The yellow rootstock is the main, known medicinal part of the herb. In cultivation, goldenseal requires up to four years growth before the rootstock is ready for harvest. The thick and knotty rhizome produces a hairy stem that grows to 2 ft (61 cm) high. Goldenseal has only two large leaves, each five-lobed with double-toothed edges growing atop a forked stem. Leaves are serrated at the top edges. A single flower with greenish-white sepals crowns the hairy stem. The fruit looks like a **raspberry**, hence one of the plant's common names. Pharmaceutical companies harvest goldenseal root in large quantities for use. The herb is fully endangered on extinction risk lists in the wild due to over-collection of the rhizome. An estimated 250,000 lbs (113,400 kg) of rootstock of this popular herbal remedy are sold each year, and most of this has been collected in the wild.

General use

The underground portion of the stem, called the rhizome, as well as the inner twig bark, are the medicinal part of this multiple-use native remedy. The goldenseal rhizome is rich in alkaloids: hydrastine, berberine, and canadine, in addition to other phytochemicals, oils, and resin. Goldenseal has been considered a cure-all medicinal herb because of its wide variety of medicinal applications. It is a bitter herb that is effective when taken internally to promote digestion. The herb is particularly helpful when used to treat inflammation and infection of the mucous membranes lining the upper respiratory tract, and the digestive and genitourinary tract. Its anti-bacterial properties improve all catarrhal conditions, and it is helpful against amoebic infection. Goldenseal potentiates insulin and stimulates liver, kidney, and lung function. The astringent herb may also be used to help control bleeding, so it is helpful in circumstances of excessive and painful **menstruation** or postpartum hemorrhage. It is antiseptic, diuretic, and acts as a mild laxative and internal body cleanser. Goldenseal is used in treatment of peptic ulcers, and stimulates the flow of bile. Applied externally as rhizome bark powder or tincture, the herbal preparations can help treat **gum disease**, vaginal infection, **eczema**, **impetigo**, **conjunctivitis**, inflammations of the ear, and possibly ringworm. Its diuretic and anti-inflammatory effects can help lower blood pressure. The berberine alkaloid in goldenseal stimulates uterine contractions, and the herb is useful to treat **pelvic inflammatory disease** (PID). Goldenseal is high in **iron**, **manganese**, silicon, and other minerals. Goldenseal was once considered a good substitute for quinine. The herb has been used as a remedy for diphtheria, **tonsillitis**, chronic catarrh of the intestines, typhoid **fever**, **gonorrhea**, leucorrea, and **syphilis**. It is no wonder that with all these medicinal benefits, this herb is disappearing in the wild.

Preparations

The rootstock of goldenseal, harvested in spring or fall in the third or fourth year of growth, can be used in decoction, liquid extract, tablet, and tincture. When purchasing commercially prepared remedies, avoid the wild-crafted sources to help protect this valuable herb in its wild habitat.

To prepare an eyewash of goldenseal, mix equal parts of powdered rootstock and boric acid with boiling hot water. Stir well and allow to cool. Strain the mixture and store in a dark glass container. For one dosage, retrieve 1 tsp of the resulting liquid per 1/2c water as a soothing eyewash solution. It is important to keep all equipment totally sterile, apply with a sterilized eyedropper, and discard old liquid eyewash (over 1–2 days).

For an infusion, use 1 tsp of powdered rootstock to a pint of boiling water. Let stand until cold. Dosage is 1–2 tsp, three to six times per day, for up to seven days. The infusion may also be used as a gargle.

To prepare a tincture, combine one part fresh herb to three parts alcohol (50% alcohol/water solution) in glass container. Set aside in dark place. Shake daily for two weeks. Strain through muslin or cheesecloth, and store in dark bottle. The tincture should maintain potency for two years. Standard dosage, unless otherwise prescribed, is 1 tsp, three times daily, for short periods (1–2 weeks).

To make capsules, pulverize the dried root into a fine powder. Place in gelatin capsules. Dosage is two capsules, three times daily for three weeks, then discontinue for the next three weeks.

Precautions

Pregnant and breastfeeding women should not use this herb as it may stimulate uterine contraction. Patients with high blood pressure should also avoid goldenseal. The herb should be taken only for very limited periods, as it builds up in the mucosa of the system and its strong alkaloids are neurotoxic over an extended time (i.e., several months of daily use). Three weeks on and three weeks off is a good routine for dosage. Do not eat the plant fresh, as it can irritate mucous tissues.

Side effects

Goldenseal use can destroy organisms that are beneficial to the body, as well as those that are pathological. It should be used only for limited periods of time.

Interactions

Goldenseal is often combined with other herbs in preparations. **Myrrh** gum (*Commiphora myrrha*) and **echinacea** (*Echinacea augustifolia*) extract may be added to goldenseal in salve preparations. Goldenseal combines well with **mullein** (*Verbascum thapus*) for **earache**, and with **chamomile** (*Matricaria chamomilla*) and meadowsweet (*Filipendula ulmaria*) for stomach aches. Combine in infusion with **gotu kola** (*Centella asiatica*) for a brain tonic.

Gonorrhea

Definition

Gonorrhea is a highly contagious sexually transmitted disease (STD) caused by the *Neisseria gonorrhoeae* bacterium. The genitourinary tract is the main system that is usually affected, but gonorrhea can also spread to the rectum, the throat, and the eyes. Left untreated, gonorrhea can spread through the bloodstream and infect the brain, heart valves, joints, and the reproductive system. Exposure to an infected mother during birth may cause permanent blindness in the newborn.

Description

Gonorrhea, commonly referred to as "the clap," is the second most prevalent reportable disease in the United States. Adolescents and young adults are in

the highest risk category, with more than 80% of gonorrhea cases affecting the 15–29 year-old age group. Individuals living in urban areas who have multiple sex partners have the highest risk of contracting the disease. Still, the incidence of gonorrhea steadily declined after 1987. This trend appeared to be largely due to increased public awareness about the risks and prevention of contracting STDs such as herpes and HIV. However, in a report on sexually transmitted diseases (2007), the Centers for Disease Control (CDC) expressed concern about rising rates of gonorrhea in certain urban areas during preceding years. The CDC reported that 358,366 new cases of gonorrhea were diagnosed in 2006. Experts believe that the true number of cases of gonorrhea is much greater than this number, however, because many people do not see a health specialist for treatment of the disease.

Causes and symptoms

Gonorrhea is transmitted efficiently. It can be spread merely by coming into contact with the fluids of an infected person as well as by sexual contact. A person runs a 60–90% chance of contracting the disease after just one sexual encounter with an infected person. The symptoms usually begin between one day and two weeks after the initial encounter with the infection.

People who are infected with gonorrhea commonly experience increasingly frequent and painful urination, and the urethra may be painful and swollen. There may be a thick white, yellowish, or bloody discharge from the penis or vagina. Other symptoms may include **nausea**, **vomiting**, **fever**, **chills**, and **pain** during intercourse. In the case of oral infection, there may be a **sore throat** or pain during swallowing. An anal infection may cause rectal **itching**, rectal discharge, and a constant urge to move the bowels. Women who show symptoms of gonorrhea often have abdominal pain and breakthrough bleeding (spotting) between menstrual periods. However, many women who have gonorrhea experience no symptoms.

In infants and children, irritation, redness, swelling with a pus-like discharge, and possibly pain and a change in urination may point to a gonorrhea infection. The infection may be due to child abuse or exposure to infected materials. An in-depth history should be taken if gonorrhea is suspected.

Diagnosis

The initial diagnosis of gonorrhea is based on symptoms, sexual history, and at-risk behavior. One laboratory test for diagnosis involves the observation of a gram-stained sample of the discharge under a microscope. In the gram stain test, the sample is dyed, washed with various solutions, and dyed with a different color. The final color identifies the class of bacteria present in the sample. The advantage of this test is that results can be obtained very quickly so that treatment can commence at the initial visit. In the vast majority of men, it is quite accurate; however, the test is not very accurate for women.

For all women and for men with a questionable gram-stain reading, samples of the discharge from the infected area can be collected and cultured. The sample is incubated for up to two days, which provides enough time for the bacteria to multiply and be accurately identified. This test is highly accurate and specific for gonorrhea, but improper handling can lead to a false-negative reading. Other tests that are also used include the ELISA (enzyme-linked immunosorbent assay) antibody test and DNA probe testing of genetic material from the discharge, both of which are quite accurate in identifying *Neisseria gonorrhoeae*.

Treatment

Although there is nothing that can totally replace antibiotics in the treatment of gonorrhea, certain herbs and minerals may be used to supplement the treatment. These may be used to improve the body's immune function: **zinc**, multivitamins and mineral complexes, **vitamin C**, and **garlic** (*Allium sativum*). *Lactobacillus acidophilus* in supplements and live-culture yogurts help replenish gastrointestinal flora that may be destroyed by the intake of antibiotics.

Several herbs may reduce symptoms and help speed healing. These include **kelp** (*Macrocystis pyrifera* and related species), *Calendula officinalis*, **myrrh** (*Commiphora molmol*), and *Thuja occidentalis*. These herbs can be taken by the mouth or used as a douche. The Chinese herb *Coptis chinensis*, used for damp-heat **infections**, is helpful in treating the genitourinary tract, especially if **pelvic inflammatory disease** (PID) develops. An herbalist should be consulted to make recommendations for further complications. Some recommend a three-day cleansing fast to quicken and support healing. **Fasting** should be done only with the approval and supervision of a physician. Referral to an acupuncturist is also recommended, as there may be **acupressure** and **acupuncture** points that will help with system cleansing.

Allopathic treatment

For many years, the most effective treatment for gonorrhea was one of two antibiotics: penicillin, or one

of its derivatives, and tetracycline. Over time, the *Neisseria gonorrhoeae* bacterium became significantly more resistant to these drugs, and other treatments were developed. In the late 2000s the most popular of those treatments were two broad-spectrum cephalosporins (ceftriaxone and cefixime), and three fluoroquinolones (ciprofloxacin, ofloxacin, and levofloxacin). In its 2006 report on drug-resistant gonorrhea, the CDC reported that approximately 15% of all cases of gonorrhea are resistant to treatment by penicillin and tetracycline, and new **strains** of the bacterium resistant to the fluoroquinolones have also begun to develop. The treatment of gonorrhea continued to be an on-going challenge for researchers and medical workers.

Since other STDs, such as **chlamydia** and **syphilis**, often occur with gonorrhea, patients may also be tested and treated for these related infections. Patients should refrain from sexual intercourse until treatment is complete and should return for follow-up testing. Anyone with whom the patient has had sexual contact during the time of infection should be notified and treated, even if those persons do not show symptoms. Doctors are required to report this disease to public health officials.

More than one healthcare provider may have to be consulted. Physicians trained in obstetrics or gynecology may be involved if gynecological complications occur. Men who experience complications may be referred to a urologist. There are also infectious disease doctors who specialize in the treatment of STDs.

Expected results

The prognosis for patients with gonorrhea varies based on how early the disease is detected and treated. Patients who are treated early and properly can be entirely cured of the disease. The most common complication is pelvic inflammatory disease (PID). PID can occur in up to 40% of women with gonorrhea and may result in damage to the fallopian tubes, an ectopic **pregnancy**, or sterility. If an infected woman is pregnant, gonorrhea can be passed on to the eyes of the newborn during delivery, which can lead to infection and blindness.

Although the risk of **infertility** due to gonorrhea is higher in women than in men, men may also become sterile if urethritis (inflammation of the urethra) develops. Complications of gonorrhea can affect the prostate, testicles, and surrounding glands as well. In either gender, inflammation, abscesses, and scarring can occur. In approximately 2% of patients with untreated gonorrhea, the infection may spread throughout the body and can cause fever, arthritis-like joint pain, and skin lesions.

KEY TERMS

Chlamydia—The most common bacterial sexually transmitted disease in the United States.

Ectopic pregnancy—A pregnancy that occurs outside the uterus, often in the fallopian tubes. The fetus will not survive, and in some cases, the pregnancy can result in the death of the mother.

False-negative—A laboratory result that does not detect the presence of a disease that is actually present.

Pelvic inflammatory disease (PID)—An infection of the upper genital tract.

Sexually transmitted diseases (STDs)—A group of diseases that are transmitted by sexual contact. In addition to gonorrhea, this group generally includes chlamydia, HIV (AIDS), genital herpes, genital warts, and syphilis.

Urethra—The canal leading from the bladder, and in men, also a path for semen.

Urethritis—Inflammation of the urethra.

Prevention

As of 2008, there was no vaccine for gonorrhea. The best prevention is to abstain from having sex or to engage in sex only when in a monogamous relationship in which both partners have been tested for STDs. The next line of defense against gonorrhea is the use of condoms, which have been shown to be highly effective in preventing this disease. The use of a diaphragm can also reduce the risk of infection. Since the risk of contracting gonorrhea increases with the number of sexual partners, those who have sexual contact with more than one partner are advised to be tested regularly for gonorrhea and other STDs.

Gotu kola

Description

Gotu kola (*Centella asiatica*) is a member of the Apiaceae carrot family. It is also called pennywort, marsh penny, water pennywort, and sheep rot. The name sheep rot comes from the erroneous belief in Europe that gotu kola caused foot rot in sheep. Gotu kola is often mistaken for the **kola nut** plant (*Cola nitida*). However, the two are not related and gotu kola, unlike the kola nut, contains no **caffeine**. Gotu kola is noted in India as a very powerful spiritual herb, and **Ayurvedic medicine** refers to it as *Brahmi* because it helps obtain knowledge of the spiritual being.

Gotu kola, a perennial, grows in India, Sri Lanka, Madagascar, South Africa, China, Indonesia, Australia, and North America. It can grow like a weed, but its description depends on its location. For example, in shallow water, the leaves float; but in dry areas, the plant develops many roots and thin, tiny leaves. The fan-shaped leaves may be smooth or lobed. Red flowers turn into fruit with a diameter of about 0.2 in (5 mm).

Gotu kola's main active components are triterpenoids, although the gotu kola found in India, Sri Lanka, and Madagascar does not have the same properties. Gotu kola's triterpenes can have a concentration from 1.1-8%, with most concentrations in the middle range.

Gotu kola from Madagascar is used for most standardized extracts, and its four main triterpene properties are:

- asiatic acid (29-30%)
- madecassic acid (29-30%)
- asiaticoside (40%)
- madecassoside (1-2%)

Gotu kola also contains the following:

- volatile oil of a terpene acetate (36% of all the volatile oil)
- camphor
- cineole
- glycerides of some fatty acids
- plant sterols (campesterol, stigmasterol, sitosterol)
- polyacetylene compounds
- flavonoids (kampferol, quercetin)
- myo-inositol (glycoside from the flavonoids)
- sugars
- vellarin
- amino acids
- resins

General use

Traditional use of gotu kola in India and Indonesia included wound treatment. In the 1800s, it became part of Indian medicine practice and was used to treat many skin conditions including leprosy, varicose ulcers, and **eczema**, as well as **fever**, **diarrhea**, and absence of menses.

Chinese medicine uses various parts of the plant. The leaves are used for leukorrhea and fevers that are toxic, while other types of fevers and **boils** are treated with gotu kola shoots. Gotu kola used for longevity has become very popular. Chinese herbalist, Li Ching Yun, is supposed to have lived 256 years from drinking a herbal mixture containing gotu kola. An ancient Sinhalese saying, "Two leaves a day will keep old age

Gotu kola. *(©PlantaPhile, Germany. Reproduced by permission.)*

away," also illustrates gotu kola's popularity as an agent for longevity.

The plant enhances brain and peripheral circulation, and is said to enhance memory. In the 1880s, the French began using gotu kola as part of regular pharmaceutical medicines.

Many current uses are similar to traditional uses of the plant. In a 1992 study at Kasturba Medical College, researchers fed rats gotu kola extract. After 14 days, the gotu kola-treated rats showed 3-60 times better retention of learned behavior than did rats who did not receive the extract.

Gotu kola may also play a role in fighting **Alzheimer's disease**, which affects over four million people in the United States. People with this dementia-causing disease have unusual amounts of the protein beta-amyloid (also called plaque) in the brain. A 1999 study conducted by pathology professor Alan Snow at Seattle's University of Washington showed gotu kola's potential for treatment. Snow first mixed a compound from **cat's claw** and tested it in rats and in test tubes. Results showed that cat's claw intervenes with plaque formation. When other extracts were added to the test tubes, including gotu kola and **rosemary**, the results were more pronounced.

Besides its use as a general memory aid, gotu kola has become popular in the Western world for its calming effects as well as for improving concentration. This duality occurs because gotu kola affects both the central nervous system and the brain. It relaxes the nervous system while stimulating the brain to focus better. In a 1999 study at the West Palm Beach Veterans Affairs Medical Center, researchers tested several dietary supplements, including gotu kola, for use in **depression**, **anxiety**, and **sleep disorders**. Researchers found little difference in the results of the natural supplements and low- and high-dose antidepressants. However, the studies indicated patients switch to natural supplements because they think they are safer. The research served as a guideline for healthcare professionals to aid their patients' choice of treatment.

Studies have also shown that gotu kola has positive effects on **varicose veins**, poor blood circulation in the legs and the rest of the circulatory system, leg cramps, and leg swelling. The circulatory improvement occurs

KEY TERMS

Amino acids—Nitrogen compounds that make up the main structure of proteins in the body.

Dementia—Irreversible mental deterioration.

Episiotomy—A surgical incision of the vaginal opening made during childbirth to avoid tearing during delivery.

Flavonoids—Generic term for compounds, such as plant compounds that help in treatment and prevention of diseases. Over 4,000 flavonoids are classified based on their chemical composition. These include citrus bioflavonoids, green tea polyphenols, and quercetin.

Glycoside—Compound containing a sugar component such as glucose and a nonsugar component such as triterpenes.

Leukorrhea—White discharge from the vagina, normally occurring during the menstrual cycle, pregnancy, lactation, and menopause. A change in color, amount, or odor is a symptom of a reproductive tract disorder.

Scleroderma—Immune system disorder where collagen (a protein found in connective tissue, bone, skin, etc.) forms in an abnormal manner. Can affect many body organs and tissues such as the heart, lungs, gastrointestinal tract, joints, kidneys, and skin.

because gotu kola decreases vein hardening, improves the connective tissue around veins, and helps the blood to flow through veins. These circulatory and leg benefits were evident in 80% of patients tested in studies conducted in the late 1980s.

Gotu kola also has positive effects on various skin problems. Animal research has shown that tripenoid asiaticoside may help **wounds** heal quicker. Other studies showed that gotu kola helped in healing surgical wounds of the ear, nose, and throat, and promoted healing of episiotomies, **gangrene**, skin grafts, and some skin ulcers. Asiaticoside can also toughen skin, hair, and nails. Research has shown that asiaticoside may provide treatment for leprosy. Leprosy-causing bacteria are coated in a wax-like substance that the immune system cannot penetrate. However, gota kola disintegrates this substance, allowing the immune system to attack the bateria.

Clinical trials also show that gotu kola's tripenoids, when purified, can lessen the ravages of scleroderma. Gotu kola can reduce hardening of the skin, decrease joint **pain**, and increase finger movement.

Gotu kola extracts can heal second- and third-degree **burns** from boiling water or **gas** explosions if the burn is treated immediately. Either topical application or intramuscular injections can stop the effects of skin **infections** from burns and can stop or reduce skin shrinkage, inflation, and scarring.

Gotu kola extract might be effective in fighting tumors. However, researchers are cautious because animal and human studies need to be completed.

Preparations

Gotu kola is often eaten in a salad. It can also be made into a tea by using 0.5–1 tsp (2.5–5 ml) of gotu kola in 1 cup (250 ml) of boiling water. The plant is steeped for 10–15 minutes and the tea is then drunk. This amount can be consumed up to three times a day. Because of its bitter taste, the tea can be enhanced with honey or lemon to taste.

For a poultice on wounds or skin problems, gotu kola leaves can be crushed and applied, or a tincture may be used. A poultice can also be made from gotu kola tea.

For scleroderma, suggestions include 70 mg twice a day. The usual dosage is 0.5–1 g three times daily, a standardized extract dosage is 60–120 mg a day, and a liquid extract approximately 0.5–1 tsp can be taken daily.

