaxant. Raspberry leaves are commonly used throughout pregnancy for many reasons, including helping **morning sickness**, preventing miscarriage, strengthening the uterus, regulating contractions, and relaxing the uterus during labor. Some pet breeders give a tincture of red raspberry leaves to pregnant cats who are likely to have difficulty in kittening.

Gastrointestinal disorders

Because it is an astringent, raspberry is a gentle antidiarrheal. It is also used to reduce **nausea** and **vomiting**, usually for morning sickness.

Mouth and throat sores

Raspberry tea is helpful for healing mouth and throat sores when used as a mouthwash or gargle. It can also be used for bleeding gums and other oral inflammations. Some herbalists recommend it for colds, **measles**, and coughs.

Cancer treatment

The fruit of the raspberry may help prevent **cancer**, according to a January 1999 report in *Cancer Weekly Plus*. "Ellagic acid in raspberries has been shown in previous studies to be effective in inhibiting cancers in rats and mice," the study detailed. "The compound is . . . at especially high levels in blackberries and raspberries." Researchers at the Hollings Cancer Center at the Medical University of South Carolina in Charleston gave one cup of raspberries a day to each participant for one year. The study concluded that " . . . eating red raspberries may possibly prevent cancer by inhibiting the abnormal division of cells and promoting the normal death of healthy cells."

A 2001 study has found that black raspberries appear to be as helpful as red raspberries in preveting or slowing the growth of cancer. Black raspberries, according to an article in the journal Cancer Research, help to protect against esophageal cancer, which is the sixth-leading cause of deaths from cancer worldwide. Esophageal cancer is one of the deadliest forms of the disease— five-year survival rates range from 8% to 12%. Researchers think that ellagic acid is not the only beneficial compound in raspberries, however, and are presently studying other substances found in the fruit.

Diabetes

Some studies have shown that raspberries may help reduce glucose levels and therefore may be helpful to people with diabetes.

Preparations

Raspberry leaf tea can be made by adding 1 tsp of the leaf to one cup of boiling water. The leaf should be infused for 10 min and then strained. The infusion can be taken once or twice a day. During pregnancy, use 0.5 oz of leaf to one pt of boiling water and drink once a day. For infant **diarrhea**, dilute this infusion by 50%. A tincture made of raspbery leaf can be taken three times a day, in 2–4 ml doses.

Precautions

Wilted raspberry leaves develop a mild poison that may make people ill. When picking the leaves for the tea, the user should make sure that the plant is flowering. Leaves used for steeping to make tea must be fully dried. Another important precaution is to be sure that the raspberries are not contaminated by a gastrointestinal parasite called *Cyclospora*. The parasite causes a disease called *cyclosporiasis,* which caused several serious outbreaks in the mid-1990s in the United States and Canada. The *Cyclospora* parasite was found in raspberries imported from Guatemala.

Side effects

Although raspberry is used as an antidiarrheal herb, overuse may actually cause diarrhea. In addition, some people may be allergic to raspberries and other berries. Lastly, the tea may sometimes be too tonifying in the early stages of pregnancy; it should be discontinued if contractions increase.

Interactions

No known adverse interactions with other medications have been reported.

Raynaud's syndrome

Definition

Raynaud's syndrome is a disorder in which the fingers or toes (digits) suddenly experience decreased blood circulation. It is also called Raynaud's disease.

Description

Raynaud's syndrome can be classified as one of two types: primary, or idiopathic (of unknown cause) disease; and secondary, which is also called Raynaud's phenomenon.

Primary Raynaud's disease is milder and causes fewer complications. About half of all cases of Raynaud's disease are of this type. Women are four times more likely than men to develop primary Raynaud's disease, and the average age of diagnosis is between 20 and 40 years. About 30% of all cases of primary Raynaud's disease progress after diagnosis, while 15% of cases actually improve.

Secondary Raynaud's disease is more complicated, severe, and more likely to get worse over time. A number of medical conditions or other triggers predispose a person to secondary Raynaud's disease, but do not directly cause the disorder. These include:

- Scleroderma. Scleroderma is a serious disease of the connective tissue, in which tissues of the skin, heart, esophagus, kidney, and lung become thickened, hard, and constricted. About 30% of patients

Raynaud's syndrome. *(© Hercules Robinson / Alamy)*

diagnosed with scleroderma will then develop Raynaud's disease.

- Other diseases of connective tissue. These include systemic lupus erythematosus, rheumatoid arthritis, dermatomyositis, and polymyositis.
- Diseases that cause arterial blockage. These include atherosclerosis or hardening of the arteries.
- A severe form of high blood pressure which is caused by diseased arteries in the lung, called pulmonary hypertension.
- Disorders of the nervous system. These include herniated discs in the spine, strokes, tumors within the spinal cord, polio, and carpal tunnel syndrome.
- Other blood disorders.
- Trauma. Injuries that lead to Raynaud's are typically caused by exposure to constant vibration (workers who use chainsaws, jackhammers, or other vibrating equipment); repetitive movements (keyboard instrumentalists, assembly line workers, typists); electric shock; repeated use of the lower side of the palm as a hammer; or extreme cold (frostbite).
- Environmental toxins. Workers in the plastics industry who are exposed to high levels of vinyl chloride may develop a scleroderma-like illness that includes Raynaud's syndrome.
- Prescription medications. Drugs that increase the risk of developing Raynaud's include those used for migraine headaches or high blood pressure, and some cancer chemotherapy agents. Cases have also been reported of Raynaud's disease developing in reaction to quinine.

KEY TERMS

Contract—To squeeze down, become smaller.

Cyanosis—Blueness of the skin, caused by inadequate blood flow or oxygen supply. The affected area of skin is said to be cyanotic.

Dilate—To expand in diameter and size.

Endothelium—A thin layer of smooth tissue that lines the inside of blood vessels, the heart and abdomen, and other body cavities.

Idiopathic—Of unknown cause. Primary Raynaud's is an idiopathic disorder.

Prostaglandins—Unsaturated fatty acids that are associated with the contraction of smooth muscle, control of inflammation, and regulation of body temperature. Researchers think that prostaglandins may hold a clue to the cause of Raynaud's.

Rheumatology—The branch of medicine that specializes in the treatment of arthritis and related conditions, including Raynaud's disease.

Causes and symptoms

Causes

Both primary and secondary types of Raynaud's symptoms are believed to be due to overreactive arterioles, or small arteries. While cold normally causes the muscle which makes up the walls of arteries to contract (squeeze down to become smaller), in Raynaud's disease the degree is extreme. Blood flow to the area is severely restricted. Some attacks may also be brought on or worsened by **anxiety** or emotional distress.

Although the cause of primary Raynaud's is not known as of 2002, researchers are focusing on prostaglandin metabolism and the function of endothelial cells in the body. Prostaglandins are a group of unsaturated fatty acids involved in the contraction of smooth muscle and the control of inflammation and body temperature. Endothelial cells form the layer of smooth tissue that lines the inside of the heart, blood vessels, and other body cavities.

Recent advances in gene mapping and sequencing indicate that Raynaud's may be linked to abnormal forms of a gene known as the Fibrillin-1 gene. This gene affects the composition of the protein molecules in human connective tissue.

Symptoms

Classically, there are three distinct phases to an episode of Raynaud's symptoms. When first exposed to cold, the arteries respond by contracting intensely. The digits in question, or in rare instances, the tip of the nose or tongue, become pale and white as they are deprived of blood flow and the oxygen carried by the blood. In response, the veins and capillaries dilate, or expand. Because these vessels carry deoxygenated blood, the digit becomes cyanotic, which means that it turns blue. The digit often feels cold, numb, and tingly. After the digit begins to warm up again, the arteries dilate. Blood flow increases significantly, and the digits turn a bright red. During this phase, the patient often describes the digits as feeling warm, and throbbing painfully.

Raynaud's disease may initially only affect the tips of the fingers or toes. When the disease progresses,

it may eventually affect the entire finger or toe. Ultimately, all the fingers or toes may be affected. About 10% of the time, a complication called sclerodactyly may occur. In sclerodactyly, the skin over the affected digits becomes tight, white, thick, smooth, and shiny.

When the most serious complications of Raynaud's disease or phenomenon occur, the affected digits develop deep sores, or ulcers, in the skin. The tissue may even die, thus becoming gangrenous, and requiring amputation. This complication occurs only about 1% of the time in primary Raynaud's disease.

Diagnosis

While the patient's symptoms will be the first clue pointing to Raynaud's disease, a number of tests may also be performed to confirm the diagnosis. Special blood tests called the antinuclear antibody test (ABA) and the erythrocyte sedimentation rate (ESR) are often abnormal when an individual has a connective tissue disease.