Precautions

Children under two years old, pregnant women, and people with **epilepsy** should avoid gotu kola. Fair-skinned people and others who have had an allergic reaction to sunlight or other ultraviolet light sources should avoid these sources if they take gotu kola.

Side effects

A rash is the most common side effect when gotu kola is taken internally or applied topically. If injected, some pain and bruising may occur at the injection sight. The asiaticoside component could be a mild skin carcinogen. It is not wise to apply gotu kola topically over a long period of time. The plant may also cause mild headaches or **nausea**. As with any supplement, consultation with a healthcare professional should occur before beginning treatment.

Interactions

Gotu kola should not be mixed with oral diabetes medication or drugs such as Lipitor, Lopid, Mevacor, and Zocor, all of which lower **cholesterol**. Gotu kola can raise cholesterol. It is also best not to mix gotu kola with alcohol or sedatives.

Gout

Definition

Gout is a form of acute arthritis that causes severe **pain** and swelling in the joints. It most commonly affects the big toe, but may also affect the heel, ankle, hand, wrist, or elbow. It affects the spine often enough to be a factor in lower back pain. Gout is often a recurring condition. An attack usually comes on suddenly and goes away after 5–10 days. Gout occurs when there are high levels of uric acid circulating in the blood, and the acid crystallizes and settles in the body. According to the National Institutes of Health (NIH), gout accounts for about 5% of all cases of arthritis reported in the United States.

Gout appears to be on the increase in the American population. According to a study published in November 2002, there was a twofold increase in the incidence of gout over the 20 years between 1977 and 1997. It is not yet known whether this increase is the result of improved diagnosis or whether it is associated with risk factors that have not yet been identified.

Gout

Gout risk factors

- Family history of the disease
- Male
- Overweight
- Excessive alcohol
- Purine-rich diet
- Enzyme defect that makes it difficult for the body to break down purines
- Exposure to lead in the environment
- Organ transplant recipient
- Use of medicines such as diuretics, aspirin, cyclosporine, or levodopa
- Take niacin (vitamin)

Signs of gout

- Hyperuricemia
- Presence of uric acid crystals in joint fluid
- More than one attack of acute arthritis
- Arthritis that develops in a day, producing a swollen, red, and warm joint
- Attack of arthritis in only one joint, often the toe, ankle, or knee

Description

Uric acid is formed in the bloodstream when the body breaks down waste products, mainly those containing purines. Purines can be produced naturally by the body, and they can be ingested from such high-purine foods as meat. Normally, the kidneys filter uric acid particles out of the blood and excrete it into the urine. If the body produces too much uric acid or the kidneys are not able to filter enough of it out, there is a buildup of uric acid in the bloodstream. This condition is known as hyperuricemia.

Uric acid does not tend to remain dissolved in the bloodstream. Over the course of years, or even decades, hyperuricemia may cause deposits of crystallized uric acid throughout the body. Joints, tendons, ear tips, and kidneys are favored sites. When the immune system becomes alerted to the urate crystals, it mounts an inflammatory response that includes the pain, redness, swelling, and damage to joint tissue that are the hallmarks of an acute gout attack.

The body's uric acid production tends to increase in males during puberty. Therefore, nine out of ten people with gout are men. Since it can take up to 20 years of hyperuricemia to have gout symptoms, men do not

KEY TERMS

Allopurinol—A drug that corrects hyperuricemia by inhibiting urate production.

Colchicine—A drug used to treat painful flare-ups of gout.

Constitutional remedy—A homeopathic medicine prescribed according to each person's character and temperament as well as symptoms.

Corticosteroids—Medications related to a natural body hormone called hydrocortisone, which are used to treat inflammation.

Hyperuricemia—High levels of uric acid in the bloodstream.

Kidney stones—Hard lumpy masses of mineral wastes that are formed in the kidneys and may cause blockages.

Purine—A substance found in foods that is broken down into urate and may contribute to hyperuricemia and gout.

Synovial fluid—Fluid surrounding the joints which acts as a lubricant, reducing the friction between the joints.

Tophus (plural, tophi)—A chalky deposit of a uric acid compound found in gout. Tophi occur most frequently around joints and in the external ear.

commonly develop gout until reaching their late 30s or early 40s. If a woman does develop gout, typically, it will be later in her life. According to some medical experts, this is because estrogen protects against hyperuricemia. It is not until estrogen levels begin to fall during **menopause** that urate crystals can begin to accumulate.

Hyperuricemia does not necessarily lead to gout. The tendency to accumulate urate crystals may be due to genetic factors, excess weight, or overindulgence in the wrong kinds of food. In addition, regular use of alcohol to excess, the use of diuretics, and the existence of high levels of **cholesterol** and triglycerides in the blood can increase the risk of developing the disease. In some cases, an underlying disease such as lymphoma, **leukemia**, or hemolytic **anemia** may also lead to gout.

Causes and symptoms

An acute episode of gout often starts without warning. The needle-like urate crystals may be present in the joints for a long time without causing symptoms. Then, there may be a triggering event such as a stubbed toe, an infection, surgery, **stress**, **fatigue**, or even a heavy drinking binge. Patients in intensive care units (ICUs) may have an acute flare-up of gout. In addition, it is now known that chronic occupational exposure to lead leads to decreased excretion of urates and an increased risk of developing gout.

In many cases, the gout attack begins in the middle of the night. There is intense pain, which usually involves only one joint. Often it is the first joint of the big toe. The inflamed skin over the joint is warm, shiny, and red or purplish, and the pain is often so excruciating that the individual cannot tolerate the pressure of bedcovers. The inflammation may be accompanied by a **fever**.

Acute symptoms of gout usually resolve in about a week, and then disappear altogether for months or years at a time. Eventually, the attacks may occur more frequently, last longer, and do more damage. The urate crystals may eventually settle into hard lumps under the skin around the joints, leading to joint deformity and decreased range of motion. These hard lumps, called tophi, may also develop in the kidneys and other internal organs, under the skin of the ears, or at the elbow. People with gout also have a heightened risk of kidney disease, and almost 20% of people with gout develop **kidney stones**. The relationship between gout and kidney stone formation is still not completely understood.

Diagnosis

Doctors can diagnose gout based on a physical examination and the patient's description of symptoms. In order to detect hyperuricemia, doctors can administer a blood test to measure serum urate levels. However, high urate levels merely point to the possibility of gout. Many people with hyperuricemia do not have urate crystal deposits. Also, it has been shown that up to 30% of people with gout have normal serum urate levels, even at the time of an acute gout attack. The most definitive way to diagnose gout is to take a sample of fluid from an affected joint and test it for the presence of the urate crystals.

Treatment

The symptoms of gout will stop completely a week or so after an acute attack without any intervention. It is important, however, to be diagnosed and treated by a health care practitioner in order to avoid attacks of increasing severity in the future and to prevent permanent damage to the joints, kidneys, and other organs.

During an acute attack, treatment should focus on relieving pain and inflammation. On an ongoing basis, the focus is on maintaining normal uric acid levels, repairing tissue damage, and promoting tissue healing.

Diet

Generally, gout is unheard of in vegetarians. It is a condition that responds favorably to improvements in diet and **nutrition**. Recurrent attacks can be avoided by maintaining a healthy weight and limiting the intake of purine-rich foods. A diet high in fiber and low in fat is also recommended. Processed foods should be replaced by complex carbohydrates, such as whole grains. Protein intake should be limited to under 0.8g/kg of body weight per day.

Nutritional supplements

Vitamin E and **selenium** are recommended to decrease the inflammation and tissue damage caused by the accumulation of urates.

Folic acid has been shown to inhibit xanthine oxidase, the main enzyme in uric acid production. The drug allopurinol is used for this same purpose in the treatment of gout. The therapeutic use of folic acid for this condition should be prescribed and monitored under the supervision of a heath care practitioner. The recommended dosage range is 400-800 micrograms per day.

The **amino acids** alanine, aspartic acid, glutamic acid, and glycine taken daily improve the kidneys' ability to excrete uric acid. **Bromelain**, an enzyme found in pineapples, is an effective anti-inflammatory. It can be used as an alternative to NSAIDs and other prescription anti-inflammatory drugs. It should be taken between meals at a dosage of 200-300 mg, three times per day.

The bioflavonoid **quercetin** helps the body absorb bromelain. It also helps decrease uric acid production and prevents the inflammation that leads to the acute symptoms of gout and the resulting tissue destruction. Quercetin should be taken at the same time and dosage as bromelain: 200-400 mg, between meals at a three times per day.

Herbs

Dark reddish-blue berries such as cherries, blackberries, **hawthorn** berries, and elderberries are very good sources of flavonoid compounds that have been found to help lower uric acid levels in the body. Flavonoids are effective in decreasing inflammation and preventing and repairing the destruction of joint tissue. An amount of the fresh, frozen, dried, juiced, or otherwise extracted berries equal to half a pound (about 1 cup) fresh should be consumed daily.

Devil's claw (*Harpagophytum procumbens*) has been shown to be of benefit. It can be used to reduce uric acid levels and to relieve joint pain.

Gout represents a serious strain on the kidneys. The dried leaves of nettles, *Urtica dioica,* can be made into a pleasant tea and consumed throughout the day to increase fluid intake and to support kidney functions. However, some people are allergic to nettles.

Therapy

Colchicum is a general homeopathic remedy that can be used for pain relief during a gout attack. It is formulated from the same plant, Autumn crocus, as the drug colchicine, used in the conventional treatment of gout. Gout may be improved by having a constitutional remedy prescribed that is based on the tendency to develop the disease and its symptoms.

During the acute phase of gout, **acupuncture** can be helpful with pain relief.

Applications of ice or cold water can reduce pain and inflammation during acute attacks.

Allopathic treatment

Standard medical treatment of acute attacks of gout includes nonsteroidal anti-inflammatory drugs (NSAIDs) such as naproxen sodium (Aleve), ibuprofen (Advil), or indomethacin (Indocin). Daily doses until the symptoms have subsided are recommended. Colchicine (Colbenemid), is also used. Corticosteroids such as prednisone (Deltasone, prednisolone, and corticotropin [ACTH]) may be given orally or may be injected directly into the joint for a more concentrated effect. Because these drugs can cause undesirable side effects, they are used for only about 48 hours so as not to cause major problems. Aspirin and other salicylates should be avoided, because they can impair uric acid excretion and may interfere with the actions of other gout medications.

Once an acute attack has been successfully treated, doctors try to prevent future attacks of gout and long-term joint damage by lowering uric acid levels in the blood. Colchicine is the drug of choice to deter recurrence. This medication can be very hard on the vascular system and the kidneys, however, and it is incompatible with a number of antidepressants, tranquilizers, and antihistamines. It should be avoided by pregnant women and the elderly.

There are two types of drugs used for lowering uric acid levels. Sometimes these drugs resolve the problem completely. However, the use of low-level amounts may be required for a lifetime. Uricosuric drugs, such as probenecid (Benemid) and sulfinpyrazone (Anturane), decrease urates in the blood by increasing their excretion. These drugs may also promote the formation of kidney stones, and they are contraindicated for patients with kidney disease. Xanthine oxidase inhibitors block the production of urates in the body. They can dissolve kidney stones as well as treat gout. Allopurinol is the drug most used in this respect. Its adverse effects include reactions with other medications, and the aggravation of existing skin, vascular, kidney, and liver dysfunction.

Expected results

Gout cannot be cured, but it can be managed successfully. Prompt attention to diet and reducing uric acid levels will rectify many of the problems associated with gout. Kidney problems can also be reversed or improved. Tophi can be dissolved or surgically removed, and with the tophi gone, joint mobility generally improves. Gout is generally more severe in those whose initial symptoms appear before age 30. The coexistence of **hypertension**, diabetes, or kidney disease can make for a much more serious condition.

Prevention

For centuries, gout has been known as the "rich man's disease," a disease of overindulgence in food and drink. While this view is perhaps oversimplified, lifestyle factors clearly influence a person's risk of developing gout. For example, losing weight and limiting alcohol intake can help ward off gout. Since purines are broken down into urates by the body, consumption of foods high in purine should be limited. Foods that are especially high in purines are red meat, organ meats, meat gravies, shellfish, sardines, anchovies, mushrooms, cooked spinach, rhubarb, yeast, asparagus, beer, and wine.

Dehydration promotes the formation of urate crystals, so people taking diuretics, or "water pills," may be better off switching to another type of blood pressure medication. Increased intake of fluids will dilute the urine and encourage excretion of uric acid. Therefore, six to eight glasses of water should be consumed daily, along with plenty of herbal teas and diluted fruit juices.

Consumption of saturated fats impedes uric acid excretion, and consumption of refined carbohydrates, such as sugar and white bread and pasta, increases uric acid production. Both should be seriously limited.

The use of **vitamin C** should be avoided by people with gout, due to the high levels of acidity.

Grains-of-paradise fruit

Description

Grains-of-paradise fruit is a member of the Zingiberaceae family (**ginger** group), which is a major family of tropical and subtropical fruits. It is also known as Guinea grains, Melegueta pepper, Piper melegueta and *Aframomum melegueta roscoe,* which is its botanical name.

Aframomum melegueta roscoe is a perennial herb that produces a spicy edible fruit commonly found in the tropical regions, particularly of western Africa. It is somewhat palm-like in appearance, forming dense clumps and growing to a height of 4-5 ft (1.2-1.5 m), with divided smooth leaves that can be up to 9 in (23 cm) long.

There are two types of grains-of-paradise fruit. They resemble the spice cardamom in appearance and pungency, and the commercial variety is perhaps even closer in appearance and scent. True grains-of-paradise fruit tends to be less pungent than cardamom once cooked or heated.

The seeds are approximately oval in shape, hard, shiny, and reddish-brown color, whereas cardamom is pale buff-colored. Powdered grains-of-paradise fruit are pale gray. This spice is aromatic and can be distinguished by its hot peppery taste.

General use

In Africa and throughout the tropics, grains-of-paradise fruit (*Aframomum melegueta*) is a cultivated crop and is used as a remedy for a variety of ailments, although it is now rarely used outside these areas. It is one of the plants extensively made use of by African ethnomedicine.

Some confusion surrounds the identity of the true grains-of-paradise fruit, as approximately seven species of fruit are also sometimes mistakenly referred to as grains-of-paradise fruit, particularly *Malabar cardamom, Cardamomum malabaricum*, and *Cardamomum minus*, also the Zanzibar pepper. Grains-of-paradise fruit have even been confused with ***Nux vomica***, which is used as a homeopathic remedy. In fact, it is now recognized that *Aframomum melegueta roscoe* is the authentic species. The name "grains-of-paradise fruit" dates from the Middle Ages, and denotes the fact that it was once a highly valued commodity. The west African coast became known as the Grain Coast because grains-of-paradise fruit was traded there.

KEY TERMS

Antifungal—A drug or compound effective in treating fungal infections.

Antimicrobial—A drug or medication effective against disease-causing micro-organisms.

Aphrodisiac—A food or drug that stimulates sexual desire.

Ethnomedicine—Medicine pertaining to a particular ethnic group.

Phytomedicinals—Medicinal substances derived from plants.

Schistosomiasis—Also called bilharziasis, this is a disease caused by bodily infestation of blood flukes.

Considered to be spicy, hot, and slightly bitter, the active constituents of grains-of-paradise fruit include **essential oils** such as gingerol, paradol, and shagaol. It also contains **manganese**, gum, tannin, starch, and a brown resin. It has been proven to be an effective antifungal and antimicrobial agent.

Like cardamom, it is also used as a condiment, due to its pleasant taste, which is pungent without being intensely bitter. It is mainly used nowadays to flavor wines, spirits and particularly beer, although during the Middle Ages it was a favorite spice in Europe and other parts of the world. This spice, despite its popular beginnings, is hardly known outside of Africa today. Nevertheless, it remains popular as a spice in Arab cuisine, particularly Morocco and Tunisia. It has also been used as a pepper substitute, and may be chewed in cold weather to warm the body. In addition, it is a common addition to veterinary remedies.

The essential oil of grains-of-paradise is available, though not easy to find. Its properties are similar to those of the fruit, but it is often chosen for its fragrance. Grains-of-paradise fruit is used in African countries as an aphrodisiac as well as a treatment for **measles** and leprosy. Interestingly, extract of *Aframomum melegueta* has been shown in laboratory studies to increase sexual arousal and behavior in male rats. It is also used to reduce hemorrhage, particularly associated with **childbirth**.

Other phytomedicinal uses of grains-of-paradise include as a purgative (strong laxative), galactogogue (to increase production of breastmilk), anthelmintic (antiparasitic—it is effective against **worms**, etc.), and

hemostatic agent (purifies the blood). It has even been found to be effective against the dreaded schistosomiasis, which is a major problem to the medical authorities on the African continent.

Grains-of-paradise fruit is also effective against intestinal **infections** and infestations, and is also used to calm **indigestion** and **heartburn**. Interestingly, grains-of-paradise fruit is one of the plants presently being researched as a possible alternative to allopathic medicines in tropical countries, where they are attempting to find cheaper and more readily available local phyto-medicinal alternatives to their common health problems, which are chiefly the effects of tropical diseases. Phyto-medicines have often proved to be more effective than synthetic agents. In addition they have a more sympathetic effect on the body, and their production is compatible with current environmental concerns.

Grains-of-paradise are also used in Chinese herbal medicine, their use being interchangeable with the more readily available cardamom. It is taken for **nausea** and **vomiting**, intestinal discomfort, and **pain** and discomfort during **pregnancy**.

Preparations

The fruit is exclusively the part of the plant used, dried, whole, or powdered. The essential oil can also be obtained. The whole grains may be chewed or can be ground and incorporated into mixtures.

Precautions

As grains-of-paradise fruit is a name given to so many other spices, it is advisable to ensure that the correct species is obtained.

Aframomum melegueta roscoe is included in the FDA's list of botanicals that are generally recognized as safe.

Side effects

No side effects have been reported from grains-of-paradise fruit; however, this spice is not frequently used in the United States. People who are allergic to cardamom or ginger should use grains-of-paradise fruit with caution.

Interactions

No interactions have been reported with standard prescription medications.

Grape seed extract

Description

Grape seed extract is the primary commercial source of a group of powerful **antioxidants** known as oligomeric proanthocyanidins (OPCs), also generically called pycnogenol, a class of flavonoids. Laboratory studies have indicated OPCs are much more effective than **vitamin C** and **vitamin E** in neutralizing free oxygen radicals, which contribute to organ degeneration and **aging** in humans. The primary sources of OPCs are **pine bark extract** and grape seed extract. However, the grape seed extract is more widely recommended for its lower cost and because it contains an antioxidant not found in pine bark. Grape skins contain a compound known as **resveratrol**, found to contain protective properties against cardiovascular disease and a variety of cancers.

General use

Grape seed extract is a mixture of complex compounds. It has a wide range of therapeutic uses, from preventing **cancer** and cardiovascular disease to alleviating symptoms of **allergies**, ulcers, and **cataracts**. Its antioxidant properties are believed to help slow the aging process. Procyanidins, a group of compounds found in the extract, are thought to increase the effectiveness of other antioxidants, especially vitamin C and vitamin E, by helping them regenerate after neutralizing free radicals in the blood and tissue. OPCs in the extract are water-soluble, making them easily

absorbed by the body. They also are able to cross the stubborn blood-brain barrier, providing antioxidant protection to the brain and nervous system. Most of the research on grape seed extract has been done in Europe, so many of its reported benefits have not been reviewed or approved by the U.S. Food and Drug Administration. It is available as an over-the-counter supplement. According to Varro E. Tyler, dean emeritus of the Purdue University School of Pharmacy and Pharmacal Sciences, the procyanidin compounds found in grape seed extract are useful in treating vascular disorders. They also are antioxidants, or free-radical scavengers, that help prevent some age-related cancers and **atherosclerosis**. Grape seed extract is a relatively new supplement in the United States, although it has been used in Europe for several decades. Its antioxidant properties were realized in the 1980s with the so-called French paradox, in which researchers discovered that the French had low rates of **heart disease** even though their diet was high in **cholesterol**. This was credited to their widespread consumption of red wine. Further research led to the OPCs concentrated in grape seeds. Subsequent research suggested that grape seed extract may work at the genetic level, activating a gene that stops oxidation of bad cholesterol. A 2003 study found that grape seed extract worked well in replacing estrogen and blunting **hypertension** in postmenopausal women.