When a person has connective tissue disease, his or her capillaries are usually abnormal. A test called a nailfold capillary study can demonstrate such abnormalities. In this test, a drop of oil is placed on the skin at the base of the fingernail. This allows the capillaries in that area to be viewed more easily with a microscope.

A cold stimulation test may also be performed. In this test, specialized thermometers are taped to each of the digits that have experienced episodes of Raynaud's disease. The at-rest temperature of these digits is recorded. The hand or foot is then placed completely into a container of ice water for 20 seconds. After removing the hand or foot from this water, the temperature of the digits is recorded immediately. The temperature of the digits is recorded every five minutes until they reach the same temperature they were before being put into the ice water. A normal result occurs when this pretest temperature is reached in 15 minutes or less. If it takes more than 20 minutes, the test is considered suspicious for Raynaud's disease or phenomenon.

Treatment

The first type of treatment for Raynaud's symptoms is simple prevention. Patients need to stay warm, and keep hands and feet well covered in cold weather. Patients who smoke cigarettes should stop, because nicotine worsens the problem. Most people—especially those with primary Raynaud's—are able to deal with the disease by taking these basic measures.

Because episodes of Raynaud's disease have also been associated with **stress** and emotional upset, the disease may be improved by helping a patient learn to manage stress. Regular **exercise** is known to decrease stress and lower anxiety. Hypnosis, **relaxation** techniques, and visualization are also useful methods to help a patient gain control of his or her emotional responses. **Biofeedback** training is a technique during which a patient is given continuous information on the temperature of his or her digits, and then taught to voluntarily control this temperature. **Acupuncture** is also used for treating these circulatory and heat distribution problems.

Some alternative practitioners believe that certain dietary supplements and herbs may be helpful in decreasing the vessel spasm of Raynaud's disease. Suggested supplements include **vitamin E** (found in fruits, vegetables, seeds, and nuts), **magnesium** (found in seeds, nuts, fish, beans, and dark green vegetables), and fish oils. Several types of herbs have been suggested, including peony (*Paeonia lactiflora*) and **dong quai** (*Angelica sinensis*). The circulatory herbs **cayenne** (*Capsicum frutescens*), **ginger** (*Zingiber officinale*), and prickly ash (*Zanthoxylum americanum*) can help enhance circulation to the extremities. Additionally, a tincture of one-half teaspoon of a combination of equal parts of *ginkgo biloba*, prickly ash, and ginger may be consumed three times daily.

Practitioners of **traditional Chinese medicine** (TCM) recommend certain formulas called *si ni*, which means cold extremities. TCM regards Raynaud's as an indication that the person is hypersensitive to cold outside the body because he or she is already cold inside. The Chinese practitioner will typically recommend various combinations of herbs regarded as warming to correct this condition. The *si ni* formulas contain different combinations of ginger, **aconite**, bupleurum, bitter orange, and honey-baked **licorice**.

Allopathic treatment

People with more severe cases of Raynaud's disease may need to be treated with medications to attempt to keep the arterioles relaxed and dilated. Some medications that are more commonly used to treat high blood pressure, such as calcium-channel blockers, or reserpine, are often effective for treatment of Raynaud's symptoms. Nitroglycerin paste can be used on the affected digits, and seems to be helpful in healing skin ulcers.

When a patient has secondary Raynaud's phenomenon, treatment of the coexisting condition may help control the Raynaud's as well. In the case of

connective tissue disorders, this often involves treatment with corticosteroid medications.

Expected results

The prognosis for most people with Raynaud's disease is very good. In general, primary Raynaud's disease has the best prognosis, with a relatively small chance for serious complications (1%). In fact, about 50% of all patients do well by taking simple precautions, and never even require medications. The prognosis for people with secondary Raynaud's disease or phenomenon is less predictable. This prognosis depends greatly on the severity of the patient's other associated condition, such as scleroderma or lupus.

Prevention

As of 2002, there is no known way to prevent the development of Raynaud's disease. Once a person realizes that he or she suffers from this disorder, however, steps can be taken to reduce the frequency and severity of episodes.

Red cedar

Description

Red cedar, also called western red cedar or western redcedar, is the species *Thuja plicata*. It should not be confused with the eastern red cedar, *Juniperus virginiana*, or the Lebanon cedar, *Cedrus libani*, which are unrelated species. Eastern red cedar is toxic if taken internally.

Western red cedar is a tree that grows to a height of 125 ft (60 m) in moist soils in mixed coniferous forests. It has red-brown or gray-brown bark with thick longitudinal fissures that is easily peeled. Its foliage develops in sprays about 6 in (15 cm) long with small, highly aromatic leaves. The leaves, twigs, bark, and roots are all used medicinally.

Western red cedar is found in northwestern North America, in the United States and western Canada from Alaska through northern California and in the Rocky Mountains from British Columbia through Montana. Other names for *Thuja plicata* include giant red cedar, giant arborvitae, shinglewood, and canoe cedar. It is one of the most commercially important logging trees in the western United States.

A relative of the western red cedar, *Thuja orientalis* grows in the eastern part of the United States and

Red Cedar. *(© blickwinkel / Alamy)*

Canada as well as in China where it is called *ce bai ye or ya bai shu*. The naming of this species is confusing. It is called yellow cedar and sometimes also arbor vitae while *Thuja plicata* is sometimes called giant arbor vitae. More confusing, another relative, Chinese arbor vitae, is referred to in literature interchangeably as *Biota orientalis* and *Thuja orientalis*. It is used in **traditional Chinese medicine** in many of the same ways as *Thuja plicata*.

General use

Red cedar is of major cultural importance to Native American tribes living in the Pacific Northwest. The wood, bark, limbs, and roots were used to provide many of the needs of the tribe, ranging from shelter to cooking implements to medicine. Red cedar also has spiritual significance to some of these tribes and is used in ritual ways. Red cedar was a major medicinal herb for these Pacific Northwest cultures, although by the late 2000s it was not much used medicinally.

Native American tribes used the twigs, leaves, roots, bark, and leaf buds of red cedar to treat many different symptoms. Internal uses include:

- boiling limbs to make a tuberculosis treatment
- chewing leaf buds for sore lungs
- boiling leaves to make a cough remedy
- making a decoction of leaves to treat colds
- chewing leaf buds to relieve toothache pain
- making an infusion to treat stomach pain and diarrhea
- chewing the inner bark of a small tree to bring about delayed menstruation
- making a bark infusion to treat kidney complaints
- making an infusion of the seeds to treat fever
- using a weak infusion internally to treat rheumatism and arthritis

External uses include:

- making a decoction of leaves to treat rheumatism
- washing with an infusion of twigs to treat venereal disease, including the human papilloma virus and other sexually transmitted diseases
- making a poultice of boughs or oil to treat rheumatism
- making a poultice of boughs or oil to threat bronchitis
- making a poultice or oil from inner bark to treat skin diseases, including topical fungal infections and warts
- using shredded bark to cauterize and bind wounds

Scientific research supports some of these traditional uses of red cedar. Extracts of red cedar have been shown to have antibacterial properties against common bacteria. Compounds with antifungal properties have also been isolated. The aromatic and decay-resistant properties of western red cedar are attributed to organic compounds called tropolones.

Preparations

Most preparations of red cedar call for boiling the medicinal parts to make a decoction or for making a tea or infusion. As of 2008, little information existed on dosages.

An essential oil to be used topically can be prepared from red cedar. It is toxic if taken internally and has the ability to produce convulsions or even death if taken in even small quantities. A 1999 study done in Switzerland noted an increase in poisoning deaths from plant products, including *Thuja*, due possibly to an increase in people practicing herbal healing and **aromatherapy**.

KEY TERMS

Decoction—A preparation made by boiling an herb, then straining the solid material out. The liquid is then taken internally as a drink.

Precautions

As noted above, the oil of all species of *Tthuja* can cause convulsions. Decoctions of the bark of red cedar can also cause miscarriage. Therefore, pregnant women should not use red cedar.

Side effects

Many people develop **asthma** and bronchial spasms from exposure to red cedar or red cedar dust. This response is an allergic reaction to plicatic acid present in the wood. Red cedar-induced asthma is a serious occupational hazard to loggers in western North America. Estimates of the number of loggers who develop occupational asthma due to red cedar exposure range from 4–13.5%. There are also reports of **contact dermatitis** (rash) caused by exposure to western red cedar heartwood.

Interactions

There were no studies and little observational evidence as of 2008 to indicate whether red cedar interacts with other herbs or with Western pharmaceuticals.

Red clover

Description

Red clover (*Trifolium pratense*) is a familiar meadow herb, one of 250 species in the Leguminosae, or pea family. The Irish shamrock is another species in this family of plants. Red clover is a European native naturalized throughout North America and Canada. This familiar short-lived perennial grows wild along roadsides, in meadows, and in fields, and is extensively cultivated as a forage crop for cattle. It grows best in soils that are rich in **calcium**, **potassium**, and **phosphorus**. The common names for this sweet herb include wild clover, meadow trefoil, bee bread, trefoil, cow grass, purple clover, and three-leafed grass.

Red Clover. *(© Arco Images / Alamy)*

Red clover grows to about 2 ft (61 cm) high from a short, woody rootstock. The leaves are palmate and arranged alternately along the round, grooved, and hairy stem. They are divided into three oblong or oval leaflets, a characteristic that has given the genus its name. The dark green leaves often have a splash of a pale green or white on each leaflet. The leaf margins are toothed. The red-purple or magenta-hued blossoms comprise numerous florets that form a globe-shaped flower on the end of the stalk. Red clover blooms throughout the summer. The edible blossoms are sweet-tasting with a honey-like fragrance. Bees are attracted to clover blossoms, but seem to prefer the white blossoms of another common variety of clover, often growing nearby.

General use

In folk tradition, red clover was associated with the Christian doctrine of the Trinity because of its threefold leaflets. In England it was worn as a magic charm to protect against evil. The herb's value as a medicinal remedy was not well known until the herb made its way to North America. Native American herbalists soon found numerous medicinal uses for this common wayside beauty. Red clover was used as a **cancer** treatment; the blossoms, combined with other herbs, became commercially popular in the United States in the 1930s. Numerous so-called "Trifolium Compounds" were marketed as blood purifiers, or alteratives, to help clear the body of metabolic toxins. The herb was listed in the *National Formulary* of the United States until 1946.

Red clover has most often been used to treat such skin inflammations as **psoriasis** and **eczema**. It also acts as an expectorant and demulcent, and is helpful in the treatment of **bronchitis** and spasmodic coughs, particularly **whooping cough**. Red clover may stimulate the liver and gall bladder and has been used for **constipation** and sluggish appetite. The blossoms were smoked as a remedy for **asthma**. An infusion of red clover blossoms used as a skin wash, or a poultice prepared from fresh blossoms, may relieve the irritation of **athlete's foot** or insect **bites**. The infusion is also useful as an external skin wash in the treatment of persistent sores and ulcers, and may help speed healing. As an eyewash, red clover tincture diluted with fresh water may relieve **conjunctivitis**. An ointment prepared from red clover is helpful for lymphatic swellings, and a compress made with it may relieve the **pain** of arthritis and **gout**. More recently, red clover has been studied as an alternative remedy for **hot flashes** in menopausal women as well as hot flashes in men following surgery for **prostate cancer**.

Many of the chemical constituents present in red clover have been identified, including volatile oil, isoflavonoids, coumarin derivatives, and cyanogenic glycosides. Few scientific studies, however, have confirmed the folk use of red clover remedies. The genistein found in red clover has been found to contribute to the shrinking of cancerous tumors in vitro by preventing growth of the new blood vessels that feed the tumors. One of the first studies using purified extract of red clover, published in 1999, concluded that use of red clover in standardized extracts that include specific quantities of the four isoflavones genistein, daidzein, biochanin and formononetin, resulted in improved heart health in postmenopausal women. Red clover is considered by some herbalists to be a phytoestrogenic herb, useful in restoring estrogen balance in women. The chemical formononetin, found in red clover, acts on the body in a similar way as estrogen.

KEY TERMS

Alterative—A herb that changes one's physical condition, especially a blood cleanser.

Demulcent—A substance or agent used to soothe irritated mucous membranes.

Expectorant—A substance or medication that causes or eases the bringing up of sputum or phlegm from the respiratory tract.

Infusion—An herbal preparation made by adding herbs to boiling water and then steeping the mixture to allow the medicinal herb to infuse into the water.

Isoflavone—A type of phytoestrogen, or compound derived from plants that has weak estrogen-like activity. Red clover contains measurable quantities of four different isoflavones.

Palmate—A type of leaf that has lobes or leaflets radiating from a central point.

Tincture—A liquid extract of an herb prepared by steeping the herb in an alcohol and water mixture.

Preparations

Red clover blossoms are the medicinally active part of this herb. Fully open blossoms can be harvested throughout the flowering season. Pick the flower heads on a sunny day after the morning dew has evaporated. Spread the blossoms on a paper-lined tray to dry in a bright and airy room away from direct sun. The temperature in the drying room should be at least 70°F (21°C). When the blossoms are completely dry, store dried flowers in a dark glass container with an air-tight lid. The dried herb will maintain medicinal potency for 12–18 months. Clearly label the container with the name of the herb and the date and place harvested.

Tincture: Combine 4 oz of fresh or dried red clover blossoms with 1 pint of brandy, gin, or vodka in a glass container. The alcohol should be enough to cover the flowers. The ratio should be close to 50/50 alcohol to water. Stir and cover. Place the mixture in a dark cupboard for three to five weeks. Shake the mixture several times each day. Strain and store in a tightly capped, clearly labeled dark glass bottle. A standard dose is 1–3 mL of the tincture three times a

day. Tinctures properly prepared and stored will retain medicinal potency for two years or longer.

Infusion: Place 2 oz fresh clover blossoms, less if dried, in a warmed glass container. Bring 2.5 cups of fresh nonchlorinated water to the boiling point and add it to the herbs. Cover the tea and steep for about 30 minutes, then strain. Drink cold, a few mouthfuls at a time throughout the day, up to one cup per day. The prepared tea may be kept for about two days in the refrigerator.

Ointment: Add fresh clover blossom to a glass pan of nonchlorinated water. Simmer on low heat or in a crock pot for two days. Strain. Allow most of the water to evaporate and combine the plant extract with an equal amount of melted beeswax. Pour while warm into small airtight containers.

Precautions

Red clover is a safe and mild remedy. No adverse effects have been reported in humans when taking therapeutic doses of the herb. Allergic reactions to red clover are rare but possible. Numerous reports of toxicity, even death, however, have been reported in cattle who overgraze in fields of clover.

Side effects

No side effects in humans have been reported for nonfermented red clover. Fermented extracts of red clover, however, may cause bleeding.

Interactions

No interactions have been reported between red clover and other herbs. It has, however, been reported to have adverse interactions with certain allopathic medications, particularly heparin, ticlopidine, and warfarin. Red clover also reduces the body's absorption of combined estrogens.

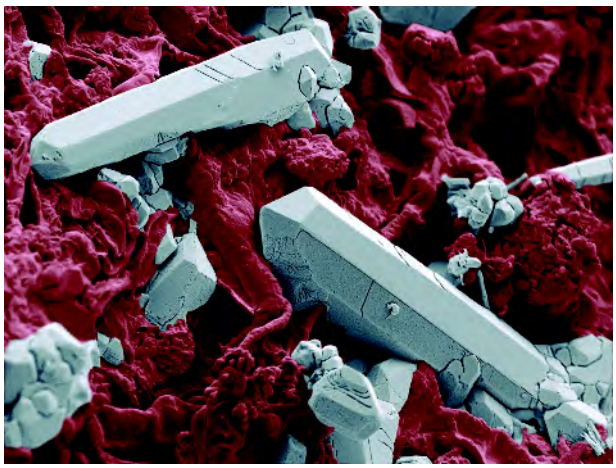
Red yeast rice extract

Description

Native to China, red yeast rice extract is the by-product of *Monascus purpureus* Went (red yeast) fermenting on rice. Part of the Monascaceae family, *Monascus purpureus* is identified by its ascospores. The color of the mycelium is initially white, but soon changes to pink and then yellow-orange due to an increase in acidity and the development of hyphae. They explain that as the culture ages, it is characterized by a dark crimson color at the substratum.

General use

Documented as early as 800 ***A.D.***, Chinese red yeast rice was used in the preserving, flavoring, and coloring of food and wine. However, in addition to red yeast rice's culinary properties, it was soon discovered that red yeast rice possessed medicinal properties as well. The ancient Chinese pharmacopoeia, *Ben Cao Gang Mu-Dan Shi Bu Yi*, published during the Ming Dynasty (1368–1644), recorded a detailed description of red yeast rice and its manufacture. According to the pharmacopoeia, red yeast rice promotes blood circulation and stimulates the digestive system and spleen.



Red yeast rice results from fermenting regular rice with a fungus Monascus purpureus. *(Scimat / Photo Researchers, Inc.)*

KEY TERMS

Ascomycete—Any class of higher fungi with septate hyphae and spores formed in the asci.

Ascospores—Any spores contained in the ascus, which is the oval or tubular spore case of an ascomycete.

Cholesterol—A waxy, fat-like substance, or lipid, required for important body functions. Excess cholesterol, however, can cause hardening of the arteries, which can lead to such serious health problems as heart disease. LDL cholesterol is considered "bad" because it can promote cholesterol build-up and hardened arteries. HDL cholesterol is considered "good" cholesterol because it helps break up cholesterol build-up.