Cardiovascular disease

European studies have shown procyanidins to be useful in treating blood vessel disorders, such as fragile capillaries and poor circulation in the veins. Components bind to the walls of the capillaries, making them less likely to break down with the effects of aging. In one European study, researchers found that treatment with grape seed extract quickly relieved a chronic condition of poor circulation in the veins. Grape seed extract also has been beneficial in treating **edema**, an excessive accumulation of fluid in tissue. Another use of grape seed extract is reducing blood pressure in people with hypertension.

Cancer

Researchers at the University of Colorado Health Sciences Center, working with cell cultures and laboratory mice, demonstrated that grape seed extract can inhibit growth of colorectal tumors. Tumors decreased by 44%, according to a 2006 article in *Drug Discovery & Development*. The preclinical study demonstrated that grape seed extract has cancer fighting properties, and the research revealed the molecular mechanism at work in the process. Researchers caution that more studies are needed.

A 2006 study at City of Hope, a cancer treatment facility in California, found that components in grape seed extract and red wine can suppress the production of estrogen, a hormone that contributes to the growth of **breast cancer**. Researchers say that the study demonstrates that grape seed extract may be potentially useful in both the treatment as well as the prevention of hormone-dependent breast cancer. The National Cancer Institute continues to fund studies evaluating whether grape seed extract is effective in preventing breast and prostate cancers.

Respiratory conditions

Grape seed extract has been found to be beneficial in treating several respiratory conditions, including **asthma**, **emphysema**, allergies, and sinusitis. Pycnogenol helps inhibit the production of histamines, which decreases sensitivity to pollens and food allergens, thereby reducing allergic reactions.

High blood pressure

A small-scale, placebo-controlled clinical trial, reported in 2005, studied grape seed extract's effect on high blood pressure in three groups of eight men and women. Two groups received grape seed extract, one in 150 mg daily dosage and the other is a 300 mg daily dosage for the one-month trial period. Researchers found that both groups demonstrated a drop in blood pressure, with the group taking the higher daily dosage also showed a decrease in LDL cholesterol levels.

Other conditions

OPCs in grape seed extract have shown effectiveness in treating a variety of other conditions. As an anti-inflammatory, it helps prevent swelling of joints, heals damaged tissue, and eases **pain** in people with arthritis. Studies have shown OPCs can stop cataract progression, treat and prevent **glaucoma**, and aid in treating several types of retinal disease. One of the extract's most popular uses is in treating the effects of aging, including preventing wrinkles by protecting the skin against ultraviolet radiation damage from **sunburn**, improving skin elasticity and tone, and helping reduce the appearance of scars and stretch marks. A wide range of anecdotal reports tell of grape seed extract helping treat or reduce the effects of headaches, **hemorrhoids**, diabetes, **prostate enlargement**, and **cellulite**, although no clinical research supports these claims.

Resveratrol

In 1992, scientists began exploring potential health benefits of resveratrol, a compound derived from grape skins and found in red wine. Researchers working with cell cultures found that resveratol has cardioprotective and anticancer properties, suppressing the proliferation of a wide variety of tumor cells. However, in a 2004 study at the Medical University of South Carolina, researchers studying the human metabolism of resveratrol found that even when ingesting resveratrol in very high dietary amounts, there may not be high enough levels of the compound remaining in the tissue to bring about the cardioprotective and anticancer effects demonstrated in cell culture studies.

Preparations

Grape seed extract generally is available in 50 mg and 100 mg capsules. The acceptable adult daily dosage has been estimated at up to 150–200 mg, or 50 mg per 50 lb (22.7 kg) of body weight. In Europe, OPCs usually are prescribed at 300 mg a day to treat medical conditions such as **varicose veins**, edema, allergies, inflammation, and skin aging. The extract contains varying amounts of proanthocyanics, although the label should indicate about 75–80% proanthocyanidins to be effective. Products standardized to 95% OPC will maximize potency. Research in the United States and Europe has shown it is most effective when used in combination with other antioxidants, especially vitamin C and vitamin E. Grape seed extract is fully absorbed by the body within one hour after consumption. One-half the original dose is still functional within the body after seven hours.

In 2003, a liquid grape seed extract was made available in the United States. This version can be used in a number of beverages, including bottled water, without changing their taste. A 2003 trial at Ohio State University found that lotions made with grape seed extract helped **cuts** heal more quickly than they would on their own. The lotion helped improve blood flow to the wound site.

Precautions

Persons with serious conditions such as cancer, diabetes, and cardiovascular disease should not substitute grape seed extract for their existing treatments without first consulting with their doctor. There is no clinical evidence that grape seed extract can cure any of these conditions. Since grape seed extract is water-soluble, any excess intake that is not used by the body is eliminated in the urine. Studies have shown it is not carcinogenic, does not cause birth defects, and does not cause cells to mutate. Pregnant women and those with autoimmune conditions should probably avoid grape seed extracts. It is best to check with a clinician to ensure the safest dosage is being taken, as reports may vary on the latest research. Grape seed extract is not recommended for pregnant women. Some researchers caution that grape seed proanthocyanidins may interfere with blood-clotting drugs.

KEY TERMS

Antioxidant—A substance that opposes oxidation damage in the body caused by free oxygen radicals.

Atherosclerosis—A buildup of fatty substances in the inner layers of the arteries.

Flavonoids—Also known as bioflavonoids, a group of about 5,000 substances, mostly derived from food, that have super-antioxidant qualities.

Free oxygen radicals—Also called free radicals, these by-products of oxygen cause oxidative damage to the body's cells.

Histamine—A compound found in tissue that plays a major role in allergic reactions.

Resveratrol—A polyphenolic compound found in various plants, including wine grapes (especially the skins), berries, and peanuts.

Side effects

Nausea and upset stomach have been reported on occasion. More rarely, allergic reactions in the form of temporary skin **rashes** have occurred in persons sensitive to grape products. As of 2008, there were no reported serious side effects associated with taking grape seed extract. It is non-toxic, even at high dosages.

Interactions

As of 2008, there were no reported negative interactions associated with grape seed extract. Several studies done in the United States and Europe show the extract has a positive reaction with vitamin C and vitamin E. Studies have shown that OPCs in grape seed extract are as much as 50 times more potent than those in vitamin E and up to 20 times more potent than OPCs in vitamin C.

Grape skin

Description

Appearance

Grape skin, the outer layer of the grape (*Vitis vinifera*), is either green, red, or purplish-black in color. The skin, stem, seeds, and juice of the grape are used in making wine. Although the skin, stem, and seeds are often used in making the nutritional supplement, grape skin extract, the extract sometimes contains grape skin only. Generally, the skin of red grapes is used in making nutritional supplements.

History

In 1535, sailors on Jacques Cartier's expedition to Canada became seriously ill with scurvy, a vitamin deficiency. This degenerative disease of connective tissues was caused by the lack of vitamins in the typical seafarer's diet—a menu of dried meat and biscuits. The crew was saved by the advice of a Native American, who recommended drinking tea made from the bark of a particular species of pine tree. In the 1930s, researchers discovered that the ascorbic acid (**vitamin C**) in fruits and vegetables prevented scurvy.

The pine extract, however, contained very little vitamin C. For more than 50 years, European biochemists have been researching the seafarers' more likely rescuer—a family of antioxidant polyphenols (acid compounds) called pycnogenols, whose primary active compounds are pigments called oligomeric proanthocyanidins (OPCs). French chemist Jack Masquelier isolated OPCs from peanut skins in 1947 and coined the term "pycnogenols" to describe the unique class of polyphenols to which OPCs belong.

KEY TERMS

Antioxidant—Agent that helps rid the body of damaging free radicals (unstable oxygen molecules).

Bioflavonoid—A large group of phytochemicals with antioxidant and immune-boosting properties.

Oligomeric proanthocyanidins (OPCs)—Part of a large group of phytochemicals called bioflavonoids.

Polyphenol—Acid compound in plants.

Resveratrol—An enzyme that promotes health and is found in 72 varieties of plants.

Although people have been drinking wine for centuries, scientific research into the health benefits of products derived from red grapes began in Europe in the mid to late twentieth century. Supplemental OPCs have been used in Europe since 1950 to treat weak blood capillaries, postsurgical **edema** (swelling), **cirrhosis** (liver disease), **varicose veins**, and diabetic **retinopathy** (eye disease resulting from diabetes). Early identification of OPCs as useful for treating capillary fragility gave researchers some indication of their potential value in connective tissue disorders. However, this limited focus tended to overlook the additional therapeutic possibilities of OPCs and, until the latter part of the twentieth century, distracted scientists from investigating broader uses for OPCs.

Aside from pine bark, OPCs are concentrated in grape seeds and skins, wine, green and black teas, beans, and the skins of many fruits. Generally, the more intense the color, the more OPCs in the food, which explains why red wine has a greater health benefit than white wine. When red wine is made, the "must" is used—the skins, seeds, and stems. The must is left in the mixture for a long period of time as the wine ferments and the OPCs emerge, giving red wine its characteristic flavor and color.

In the case of white wine, the must is taken out early, so the wine neither darkens nor absorbs as many OPCs. Grape juice also contains OPCs. However, researchers have found that grape juice may not confer the same health benefits as red wine.

Biologic components

Red grape skins contain an array of **bioflavonoids** (**quercetin**, catechins, flavonols, and anthocyanidins) and nonbioflavonoid polyphenols (acid derivatives).

One important nonbioflavonoid in grape skin is called **resveratrol**. Resveratrol is a plant-specific enzyme that exists in 72 plant species, such as grapes, peanuts, and pine trees. Grapes are the most abundant source of this health-promoting enzyme.

Resveratrol's presence in the plant is induced by **stress**, injury, infection or ultraviolet irradiation. It is thought that the injury to the grape skin, produced during the wine-making process, significantly increases resveratrol levels. The relatively high quantities of the enzyme in the grape skins are thought to help the plant resist **fungal infections**, diseases, adverse weather, and insect or animal attack.

General use

There are many possible therapeutic applications of the resveratrol in red grape skin. In clinical studies, resveratrol demonstrated equivalent or better anti-inflammatory effects compared to the well-established anti-inflammatory drugs phenylbutazone and indomethacin. In animal studies, resveratrol inhibited both the acute and chronic phases of inflammation.

In humans, some researchers have found that resveratrol thins the blood more effectively than aspirin, which is often used to decrease the risk of a **heart attack**. In fact, the phrase "French paradox" refers to the idea that although French men consume a high-fat diet, they have one-third as many heart attacks as American men. Moreover, French men have high **cholesterol** and blood pressure levels similar to their American counterparts. Researchers have discovered that the main reason for this phenomenon is the OPCs from the grape skin, not the alcohol content, in the red wine that the French drink.

Preliminary tests in animals also indicate that resveratrol may interfere with the development of **cancer** in three ways: by blocking the action of cancer-causing agents, by inhibiting the development and growth of tumors, and by causing precancerous cells to revert to normal.

Although researchers are uncertain about how much resveratrol is needed to produce beneficial effects in humans, supplementation with red grape skin extract or consuming a glass or two of red wine may prevent or alleviate the following conditions:

- aging
- bruising (capillary fragility)
- cancer (cancer-inhibiting effects)
- diabetes
- fungal infection
- heart disease (hardening of the arteries and high cholesterol)
- inflammation (including bursitis and tendonitis)
- Raynaud's syndrome (a blood vessel disorder)
- varicose veins
- vision problems (including cataracts and glaucoma)
- wound healing

Preparations

Red grape skin extract is prepared in capsule form as a nutritional supplement. For adult maintenance, the therapeutic range is thought to be 200–600 mg at 30% anthocyanins (OPCs), although guidelines have not been definitively established.

The resveratrol found in red grape skin and its extract is also found in red wine and concord grape juice. However, grape juice has been found to have fewer benefits than red wine, due to the technique for processing the grapes. For example, grape juice has only one-third the anti-clotting properties of red wine.

Precautions

Although research is limited, scientific investigators have not issued any precautions regarding the use of grape skin or grape skin extract. However, people should be aware of the known side effects of red wine and resveratrol.

Side effects

There are many potential side effects to consuming excessive quantities of red wine (such as allergic reactions to sulfites, intoxication, and liver damage) in order to obtain the health benefits of resveratrol. Each individual must weigh the risks versus the benefits of consuming alcohol.

Resveratrol itself is also a phytoestrogen (plant estrogen). The estrogenic properties of this chemical may play a role in the beneficial cardiovascular effects in red wine. These positive effects include increasing high-density lipoprotein (HDL), the "good cholesterol." On the other hand, it has been noted that drinking red wine may support the proliferation of certain **breast cancer** cells that require estrogen for growth. Thus, resveratrol may have undesirable side effects in some people, including those women with a history of breast cancer or postmenopausal women taking hormone replacement therapy.

Interactions

Scientific investigation on the interactions of grape skin or grape skin extract with drugs, foods, or diseases is very limited and inconclusive. However, if the resveratrol in grape skin is consumed in red wine, a wide range of adverse interactions with drugs and foods may result. It is advisable to consult a physician before consuming alcohol in combination with any type of prescription or over-the-counter medication.

Grapefruit seed extract

Description

Grapefruit seed is prepared in extract form from the seeds, pulp, and white membranes of grapefruits from grapefruit trees (*Citrus paradisi*). The grapefruit tree, first discovered on the Caribbean island of Barbados in the seventeenth century, was brought to Florida in 1823 for commercial cultivation. The plant was probably named grapefruit because its fruits grow in bunches or clusters. Grapefruit seed extract (GSE) is used as a broad spectrum, non-toxic, antimicrobial compound. The extract comes in two forms, liquid and powder.

GSE was developed by Dr. Jacob Harich, a physicist who was born in Yugoslavia in 1919 and educated in Germany. His education in nuclear physics was interrupted by Word War II. After witnessing the horror of war as a fighter pilot, Harich decided to devote the rest of his life to improving the human condition. He then expanded his educational pursuits to include medicine, including gynecology and immunology. He came to the United States in 1957 to study at Long Island University in New York. As an immunologist, he was interested in studying natural substances that might help protect the body from undesirable microorganisms. In 1963, he moved to Florida, the heart of grapefruit country, and began research on the use of grapefruit seeds as a biocide. By 1990, holistic health practitioners began to recommend the use of GSE to their patients. In 1995, Harich was invited to the Pasteur Institute of France, a leading **AIDS** research center. Researchers at the Center have been investigating the potential of GSE as a prophylactic against the HIV virus as well as against some of the secondary **infections** associated with AIDS. He was also honored by farmers in Europe who use a powdered form of GSE in fish and poultry feed to control *Salmonella* and *Escherichia coli*. In 1996, Harich passed away.

General use

GSE is a broad spectrum bactericide, fungicide, antiviral, and antiparasitic compound. When used in vitro, GSE has been shown to be highly effective against a broad spectrum of bacteria, including *Staphyloccus aureus*, *Streptococcus pyogenes*, *Salmonella typhi*, *Escherichia coli*, *Pseudomonas aeruginosa*, *Klebsiella pneumoniae*, *Shigella dysenteriae*, *Legionella pneumoniae*, *Clostridium tetani*, *Diploccus pneumoniae*, and many others. GSE also strongly inhibits many types of pathogenic fungi and yeast.

Examples of external uses of GSE include:

- mouth and lips: mouthwash, mouth ulcers, thrush, bad breath, cracked lips, sunburned lips, and cold sores
- teeth and gums: plaque, tooth decay, toothaches, tooth extraction, gingivitis, and toothbrush cleaner
- nose and sinuses: sinusitis, runny nose (rhinitis), and nasal ulcer
- throat: sore throat, tonsillitis, coughs, hoarseness, and laryngitis

- ears: ear cleaning, earaches, and inflammation of the middle ear (otitis media) in conjunction with internal use
- face: acne and shaving
- scalp and hair: shampoo, dandruff, itching scalp, and head lice
- skin: small cuts, skin abrasions, scratches, minor burns, rashes, dermatitis, psoriasis, shingles, eczema, nettle rash, insect bites and stings, tick and leech bites, leg ulcers, warts, and skin fungi
- feet: athlete's foot, sweaty feet, calluses, corns, blisters, nail fungi, and cuticular infections
- vagina and genitals: vaginitis, yeast infections, vaginal parasites, feminine hygiene, and fungal and parasitic diseases in the male genital area

Examples of internal uses include:

- acute and chronic inflammations in general
- colds and flu
- gastrointestinal infections
- vastritis and gastric and duodenal ulcers
- *Candida albicans* and other fungal diseases
- parasitic diseases
- allergies

Preparations

Grapefruit seeds and pulp contain a combination of **bioflavonoids** and polyphenolic compounds. The polyphenols are unstable but are chemically converted during the GSE synthesis process into more stable substances that belong to a class of compounds called quaternary ammonium compounds. The active quaternary ammonium compound in GSE, believed to be responsible for its antimicrobial properties, is a diphenol hydroxybenzene complex. The antimicrobial activity appears to develop in the cytoplasmic membrane of the microorganisms. The active ingredients disorganize the cytoplasmic membrane so that the uptake of **amino acids** is prevented. At the same time there is a leakage of low molecular weight cellular contents through the cytoplasmic membrane. Studies have also shown that GSE inhibits cellular respiration.

The extract is prepared by grinding grapefruit seeds and pulp into a fine powder. The powder is dissolved into purified water and distilled to remove fiber and pectin. The distilled slurry is spray dried at low temperatures forming a concentrated grapefruit bioflavonoid powder. This concentrated powder is dissolved in vegetable glycerin and heated. Food grade ammonium chloride and ascorbic acid are added. This mixture is heated under pressure where it undergoes catalytic conversion using natural catalysts, including hydrochloric acid and natural enzymes. The slurry is then cooled, filtered, and treated with ultraviolet light. Residual ammonium chloride in the final product is between 15 and 18%; residual ascorbic acid is between 25 and 35 mg/kg. There is no residue of hydrochloric acid in the final product. In the United States, standardized GSE contains 60% grapefruit extract materials and 40% vegetable glycerin. A powdered form of GSE is also available that contains 50% grapefruit extract materials, 30% silicon dioxide, and 20% vegetable glycerine.

To treat infections, 15 drops in 8 oz of water is used. For diaper yeast infections and as a vaginal douche, 10–15 drops of grapefruit seed extract is used in 4 oz of water.

Precautions

GSE has been shown to be non-toxic at levels many times greater than the recommended dosages. Even when taken daily, GSE seldom produces a significant allergic reaction. However, people who are allergic to citrus fruits should exercise caution in the use of GSE.

Citricidal®, the brand name of a GSE product in the United States containing 60% grapefruit seed extract in an aqueous, vegetable glycerine solution, has, in the United States, been labeled as GRAS (Generally Recognized as Safe) in the Code of Regulations. The U.S. Food and Drug Administration (FDA) has approved Citricidal® for cosmetic preparations. In addition, Citricidal® has also been approved by the FDA for the disinfection of foods.

Generally, GSE should never be used at full strength. GSE is extremely irritating to the eyes. If it gets into the eyes, a person should wash the eyes with large amounts of warm water and consult a physician, if necessary.

After an excessive ingestion of GSE, an individual should drink large amounts of water and take up to 3 tsp of **psyllium** husks (or up to 6 psyllium capsules). A doctor should be consulted, if necessary.

Side effects

Since GSE is quite acidic, if it is not properly diluted, it may further irritate already irritated tissues, such as a stomach or intestinal lining.

Interactions

Over 75 different combination herbal preparations containing GSE are available, based on the

assumption of Chinese herbal medicine that combinations of substances are more beneficial than single remedies. In addition, the antimicrobial properties of GSE make it an excellent preservative, thus enabling the herbs it accompanies to retain their potency.