HMG-CoA reductase—Hepetic hydroxy-methyl-glutaryl coenzyme A is an enzyme created in the liver that promotes the production of cholesterol.

Monacolin—An HMG-CoA reductase inhibitor, which assists in the lowering of cholesterol levels.

Rhabdomyolysis—The necrosis or disintegration of skeletal muscle.

Statin—An HMG-CoA reductase inhibitor, which assists in the lowering of cholesterol levels.

Triglycerides—A blood fat lipid that increase the risk of heart disease.

Recent studies of red yeast rice indicate that it contains substances similar to those found in cholesterol-reducing (statin) prescription medications. In addition, research indicates red yeast rice may contain other cholesterol-reducing and be itself an agent useful in lowering **cholesterol**.

Traditional red yeast rice can be purchased in typical Chinese groceries. However, in this form, the extract possesses negligible to very low levels of statin compounds. Instead, manufacturers grow and process the *M. purpureus* Went under controlled conditions to increase the levels of statin. The powdered extract is then sold in capsule form.

In 2001, the Food and Drug Administration (FDA) determined that standardized red yeast rice extract (in this case, Cholestin®; developed by Pharmanex) possessed strong chemical similarities to the drug lovastatin, another cholesterol-reducing drug. Unfortunately, a pharmaceutical company, Merck & Co., trademarked lovastatin as Mevacor®. Because of the similarity, the FDA classified standardized red yeast rice extract as a drug. Under the Dietary Supplement Health Education Act of 1994, it could no longer be sold as a dietary supplement under penalty of law. As such, standardized red yeast rice extract has virtually disappeared from the United States marketplace.

Recent studies have indicated that taking the standardized dose (600 mg) of red yeast rice extract orally, two to four times per day, may assist in a significant reduction of total cholesterol (TC), low-density lipoprotein (LDL) cholesterol ("bad" cholesterol), and triglycerides (TG). It can also slightly increase levels of high-density lipoprotein (HDL) cholesterol ("good" cholesterol). Red yeast rice appears to achieve these benefits by reducing the production of cholesterol in the liver. This cholesterol synthesis reduction stems from one ingredient in particular, monacolin, which acts as an inhibitor of the enzyme responsible for cholesterol production. (The enzyme is known as hepatic hydroxy-methyl-glutaryl coenzyme A (HMG-CoA) reductase.) By lowering high cholesterol levels and promoting blood circulation, red yeast rice may help reduce the risks of heart, coronary, and cerebral vascular diseases. As such, people suffering from high cholesterol (240 mg/dl or above) could benefit from using red yeast rice extract. According to the Natural Dietary Supplements Pocket Reference, a 20% decrease in total cholesterol has been documented for treatments longer than one month. Additionally, red yeast rice extract possesses antioxidant qualities.

Preparations

Although there have been several studies on red yeast rice extract, there remains little information regarding its safety for long-term usage. There are also certain medical risks associated with this extract. As such, it is strongly suggested that anyone considering

using red yeast rice extract for the prevention and treatment of high cholesterol consult with their physician before doing so. This is particularly important for people suffering from high cholesterol and/or **heart disease**. A baseline liver enzyme check is recommended beforehand, in addition to subsequent checks thereafter. In general, however, the recommended dose for adults is 600 mg (oral dose), two to four times per day.

Additionally, due to the 2001 FDA decision, only a doctor may legally prescribe standardized red yeast rice extract. As such, health-food stores now selling this product are doing so illegally. There are, however, several dietary supplements available to the public, which can be as effective as red yeast rice extract. Pharmanex, for example, has removed red yeast rice extract from their supplement, Cholestin®, and replaced it with other cholesterol-reducing, natural substances. It is advisable to consult with a physician regarding the available options.

Precautions

Due to the lack of medical evidence regarding red yeast rice extract's safety for use by youths and children, it is recommended that it not be given to people younger than age 20. Those at risk of or suffering from liver disease shouldn't take red yeast rice extract, as it may affect liver function. Due to the product's statin content, usage is also contraindicated for people with serious **infections** or physical disorders, who are pregnant or breastfeeding, or have had an organ transplant.

Side effects

Although the risks are low, usage can result in liver damage, kidney toxicity, and rhabdomyolysis (disintegration of skeletal muscle). Side effects are mild, including **headache**, **dizziness**, flatulence, **heartburn**, and stomachache. When the extract is no longer being taken, any side effects fade quickly.

Interactions

Because of its statin content, red yeast rice extract should not be taken with other HMG-CoA reductase inhibitors, such as atorvastatin and lovastatin. This interaction would increase the effects of these medications, thus increasing the risk of liver damage. However, **niacin** supplements can be safely used to enhance the cholesterol-lowering effects.

Due to the increased risk of rhabdomyolysis, red yeast rice extract should not be taken with high-dose nicotinic acid (more than 1,000 mg/per day). A physician should be contacted immediately if any muscle **pain**, tenderness, or weakness is experienced.

Alcohol consumption while using red yeast rice extract should not exceed two drinks a day. Also, grapefruit, grapefruit juice, and grapefruit products (like marmalade) should be strictly avoided. Grapefruit enhances the blood concentration of HMG-CoA reductase inhibitors by as much as 15 times, thus greatly increasing the risk of side effects and liver damage.

Reflexology

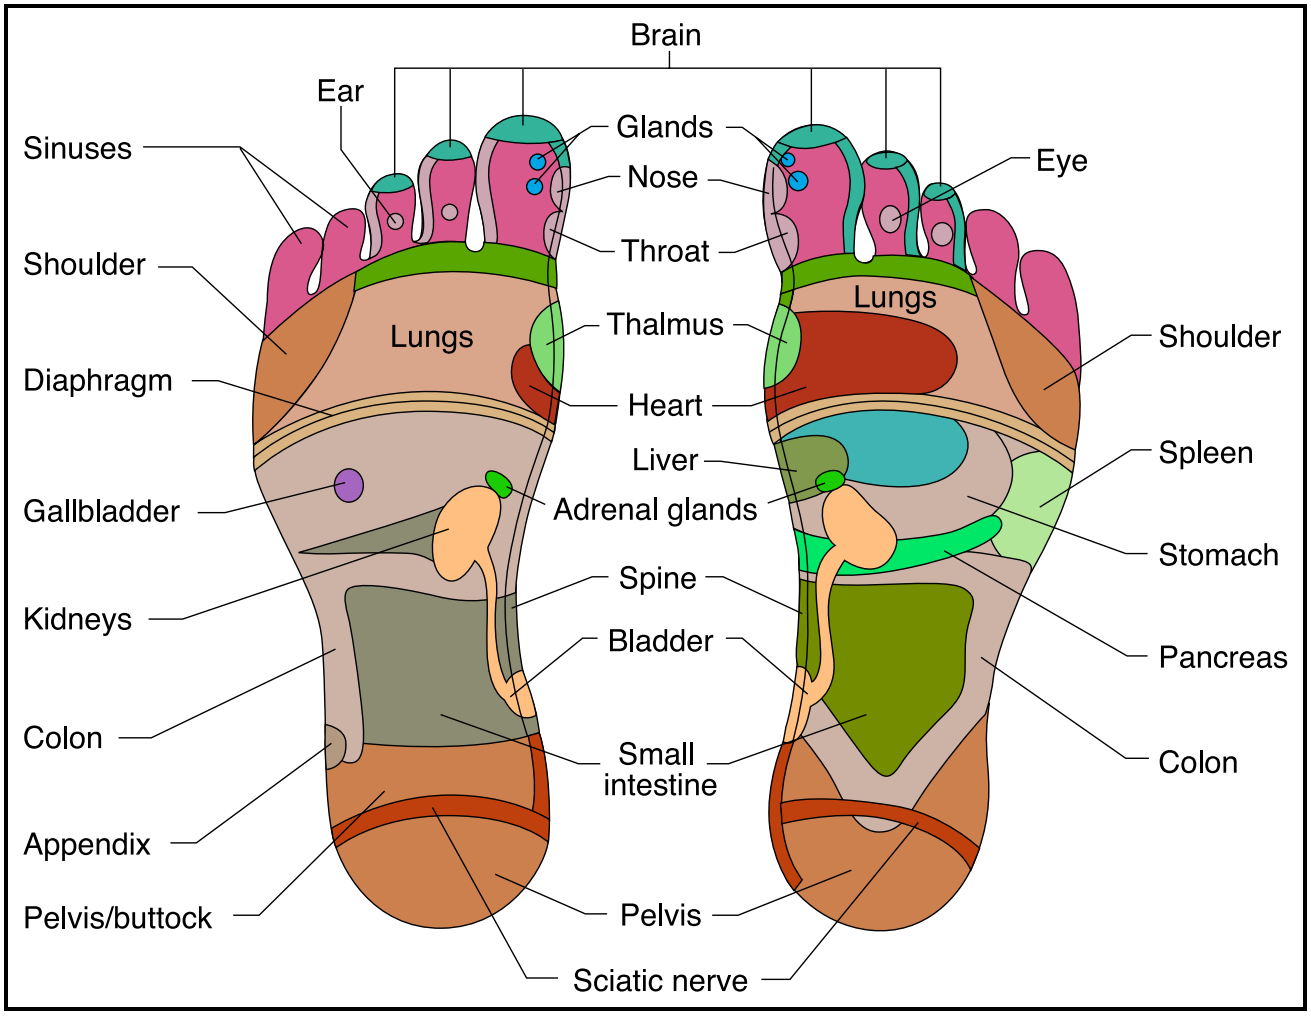
Definition

Reflexology is a therapeutic method of relieving **pain** by stimulating predefined pressure points on the feet and hands. This controlled pressure is designed to alleviate the source of the discomfort. In the absence of any particular malady or abnormality, reflexology may be as effective for promoting good health and for preventing illness as it may be for relieving symptoms of **stress**, injury, and illness.

Reflexologists work from maps of predefined pressure points that are located on the hands and feet. These pressure points are reputed to connect directly through the nervous system and to affect the bodily organs and glands. The reflexologist manipulates the pressure points according to specific techniques of reflexology therapy. By means of this touching therapy and the application of pressure at the respective foot or hand location, the reflexologist attempts to strengthen any part of the body that is the source of pain, illness, or potential debility.

Origins

Reflexology is a healing art of ancient origin. Although its origins are not well documented, it



Reflexology employs the principle that the reflex points on the feet, when hand pressure is applied, will reflexively stimulate energy to a related muscle or organ in the body and promote healing. *(Illustration by GGS Information Services. Cengage Learning, Gale)*

dates to 4,000-plus years ago. Evidence of this exists in reliefs found on the walls of a Sixth Dynasty Egyptian tomb (c. 2450 B.C.) that depict two seated men receiving massage on their hands and feet. From Egypt, the practice may have entered the Western world during the conquests of the Roman Empire. The concepts of reflexology have also been traced to pre-dynastic China (possibly as early as 3000 B.C.) and to ancient Indian medicine. In addition, the Inca civilization may have subscribed to the theories of reflexology and passed on the practice of this treatment to the Native Americans in the territories that eventually became parts of the United States.

In modern times, Sir Henry Head first investigated the concepts underlying reflexology in England in the 1890s. Therapists in Germany and Russia were researching similar notions at approximately the same time, although with a different focus. Less than two decades later, the physician William H. Fitzgerald presented a similar concept that he called zone analgesia or zone therapy. Fitzgerald's zone analgesia was a method of relieving pain through the application of pressure to specific locations throughout the entire body. Fitzgerald divided the body into 10 vertical zones, five on each side, that extended from the head to the fingertips and toes, and from front to back. Every aspect of the human body appears in one of these 10 zones, and each zone has a reflex area on the hands and feet. Fitzgerald and his colleague, Edwin Bowers, demonstrated that by applying pressure on one area of the body, they could anesthetize or reduce pain in a corresponding part. In 1917, Fitzgerald and Bowers published *Relieving Pain at Home*, an explanation of zone therapy.

In the 1930s, the physical therapist Eunice D. Ingham explored the direction of the therapy and made the startling discovery that pressure points on the human foot were situated in a mirror image of the corresponding organs of the body with which the respective pressure points were associated. Ingham documented her findings, which formed the basis of reflexology, in *Stories the Feet Can Tell*, published in 1938. Although Ingham's work in reflexology was inaccurately described as zone therapy by some, there are differences between the two therapies of pressure analgesia. Among the more marked differences, reflexology defines a precise correlation between pressure points and afflicted areas of the body. Furthermore, Ingham divided each foot and hand into 12 respective pressure zones, in contrast to the 10 vertical divisions that encompass the entire body in Fitzgerald's zone therapy.

In 1968 two siblings, Dwight Byers and Eusebia Messenger, established the National Institute of Reflexology. By the early 1970s the institute had grown and was renamed the International Institute of Reflexology.

Reflexology foot massage. *(© Niall McDiarmid / Alamy)*

Benefits

Reflexology promotes healing by stimulating the nerves in the body and encouraging the flow of blood. In the process, reflexology not only quells the sensation of pain but relieves the source of the pain as well.

Anecdotally, reflexologists claim success in the treatment of a variety of conditions and injuries. One condition is **fibromyalgia**. People with this disease are encouraged to undergo reflexology therapy to alleviate any of a number of chronic bowel syndromes associated with the condition. Frequent brief sessions of reflexology therapy are also recommended as an alternative to drug therapy for controlling the muscle pain related to fibromyalgia and for relieving difficult breathing caused by tightness in the muscles of the patient's neck and throat.

EUNICE D. INGHAM (1889–1974)

Eunice D. Ingham was born on February 24, 1889. A physical therapist by occupation, she was a colleague of Dr. Shelby Riley, who along with Dr. W. H. Fitzgerald actively developed zone therapy, a similar but distinct therapy from reflexology. Unlike reflexology, zone therapy does not connect the zones with the body as a whole. In the 1930s, Ingham discovered an unmistakable pattern of reflexes on the human foot; she subsequently devoted the rest of her life to publicizing the message of reflexology until shortly before her death on December 10, 1974.

Ingham traveled and lectured widely about reflexology, initially to audiences of extremely desperate or aging patients who had lost hope in finding relief. Because of their sometimes astonishing improvement, reflexology became better known and respected among the medical community and gained credibility for its therapeutic value. Ingham described her theories of reflexology in her 1938 book, entitled *Stories the Feet Can Tell*, which included a map of the reflex points on the feet and the organs that they parallel. The book was translated into seven languages, although it was erroneously published as *Zone Therapy* in some countries, an error which led to misunderstanding about the true nature of reflexology and inaccurately linked it to zone therapy.

Practitioners claim that when applied properly, reflexology can alleviate allergy symptoms, as well as stress, back pain, and chronic **fatigue**. The techniques of reflexology can be performed conveniently on the hand in situations in which a session on the feet is not practical, although practitioners consider the effectiveness of limited hand therapy to be less pronounced than with the foot pressure therapy.

Description

In a typical reflexology treatment, the therapist and patient engage in a preliminary discussion prior to therapy to enable the therapist to focus more accurately on the patient's specific complaints and to determine the appropriate pressure points for treatment.

A reflexology session involves pressure treatment that is most commonly administered in foot therapy sessions of approximately 40 to 45 minutes in duration. The foot therapy may be followed by a brief 15-minute hand therapy session. No artificial devices or special equipment are associated with this therapy. The human hand is the primary tool used in reflexology. The therapist applies controlled pressure with the thumb and forefinger, generally working toward the heel of the foot or the outer palm of the hand. Most reflexologists apply pressure with their thumbs bent; however, some also use simple implements, such as the eraser end of a pencil. Reflexology therapy is not massage, and it is not a substitute for medical treatment.

Reflexology is a complex system that identifies and addresses the mass of 7,000 nerve endings that are contained in the foot. Additional reflexology addresses the nerves that are located in the hand. This completely natural therapy is used to afford relief without the use of drugs.

Preparations

In order to realize maximum benefit from a reflexology session, the therapist as well as the patient should be situated so as to afford optimal comfort for both. Patients in general receive treatment in a reclining position, with the therapist positioned as necessary—to work on bare feet or on bare hands.

A reflexology patient removes both shoes and socks in order to receive treatment. No other preparation is involved. No prescription drugs, creams, oils, or lotions are used on the skin.

Precautions

Reflexology is completely safe. It may even be self-administered in a limited form whenever desired. The qualified reflexologist offers a clear and open disclaimer that reflexology does not constitute medical treatment in any form, nor is reflexology given as a substitute for medical advice or treatment. The ultimate purpose of the therapy is to promote wellness; fundamentally it is a form of preventive therapy.

People with serious and long-term medical problems are urged to seek the advice of a physician. Diabetes patients in particular are urged to approach this therapy cautiously. Likewise pregnant women are cautioned emphatically to avoid reflexology during the early phases of **pregnancy** altogether, as accidentally induced labor and subsequent premature delivery can result from reflexology treatment.

A consultation with a reflexologist is recommended in order to determine the safety and appropriateness of reflexology therapy for a specific health problem or condition.