Green tea

Description

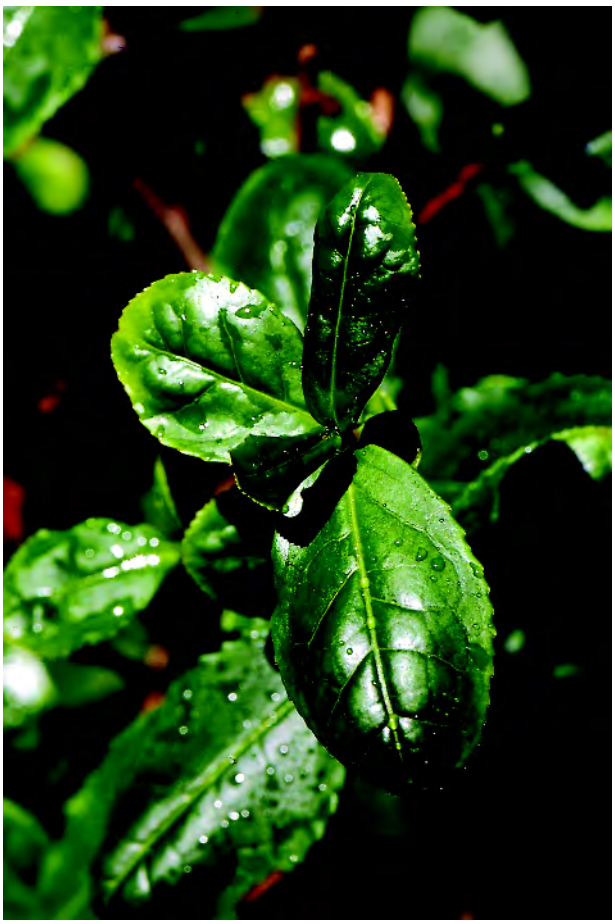
Green tea is produced from the leaves of the *Camellia sinensis*, or tea plant. Oolong and black tea are also produced from the plant but are processed and oxidized in different manners. Of the three, green tea contains the highest levels of polyphenols, the antioxidant substance that is believed to be beneficial in protecting against both **cancer** and **atherosclerosis**.

The tea plant is actually a variation of evergreen bush, with glossy green leaves and small white to pink flowers. The plants can reach a height of 30–40 ft (9–12 m) or taller in the wild, but are generally kept to a height of 6 ft (1.2 m) or less on the tea plantations and gardens where they are grown in China, Argentina, Japan, India, Indonesia, Kenya, Malawi, Sri Lanka, Turkey, Pakistan, Bangladesh, and Tanzania. Tea plants are cultivated in countries where warm, rainy growing conditions are abundant, and they are also frequently grown at high altitude.

When tea plants reach maturity at three or four years of age, the young leaves and leaf buds—the parts of the plant highest in polyphenols—are harvested. Green tea is produced by steaming or roasting the leaves as soon as they are picked and then rolling and drying the tea leaves to remove any moisture.

General use

Approximately 2.5 million tons of tea are grown and produced worldwide on an annual basis. Written records date the use of the plant as a beverage since at least the tenth century B.C. in China, and it is thought to be close to 5,000 years old. Tea is the most consumed beverage worldwide (after water). It is also one of the most popular herbal infusions—drunk regularly by over half the world's population.



Green tea plant. *(©PlantaPhile, Germany. Reproduced by permission.)*

Clinical and laboratory studies continue to demonstrate the benefits of green tea and its major extract, the antioxidant epigallocatechin-3-gallate (EGCG), as an effective treatment for various diseases.

Cancer

The polyphenols in green tea that act as **antioxidants** may actually inhibit the growth of existing cancer cells. In some animal studies, injections of tea extracts reduced the size of cancerous tumors in animals. In 2004, Hasan Mukhtar, Ph.D., of the University of Wisconsin, demonstrated in mice that the green tea extract EGCG is effective in fighting **prostate cancer**. Studies have also indicated that regular use of green tea may reduce the risk of other cancers, including oral, skin, colon, stomach, and rectal. In one clinical trial,

patients with pre-cancerous mouth lesions who were treated with green and black tea extracts achieved a 38% decrease in the number of pre-cancerous cells. Research suggests that green tea can reduce the risk of basal-cell carcinoma and squamous-cell carcinoma. The *Journal of the American College of Surgeons* reported in 2006 that the antioxidants in green tea may block tumor formation and growth and also may inhibit formation of clots and help keep artery walls functioning properly.

Arthritis

One study, reported in 2007 in *Arthritis Today*, examined the anti-inflammatory properties of green tea using the synovial cells from people with **rheumatoid arthritis**. Researchers discovered that the green tea-treated cells acted to block the ability of inflammatory chemicals to cause joint damage.

Alzheimer's disease

In 2005, researchers at the University of South Florida, working with tissue cultures and with mice genetically programmed to develop degenerative brain disease, reported that a concentrated extract of the antioxidant EGCG found in green tea is effective in preventing Alzheimer's-like damage in mice brains. Researchers note that in humans, merely drinking the herbal beverage would not bring about similar benefits. Researchers advise that a daily dosage of 1,500–1,600 mg of EGCG would be required in people to approximate the dosage that benefited the mice.

Muscle damage

Researchers at Baylor University, in a 2006 two-week study with college-age males, tested the ability of EGCG to prevent muscle damage after a physical exertion by heavy lifting. Researchers found that the men receiving the daily dosage of green tea extract had less muscle damage and soreness after heavy exertion than the control group.

Dental health

In addition to polyphenols, green tea contains several minerals, including fluoride and aluminum. The fluoride in green tea may be useful in fighting tooth decay. Green tea is also an antibacterial agent and can help to prevent gingivitis and periodontal disease by killing *E. coli* and streptococcus bacteria. This antibacterial action can also be effective in treating **halitosis**, or bad breath, by killing odor-causing bacteria.

Diabetes

In a study reported in 2006, Japanese researchers studied 17,413 men and women in 25 communities across the country. As many as half of the participants reported having type 2 diabetes. Researchers sought to discover the benefits of drinking green tea and coffee on development of type 2 diabetes. After a five-year follow up with participants, they found that those who reported drinking more green tea and coffee were less likely to get type 2 diabetes. The reliability of the outcome is limited by the accuracy of participants' reports about their tea and coffee consumption.

Preparations

Green tea leaves and tea bags can be purchased at most grocery, drug, and health food stores. It is graded by leaf size, with tea containing whole leaves and leaf tips considered the highest quality tea. Tea grades include Broken Orange, Pekoe, Broken Pekoe Souchong, Broken Orange Pekoe, Fannings, and Dust.

Although green tea is grown from a single plant, slight variations in tea processing (usually in the way the tea is rolled) have created a number of varieties of green tea. Popular green tea varieties include Gunpowder, Hyson, Dragonwell, Sencha, and Matcha.

Tea leaves should be kept in an air-tight container to retain flavor and prevent odors and moisture from being absorbed by the tea. It should also be stored in a cool place for no longer than six months before use.

The most common method of preparing green tea is as an infusion. The tea is mixed with boiling water, steeped for several minutes, and then strained or removed from the infusion before drinking. Approximately two teaspoons of loose tea, or a single tea bag, should be used for each cup of boiling water. A strainer, tea ball, or infuser can be used to immerse loose tea in the boiling water before steeping and separating it.

A second method of infusion is to mix loose tea with cold water first, bring the mixture to a boil in a pan or teapot, and then separate the tea from the infusion with a strainer before drinking.

Flavonoids—polyphenols with antioxidative properties—are released into the infusion as the tea steeps. The longer the steeping time, the more flavonoids are released by the tea leaves, although most will infuse into the water during the first five minutes of brewing. Longer steeping time also results in a higher **caffeine** content in the brewed tea.

Green tea leaves can be used in a poultice for treating insect **bites** and other skin irritations. Green

tea leaves are chopped and boiled in water for two to three minutes. After the excess water is squeezed from the leaves, the green tea is applied to the area to be treated and wrapped in a bandage. Green tea also makes an effective astringent, and tea-soaked cloth or tea leaf poultice may help renew tired and puffy eyes.

The antibacterial activity of green tea also makes it appropriate for use in compresses for **cuts** and abrasions. A quick compress can be made by soaking a pad or bandage in hot tea, wringing out the excess fluid, and holding the pad firmly against the wound. Once the compress cools, the process can be repeated.

Precautions

The U.S. Food and Drug Administration (FDA) includes tea on its list of "Generally Recognized as Safe" substances. However, pregnant women and women who breast feed should consider limiting their intake of green tea because of its caffeine content. Caffeine can pass into breast milk and cause **sleep disorders** in nursing infants. Decaffeinated green tea is available that contains only trace amounts (5 mg or less) of caffeine. Women should check with their healthcare professional about drinking tea when they are pregnant or nursing.

Tea can stimulate the production of gastric acid, and individuals with ulcers may want to avoid drinking green tea for this reason. Those taking warfarin or any blood-thinning drugs should first consult with the physicians before consuming green tea, as it may counter the effects of the drug.

Side effects

Green tea contains caffeine, a central nervous system (CNS) stimulant that can cause restlessness, irritability, difficulty sleeping, **tremor**, heart palpitations, loss of appetite, and upset stomach. To avoid side effects, caffeine intake should be limited to 300 mg or less a day (the equivalent of 4–8 cups of brewed hot tea). Caffeine-free green tea preparations are available commercially.

The tannin in tea can cause **nausea** when drunk on an empty stomach and inhibit the absorption of non-heme **iron**. Individuals with iron-deficiency **anemia** who take iron supplements should avoid drinking green tea several hours before and after taking supplements. Iron absorption with tea can be increased by consuming foods rich in **vitamin C** with tea, such as a slice of lemon.

KEY TERMS

Antioxidants—Enzymes that bind with free radicals to neutralize their harmful effects.

Atherosclerosis—A type of arteriosclerosis, or hardening of the arteries, caused by fatty deposits of cholesterol and calcium that build up on the interior walls of the blood vessels and arteries.

Chemopreventative—A chemical or drug that is thought to prevent a disease.

Flavonoids—Polyphenol substances in tea that act as antioxidants.

Free radicals—Reactive molecules created during cell metabolism that can cause tissue and cell damage like that which occurs in aging and with disease processes such as cancer.

Gingivitis—Inflamed and bleeding gums caused by poor dental hygiene, respiratory diseases, and other disease processes.

Infusion—An herbal preparation made by mixing boiling water with an herb, letting the brew steep for 10 minutes, and then straining the herb out of the mixture.

Non-heme iron—Dietary or supplemental iron that is less efficiently absorbed by the body than heme iron (ferrous iron).

Periodontal disease—Disease of the gums and teeth. Symptoms include bleeding and receding gums, gingivitis, abscesses, and loose teeth.

Phytochemical—A naturally occurring chemical substance in a plant.

Polyphenols—Phytochemicals that act as an antioxidant, protecting cells against damaging free radicals.

Grippe *see* **Influenza**

Guggul

Description

The mukul **myrrh** tree, or *Commiphora mukul*, is small, thorny, and usually devoid of foliage. It grows naturally throughout India and Arabia. Guggul is the gum resin that comes from this tree, which belongs to the same genus as myrrh and has some similar components and actions. Guggul resin contains steroids, diterpenoids, alipathic esters, and carbohydrates. These factors appear to work together to exert the beneficial effects of this botanical.

Guggul has been traditionally used in **Ayurvedic medicine** to treat arthritis, inflammation, bone **fractures**, obesity, and disorders of lipid metabolism. One ancient Ayurvedic reference describes the power of guggul to treat "coating and obstruction of channels." This description stimulated further research into the properties of this **botanical medicine** for preventing and treating **atherosclerosis**, as well as other conditions resulting from high levels of lipids in the body.

General use

Guggul has been recommended for the treatment of arthritis, hypercholesterolemia, nodulocystic **acne**, and overweight. It is one of the primary therapeutic substances used in Ayurvedic medicine to prevent atherosclerosis, as well as one of the most promising herbs or supplements for the prevention and treatment of this condition. Studies in animals have documented not only the protective effects of guggul against atherosclerosis, but have shown actual regression of the condition in animals that already had it.

The active portion of the plant is the gum resin, which contains guggulsterone, a steroid compound. It appears to be effective in lowering blood levels of both total **cholesterol** and low-density lipoprotein (LDL) cholesterol. In trials lasting one to three months, cholesterol levels were reduced by 14–27% and triglycerides by 22–30%. These results are equal to or better than those of some conventional medications used to lower cholesterol, but with fewer side effects. There are several hypotheses to account for the effectiveness of guggul in decreasing serum lipids. It may decrease the production of cholesterol in the liver. Excretion of cholesterol and bile acids are increased, so that less fat and cholesterol are absorbed. Guggul also increases the production of thyroid hormones, which lower the levels of serum lipids. The lowering of serum lipids is what consequently decreases the risk of atherosclerosis. One of the most important ways that gugulipid lowers cholesterol may be by stimulating the liver to remove LDLs from the bloodstream. The effect on high-density lipoprotein (HDL) cholesterol is undetermined, as two studies yielded different conclusions. To lower cholesterol, one recommended dose of gugulipid is 100–500 mg taken daily. This dosage contains 25 mg of guggulsterone. It may take a month or so for the full effect to be experienced. Similar doses of gugulipid are used to promote weight loss.

The thyroid gland is stimulated by guggulsterone. This effect may play a role both in the ability of the substance to decrease cholesterol levels and to promote weight loss by increasing the body's rate of metabolism.

Guggulsterone has significant anti-inflammatory properties, although they are somewhat overshadowed by its effects on lipid metabolism. This finding supports its traditional use in the treatment of **rheumatoid arthritis** and other inflammatory conditions. Studies have shown guggulsterone to be at least as effective as the conventional medications phenylbutazone and ibuprofen (Advil, Motrin) for both acute and chronic types of inflammation in animal models.

Platelet stickiness appears to be reduced by guggul, which is desirable for decreasing the risk of coronary artery disease. Guggul may also promote fibrinolysis (dissolving the fibrin in **blood clots**) and act as an antioxidant. More research is warranted for

KEY TERMS

Antioxidant— A substance that blocks the destructive action of free radicals.

Ayurveda—An ancient Indian system of holistic healing.

Embolism—Obstruction of a blood vessel by a loose clot.

Fibrinolysis—The breakdown of fibrin, an insoluble protein that is the end product of blood clotting. Fibrinolysis results in the dissolution of small clots.

Nodulocystic acne—A disorder of the sebaceous (oil-secreting) glands in which deep, and sometimes painful, cysts and pustules are formed.

these properties. They have potential benefits in the prevention of strokes and embolisms.

Studies have shown guggulsterone to have approximately the same effectiveness as the antibiotic tetracycline for the treatment of nodulocystic acne. It decreases inflammation and lowers the risk of recurrence of the condition. Guggul is also thought to have astringent, antiseptic, and antisuppurative (preventing pus formation) qualities that lend themselves to the treatment of this severe, and sometimes scarring, form of acne.

Preparations

In India, guggul has been a standard and approved treatment for high cholesterol since 1986. Guggul is most often available in tablet or capsule form, as a purified extract. Formulations should have a standardized concentration of guggulsterone. Most extracts contain from 5–10% guggulsterone. It is readily available in the United States, but available only by prescription, if at all, in the United Kingdom.

Gugulipid is also a component of some combination nutritional products that are being promoted for the support of normal metabolism of cholesterol and triglycerides. Other components may include **inositol** hexaniacinate, **chromium**, and vitamin **antioxidants**.

Precautions

Studies in both humans and animals have demonstrated a wide margin of safety and negligible toxicity for guggul, although some cases of liver toxicity have been reported for very high doses. Although it is apparently not toxic to the embryo or fetus either, guggul gum resin should not be used during **pregnancy** or lactation as it is thought to be a uterine stimulant.

Patients who are taking prescribed medications for **heart disease** should use caution in taking this herb.

Side effects

Crude extracts of guggul are more likely to produce side effects than purer products. In the past, effects included loss of appetite, abdominal **pain**, **diarrhea**, and **rashes**. In studies using purer extracts, significant adverse effects have not occurred. **Headache** and mild **nausea** are sometimes reported.

Interactions

Guggul can be problematic for people being treated for thyroid conditions. Since guggul stimulates production of thyroid hormone, it may alter the dosage requirements for thyroid replacement medication. It can also reduce the availability and effectiveness of the heart medications propranolol (Inderal) and diltiazem (Cardizem). Patients should consult a health care practitioner before taking guggul along with any other herbs or medications.

Judith Turner

Guided imagery

Definition

Guided imagery is the use of **relaxation** and mental visualization to improve mood and/or physical well-being.

Benefits

The connection between the mind and physical health has been well documented and extensively studied. Positive mental imagery can promote relaxation and reduce **stress**, improve mood, control high blood pressure, alleviate **pain**, boost the immune system, and lower **cholesterol** and blood sugar levels. Through guided imagery techniques, patients can learn to control functions normally controlled by the autonomic nervous system, such as heart rate, blood pressure, respiratory rate, and body temperature.

One of the biggest benefits of using guided imagery as a therapeutic tool is its availability. Imagery can be used virtually anywhere, anytime. It is also an equal opportunity therapy. Although some initial training in the technique may be required, guided imagery is accessible to virtually everyone regardless of economic status, education, or geographical location.

Guided imagery also gives individuals a sense of empowerment, or control. The technique is induced by a therapist who guides the patient. The resulting mental imagery used is solely a product of the individual's imagination. Some individuals have difficulty imagining. They may not get actual clear images but perhaps vague feelings about the guided journey. However, these individuals' brains and nervous systems responses seem to be the same as those with more detailed imaginings.

Patients who feel uncomfortable "opening up" in a traditional therapist-patient session may feel more at ease with a self-directed therapy like guided imagery.

Description

Guided imagery is simply the use of one's imagination to promote mental and physical health. It can be self-directed, where the individual puts himself into a relaxed state and creates his own images, or directed by others. When directed by others, an individual listens to a therapist, video, or audiotaped exercise that leads him through a relaxation and imagery exercise. Some therapists also use guided imagery in group settings.

Guided imagery is a two-part process. The first component involves reaching a state of deep relaxation through breathing and muscle relaxation techniques. During the relaxation phase, the person closes her eyes and focuses on the slow, in and out sensation of breathing. Or, she might focus on releasing the feelings of tension from her muscles, starting with the toes and working up to the top of the head. Relaxation tapes often feature soft music or tranquil, natural sounds such as rolling waves and chirping birds in order to promote feelings of relaxation.

KEY TERMS

Aromatherapy—The therapeutic use of plant-derived, aromatic essential oils to promote physical and psychological well-being.

Autonomic nervous system—The part of the nervous system that controls so-called involuntary functions such as heart rate, salivary gland secretion, respiratory function, and pupil dilation.

Once complete relaxation is achieved, the second component of the exercise is the imagery, or visualization, itself. There are a number of different types of guided imagery techniques, limited only by the imagination. Some commonly used types include relaxation imagery, healing imagery, pain control imagery, and mental rehearsal.

Relaxation imagery

Relaxation imagery involves conjuring up pleasant, relaxing images that rest the mind and body. These may be experiences that have already happened, or new situations.

Healing imagery

Patients coping with diseases and injuries can imagine **cancer** cells dying, **wounds** healing, and the body mending itself. Or, patients may picture themselves healthy, happy, and symptom-free. Another healing imagery technique is based on the idea of *qi*, or energy flow, an idea borrowed from **traditional Chinese medicine**. Chinese medicine practitioners believe that illness is the result of a blockage or slowing of energy flow in the body. Individuals may use guided imagery to imagine energy moving freely throughout the body as a metaphor for good health.

Pain control imagery

Individuals can control pain through several imagery techniques. One method is to produce a mental image of the pain and then transform that image into something less frightening and more manageable. Another is to imagine the pain disappearing, and the patient as completely pain-free. Or, one may imagine the pain as something over which he has complete control. For example, patients with back problems may imagine their pain as a high voltage electric current surging through their spine. As they use guided imagery techniques, they can picture themselves reaching for an electrical switch and turning down the power on the current to alleviate the pain.

MARTIN ROSSMAN (1945-)

Martin L. Rossman received his B.A. and M.D. degrees from the University of Michigan in Ann Arbor. The Colorado native then set up practice in San Francisco, where he is a Clinical Associate in the Department of Medicine at the University of California Medical Center as well as director and founder of the Collaborative Med icine Center in Mill Valley, and Co Director of the Acad emy for Guided Imagery, also in Mill Valley. Dr. Rossman has been a Diplomat of Acupuncture for the National Commission for the Certification of Acupuncturists since 1986, and, since 1989, has been certified for Interactive Guided Imagery through the Academy for Guided Imagery. He also serves as a member of various medical related associations throughout the United States.