Side effects

Because reflexology is intended to normalize the body functions, the therapy does not cause a condition to worsen. Most patients find that pain diminishes over the course of the therapy. It has been noted, however, that some patients experience greater discomfort in the second session than in the first session because a significant easing of pain and tension is generally associated with the initial therapy session. As a result, when pressure is reapplied to the tender points of the foot during the second session, the sensitivity has been heightened. This increase in sensitivity may cause minor additional discomfort for the patient.

Research and general acceptance

Reflexology is practiced worldwide at different levels of medical care. The Association of Reflexologists lists nearly six dozen professional organizations worldwide from the United States to the Japan, and from Ireland to India. These associations include:

- Academy of Reflexology Austria
- Reflexology Association of British Columbia
- China Reflexology Association
- Danish Reflexologists Association
- Holistic Association of Reflexologists Japan
- Polish Instytut of Reflexology (Polish language)
- Association of Reflexology Portugal
- South African Reflexology Society
- British Reflexology Association
- Reflexology Association of America

Several studies and/or reports have indicated the reflexology is effective in treating pain associated with child birth, **cancer**, and **multiple sclerosis**; in treating so-called "mousearm" arising from extended use of a computer mouse; and in treating back pain. Additional research, however, is necessary.

Regulatory status

Ongoing legislative debate ensued during the 1990s regarding the legal status of the reflexology trade. The reflexology community, along with legislators and other bodywork practitioners, engaged in reassessment of the reflexology business and its relationship to **massage therapy** and massage parlors. Organizations and individuals brought judicial appeals of certain court cases that threatened the legitimate licensing of reflexologists as practitioners of alternative medicine. Such professional reflexology interests as the RAA documented in detail the disparities between reflexology and massage, citing the purpose of reflexology, which is to stimulate internal body functions (glands and organs) as opposed to the topical muscular and joint relief associated with massage. In a status update in 1998 the association reported that 19 states had laws requiring the licensing of massage/reflexology therapists. Licensing laws established educational requirements and required candidates to pass written, oral, and/or practical examinations.

Also at issue was a trend among municipalities to license massage parlors (and reflexologists) under the business codes affecting adult entertainment business. B. Kunz and K. Kunz reported that judicial decisions in two states—Tennessee and New Mexico—had excluded the practice of reflexology practice from the laws pertaining to massage parlors. Those courts held that reflexology is a business separate and distinct from massage parlors and deserving of its own respective licensing standards. In Sacramento, California, reflexologists petitioned successfully to become licensed as practitioners of somatic therapy rather than as providers of adult entertainment. Likewise, in the Canadian province of Ontario, a nonprofit organization to register reflexology practitioners was established in order to define a distinct classification for therapists separate from erotic body rubbers, which was the original classification given to reflexologists. Work to legitimize reflexology was continuing as of 2008.

Training and certification

Reflexology is taught in seminars, classes, and training films. In the United States, certification is earned after students meet national standards for skill and knowledge by taking and passing an examination that has written, practical, and documentation components. The documentation component of the certification exam is the performance of reflexology sessions on clients. The exam is prepared by the independently organized American Reflexology Certification Board (ARCB), which certifies the competency of reflexology practitioners on an individual basis. To prepare for the exam, students frequently enroll in reflexology programs, but it lieu of that, the ARCB recommends the following:

- 40 hours of reflexology history, theory
- 55 hours of anatomy and physiology

KEY TERMS

Pressure points—Specific locations on the feet and hands that correspond to nerve endings. Pressure on these locations are used to connect to and affect the organs and glands of the human body via the spinal cord.

Zone therapy—Also called zone analgesia, a method of relieving pain by applying pressure to specific points on the body. It was developed in the early 20th century by William Fitzgerald.

- five hours of business ethics and standards
- 10 hours of supervised practicum

In addition, the ARCB makes a study guide available to students who apply for and are accepted for testing with the exam.

Individuals can only legally practice reflexology in the United States by abiding by any and all state, city, and county laws and regulations. According to the ARCB, only North Dakota and Tennessee had reflexology state-level laws regulating reflexology as of early 2008. The ARCB noted that other states had statewide massage laws that may refer to reflexology.

Once individuals are certified, they must pay an annual fee to the ARCB and obtain continuing education in the amount of 12 hours every two years to maintain the certification. If certification lapses in annual fee or continuing education for a certain period of time, they must retake the written and practical exams.

Reiki

Definition

Reiki is a form of therapy that uses simple hands-on, no-touch, and visualization techniques, with the goal of improving the flow of life energy in a person. Reiki (pronounced *ray-key*) means "universal life energy" in Japanese, and Reiki practitioners are trained to detect and alleviate problems of energy flow on the physical, emotional, and spiritual level. Reiki touch therapy is used in much the same way to achieve similar effects that traditional **massage therapy** is used—to relieve **stress** and pain, and to improve the symptoms of various health conditions.

Origins

Reiki was developed in the mid–1800s by Dr. Mikao Usui, a Japanese scholar of religion. According to the story that has been passed down among reiki teachers, Usui was a Christian who was intrigued by the idea that Christ could heal sick people by touching them with his hands. Searching for clues that would explain the secrets of healing with hands, Usui made a long pilgrimage around the world, visiting many ancient religious sects and studying ancient books. Some reiki teachers claim that Usui found clues leading back nearly 10,000 years to healing arts that originated in ancient Tibet. During his intense studies, Usui claimed he had a spiritual experience, which enabled him to heal with his own hands by becoming aware of and tapping into the universal life force. After that, he dedicated his life to helping the sick and poor. His reputation grew as he healed sick people for many years in Kyoto, Japan. Before his death, Usui passed on his healing insights using universal life energy to Dr. Chujiru Hayashi, a close acquaintance. Hayashi, in turn, passed on the healing techniques in 1938 to Hawayo Takata, a Japanese woman from Hawaii, whom he had cured of life-threatening illness using reiki methods. Takata became a firm believer and proponent of reiki, and during the 1970s formed an initiation

program for training reiki masters to preserve Usui's teachings. Before she died, she prepared her granddaughter, Phyllis Lei Furumoto, to continue the lineage. Takata had personally trained 21 practitioners before she died at the age of 80 in 1980. Along with other reiki masters authorized by Takata, Furumoto formed the reiki Alliance. A faction led by Barbara Ray formed the American Reiki Association, which was known as Radiance Technique Association International. Today, there are over 1,000 reiki masters practicing around the world, whose methods can all be traced back directly to Dr. Usui.

KEY TERMS

Attunement—Life energy teaching given by a Reiki master to a student.

Chakra—One of seven major energy centers in the body, as defined by Hindu and yoga philosophy.

Relaxation response—The body's response to relaxation techniques,during which metabolism and stress levels decrease and immune response increases.

Benefits

Reiki claims to provide many of the same benefits as traditional massage therapy, such as reducing stress, stimulating the immune system, increasing energy, and relieving the **pain** and symptoms of health conditions. Practitioners have reported success in helping patients with acute and chronic illnesses, from **asthma** and arthritis to trauma and recovery from surgery. Reiki is a gentle and safe technique, and has been used successfully in some hospitals. It has been found to be very calming and reassuring for those suffering from severe or fatal conditions. Reiki can been used by doctors, nurses, psychologists and other health professionals to bring touch and deeper caring into their healing practices.

Description

The basic philosophy of reiki

The basic concept underlying reiki is that the body has an energy field that is central to its health and proper functioning, and this energy travels in certain pathways that can become blocked or weakened. This idea of energy flow in the body is also a central concept in Ayurvedic medicine and **traditional Chinese medicine**, including acupuncture.

Reiki practitioners believe that everyone has the potential to access the universal life energy, but that over time most people's systems become blocked and the energy becomes weakened in them. A reiki practitioner is trained to be able to detect these blockages, and practitioners will use their hands, thoughts, and own energy fields to improve the energy flow in a patient. Reiki is one of the more esoteric alternative medical practices, because no one is sure exactly how it works on the physiological level. Practitioners claim that it works on very subtle energy levels, or possibly works on the *chakra* system. The chakras are the system of seven energy centers along the middle of the body believed to be connected with the nervous and endocrine systems, as defined by **yoga** and Ayurvedic medicine. Reiki masters claim that healing energy can even be sent to a person from far away, noting that reiki works on the same principles that enables praying to work for some patients, although a practitioner needs advanced training to be able to send energy from afar.

According to the original principles of Usui, patients must also have a proper attitude for reiki to work most effectively. Patients must take responsibility for their own health, and must want to be healed. Furthermore, when energy is received from a reiki healer, patients must be willing to give back energy to others, and to compensate the healer in some way, as well. Finally, Usui claimed that a healing attitude was free from worry and fear, was filled with gratitude for life and for others, and placed emphasis on each person finding honest and meaningful work in their lives—all this, in order to complete the picture of overall health.