According to Rossman, imagination is the key to understanding the self, and can be used to resolve many issues of mind and body fitness, including stress. Rossman prefers the term complementary medicine to alternative medicine, noting that so many of the therapies have moved into the medical mainstream that they all play a crucial role in health. Rossman's book, *Healing Yourself: A Step by Step Program for Better Health Through Imagery*, is one of many writings he has done on imagery. Rossman is a popular speaker in both professional and public settings, and a television and radio personality discussing the virtues of imagery, acupuncture, and other holistic treatments.

He can be reached through The Collaborative Medi cine Center, Mill Valley, California at (415) 383 3197 or through the Academy for Guided Imagery in Mill Valley at (800) 726 2070.

Mental rehearsal

Mental rehearsal involves imagining a situation or scenario and its ideal outcome. It can be used to reduce **anxiety** about an upcoming situation, such as labor and delivery, surgery, or even a critical life event such as an important competition or a job interview. Individuals picture themselves going through each step of the anxiety-producing event and then successfully completing it.

Preparations

For a successful guided imagery session, individuals should select a quiet, relaxing location where there is a comfortable place to sit or recline. If the guided imagery session is to be prompted with an audiotape or videotape, a stereo, VCR, or portable tape player should be available. Some people find that quiet background music improves their imagery sessions.

The session, which can last anywhere from a few minutes to an hour, should be uninterrupted. Taking the phone off the hook and asking family members for solitude can ensure a more successful and relaxing session.

Imagery combined with other relaxation techniques such as **yoga**, massage, or **aromatherapy** can greatly enhance the effects of these therapies. It can be done virtually anywhere.

Precautions

Because of the state of extreme relaxation involved in guided imagery, individuals should never attempt to use guided imagery while driving or operating heavy machinery.

Side effects

Guided imagery can induce sleepiness, and some individuals may fall asleep during a session. Other than this, there are no known adverse side effects to guided imagery.

Research and general acceptance

Use of guided imagery is a widely accepted practice among mental healthcare providers and is gaining acceptance as a powerful pain control tool across a number of medical disciplines. Results of a study conducted at The Cleveland Clinic Foundation and published in 1999 found that cardiac surgery patients who used a guided imagery tape prior to surgery experienced less pain and anxiety. These patients also left the hospital earlier following surgery than patients who used pain medication only.

Another study conducted by Harvard Medical School researchers found that for more than 200 patients undergoing invasive vascular or renal surgery, guided imagery controlled pain and anxiety more effectively than medication alone.

Training and certification

Guided imagery is used by many licensed therapists, counselors, psychologists, and psychiatrists. There are many self-help books, audiotapes, and videos available that offer instruction in guided imagery techniques.

Gulf War syndrome

Definition

Gulf War syndrome describes a wide spectrum of illnesses and symptoms ranging from **asthma** to **sexual dysfunction** that have been reported by U.S. and U.S. allied soldiers who served in the Persian Gulf War in Operation Desert Shield, Operation Desert Storm, and Operation Iraqi Freedom.

Description

Hundreds of federally funded research studies on Gulf War-related illnesses have been undertaken at a cost of hundred of millions of dollars. Despite this investment and the data collected from veterans who have registered with the Department of Defense and/or Veterans Administration (VA) as having Gulf War-related illnesses, there is still much debate over the existence of Gulf War syndrome. Veterans believed to have the illness experience a wide range of debilitating symptoms that elude a single diagnosis. These symptoms include **fatigue**, trouble breathing, headaches, poor sleep, forgetfulness, and trouble concentrating. Similar experiences among Gulf War veterans have been reported in the United Kingdom and Canada.

Causes and symptoms

As of 2008 the possible causative agent for Gulf War syndrome other than the **stress** of warfare was much debated. The VA and other public and private institutions have investigated a wide range of potential factors. These include chemical and biological weapons, the immunizations and preventive treatments used to protect against them, smoke from oil well fires, exposure to depleted uranium, and diseases endemic to the Arabian peninsula. As of 2008, investigators had not approached a consensus. They even disagreed on the likelihood that a specific agent is responsible, as a combination of these risk factors may have negative health consequences. There is a likelihood that sarin and/or cyclosarin (nerve gases) were released during the destruction of Iraqi munitions at Kharnisiyah, Iraq; however, veterans who served in that area were not found to have a higher rate of illness than veterans serving in the Persian Gulf in general.

Statistical analysis shows that the following symptoms are about twice as likely to appear in Gulf War veterans than in their non-combat peers: **depression**, posttraumatic stress disorder (PTSD), chronic fatigue, cognitive dysfunction (diminished ability to calculate, order thoughts, evaluate, learn, and remember), **bronchitis**, asthma, **fibromyalgia**, alcohol abuse, **anxiety**, and sexual dysfunction. PTSD is the modern equivalent of shell shock (the term used in World War I) and battle fatigue (World War II). It encompasses most of the psychological symptoms of war veterans, including nightmares, panic at sudden loud noises, and inability to adjust to peacetime living.

Chronic fatigue syndrome has a specific medical definition that attempts to separate common fatigue from a more disabling illness in hope of finding a specific cause. Fibromyalgia is another newly defined syndrome, and as such it has arbitrarily rigid defining characteristics. These include a certain duration of illness, a specified minimum number of joint and muscle pains located in designated areas of the body, sleep disturbances, and other associated symptoms and signs. One study comparing unexplained symptoms in Gulf War veterans with symptoms in control subjects found that over half the veterans with unexplained muscle **pain** met the criteria for fibromyalgia, and a significant portion of the veterans with unexplained fatigue met the criteria for chronic fatigue syndrome. Amyotrophic lateral sclerosis (ALS), also known as **Lou Gehrig's disease**, also occurs more frequently in veterans of the Gulf Wars. Gulf War veterans are twice as likely as other veterans to develop ALS, which causes wasting of muscle tissue and is fatal within three to five years.

Researchers identified three distinct syndromes and several variations in Gulf War veterans. Type one

patients suffer primarily from impaired thinking. Type two patients have a greater degree of confusion and ataxia (loss of coordination). Type three patients are the most affected by joint pains, muscle pains, and extremity paresthesias (unnatural sensations such as burning or tingling in the arms and legs). In each of the three types, researchers found different but measurable impairments on objective testing of neurological function. The functioning of the nervous system is much more complex and subtle than other body systems. Measuring it requires an equally complex effort. The tests used in this study carefully measured and compared localized nerve performance at several different tasks against the same values in normal subjects. Brain wave response to noise and touch, eye muscle response to spinning, and caloric testing (stimulation of the ear with warm and cold water, which causes vertigo) were clearly different between the normal and the test subjects. The researchers concluded that there must be a generalized injury affecting the nervous system. Another research group concluded that there was a neurologic injury involving the central, peripheral, and autonomic nervous systems.

After many years of vigorous study, the VA concluded that the signs and symptoms experienced by veterans believed to have Gulf War syndrome are real but that there is no unexplained, underlying single disease or condition affecting the veterans. Although some veterans do have unexplained, undiagnosed illnesses, this does not occur at a rate greater than that of the general population. They have also concluded that there was no area of deployment more likely than any other to produce veterans with the symptoms of Gulf War syndrome. This finding, however, remained extremely controversial. Many people believe that there is an underlying common condition, and many scientists continued as of 2008 doing research to determine if there was a common condition, and if so what the underlying cause may be.

Diagnosis

As there is no clear definition of the disease, diagnosis is primarily an exercise in identifying those Gulf War veterans who have an undefined illness in an effort to learn more about them and their symptoms. Both the Department of Defense (DoD) and the VA have programs devoted to this problem. Both the DoD Comprehensive Clinical Evaluation Program and the VA Persian Gulf Registry provide free, in-depth medical evaluations of Gulf War veterans and their families. In addition to providing individual veterans with critical medical care, these organizations use the cumulative data from these programs to advance research on diseases and disorders more likely to occur in the veteran community.

KEY TERMS

Ataxia—Lack of coordination.

Caloric testing—Flushing warm and cold water into the ear stimulates the labyrinth and causes vertigo and nystagmus (involuntary movement of the eyes in a horizontal direction) if all the nerve pathways are intact.

Endemic—Belonging or native to a particular locality or people.

Paresthesia—An abnormal sensation often described as burning, numbness, tingling, or pin pricks.

Syndrome—Common features of a disease or features that appear together often enough to suggest they may represent a single, as yet unknown, disease entity. When a syndrome is first identified, an attempt is made to define it as strictly as possible, even to the exclusion of some cases, in order to separate out a pure enough sample to study. This process is most likely to identify a cause, a positive method of diagnosis, and a treatment.

Treatment

There is no specific treatment for Gulf War syndrome. Treatment mainly focuses on relieving the symptoms experienced by each individual. The overall key to successful treatment is long-term, ongoing care, which may include medication, **hypnotherapy**, **acupuncture**, **homeopathy**, **nutrition**, vitamin/mineral therapy, and bodywork.

Allopathic treatment

There are many drugs available for symptomatic relief. Psychological counseling by those specializing in this area can be immensely beneficial, even life-saving, for those contemplating suicide. Veterans' benefits are available for those who are impaired by their symptoms.

Expected results

The outlook for war veterans was unclear as of 2008, but improvement was hoped for as more information was gathered about the illness. Gradual return to a functioning life may take many years of work and much help. However, even in the absence of an identifiable and curable cause, recovery is possible.

Gum disease

Definition

Gum disease, also called periodontal disease, is defined as the inflammation of the structures that surround and support the teeth. If left untreated, gum disease may progress to the point where there is destruction of the jawbone. It is one of the most common causes of tooth loss. Periodontal disease is also a risk factor for coronary **heart disease** and preterm low birth weight.

Description

Gingivitis is the earliest stage of a gum infection. It may recur or even become chronic. If gingivitis is not treated properly, it may progress to periodontitis, an inflammation of the periodontal ligament that helps hold the teeth in the bone. Periodontitis is sometimes called pyorrhea, which means a pus discharge.

Chronic periodontis results in the inflammation within the supporting tissues of the teeth, leading to progressive loss of tissue attachment and bone. It is the most frequent form of periodontis and is characterized by pocket formation and receding gum tissue.

Aggressive periodontis is a highly destructive form that causes rapid loss of tissue attachment and jawbone destruction. It often occurs in patients who are otherwise healthy.

Necrotizing periodontal diseases—also known as necrotizing ulcerative gingivitis or Vincent's infection—are **infections** characterized by gingival tissue death, and loss of tissue attachment and bone.

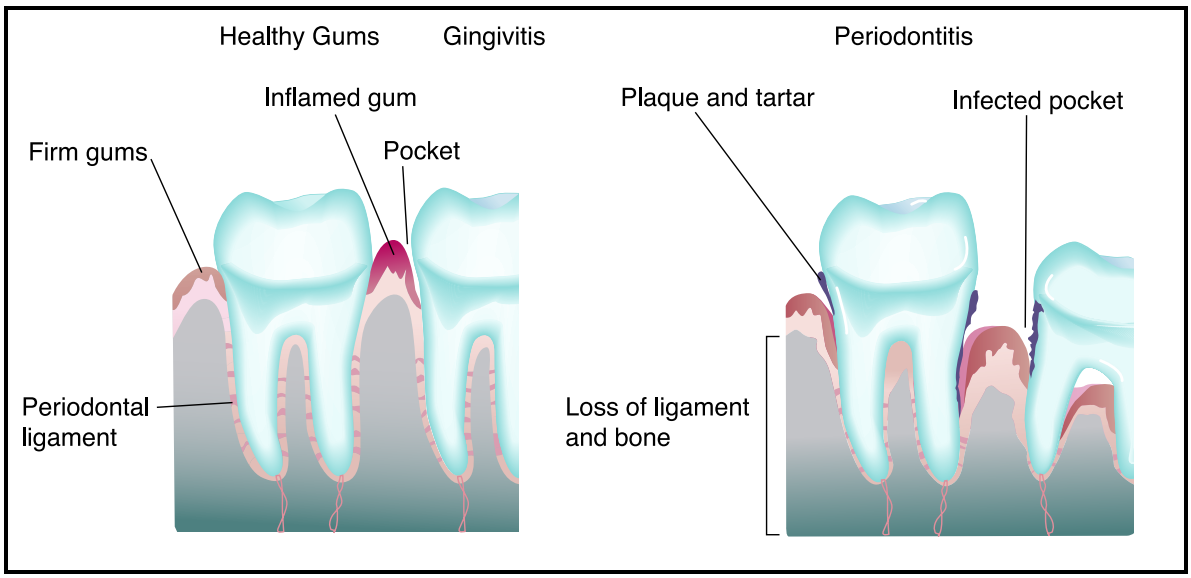
Severe cases of periodontitis may affect the jawbone. Severe sudden onset of gum disease is known as trench mouth. It is caused by an infection of both spirochetes and fusiform bacilli. It was once a major problem for soldiers during World War I. In the late 2000s, trench mouth is particularly common among teenagers and young adults under **stress**, often at examination time. Inflammation from trench mouth can also spread to nearby tissues of the face and neck.

Causes and symptoms

Causes

By far, the most common cause of gum disease is poor dental hygiene. Regular daily brushing and flossing of the teeth generally clears away food and bacteria buildup in the mouth. If the teeth are neglected, bacteria collect, and plaque forms on the teeth and gums. If the plaque is not removed, it mixes with saliva and hardens into tartar. Tartar irritates the gums and causes them to shrink away from the teeth, opening up spaces where more bacteria and plaque can collect. This cycle encourages increasingly severe inflammation and infection.

The mechanisms by which bacteria cause tissue destruction in advanced gum disease are not fully understood. Several bacterial products that diffuse through tissue are thought to play a role in gum disease. Toxins produced by some bacteria can kill cells. Studies show that the amount of endotoxin present correlates with the severity of periodontal disease. Other bacterial products include proteolytic enzymes, which are molecules that digest protein found in cells, thereby causing cell destruction. The human immune response has also been implicated in tissue destruction. As part of a normal immune response, white blood cells enter regions of inflammation to destroy



Healthy gums support the teeth. When gingivitis goes untreated, the gums become weak and pockets form around the teeth. Plaque and tartar build up in the pockets, the gum recedes, and periodontitis occurs. *(Illustration by Argosy, Inc. Cengage Learning, Gale)*

bacteria. In the process of destroying bacteria, periodontal tissue is also destroyed.

Other factors can contribute to the development of gum disease. Patients who have a family history of tooth loss or periodontal disease have an increased risk of developing the condition. Smokers and tobacco users are more than two times as likely as nonsmokers to develop gum disease. Hormone levels contribute to the development of bacteria in the mouth. **Pregnancy**, puberty, **menopause**, and the use of oral or injectable contraceptives may create a climate that promotes the development of gum disease. Additional factors include **diabetes mellitus**, scurvy, pellagra, **allergies**, **leukemia**, **Crohn's disease**, **AIDS**, chemotherapy, nutritional deficiencies, hydrochloric acid deficiency, poorly fitted fillings, radiation treatments, and exposure to heavy metals (mercury, lead, arsenic, and nickel). Medications that may contribute to the development of gum disease include steroids; phenytoin for controlling seizures; cyclosporine, which is taken by people who have had organ transplants; certain **cancer** drugs; and the **calcium** channel blockers used to control blood pressure and heartbeat.

Symptoms

The main symptoms of gingivitis are dark red, swollen, and tender gums that bleed easily. **Pain** is usually minimal. People with periodontitis have the same symptoms. In addition they may also have pain, loose teeth, and persistent bad breath. Abscesses and pus may develop. The symptoms of trench mouth include sudden onset of illness accompanied by pain, bleeding gums, bad breath, and a grayish mucus that covers the gums.

Diagnosis

A dental examination and history are taken. As the disease progresses, a dentist will be able to find hollowed pockets near the gums upon examination with a periodontal probe that gently measures the depth of the pockets surrounding each tooth. Dental x rays may be used to reveal the breakdown of bone. A smear of the gum area may be taken to determine the existence of any bacterial infections. The visualization of spirochetes can be used to confirm the diagnosis of trench mouth.

Treatment

Naturopathic treatment

Zinc, **copper**, **folic acid**, **vitamin E**, **selenium**, and **vitamin A** or beta-carotene are very helpful in slowing the progression of gum disease, especially if the patient has dietary deficiencies. Daily CoQ10 supplementation is also recommended. Mouthwashes that contain either a 0.1% folate solution or a 5% solution of zinc, or both, swished in the mouth and held there for at least a minute, can be taken twice daily.

Flavonoids help reduce inflammation and strengthen the gum tissue. A daily menu that includes foods rich in flavonoids is recommended. These foods include

blueberries, **hawthorn** berries, onions, and grapes. Extracts of these foods may be used as well.

Supplementation with **lycopene** (a phytochemical found in tomato products), in combination with routine preventive care, has been found to decrease the occurence of gingivitis, both as monotherapy and as adjunctive therapy after scaling and root planing procedures.

Homeopathy

The main homeopathic remedy for mild gum disease is *Mercurius solubilis hahnemanni* in a 6c potency. *Natrum muriaticum,* also in a 6c potency, is for more severe disease, especially if there is formation of pus. Homeopathic remedies can be taken four times daily for up to three days.

Ayurvedic medicine

Ayurvedic practitioners recommend a daily cup of water with the juice of a fresh lemon squeezed into it for bleeding gums. Five grams of amla powder in a cup of water daily is also recommended. The teeth can be brushed with catechu or **neem** powder or both.

Traditional Chinese medicine

According to **traditional Chinese medicine**, the gums are nourished by the liver's function. If the level of toxins in the body exceeds the liver's blood-cleansing limits, eventually the gums (and other parts of the body) become a breeding ground for disease. The Chinese also consider the liver as a reservoir of blood; it ensures that adequate blood and Qi (vital energy) are delivered to the muscles, gums, and joints.

Herbal therapies

The teeth can be brushed with a mixture of baking soda and hydrogen peroxide to clean them thoroughly and to fight infection. **Goldenseal** root powder, *Hydrastis canandensis,* can be used in the same way. **Myrrh**, *Commiphora molmol,* can be applied directly to the gums. *Aloe vera* may be applied directly to the gums to reduce pain and inflammation. In addition, a cup of water with a teaspoon of **apple cider vinegar** makes a good daily mouth rinse. An herbal mouth rinse can be prepared from 1 oz hydrastis, 1 oz myrrh, and 1 pint of water. Herbal mouthrinse preparations containing **chamomile**, **echinacea**, myrrh, mint, **sage**, and ratania have been shown to reduce inflammation. Gum products containing oligomeric proanthocyanidins have been shown to have antioxidant and anti-inflammatory properties to relieve symptoms and promote oral health.

Allopathic treatment

Dentists may advise mouth rinses with warm salt water as well as measures for symptom relief, such as over-the-counter anesthetic ointments.

Bone loss may be addressed by a variety of techniques to encourage growth, including bone grafting, splinting, and bite guards or other appliances to stabilize loose teeth. In some cases of advanced disease, the teeth in the affected areas may have to be pulled.

For moderate to severe periodontal disease, the dentist may recommend a procedure called nonsurgical root planing in which damaged gum tissue is scraped away and root surfaces are scraped and deep cleaned. If the gums are badly damaged, gum flap surgery (called excisional new attachment procedure) may be performed to surgically remove diseased gum tissue and underlying diseased tissue. Root surfaces are scraped and sutures are used to repair and tighten the gum tissue.

A less invasive laser technique is available, called laser-assisted new attachment procedure (LANAP). This technique, approved by the U.S. Food and Drug Administration, uses a laser instead of a scalpel to clean away diseased tissue without the need for cutting or stitching. The procedure is less painful with a faster recovery than the excisional technique, as well as a greater predictability for reattachment of gum tissue and bone growth.