A reiki session

Reiki sessions can take various forms, but most commonly resemble typical bodywork appointments, where the receiver lies clothed on his or her back on a flat surface or massage table. A session generally lasts from an hour to an hour and a half. Reiki is a simple procedure, consisting of calm and concentrated touching, with the practitioner focusing on healing and giving energy to specific areas on the receiver's body. Practitioners place their hands over positions on the body where the organs and endocrine glands reside, and the areas that correspond to the chakra centers. Practitioners also use mental visualization to send healing energy to areas of the receiver's body that need it. In special cases or with injuries, a no-touch technique is used, in which the practitioner's hands are sometimes held just above the body without touching

it. Advanced practitioners rely on intuition and experience to determine which areas of a body need the most energy healing.

The practitioner's hands are held flat against the receiver's body, with the fingertips touching. There can be over 20 positions on both sides of the body where the hands are placed. The positions begin at the crown of the head and move towards the feet. The receiver usually turns over once during the session. The practitioner's hands are held in each position for a usually five minutes, to allow the transfer of energy and the healing process to take place. In each position, the hands are kept stationary, unlike typical massage where the hands move, and both the giver and receiver attempt to maintain an attitude of awareness, openness, and caring.

Reiki practitioners recommend that those receiving reiki for the first time go through a series of three to four initial treatments over the course of about a week, to allow for cleansing and the initial readjustment of energy. Reiki sessions can cost from $30–100 per session. Insurance coverage is rare, and consumers should consult their individual policies as to whether or not such therapies are included.

Self-treatment with reiki

Although reiki practitioners believe that formal training is necessary to learn the proper methods of energy channeling and healing, individuals can still use some of the basic positions of reiki to relieve stress and to stimulate healing on themselves or another. The positions can be performed anywhere and for however long they are needed. Positions generally move from the top of the body down, but positions can be used wherever there is pain or stress. Mental attitude is important during reiki; the mind should be cleared of all stressful thoughts and concentrated on compassion, love, and peace as forms of energy that are surrounding, entering, and healing the body.

The following positions are illustrated in *Reiki: Energy Medicine:*

- Position one: Hands are placed on the top of the head, with the wrists near the ears and the fingertips touching on the crown of the head. Eyes should be closed. Hold for five minutes or more, until the mind feels clear and calm.
- Position two: Cup the hands slightly and place the palms over the closed eyes, with the fingers resting on the forehead.
- Position three: Place the hands on the sides of the head, with the thumbs behind the ear and the palms over the lower jaws, with the fingers covering the temples.
- Position four: Place one hand on the back of the neck, at the base of the skull, and put the other hand on the head just above it, parallel to it.
- Position five: Wrap the hands around the front of the throat, and rest them there gently with the heels of the hands touching in front.
- Position six: Place each hand on top of a shoulder, close to the side of neck, on top of the trapezius muscle.
- Position seven: Form a T-shape with the hands over the chest, with the left hand covering the heart and the right hand above it, covering the upper part of the chest.
- Position eight: The hands are placed flat against the front of the body with fingertips touching. Hold for five minutes or so, and repeat four or five times, moving down a hand-width each time until the pelvic region is reached, which is covered with a v-shape of the hands. Then, for the final position, repeat this technique on the back, beginning as close to the shoulders as the hands can reach, and ending by forming a T-shape with the hands at the base of the spine.

Side effects

Reiki generally has no side effects, as it is a very low-impact and gentle procedure. Some receivers report feeling tingling or sensations of heat or cold during treatment. Others have reported sadness or anxiety during treatment, which practitioners claim are buried or repressed emotions being released by the new energy flow.

Research and general acceptance

Reiki has been used in major clinics and hospitals as part of alternative healing practice, and doctors, dentists, nurses, and other health professionals have been trained to use its gentle touch techniques as part of their practice. It appears to offer particular benefits to special-care patients and their caregivers. Reiki has also become increasingly popular among veterinarians in small-animal practices for treating behavioral disorders as well as physical illnesses in dogs and cats. To date, the little scientific research that has been conducted with reiki implies that its techniques bring about the *relaxation response*, in which stress levels decrease, and immune response increases. Reiki practitioners claim that the most important measurement of their technique is whether the individual feels better after treatment. They also claim that science cannot measure the subtle energy changes that they are attempting to make.

MIKAO USUI (1865–1926)

Mikao Usui, born in the Gifu Prefecture (Japan), was an ethereal child who sought to unravel the mysteries of the universe. As an adult he developed an interest in the meta physical healing talent of Buddha. Usui became determined to regenerate the healing secrets of Buddha in order to improve the lot of humanity. He traveled to many temples and spoke with holy people, but all said that the secret of Buddha's powers were lost to the world due to lack of use.

Eventually the abbot of a Zen monastery encouraged Usui to study the ancient writings containing the secrets on healing. Usui learned two new languages, Chinese and Sanskrit, in order to understand the writings better, and from his reading he obtained the formula for healing. The Sutras in particular provided the enlightenment that he sought.

Usui next set out to obtain the power to heal. It is widely believed that he developed that ability after spend ing 21 days in retreat and in fasting on the holy Mountain of Kori yama, where he had a vision of light and received the knowledge of the symbols of reiki and their use in healing. He officially formulated Usui Reiki therapy in 1922 and touted as many as one million followers during his lifetime.

Prior to the transition (death) of Usui, he imparted the secrets of healing to 16 teachers in order that the secrets would not be lost again.

Training and certification

Reiki practitioners undergo a series of *attunements*, which are sessions with reiki masters that teach the basic methods of energy healing. Several organizations provide resources for reiki training. Reiki practitioners believe these attunements are necessary for correct technique. The masters teach each person how to activate the universal life energy in themselves before they can pass it on to others. These initiations often are held during weekend workshops. Trainees can achieve up to four levels of attunements, until they reach the level of master themselves. The certification process is not a formal one; masters approve students when they feel satisfied with their progress.

Reishi mushroom

Description

Reishi mushrooms are some of the most widely used medicinal mushrooms in the world. Their scientific name is *Ganoderma lucidum*. In Chinese medicine, reishi mushrooms are known as *ling zhi*, which means spiritual plant as the Chinese believe the herb is healing for the spirit. Some Asians make good luck charms from the mushrooms in addition to using them as medicine.

The Latin name *Ganoderma* means shiny skin, which describes the reddish brown caps of the mushrooms. Reishi mushrooms are kidney-shaped and grow to 8 in (20 cm) or more in diameter. They grow in moist and temperate forest areas of Asia, Europe, South America, and the United States. Reishi mushrooms typically attach themselves to trees, particularly **oak** and plum trees.

Reishi mushrooms have a long history. They have been used in China and Japan for nearly 4,000 years as a

Reishi mushroom. *(© blickwinkel / Alamy)*

KEY TERMS

Antioxidant—An enzyme or other organic substance that is able to counteract the damaging effects of oxidation in living tissue.

Bronchitis—An infection in the lungs.

Chronic—Referring to a disease or condition that is severe and occurring over a long period of time.

Hepatitis—A viral infection of the liver.

health tonic and as folk medicine for liver problems, heart conditions, **asthma**, **cancer**, high blood pressure, and arthritis. In **Traditional Chinese medicine**, reishi mushrooms are classified in a group of herbs known as *Fu Zheng*, which Chinese herbalists believe are the most powerful herbs for all-around strength, health, and longevity. Other Fu Zheng herbs include **Korean ginseng** and **astragalus**. Reishi mushrooms have been rare and expensive for most of their history because they are difficult to cultivate and find in the wild. In the 1980s, a Japanese man named Shigeaki Mori developed an intricate and effective method of cultivating them, which has made them widely available and affordable.

Reishi mushrooms have been well researched and tested, mostly in China and Japan. Scientists have isolated several chemicals in them that have pharmacological (medicinal) effects on the body. Reishi mushrooms contain compounds called polysaccharides, which have been shown to help the body fight cancerous tumors and also stimulate the immune system to combat **infections** and viruses. In studies on mice, reishi mushrooms have shown very strong results against cancerous tumors. One Japanese study suggests that reishi mushrooms may serve as a chemopreventive against colon cancer.

Other substances called triterpenes have been found in reishi mushrooms and shown to lower blood pressure and improve circulation. Reishi mushrooms also contain sterols, which may influence the hormonal system; and natural antihistamines, which reduce allergic reactions and inflammation in the body. More recently, reishi mushrooms have been identified as a source of **antioxidants**, which are enzymes or other organic compounds that counteract the damaging effects of oxidation on human tissue.

In Asia, numerous clinical studies with humans have documented reishi mushrooms' healing properties. They have shown significant results in treating **hepatitis**, chronic **bronchitis**, asthma, and **heart disease**. Reishi mushrooms have also been shown to lower blood pressure, lower **cholesterol**, increase white blood cell count, reduce allergic reactions, and have a calming effect on the central nervous system when given to humans in observed studies.

General use

Reishi mushrooms are recommended as a general tonic for health, energy, and longevity. They are prescribed for diseases including coronary heart disease, cancer, and **AIDS**; and for such chronic infections as bronchitis, hepatitis, and **mononucleosis**. Reishi mushrooms are also used to treat high blood pressure, asthma, nervous disorders, **chronic fatigue syndrome**, and arthritis. In China, they are used by mountain climbers to combat altitude sickness and are given as an antidote to patients who have eaten poisonous mushrooms.

Preparations

Reishi mushrooms are available dried and as powder, tinctures, tablets, capsules, and syrup. Reishi products can be found in health food stores, herb stores, and Chinese markets. The recommended daily dosage varies with conditions. For severe conditions such as cancer, heart disease, and chronic infections, 9–15 g daily in three equally divided dosages is recommended. For a general health tonic and for less severe conditions of asthma, high blood pressure, infections, and nervous disorders, 2–6 g can be taken daily, in three equal portions.

Tea can be made from dried mushrooms or powder, and the recommended ratio is 2–5 g of dried mushroom per liter of water. The mixture should be simmered on low heat for more than two hours, to extract all the active ingredients. The tea can be drunk twice daily. For severe health conditions or for an antidote to mushroom poisoning, some herbalists recommend a strong reishi tea mixture, with up to 20 g of dried mushrooms per liter of water.

Precautions

People with **allergies** to molds or fungi should use care with reishi mushrooms, although allergic reactions to them are generally rare. Consumers should search for reishi products that are made by reputable manufacturers. Some dried mushrooms have been sold as Reishi mushrooms when they were actually similar mushrooms by the scientific names of *Ganoderma oregonense* and *Ganoderma tsugae*. These resemble reishi mushrooms in appearance and taste and are in the same genus, but according to herbalists have different and less-effective healing properties.

Side effects

In clinical studies, reishi mushrooms have been shown to be nontoxic in high doses, and severe side effects have not been observed. Mild side effects may include stomach upset, **dry mouth**, **diarrhea**, and skin rash, and generally disappear after several days. Side effects can be alleviated by stopping use, or in the case of stomach upset and diarrhea, taking the supplement with meals.

Interactions

For treating severe conditions, large doses of **vitamin C**, from 1–10 g per day, may be prescribed in conjunction with reishi mushrooms. Prescribing vitamin C has been observed to reduce the side effect of diarrhea that may occur with patients who are given large doses of reishi mushrooms.

Reishi mushrooms have been reported to intensify the effects of blood-thinning (anticoagulant) drugs, including aspirin, dalteparin **sodium**, enoxaparin sodium, and warfarin. Patients taking these medications should not use tonics or other preparations containing reishi mushrooms without consulting their physicians.

Relaxation

Definition

Relaxation therapy is a broad term used to describe a number of techniques that promote **stress** reduction, the elimination of tension throughout the body, and a calm and peaceful state of mind.

Origins

Relaxation therapy as a general tern includes various forms: transcendental **meditation** (TM), **yoga**, t'ai chi, **qigong**, and vipassana (a Buddhist form of meditation meaning insight and also known as mindfulness meditation). Progressive relaxation, a treatment that is designed to rid the body of **anxiety** and related tension through progressive relaxation of the muscle groups, was first described by Edmund Jacobson in his book *Progressive Relaxation*, published in 1929. In 1975, Herbert Benson published his groundbreaking work *The Relaxation Response*, which described in detail the stress-reduction mechanism in the body that short-circuits the "fight-or-flight" response and lowers blood pressure, relieves muscle tension, and controls heart rate. This work gave further credence and legitimacy to the link between mind and body medicine. A number of relaxation techniques used commonly in the

early 2000s, such as cue-controlled relaxation, are a direct result of Benson's work in this area.

Benefits

Stress and tension have been linked to numerous ailments, including **heart disease**, high blood pressure, **atherosclerosis**, **irritable bowel syndrome**, ulcers, anxiety disorders, **insomnia**, and **substance abuse**. Stress can also trigger a number of distinct physical symptoms, including **nausea**, **headache**, **hair loss**, **fatigue**, and muscle **pain**. Relaxation therapies have been shown to reduce the incidence and severity of stress-related diseases and disorders in many patients.

Description

A number of different relaxation methods are available. Some of the most widely taught and most frequently practiced by healthcare providers are progressive relaxation, cue-controlled relaxation, breathing exercises, **guided imagery**, and **biofeedback**.

Progressive relaxation

Progressive relaxation is performed by first tensing, and then relaxing, the muscles of the body, one group at a time. Muscle groups can be divided a number of different ways, but a common method is to use the following groupings: 1) Hands and arms; 2) head, neck, and shoulders; 3) torso, including chest, stomach and back; and 4) buttocks, thighs, lower legs, and feet. The patient lies or sits in a comfortable position and then starts with the first muscle group, focusing on the feeling of the muscles and the absence or presence of tension. The patient then tenses the first muscle in the group, holds the tension for approximately five seconds, and releases and relaxes for up to 30 seconds. The contrast allows the individual to notice difference between feelings of tension and those of relaxation. The procedure is repeated with the next muscle in the group and so on, until the first group is completed. The patient then starts on the next muscle group.

Progressive relaxation can be guided with verbal cues and scripts, either memorized by the patient or provided on instructional audiotapes. The procedure remains the same, but the individual is prompted on which muscles to flex and relax and given other cues about noticing the difference between the tense and relaxed state. Some individuals may prefer progressive relaxation that is prompted with a tape because it allows them to completely clear their minds and to just follow instructions.

Deep breathing exercises

Individuals under stress often experience fast, shallow breathing. This type of breathing, known as chest breathing, can lead to shortness of breath, increased muscle tension, and inadequate oxygenation of blood. Breathing exercises can both improve respiratory function and relieve stress and tension.

Before starting to learn breathing exercises, individuals should first become aware of their breathing patterns. This can be accomplished by placing one hand on the chest and one hand on the abdomen and observing which hand moves further during breathing. If it is the hand placed on the chest, then chest breathing is occurring, and breathing exercises may be beneficial.

Deep breathing exercises are best performed while lying flat on the back, usually on the floor with a mat. The knees are bent, and the body (particularly the mouth, nose, and face) is relaxed. One hand is placed on the chest and one on the abdomen to monitor breathing technique. The individual takes a series of long, deep breaths through the nose, attempting to raise the abdomen instead of the chest. Air is exhaled through the relaxed mouth. Deep breathing can be continued for up to 20 minutes. After the **exercise** is complete, the individual checks again for body tension and relaxation. Once deep breathing techniques have been mastered, an individual can use deep breathing at any time or place as a quick method of relieving tension.

Release-only relaxation

Like progressive relaxation, release-only relaxation focuses on relieving feelings of tension in the muscles. However, it eliminates the initial use of muscle tensing as practiced in progressive relaxation, focusing instead solely on muscle relaxation. Release-only relaxation is usually recommended as the next step in relaxation therapy after progressive relaxation has been mastered.

In release-only relaxation, breathing is used as a relaxation tool. The individual sits in a comfortable chair and begins to focus on breathing, envisioning tension leaving the body with each exhale. Once deep abdominal breathing is established, the individual begins to focus on releasing tension in each muscle group, until the entire body is completely relaxed.

Cue-controlled relaxation

Cue-controlled relaxation is an abbreviated tension-relief technique that combines elements of release-only relaxation and deep breathing exercises. It uses a cue,

such as a word or mental image, to trigger immediate feelings of muscle relaxation. The cue must first be associated with relaxation in the individual's mind. Individuals choose the cue and then use it in breathing and release-only relaxation exercises repeatedly until the cue starts to automatically trigger feelings of relaxation outside the treatment sessions. Cues can be as simple as a given word such as "one" and are frequently used on relaxation audiotapes. They can also be a visual cue, such as a mental image of a white sand beach, a flower-filled meadow, or clear blue sky. Guided imagery also uses visualization exercises to produce feelings of relaxation.

Guided imagery

Guided imagery is a two-part process. The first component involves reaching a state of deep relaxation through breathing and muscle relaxation techniques. During the relaxation phase, individuals close their eyes and focuses on the slow in and out of their breath. Instead, individuals might focus on releasing the feelings of tension from their muscles, starting with the toes and working up to the top of the head. Relaxation tapes often feature soft music or tranquil, natural sounds such as rolling waves and chirping birds in order to promote feelings of relaxation.

Once complete relaxation is achieved, the second component of the exercise is the imagery, or visualization, itself. Relaxation imagery involves conjuring up pleasant images that rest the mind and body. These may be past experiences or idealized new situations.