Any underlying medical conditions should be assessed and treated, as they may be contributing to the gum disease. Such dental problems as poorly aligned teeth or grinding of the teeth may need to be addressed. **Nutrition** should be improved. If a severe infection such as trench mouth is present, antibiotics are given. The antibiotics may be delivered directly to the infected gum and bone tissues to ensure that high concentrations of the antibiotic reach the infected area.

Physicians have found that the importance of treating serious gum infections with antibiotics spreads from the mouth to affect general health. By looking for markers of inflammation throughout the body after treating some patients with gum infections with antibiotics, and not treating others, researchers have found oral bacteria from gum infections in arterial plaque.

Infected abscesses, especially of bone, are difficult to treat and require long-term antibiotic treatment to prevent recurrence of infection. Patients with gum disease should be reevaluated after three months to assess progress and further treatment needs.

KEY TERMS

Azole—Any member of a group of chemical compounds with five-membered rings containing one or more nitrogen atoms. Several azoles are used as antifungal medications.

Bentonite clay—A green clay of aluminum silicate containing magnesium and trace minerals. The clay can draw out agents of infection.

Dermatophyte—A type of fungus that is parasitic on skin and causes a skin disease.

Gingivitis—A mild form of periodontal disease that causes the gums to become red, swollen, and bleed easily. The condition can be treated with good oral care and with professional treatment.

Spirochetes—A type of spiral-shaped bacteria.

Sulcus—A v-shaped crevice where the gum line meets the teeth. A healthy sulcus measurement is 3 mm. As gum tissues become diseased, this crevice can measure 6 mm and above, allowing bacteria to develop.

Tinea—Any of several fungal infections of the skin, especially ringworm.

Expected results

With good dental habits, most simple cases of gum disease resolve. If the teeth and gums are not cared for or if the disease progresses for other reasons, there may be destruction of bone and a loss of teeth. Research indicates that the bacteria connected with plaque formation and chronic gum disease may enter the bloodstream and cause an infection that may bring on heart disease, **pneumonia**, or premature births.

Prevention

The teeth should be brushed with a fluoride toothpaste and flossed daily, after meals. An antiseptic rinse should be used after brushing and flossing to reduce bacteria. Fifteen minutes per day should be spent massaging the gums with **eucalyptus**, **witch hazel**, or vitamin E, rubbing a finger in a circular motion along the gum line. Toothbrushes should be changed monthly, since there may be a tendency for bacteria to accumulate on them. The toothbrush should also be soft to avoid further injury to the gums. A dentist should regularly check the health of the gums and teeth of people who are prone to gum disease. A dental hygienist should clean the teeth regularly, especially if there is an increased tendency to form plaque.

Patients who smoke or chew tobacco should make efforts to quit. Chemicals from cigarette smoke can slow the healing process and interfere with treatment. A physician can provide a referral to community **smoking** cessation programs and other resources to help patients quit smoking.

A whole foods diet is highly recommended. It should include fresh fruit and vegetables and plenty of dietary fiber. Such processed foods as sugar and white bread and grains contribute to plaque formation and should be avoided. Foods high in **vitamin C** should be consumed daily. Vitamin C is important in maintaining healthy gums, and supplementation may also be needed. As smoking reduces vitamin C absorption, the use of tobacco products should be avoided. Calcium and **magnesium** supplementation is recommended to minimize the loss of bone in progressive gum disease.

Behavioral management approaches to increase adherence to oral hygiene instructions may improve oral hygiene-related behaviors, but further research is needed in this area to determine exact effects.

Gymnema

Description

Gymnema (*Gymnema sylvestre*) is a climbing plant that grows in the tropical forests of central and southern India. The woody gymnema plant also grows

in parts of Africa. Leaves of this long, slender plant have been used for more than 2,000 years in India to treat diabetes. Gymnema is also known as gurmar, gurmabooti, periploca of the woods, and meshasringi (ram's horn).

General use

In the past, powdered gymnema root was used to treat snakebites, **malaria**, coughs, **constipation**, stomach complaints, water retention, and liver disease. However, the Hindu word gurmar best describes the primary use of gymnema. Gurmar means "sugar destroyer," and it has been used in **Ayurvedic medicine** for thousands of years to treat adult-onset diabetes, a condition once described as "honey urine."

The plant's sugar-destroying property was thought to be released when a person chewed on one or two leaves. Gymnema was said to paralyze a person's tongue to the taste of sugar and bitter tastes. That taste-blocking reaction lasted for several hours. During that time, leaves supposedly provided a slight block to the taste for salty foods, while the taste for acidic foods was not affected.

By blocking the taste buds from tasting sugar, gymnema blocked sugar in the digestive system, resulting in a decrease in blood sugar, also known as a hypoglycemic effect. This medicinal action has been studied since the 1930s.

Gymnema and diabetes

Diabetes is a condition characterized by high levels of sugar (glucose) in the blood. The glucose is affected by insulin, a hormone created by the pancreas. Insulin is necessary for cells to utilize glucose. Type I diabetes, or juvenile diabetes, is caused by the body's inability to produce enough insulin. Type II diabetes, or adult-onset diabetes, is caused by the body's inability to adequately process insulin. Frequently, the pancreas creates much more insulin than the body requires.

Type I diabetes is also called insulin-dependent **diabetes mellitus**, and Type II diabetes is known as non-insulin-dependent diabetes mellitus. In India, gymnema has been used by both Type I and Type II diabetics.

Contemporary uses of gymnema

Gymnema has been used in folk medicine as a remedy for diabetes, **allergies**, urinary tract inflections, **anemia**, hyperactivity, digestion, **cholesterol** management, and weight control. Most of those treatments did not prove to be effective. However, some studies of rats and mice indicated that gymnema might lower LDL (low-density lipoprotein), which is also known as bad cholesterol. As of early 2008, there were few controlled studies into the effectiveness of gymnema in treating cholesterol in humans.

Research on humans into the use of gymnema for treating diabetes progressed to the double-blind randomized trial stage, according to information posted on the United States National Institutes of Health Web site. The trial that started in India in January 2007 compared the glucose-lowering effect of gurmar (gymnema) with metformin, a prescription drug widely prescribed to control blood sugar. The trial intended to study 100 people whose Type II diabetes was recently detected. The study was open to men and women between the ages 25 and 70.

A possible weight-loss remedy

Although gymnema will not make sugary foods taste bad, the sugar destroyer has been said to curb the desire for sweets. Due to this sugar-blocking property, gymnema is marketed as a weight-loss remedy that people take to help fight the desire for sweet treats. As a weight-loss remedy, gymnema has not been studied extensively. Some in the medical community were dubious about its effectiveness. Instead, the sugar destroyer was acknowledged as a potential treatment for diabetes.

Preparations

In studies of humans involving the use of gymnema to control blood sugar, the daily dosage frequently ranged from 400 mg to 600 mg. The strength of commercial gymnema products varies, so a person should follow the directions on the package.

Gymnema is available commercially in various forms, including capsules, tinctures, and powdered herb. The capsule dosage is usually approximately 250–400 mg per day. Tinctures consist of a liquid such as alcohol and gymnema leaf extract. Tinctures include a product containing 300 mg of gymnema. A 1 ml dosage is mixed into water and consumed once or twice daily.

Gymnema is also available in powdered form. The recommended dosage for powdered gymnema leaves is 0.5–1 tsp (2–4 g) per day. An herbal tea can be prepared by pouring 1 cup (240 ml) of boiling water over the powdered leaves. The mixture is covered and steeped for 10–15 minutes. The tea is strained before it is consumed.

Precautions

The United States Food and Drug Administration (FDA) does not regulate herbal remedies such as gymnema, which means the FDA has not indicated if the remedies have been proven to be safe or effective. Furthermore, ingredients are not standardized to comply with regulations.

The safety of gymnema has not been established for use by children, pregnant women, and nursing mothers. In addition, safety has not been determined for people with severe kidney and liver diseases.

Before beginning any herbal treatment, people should consult a physician or health practitioner. Consulting a medical professional is particularly important before taking gymnema because the remedy could potentially lower blood sugar too much, resulting in a hypoglycemic reaction.

It is especially important for diabetics to consult with a doctor. Gymnema should not be regarded as a substitute for other medications, including insulin. Diabetics take insulin to control their blood sugar; they cannot replace the hormone with gymnema.

In addition, diabetes can go undetected for some time. It may not be diagnosed until a person goes to a doctor after experiencing symptoms such as frequent urination, **dizziness**, and **fatigue**. Diabetes must be treated medically since complications from untreated diabetes include kidney failure, **heart disease**, blindness, and loss of limbs.

Side effects

Gymnema could possibly lower the level of blood sugar, placing the diabetic at risk for **hypoglycemia**.

Interactions

Gymnema could interact with insulin and prescription medications and herbal remedies taken to reduce blood sugar levels. Taking gymnema could cause the drugs or herbals to work better, resulting in hypoglycemia. Diabetes-management drugs include metformin, glipizide, and glyburide. Herbal remedies that could trigger a reaction include **fenugreek**, **kudzu**, and large amounts of **ginger**.

Furthermore, the effects of cholesterol-lowering drugs and remedies could be increased for a person who also takes gymnema.

KEY TERMS

Ayurvedic medicine—Ayurveda is the Sanskrit word for the science of life and longevity. The Ayurvedic treatment is based on the theory that health is a balance between the physical, emotional, and the spiritual.

Glucose—Blood sugar.

Hypoglycemia—Low blood sugar.

Hair loss

Definition

Hair loss, or *alopecia*, is total or partial baldness caused by hormonal changes or physical or mental **stress**.

Description

Hair loss occurs for many reasons. Some causes, such as hormonal changes, are considered natural, while others signal serious health problems. Some conditions are confined to the scalp, while others reflect disease processes throughout the body.

Causes and symptoms

Androgenetic alopecia occurs in both men and women, and is considered normal in adult males. Also known as male pattern baldness, it is easily recognized by the distribution of hair loss over the top and front of the head (leaving a horseshoe pattern of hair) and by the healthy condition of the scalp. Women with androgenetic alopecia experience hair thinning, particularly over the top of the scalp. The disorder is thought to be caused by a genetic predisposition that triggers the production of certain enzymes that convert testosterone into the hormone dihydrotestosterone (DHT). DHT is known to shrink hair follicles, and can cause partial or complete hair loss.

Alopecia areata and *alopecia circumscripta* refer to hair loss conditions that can be patchy or extend to complete baldness. The exact cause of alopecia areata is unknown, but it is thought to be triggered by an immune system disorder.

Oftentimes, conditions affecting the skin of the scalp will result in hair loss. The first clue to the specific cause is the pattern of hair loss, whether it be complete baldness (*alopecia capitis totalis*), patchy bald spots, thinning, or hair loss confined to certain areas. Also a factor is the condition of the hair and the scalp beneath it. Sometimes only the hair is affected; sometimes the skin is visibly diseased as well.

Fungal infections of the scalp usually cause patchy hair loss. The fungus, similar to the ones that cause **athlete's foot** and ringworm, often glows under ultraviolet light.

Complete hair loss is a common result of **cancer** chemotherapy, due to the toxicity of the drugs used. Placing a tourniquet around the skull just above the ears during the intravenous infusion of the drugs may reduce or eliminate hair loss by preventing the drugs from reaching the scalp. However, this technique may not be recommended in the treatment of certain types of cancer. An investigational topical gel that may prevent chemotherapy-related hair loss, known as GW 8510, was in clinical trials as of April 2000.

Systemic diseases often affect hair growth either selectively or by altering the skin of the scalp. One example is thyroid disorders. **Hyperthyroidism** (too much thyroid hormone) causes hair to become thin and fine. **Hypothyroidism** (too little thyroid hormone) thickens both hair and skin. Several autoimmune diseases also affect the skin and potentially the hair, notably lupus erythematosus.

Hair loss can also be caused by *trichotillomania*, a mental disorder or compulsion that causes a person to pull out his/her own hair. In some individuals severe mental or physical stress can cause hair loss, including major surgery or illness, significant life changes (i.e., divorce, death of a loved one), and drastic dietary changes. This type of hair loss is called *Telogen effluvium,* and is the second most common type of hair loss.

Diagnosis

Dermatologists are skilled in diagnosis by sight alone. For more obscure diseases, they may have to resort to a skin biopsy, removing a tiny bit of skin using a local anesthetic so that it can be examined

KEY TERMS

Athlete's foot—A fungal infection between the toes, officially known as tinea pedis.

Autoimmune disease—Certain diseases caused by the body's development of an immune reaction to its own tissues.

Chemotherapy—The treatment of diseases, usually cancer, with drugs (chemicals).

Hair follicles—Tiny organs in the skin, each one of which grows a single hair.

Lupus erythematosus—An autoimmune disease that can damage skin, joints, kidneys, and other organs.

Ringworm—A fungal infection of the skin, also known as tinea corporis.

Systemic—Affecting all or most parts of the body.

under a microscope. Systemic diseases will require a complete evaluation by a physician, including specific tests to identify and characterize the problem.

Treatment

Traditional Chinese medicine (TCM) has a particular understanding of baldness that is different from the allopathic view. TCM recommends foods to eat and others to avoid, herbs to treat hair loss, and special hair massage. One Chinese approach is to first understand where there is weak energy in the body and to strengthen the qi (chi) of those organ systems. Treatment is not a one-shot approach but a well-rounded response.

Vitamins B_6 and **biotin** are thought to advocate healthy hair growth, as are the minerals **zinc**, **copper**, and **silica**. Fifty milligrams of silica a day is thought to encourage hair growth in young men with alopecia. The herb **horsetail** (*Equisetum arvense*) contains silica, and can be taken as an infusion, or tea. Copper and zinc have been shown to inhibit growth of the enzyme that causes DHT production. **Iron** supplements may be useful in individuals whose hair loss is caused by **anemia** or an inadequate intake of dietary iron.

The herbal remedies **saw palmetto** (*Serenoa repens*) and pygeum (*Pygeum africanum*) may be prescribed by an herbalist, naturopath, or holistic health-care professional to stop or slow hair loss. Saw palmetto is thought to stop DHT production, and pygeum influences testosterone production. Both can be taken orally as a dietary supplement. The Chinese herb He Shou Wun (*Polygonum multiflorum*) can be taken orally or applied as a topical formula.

For hair loss caused by trichotillomania (hair pulling), **behavioral therapy** may be a useful treatment program. If the hair pulling or hair loss itself is triggered by stress, there are a number of stress reduction therapies that can promote **relaxation**, including **aromatherapy**, muscle relaxation exercises, **yoga**, **guided imagery**, and **biofeedback**.

Allopathic treatment

Successful treatment of underlying causes is most likely to restore hair growth, be it the completion of chemotherapy, effective cure of a scalp fungus, or control of a systemic disease. Drugs such as minoxidil (Rogaine) and finasteride (Propecia, Proscar) promote hair growth in a significant minority of patients, especially those with male pattern baldness and alopecia areata. When used continuously for long periods of time, minoxidil produces satisfactory results in about one-quarter of patients with androgenic alopecia and as many as half the patients with alopecia areata. Both drugs have so far proven to be quite safe when used for this purpose. Side effects of Rogaine include some dryness and irritation of the scalp. Reported side effects of Propecia include infrequent cases of diminished sexual drive and **impotence**. Propecia is not approved for women because it can cause birth defects.

In 2001, a study was made of immunotherapy with diphencyprone to treat alopecia areata. A lag of three months from start of therapy to development of noticeable hair growth occurred. Researchers noted that the extent of the disease prior to therapy and age at time hair loss began, affected treatment success. Patients who were older at onset of baldness had a better success rate than those who were younger. The study concluded that long-term therapy was required for effectiveness.

Over the past few decades, a multitude of hair replacement methods performed by both physicians and non-physicians have appeared. They range from simply weaving someone else's hair in with the remains of an individual's own hair to surgically transplanting thousands of hair follicles one at a time.

Expected results

The prognosis for individuals with hair loss varies with the cause. It is generally much easier to lose hair than to regrow it. Even when it returns, it is often thin and less attractive than the original crop.

Halitosis

Definition

Halitosis, commonly called bad breath, is an unpleasant odor of the breath. Usually it is due to poor hygiene, but it can be an indication of underlying health problems.

Description

Halitosis is likely to be experienced by most adults and many children, at least occasionally. Some people are strongly convinced that bad breath is present when it is not. Bad breath can have a significant impact on a person's social and professional life.

Causes and symptoms

Accumulation of plaque on the teeth is a major cause of halitosis. Plaque is a mucus film that mixes with food particles, saliva, and bacterial residue in the mouth. Halitosis can also be caused by any number of other problems. These include sores in the mouth, infected tonsils, tooth or **gum disease**, fermentation of food particles in the mouth, sinus **infections**, and badly cleaned dentures. Conditions that may cause bad breath are not only limited to the oral and nasal areas. Other possible sources of the problem might be **indigestion**, lung infection, kidney failure, **tuberculosis**, **syphilis**, liver disease, stomach and intestinal problems, **stress**, dehydration, **zinc** deficiency, and **cancer**.

Cigarette **smoking** can also lead to bad breath, not only in the smoker, but also in someone constantly exposed to second-hand smoke. A diet high in fats, spicy foods, or one that includes coffee may contribute to unpleasant breath odors. Medications causing **dry mouth** or dehydration may also be a source of problems, since the flow of saliva helps clean out the mouth. Antihistamines, decongestants, antidepressants, anti-anxiety medications, diuretics, and some heart medications may have a dehydrating effect and could be a cause of bad breath.

According to **traditional Chinese medicine**, halitosis is caused by too much heat in the stomach that affects the mouth. The way to prevent it is by avoiding dairy products, coffee, alcohol, sugar, spicy food, and fried food that disrupt normal acid and enzyme levels in the body. If these foods are eliminated from the diet and halitosis continues, traditional Chinese medicine recommends taking **activated charcoal** tablets.

Diagnosis

The easiest way to determine if one has bad breath is to ask a friend who is trustworthy and discrete or to ask a doctor or dentist. A test that can be attempted on one's own, is to cup a hand over the mouth, exhale, and then inhale through the nose while smelling the breath. A physical examination by a doctor or dentist may be used to diagnose other problems that may be causing the bad breath.

Treatment

Leaves of **parsley**, *Petroselinum crispum;* **wintergreen**, *Gaultheria procumbens;* or **peppermint**, *Mentha piperita;* can be chewed to freshen the breath by the introduction of their aromatic substances into the lungs. A strong tea made of *Echinacea* spp.; **myrrh**, *Commiphora molmol*; and **bloodroot**, *Sanguinaria canadensis*; can be used as a daily mouthwash. Fresh apples, citrus fruits, and celery are also good foods for helping to clean out the mouth. Possible homeopathic remedies that may be useful for bad breath include ***Nux vomica*** and *Kali phosphoricum*. Supplementing with zinc and **vitamin C** may also be of benefit.

Allopathic treatment

The most effective treatment of bad breath is to treat the cause. If bad breath is a continuing problem

or there are other symptoms, such as bleeding gums, a doctor or dentist should be consulted. A medication change may be warranted if a prescription drug is contributing to bad breath. A physician should be consulted any time a change in medication is planned. Over-the-counter mouthwashes and rinses can be used to kill odor-causing bacteria in the mouth.

Expected results

Most bad breath can be treated successfully with good oral hygiene or medical care. Occasionally, a person may develop delusional or obsessive behavior regarding breath odor problems, and mental health counseling may be appropriate.

Prevention

A healthy diet, high in fresh fruits and vegetables and whole grains, should be eaten. Eating crunchy foods such as apples, carrots, or celery after meals can help scrape off plaque. Processed foods such as sugar and white bread and grains contribute to plaque formation and should be avoided. Spicy foods such as onions, peppers, **garlic**, pastrami, salami, pepperoni, anchovies, and others should be avoided. Plenty of water should be consumed throughout the day to avoid dehydration and dry mouth. Water should be consumed after taking any food or drink to wash away residues that may accumulate with plaque.

The teeth should be brushed and flossed daily after meals. Toothbrushes should be changed monthly, since there may be a tendency for bacteria to accumulate on them. Baking soda is a good choice for cleaning the teeth when bad breath is a problem. The baking soda makes the mouth pH less hospitable to odor-causing bacteria. Gentle brushing of the tongue should also be included in the routine of daily oral hygiene, since the tongue itself may harbor tiny particles of food. A device called a tongue blade can be useful for cleaning the tongue. It may be available from a store that sells Asian or Middle Eastern products. An oral irrigation device, such as a Water Pik, is recommended to more thoroughly remove food and debris from the teeth. Mouthwashes are often helpful, especially those containing zinc. A dentist should regularly check the health of the gums and teeth for disease. A dental hygienist should clean the teeth regularly, especially if there is an increased tendency to form plaque.

Hangnail *see* **Ingrown nail**

Hangover

Definition

Hangover is the collection of physical and mental symptoms that occur after a person drinks excessive amounts of alcohol. The ingestion of five to seven cocktails over a period of four to six hours usually will lead to hangover. The economic cost of hangover in the United States as of 2008 is $148 billion each year, or $2,000 per working adult, which is related to decreased productivity and absenteeism.

Description

Hangovers have probably been experienced since prehistoric time when alcohol was first discovered. A survey found that about 75% of the persons who drank enough to be intoxicated (drunk) sometimes experienced hangover. Although very prevalent, hangovers have not been extensively studied. It is known that ethanol is the primary chemical component of alcohol to produce the effects associated with drinking.

Whether hangover affects complex mental tasks and the performance of simple tasks is unclear. Studies

on these areas have yielded conflicting results, presumably due to differences in methods. Clearly, alcohol consumption can affect sleep, and sleep deprivation is known to affect performance.

Causes and symptoms

The cause of hangover is believed to be multifactorial. Hangover is likely caused by a combination of direct effects of ethanol, effects of ethanol removal, effects of ethanol breakdown products, effects of other components of the alcoholic beverage, personal characteristics, and behaviors associated with alcohol use.

Direct effects of ethanol

Ethanol can directly affect the body by causing dehydration (loss of fluids), electrolyte (body chemicals) imbalance, stomach and intestinal irritation, low blood sugar, and sleep disruption. In addition, alcohol directly affects the circadian rhythm (internal 24-hour clock) causing a feeling similar to **jet lag**. Ethanol causes vasodilation (enlarged blood vessels) and affects bodily chemicals, such as serotonin and histamine, which may contribute to the **headache** associated with hangover.

Effects of ethanol removal

Because hangover symptoms peak at around the same time that the blood alcohol concentration falls to zero, some researchers propose that hangover is actually a mild form of withdrawal. Excessive drinking causes changes in the chemical messenger system of the brain, and when the alcohol is removed, the system becomes unbalanced. Many of the symptoms of hangover are similar to those associated with mild withdrawal. Some differences exist, however, between hangover and withdrawal; specifically, hangover symptoms do not include the hallucinations, seizures, and the lengthy impairment of withdrawal.

Effects of ethanol breakdown products

In the body, ethanol is first broken down to acetaldehyde and then to acetate. Acetaldehyde is a reactive chemical that, at high concentrations, can cause sweating, rapid pulse, skin flushing, **nausea**, and **vomiting**. Some researchers believe that acetaldehyde causes hangover. Although there is no acetaldehyde in the blood when the blood alcohol concentration reaches zero, the toxic effects of acetaldehyde on the body may still persist.

Other factors

Most alcoholic beverages contain small amounts of other active compounds besides ethanol. These compounds add to the smell, taste, and appearance of the beverage. Gin or vodka, which contain almost pure ethanol, produce fewer hangover symptoms than alcoholic beverages that contain other alcohol compounds (such as red wine, brandy, or whiskey). For example, methanol is implicated in contributing to hangover. Red wine, whiskey, and brandy all contain high levels of methanol.

Some inherent personal traits place persons at risk of experiencing hangover. In some persons, high levels of acetaldehyde accumulate (because of a deficient enzyme), which causes them to experience more severe hangovers. Persons who are neurotic, angry, or defensive, feel guilty about drinking, experience negative life events, or have a family history of **alcoholism** have increased hangover symptoms.

Certain behaviors associated with drinking increase the chance of experiencing hangover. These include drug use, disruption of normal sleep patterns, restricted food intake, and cigarette use.

Hangover symptoms begin within several hours after a person has stopped drinking and may last up to 24 hours. The specific symptoms experienced may vary depending upon the individual, the occasion, and the type and amount of alcohol consumed. The physical symptoms of hangover include headache, **fatigue**, light and sound sensitivity, muscle aches, eye redness, thirst, nausea, vomiting, and stomach **pain**. Hangover can cause rapid heartbeat, **tremor**, increased blood pressure, and sweating. Mental symptoms associated with hangover are decreased sleep, changes in sleep stages, decreased attention, decreased concentration, **depression**, **dizziness**, **anxiety**, irritability, and a sense that the room is spinning (vertigo).

British research at the University of Exeter and University of Plymouth found that complementary and traditional forms of relieving hangover are ineffective, and this research recommends avoiding alcohol or consuming it in moderation as the most effective strategy in avoiding hangover.

Treatment

Eating balanced meals, drinking extra water, and limiting total alcohol intake help to reduce or avoid hangover. There are also many alternative treatments to prevent or reduce hangover symptoms. Drinking additional alcohol to relieve hangover, although it reduces short-term symptoms, is not recommended.

Some experts believe that drinking alcohol to relieve hangover is a sign of impending alcoholism. The primary measure for fighting hangover is to drink plenty of water while drinking alcoholic beverages, before going to bed, and the day after. Sweating from exertion, **exercise**, sauna, or massage may also help.

Food therapy

Hangover symptoms may be reduced by taking in lots of extra water and fluids and by eating foods that are high in **vitamin C** and the B vitamins, which are believed to speed the removal of alcohol from the body. Oranges, guava, grapefruit, and strawberries are rich in vitamin C, and beans, fish, and whole grains are rich in the B vitamins. A cocktail prepared from orange juice (1 cup), pineapple juice (1 cup), kiwi fruit (one), vitamin-B-enriched nutritional yeast (1 tablespoon), and honey (1 tablespoon) provides important nutrients which the body needs to recover from hangover. Juice therapists recommend drinking a mixture of carrot juice (8 oz), beet juice (1 oz), celery juice (4 oz), and **parsley** juice (1 oz) twice during hangover. The Chinese drink fresh tangerine juice and eat 10 strawberries to treat hangover.

Eating bland complex carbohydrates, such as crackers or toast, is easy on the stomach and helps to raise blood sugar levels. Because alcohol can irritate the gastrointestinal tract, bland foods are more easily tolerated. Drinking tea or coffee can relieve fatigue and possibly the headache. Throughout the world, traditional food remedies for hangover have certain ingredients in common. These include eggs, tripe, hot spices, hearty soups, and fruit and vegetable juices. These foods all serve to replenish vitamins, minerals, and other nutrients lost by the body as it detoxifies alcohol.

Ayurveda

Ayurvedic practitioners believe that hangover reflects the symptoms of excess pitta. Immediate relief may be found after drinking water containing lime juice (1 teaspoon), sugar (one half teaspoon), salt (pinch), and baking soda (one half teaspoon). Orange juice containing cumin (pinch) and lime juice (1 teaspoon) helps hangover. Drinking cool lassi, water containing yogurt (1 tablespoon) and cumin powder (pinch), three or four times daily may relieve nausea, headache, and drowsiness.

Herbals

The following herbal remedies are useful in treating hangover symptoms:

- An Ayurvedic remedy is to take one-half teaspoon of a mixture of *shatavari* (5 parts), *shanka bhasma* (one-eighth part), *kama dudha* (one-eighth part), and *jatamamsi* (3 parts) with water 2 to 3 times daily.
- An Ayurvedic antidote for alcohol toxicity is one-half teaspoon of *tikta* (or myrrh, aloe vera, or *sudharshan*) with warm water three times during the day.
- Barberry (*Barberis vulgaris*) tea reduces hangover symptoms.
- Dandelion (*Taraxacum officinale*) and burdock (*Arctium lappa*) tea (with gentian extract, powdered ginger, and honey) can ease the nausea.
- Evening primrose (*Oenothera biennis*) oil helps to replenish lost gamma-linoleic acid.
- Milk thistle (*Silybum marinum*) reduces alcohol toxicity on the liver.
- Nux vomica (*Strychnos nux vomica*) is a homeopathic antidote for alcohol over-consumption.
- Siberian ginseng (*Eleutherococcus senticosus*) helps the body adjust to the stress of alcohol toxicity.
- Wintergreen (*Gaultheria procumbens*) tea with hot pepper (*Capsicum*) sauce relieves the headache.

Other hangover remedies

Other remedies for hangover are as follows:

- Acupressure. Point LI 4 (between the thumb and index finger) relieves headache and stomach ailments and the B2 points (upper edge of the eye socket) relieves headache accompanied by light sensitivity.
- Aromatherapy. The nausea of hangover may be relieved by drinking an aromatic cocktail of water, lemon juice, and a drop of fennel essential oil before breakfast.
- Imagery. The hangover sufferer may visualize being on a ship in a stormy ocean. The ocean gradually becomes calm until the ship is gently bobbing in the water.
- Probiotics. The bacteria *Bifidobacterium bifidus* is able to remove alcohol breakdown products. To fight hangover, naturopaths recommend taking *B. bifidus* before going to bed and again the following day.
- Supplements. Taking 50 mg of vitamin B_3 before going to bed may relieve hangover.
- Hydrotherapy. Drinking a glass of water containing activated charcoal powder before going to bed may absorb alcohol in the stomach and reduce hangover symptoms.

KEY TERMS

Acetaldehyde—An intermediate product in the breakdown pathway of ethanol; believed to cause hangover.

Dehydration—Loss of fluids from the body. Dehydration worsens some of the symptoms of alcohol.

Ethanol—The chemical that causes the effects and aftereffects of drinking alcoholic beverages.

Methanol—A liquid alcohol, used as a solvent or denaturant for ethanol.

Withdrawal—The physical and mental symptoms caused by removal of alcohol or other addictive substance from the body.

Allopathic treatment

Hangover symptoms may be relieved by taking antacids for nausea and stomach pain and aspirin or a nonsteroidal anti-inflammatory drugs (ibuprofen or naproxen) for headache and muscle pains. Acetaminophen (Tylenol) should be avoided while drinking or during hangover because alcohol enhances acetaminophen's toxic effects on the liver. **Caffeine**, usually taken as coffee, is historically used to treat hangover, although this has not been studied as of 2008.

Going for a walk may also relieve the symptoms.

Expected results

There is no cure for hangover. Left untreated, hangover will resolve within several hours. Treatments may reduce the severity of certain symptoms.

Prevention

Hangover may be prevented by limiting the intake of alcohol or drinking alcoholic beverages with a lesser incidence of causing hangover such as gin, vodka, or pure ethanol. Getting adequate sleep may reduce the fatigue associated with hangover. Drinking nonalcoholic beverages, both during and after drinking alcohol, may reduce dehydration and reduce hangover symptoms. Taking 120 mg of **milk thistle** before drinking can help the liver detoxify the alcohol.

Hashimoto's thyroiditis

Definition

Hashimoto's thyroiditis, also known as chronic lymphocytic thyroiditis or autoimmune thyroiditis, is an autoimmune disease characterized by thyroid gland failure due to chronic inflammation.

Description

Hashimoto's thyroiditis is the most common inflammatory thyroid disorder and is the leading cause of **hypothyroidism**, especially in iodine-sufficient regions of the world. An enlarged thyroid gland is characteristic of the disease. During the course of this disease, the cells of the thyroid are unable to convert **iodine** into thyroid hormones.

The term Hashimoto's thyroiditis can be attributed to the Japanese surgeon, Hashimoto Hakaru, who first described this chronic thyroid disorder as struma lymphomatosa in a 1912 pathology report.

Demographics

Hashimoto's thyroiditis is more common in women than in men with a ratio of approximately 7:1. It is most common in women aged 30 to 50. However, the condition can also occur in children.

Causes and symptoms

Causes

Hashimoto's thyroiditis is an autoimmune disease thought to be activated by certain antibodies that

attack the thyroid gland and inhibit the production of thyroid hormones, disrupting the body's natural metabolic processes. However, the exact mechanism of the autoimmunity is unknown.

A low prevalence of Hashimoto's thyroiditis is associated with mild iodine deficiency, although excessive iodine intake is associated with a higher prevalence of the disease.

Medications such as interferon, lithium, and amiodarone increase the risk of the disease. In some cases, treatment for **hyperthyroidism**, including radioactive iodine or surgical resection, can result in hypothyroidism. Environmental radiation exposure also increases the risk.

The condition can develop after **pregnancy** or a viral illness, and it may be related to pituitary or hypothalamus gland dysfunction or to tumors on these glands or the thyroid itself. It is considered a genetic trait, with an increased incidence among first-degree relatives who have the condition.

Symptoms

Visible thyroid enlargement or nodular growths may be signs of Hashimoto's thyroiditis. Symptoms generally develop slowly over several years and include:

- fatigue
- intolerance to cold
- menstrual cycle changes, infertility
- unexplained weight gain
- dry, coarse skin and hair
- yellowish skin
- puffy face
- hoarse voice
- muscle aches or cramps
- joint stiffness
- constipation
- mental and memory impairment, decreased concentration
- depression

Pain is not usually a symptom of Hashimoto's thyroiditis, but some patients do experience prolonged pain and tenderness.

Diagnosis

The results of the patient's medical history are evaluated, and a physical examination, including palpation of the patient's neck to detect enlargement or nodular growths, are performed. The physician may also perform skin and eye exams to rule out other conditions or possible complications.

Because thyroid antibodies are elevated in patients with Hashimoto's thyroiditis, a blood test that measures antithyroid antibody levels can be performed to help identify the disease. Measurement of thyroid-stimulating hormone (TSH or thyrotrophin) in the blood also helps identify the disease, since the level of TSH rises dramatically when the there is an underproduction of the thyroid hormone.

Cardiac function tests and an ultrasound may also be performed. A thyroid biopsy (tissue removal for laboratory analysis) is only performed if a suspicious area or nodule is found upon examination.

Although most physicians can diagnose and treat Hashimoto's thyroiditis, consultation with a clinical endocrinologist is recommended for the following patients, according to the *American Association of Clinical Endocrinologists Medical Guidelines for Clinical Practice for the Evaluation and Treatment of Hyperthyroidism and Hypothyroidism*:

- patients under age 18
- patients unresponsive to therapy
- pregnant patients
- patients with known cardiovascular disease
- patients who have a goiter, nodule, or other structural thyroid changes
- patients with other endocrine diseases

Treatment

Complementary treatment

Natural extracts that contain thyroid-derived hormone from the glands of pigs are alternative treatments for Hashimoto's thyroiditis. One such product, Armour Thyroid, contains both levothyroxine (T4) and triiodothyronine (T3). However, physicians do not recommend natural thyroid hormone extracts for several reasons. According guidelines published by the American Association of Clinical Endocrinologists, the bioequivalence of levothyroxine preparations is based on total measurement of active thyroid hormones (T3 and T4) and not TSH blood levels, so the required therapeutic dosage cannot be accurately assessed. Additionally, the balance of hormones in biological products is not the same as in humans. As of 2008, there were no safety reviews, scientific evidence, or approved therapeutic uses of natural thyroid hormone extracts by the FDA. Lastly, product formulations may

vary, depending on the manufacturer, which could alter TSH to uncertain levels.

Allopathic treatment

Synthetic hormone replacement therapy with oral levothyroxine (synthetic thyroxine, T4) is the standard treatment for Hashimoto's thyroiditis if a deficiency of TSH is confirmed in blood test results. Daily supplementation with levothyroxine can help correct symptoms of thyroid deficiency, reduce the size of the thyroid or goiter, and prevent further enlargement. Improvements in symptoms may not be noted until a few months after treatment because the thyroid hormone acts slowly in the body. The dosage is evaluated within six months after therapy initiation to determine if an adjustment is necessary. The patient's dosage continues to be adjusted until optimal effects are achieved. Blood tests may be performed periodically to monitor the patient's response to the medication.

Contraindications for levothyroxine therapy include prior **heart attack**, thyrotoxicosis, or an untreated adrenal condition. Diabetes medications may need to be adjusted at the onset of levothyroxine therapy. Some foods, including soy products, salt substitutes, and high-iron foods, and nutritional supplements (**calcium**, **iron**, **potassium**, or iodine) may interfere with the body's ability to absorb the synthetic hormone. A registered dietitian can provide specific dietary guidelines for patients taking levothyroxine. Amiodarone should not be taken with thyroxine, and patients should discuss all current medications, including vitamins and supplements, with their physician prior to starting levothyroxine treatment.

If patients develop a **fever**, rash, **jaundice**, or joint pain, they should promptly discontinue their medication and contact their physician, as these may be signs of an allergic reaction or a needed dose adjustment. To make dose adjustments, the physician reviews the results of lab tests to evaluate the patient's response to the medication. Patients should maintain a regular follow-up schedule with their physician for close monitoring.

Antiinflammatory medications, and occasionally steroid therapy, may be prescribed to manage symptoms of pain.

Surgical removal of the thyroid gland, called thyroidectomy, is uncommon but may be necessary in select cases.

KEY TERMS

Endocrinologist—A physician who specializes in the diagnosis and treatment of endocrine system conditions, including thyroid dysfunction.

Goiter—An enlargement of the thyroid gland that is often visible as a lump in the middle of the lower neck.

Hyperthyroidism—High thyroid activity marked by excessive levels of thyroid hormones.

Hypothyroidism—Low thyroid activity marked by low levels of thyroid hormones.

Iodine—A trace mineral used by the body to produce thyroid hormones.

Metabolism—Biochemical processes related to the breakdown of food and its conversion into energy.

Thyroid—A small gland, located in the middle of the lower neck. A properly functioning thyroid maintains a balance of thyroid hormones to sufficiently regulate the body's metabolism.

Thyroditis—Inflammation of the thyroid.

Thyrotoxicosis—High blood levels of the thyroid hormone levels, thyroxine (T4), triiodothyronine (T3), or both.

Prognosis

Hashimoto's thyroiditis is a chronic condition. However, with early diagnosis, proper treatment, and careful monitoring, symptoms can be managed and the patient can lead a normal, healthy life.

Potential complications of untreated Hashimoto's thyroiditis include an increased risk of **heart disease**, due to the increased levels of LDL **cholesterol** from an underactive thyroid, as well as an increased risk of **sleep apnea**. There is also an increased risk of birth defects in babies born to women with untreated hypothyroidism.

Prevention

There is no known prevention for Hashimoto's thyroiditis, although awareness of risk factors can aid early diagnosis and treatment to improve long-term outcomes.

A doctor should be notified if the following occurs:

- A fever, rash, jaundice, or joint pain
- Unfamiliar, unexplained symptoms

Hatha yoga

Definition

Hatha **yoga** is the most widely practiced form of yoga in America. It is the branch of yoga that concentrates on physical health and mental well-being. Hatha yoga uses bodily postures (*asanas*), breathing techniques (*pranayama*), and **meditation** (*dyana*) with the goal of bringing about a sound, healthy body and a clear, peaceful mind. There are nearly 200 hatha yoga postures, with hundreds of variations, which work to make the spine supple and to promote circulation in all the organs, glands, and tissues. Hatha yoga postures also stretch and align the body, promoting balance and flexibility.

Origins

Yoga was developed in ancient India as far back as 5,000 years ago; sculptures detailing yoga positions have been found in India which date back to 3000 B.C. Yoga is derived from a Sanskrit word which means "union." The goal of classical yoga to bring self-transcendence, or enlightenment, through physical, mental and spiritual health. Many people in the West mistakenly believe yoga to be a religion, but its teachers point out that it is a system of living designed to promote health, peace of mind, and deeper awareness of ourselves. There are several branches of yoga, each of which is a different path and philosophy toward self-improvement. Some of these paths include service to others, pursuit of wisdom, non-violence, devotion to God, and observance of spiritual rituals. Hatha yoga is the path that has physical health and balance as a primary goal, for its practitioners believe that greater mental and spiritual awareness can be brought about with a healthy and pure body.

The origins of hatha yoga have been traced back to the eleventh century A.D. The Sanskrit word *ha* means "sun" and *tha* means "moon," and thus hatha, or literally sun-moon yoga, strives to balance opposing parts of the physical body, the front and back, left and right, top and bottom. Some yoga masters (*yogis*) claim that hatha yoga was originally developed by enlightened teachers to help people survive during the Age of Kali, or the spiritual dark ages, in which Hindus believe we are now living.

The original philosophers of yoga developed it as an eight-fold path to complete health. These eight steps include moral and ethical considerations (such as honesty, non-aggression, peacefulness, generosity, and sexual propriety), self-discipline (including purity, simplicity, devotion to God, and self-knowledge), posture, breath control, control of desires, concentration, meditation, and happiness. According to yogis, if these steps are followed diligently, a person can reach high levels of health and mental awareness.

As it has subsequently developed, hatha yoga has concentrated mainly on two of the eight paths, breathing and posture. Yogis believe breathing to be the most important metabolic function; we breathe roughly 23,000 times per day and use about 4,500 gallons of air, which increases during **exercise**. Thus, breathing is extremely important to health, and *prana*, or life-force, is found most abundantly in the air and in the breath. If we are breathing incorrectly, we are hampering our potential for optimal health. *Pranayama*, literally the "science of breathing" or "control of life force," is the yogic practice of breathing correctly and deeply.

In addition to breathing, hatha yoga utilizes asanas, or physical postures, to bring about flexibility, balance and strength in the body. Each of these postures has a definite form and precise steps for achieving the desired position and for exiting it. These postures, yogis maintain, have been scientifically developed to increase circulation and health in all parts of the body, from the muscular tissues to the glands and internal organs. Yogis claim that although hatha yoga can make the body as strong and fit as any exercise program, its

KEY TERMS

Asana—Yoga posture or stance.

Diaphragm breathing—Method of deep breathing using the entire lungs.

Dyana—Yoga meditation.

Meditation—Technique of mental relaxation.

Prana—Yoga term for life-enhancing nutrient found in air, food and water.

Pranayama—Yoga method of breathing.

real benefits come about because it is a system of maintenance and balance for the whole body.

Yoga was brought to America in the late 1800s, when Swami Vivekananda, an Indian yogi, presented a lecture on yoga in Chicago. Hatha yoga captured the imagination of the Western mind, because accomplished yogis could demonstrate incredible levels of fitness, flexibility, and control over their bodies and metabolism. Yoga has flourished in the West. Americans have brought to yoga their energy and zest for innovation, which troubles some Indian yogis and encourages others, as new variations and schools of yoga have developed. For instance, power yoga is a recent Americanized version of yoga which takes hatha yoga principles and speeds them up into an extremely rigorous aerobic workout, and many strict hatha yoga teachers oppose this sort of change to their philosophy. Other variations of hatha yoga in America now include Iyengar, Ashtanga, Kripalu, Integral, Viniyoga, Hidden Language, and Bikram yoga, to name a few. Sivananda yoga was practiced by Lilias Folen, who was responsible for introducing many Americans to yoga through public television.

Iyengar yoga was developed by B.K.S. Iyengar, who is widely accepted as one of the great living yogis. Iyengar uses classical hatha yoga asanas and breathing techniques, but emphasizes great precision and strict form in the poses, and uses many variations on a few postures. Iyengar allows the use of props such as belts, ropes, chairs, and blocks to enable students to get into postures they otherwise couldn't. In this respect, Iyengar yoga is good for physical therapy because it assists in the manipulation of inflexible or injured areas.

Ashtanga yoga, made popular by yogi K. Patabhi Jois, also uses hatha yoga asanas, but places an emphasis on the sequences in which these postures are performed. Ashtanga routines often unfold like long dances with many positions done quickly one after the other. Ashtanga is thus a rigorous form of hatha yoga, and sometimes can resemble a difficult aerobic workout. Ashtanga teachers claim that this form of yoga uses body heat, sweating, and deep breathing to purify the body.

Kripalu yoga uses hatha yoga positions but emphasizes the mental and emotional components of each asana. Its teachers believe that tension and long-held emotional problems can be released from the body by a deep and meditative approach to the yoga positions. Integral yoga seeks to combine all the paths of yoga, and is generally more meditative than physical, emphasizing **spirituality** and awareness in everyday life. Viniyoga tries to adapt hatha yoga techniques to each individual body and medical problem. Hidden Language yoga was developed by Swami Sivananda Radha, a Western man influenced by Jungian psychology. It emphasizes the symbolic and psychological parts of yoga postures and techniques. Its students are encouraged to write journals and participate in group discussions as part of their practice. Bikram yoga has become very popular in the late 1990s, as its popular teacher, Bikram Choudury, began teaching in Beverly Hills and has been endorsed by many famous celebrities. Bikram yoga uses the repetition of 26 specific poses and two breathing techniques to stretch and tone the whole body.

Benefits

In a celebrated 1990 study, *Dr. Dean Ornish's Program for Reversing Heart Disease* (Random House), a cardiologist showed that yoga and meditation combined with a low-fat diet and group support could significantly reduce the blockage of coronary arteries. Other studies have shown yoga's benefit in reducing stress-related problems such as high blood pressure and **cholesterol**. Meditation has been adopted by medical schools and clinics as an effective **stress** management technique. Hatha yoga is also used by physical therapists to improve many injuries and disabilities, as the gentleness and adaptability of yoga make it an excellent rehabilitation program.

Yoga has been touted for its ability to reduce problems with such varying conditions as **asthma**, backaches, diabetes, **constipation**, **menopause**, **multiple sclerosis**, **varicose veins**, and **carpal tunnel syndrome**. A vegetarian diet is the dietary goal of yoga, and this change of lifestyle has been shown to significantly increase longevity and reduce **heart disease**.

Yoga as a daily exercise program can improve fitness, strength, and flexibility. People who practice yoga correctly every day report that it can promote

high levels of overall health and energy. The mental component of yoga can clarify and discipline the mind, and yoga practitioners say its benefits can permeate all facets of a person's life and attitude, raising self-esteem and self-understanding. Once individuals learn the basics of yoga, certain poses can be used to help with particular needs, such as improving memory and concentration or reducing bloating and **gas** after meals.

Description

A hatha yoga routine consists of a series of physical postures and breathing techniques. Routines can take anywhere from 20 minutes to two hours, depending on the needs and ability of the practitioner. Yoga should always be adapted to one's state of health; that is, a shorter and easier routine should be used when a person is fatigued. Yoga is ideally practiced at the same time every day, to encourage the discipline of the practice. It can be done at any time of day; some prefer it in the morning as a wake-up routine, while others like to wind down and de-stress with yoga at the end of the day.

Yoga asanas consist of three basic movements: backward bends, forward bends, and twisting movements. These postures are always balanced; a back bend should be followed with a forward bend, and a leftward movement should be followed by one to the right. Diaphragm breathing is important during the poses, where the breath begins at the bottom of the lungs. The stomach should move outward with the inhalation and relax inward during exhalation. The breath should be through the nose at all times during hatha asanas. Typically, one inhales during backward bends and exhales during forward bending movements.

The mental component in yoga is as important as the physical movements. Yoga is not a competitive sport, but a means to self-awareness and self-improvement. An attitude of attention, care, and non-criticism is important; limitations should be acknowledged and calmly improved. Patience is important, and yoga stretches should be slow and worked up to gradually. The body should be worked with, and never against, and a person should never overexert. A yoga stretch should be done only so far as proper form and alignment of the whole body can be maintained. Some yoga stretches can be uncomfortable for beginners, and part of yoga is learning to distinguish between sensations that are beneficial and those that can signal potential injury. A good rule is that positions should be stopped when there is sharp **pain** in the joints, muscles, or tendons.

Preparations

All that is needed to perform hatha yoga is a flat floor and adequate space for stretching out. A well-ventilated space is preferable, for facilitating proper breathing technique. Yoga mats are available that provide non-slip surfaces for standing poses. Loose, comfortable clothing should be worn. Yoga should be done on an empty stomach; a general rule is to wait three hours after a meal.

Yoga is an exercise that can be done anywhere and requires no special equipment. Yoga uses only gravity and the body itself as resistance, so it is a low-impact activity excellent for those who don't do well with other types of exercise. The mental component of yoga can appeal to those who get bored easily with exercise. By the same token, yoga can be a good stress management tool for those who prefer movement to sitting meditation.

Precautions

As with any exercise program, people should check with their doctors before starting yoga practice for the first time. Those with medical conditions, injuries or spinal problems should find a yoga teacher familiar with their conditions before beginning yoga. Pregnant women, particularly after the third month of **pregnancy**, should only perform a few yoga positions with the supervision of an experienced teacher. Some yoga asanas can be very difficult, and potentially injurious, for beginners, so teachers should always be consulted as preparation for advanced yoga positions. Certain yoga positions should not be performed by those with fevers, or during **menstruation**.

Side effects

Those just beginning hatha yoga programs often report **fatigue** and soreness throughout the body, as yoga stretches and exercises muscles and tendons that are often long-neglected. Some yogic breathing and meditation techniques can be difficult for beginners and can cause **dizziness** or disorientation; these are best performed under the guidance of a teacher.

Training and certification

At this time, there are no generally accepted standards for yoga teacher certification in the United States, unlike in Europe and England, where yoga schools have been standardized. Some schools in the United States require teachers to study for many years, while some will grant beginning certificates in a much shorter time. When choosing teachers, students should search

for qualities they may require, such as understanding, patience, knowledge of certain medical conditions, carefulness, and attention to individual details.

Yoga classes cost around 10 dollars per session. Many communities, schools, and health organizations offer discounted or free yoga classes as part of health awareness programs. Yoga can be reimbursed by insurance when it is part of physical therapy.

Hawthorn

Description

Hawthorn is a dense, thorny shrub that grows 5–13 ft (1.5–4 m) high. It has white flowers that look like roses and is considered one of the most beautiful of all the shrubs that flower in the spring. A member of the rose family, it has been planted along hedges to deter trespassers since the Middle Ages. Hawthorn grows throughout the world in moist areas.

Hawthorn is the common name for *Crataegus oxyacantha* or other *Crataegus* species. There are more than 300 species throughout the world. Hawthorn's flowers, leaves, and fruit (berries) are used as medicine, although the flowers have an unpleasant smell and taste slightly bitter. The hawthorn fruit is sour.

Hawthorn leaves. *(Photo by Kelly Quin. Reproduced by permission.)*

Hawthorn is one of the oldest medicinal plants known in Europe, where it has been used since the Middle Ages for heart problems. The ancient Greeks and Native Americans also recognized hawthorn's heart-healthy properties.

Hawthorn also is called *Crataegus* extract, mayflower, maybush, and whitethorn. Common trade names for hawthorn include Cardiplant, Hawthorn Berry, Hawthorn Formula, Hawthorn Heart, Hawthorn Phytosome, and Hawthorn Power.

General use

Hawthorn most commonly is used to treat **heart disease** and to treat and prevent cardiovascular disorders. Herbalists consider hawthorn to be the world's best heart tonic. It increases blood flow to the heart by dilating the coronary arteries; lowers blood pressure and eases the heart's workload by dilating arteries in the arms and legs; and increases the force of the heart's contractions.

In Europe, scientific studies have shown that the hawthorn leaf expands the blood vessels and lets more oxygen-rich blood reach the heart muscles; increases the strength of the heartbeat and slightly increases its speed; and helps the heart by reducing resistance throughout the rest of the circulatory system. Hawthorn leaf is used for **angina** and weak heart.

In addition to praising its benefits for cardiovascular insufficiency, **edema**, and the breathing difficulties associated with circulatory problems, James A.

Duke, writing in his book *Dr. Duke's Essential Herbs* (2000), suggests that dried hawthorn fruit and flowers may also be useful in treating **attention-deficit hyperactivity disorder** (ADHD).

Hawthorn is also a powerful antioxidant. There is strong evidence that **antioxidants** lower the risk of heart attacks, strokes, and deaths from heart diseases, but this has not been proven in studies. Antioxidants are believed to help the coronary arteries dilate and increase blood flow to the heart. They may prevent blockages from coming back after a surgical procedure called angioplasty.

Hawthorn is used, in conjunction with standard medical treatment, for heart failure classified as mild to moderate (stage II) by the New York Heart Association and to prevent angina. Mild to moderate heart failure includes patients with heart disease who do not have any limitations in their physical activities due to the heart disease. They are comfortable when resting and feel symptoms such as **fatigue**, palpitation, shortness of breath, or angina **pain** when performing ordinary physical activities.

Hawthorn has long been used in Europe to treat mild cases of heart failure. In Germany, the Federal Institute for Drugs and Medical Devices has approved the use of hawthorn leaf with flower extracts as a treatment for New York Heart Association functional stage II heart failure. The treatment also is listed in the German Pharmacopeia and approved in the German Commission E monographs.

A 2003 trial of more than 200 patients, consisting of 16 weeks of hawthorne treatment, demonstrated an increased **exercise** capacity and decreased signs and symptoms on heart failure. Hawthorn was slightly more effective at a higher dose (1,800 mg per day).

In two studies of heart attacks in animals, reported in 2004 in the *Journal of Pharmacy and Pharmacology*, hawthorn extract was demonstrated to significantly reduce heart injury and death.

In a 2005 study reported in *Phytomedicine* people diagnosed with orthostatic hypotension (OH) experienced significant improvement in the condition. The one-week study combined hawthorn berry extract and camphor. Patients taking the blend experienced normalized blood pressure and some relief from the rapid drop in blood pressure and the **dizziness** when standing typical in orthostatic hypotension.

The Hawthorne Extract Randomized Blinded Chronic Heart Failure (HERB CHF) trial reported at the 2004 meeting of the Heart Failure Society of America, involved 120 patients diagnosed with chronic mild to moderately severe heart failure. One group was treated with 450 mg of hawthorne extract (WS 1442, Schwabe Pharmaceuticals, Karlsruhe, Germany) twice daily in addition to receiving standard medical therapy for heart failure (ACE inhibitor, beta-blocker, digoxin, and a diuretic as needed). A control group received a placebo in addition to the standard medical therapy. After six months, investigators found no evidence that the hawthorn extract, in 450 mg dosages twice daily, brought functional improvement or relief of symptoms in patients with chronic mild to moderately severe heart failure who are also receiving standard heart failure therapy.

In another trial, known as the Survival and Prognosis Investigation of Crataegus Extract (SPICE) trial, researchers investigated the effects of hawthorn extract (WS 1442 with a 17% to 20% concentration of oligomeric procyanidins) on the mortality of patients with congestive heart failure. According to Steve Stiles, writing in 2007 in the on-line publication *Heart Wire*, "hawthorn failed to show any incremental benefit when given with standard drug therapy to patients with chronic systolic heart failure."

In addition to capsules, hawthorn may be taken in liquid form for **insomnia** and nervous conditions and is used as a gargle for sore throats. In folk medicine, hawthorn is used as a heart tonic and treatment, to regulate blood pressure, and as a sedative, but as of 2008 it had not been proven effective in clinical studies.

Preparations

Hawthorn is most commonly used in liquid or dry extracts or as capsules. It is collected and dried at room temperature. The dosage of hawthorn varies and the manufacturer's directions should always be followed. A typical dose of hawthorn might be 160 to 900 mg of extract given in two or three doses a day or 1 gram of crushed herb taken up to five times a day. Hawthorn is slow acting and should be taken for at least six weeks duration. It should be stored in a tightly sealed container and protected from the light.

Precautions

Hawthorn should only be used for diagnosed heart conditions. Women who are pregnant or breast feeding should take hawthorn only under the advice of a physician. Patients who are sensitive to other types of **Rosacea** plants should not take hawthorn.

Hawthorn leaf only is useful for angina when it is used over a long period of time. It can sometimes prevent angina, but it cannot treat an angina attack.

KEY TERMS

Angina—A type of pain in the chest caused by a temporary inadequate blood supply to the heart. Angina usually occurs after excitement or exertion.

Angioplasty—Surgery to dilate the narrowed or blocked part of a blood vessel.

Arrhythmia—An abnormal rate or rhythm of the heartbeat.

Cardiac glycosides—Drugs that block the enzyme that regulates the electrical activity of the heart.

Cardiovascular—Related to the heart and lungs.

Dyspnea—Shortness of breath.

Palpitation—A feeling of irregular or rapid heartbeat.

Side effects

Hawthorn rarely has side effects. In high doses, hawthorn can cause a severe drop in blood pressure, arrhythmias, and sedation.

Interactions

Since hawthorn performs the same function as some nitrates, cardiac glycosides, central nervous system depressants, and medications for high blood pressure, lower doses of these medications might be needed. Individuals ought to consult a qualified practitioner for appropriate dosages.

Hay fever

Definition

Hay **fever**, which is also called allergic **rhinitis**, is a common allergic condition. A main feature of the condition is an inflammation of the nasal passages, or rhinitis, caused by an allergic reaction to pollen. Hay fever usually occurs when airborne plant pollens are at their highest levels in the spring, summer, and early fall.

Symptoms of hay fever

Symptoms

Sneezing

Runny nose

Watery eyes

Postnasal drip

Sore throat and roof of mouth

Head congestion

Ear pressure

Sleep disturbances

Nasal discharge

Swollen, blue-colored skin under the eyes (allergic shiners)

Fatigue

Irritability

(Illustration by Corey Light. Cengage Learning, Gale)

Description

Hay fever is one of the most common chronic diseases in the United States. Experts estimate that about 35 million people in the United States are affected. Hay fever can develop at any age, but it shows up most often in childhood through the early 20s. The term "hay fever" is not quite accurate, since the pollen of hay grasses is only one of the many possible allergens involved, and there is no fever. Although an allergy to pollen does not appear to be inherited, the tendency to allergic sensitivity in general may run in families.

Causes and symptoms

Of all the causes of **allergies**, pollen is one of the most widespread. Trees, weeds, and grasses produce pollen in large amounts for seed production. These pollens are dispersed by the wind, and many never

reach the intended targets. Instead, they are inhaled through the nose and throat of animals, including humans. Different plants release their pollen at different times of the year, so the timing of hay fever symptoms varies from person to person, depending on which plants provoke a response.

For people with hay fever, inhaled pollen grains are identified by the body as foreign invaders. This reaction is probably due to a dysfunction in the immune system. The mast cells of the immune system act as storage containers for highly reactive chemical granules, including histamine. Allergens trigger a release of these granules, and the mast cells spill their chemicals into neighboring blood vessels and nerve cells. Histamine dilates the blood vessels, causing fluids to escape into surrounding tissues. This change results in swelling, pooling of fluid in the tissues, and redness of the nose and eyes. Histamine also stimulates **pain** receptors and causes the itchiness and discomfort of the nose, eyes, and throat that are common hay fever symptoms.

Inflammation of the nose, or rhinitis, is the major symptom of hay fever. Inflammation causes **itching**, **sneezing**, runny nose, redness, and tenderness. Swelling of the sinuses can constrict the Eustachian tube that connects the inner ear to the throat, causing a feeling of congestion and popping in the ears. Mucus from the sinuses may run down the back of the throat, leading to throat irritation and redness. Seasonal **fatigue** and sinus headaches may also be indications of hay fever, as well as respiratory congestion and a decreased sense of smell. Severe allergies can lead to dark circles under the eyes, puffy eyelids, and creases under the eyes. Characteristically, children with hay fever may push their noses upward with the palm of their hand or twitch their noses to clear the congestion.

Virtually any type of tree or grass may cause hay fever, although plants with showy flowers usually produce sticky pollen that is much less likely to become airborne. Among North American plants, weeds are the most prolific producers of allergenic pollen. Ragweed is the major culprit, but other plant pollens that routinely affect hay fever sufferers include sagebrush, lamb's quarter, Russian thistle, and English **plantain**. Grasses include timothy grass, Kentucky bluegrass, Johnson grass, Bermuda grass, redtop grass, orchard grass, and sweet vernal grass. Trees that produce allergenic pollen include **oak**, ash, elm, hickory, pecan, box **elder**, and mountain cedar.

Diagnosis

The diagnosis of hay fever is usually simple. A thorough history of the illness is important in diagnosing allergies, including whether the symptoms vary according to time of day or the season, and possible exposures. When symptoms always appear during a particular season and disappear with the onset of cold weather, hay fever is almost certainly the culprit. For a more definitive diagnosis, a skin prick test is used, in which a diluted extract of the suspected allergen is injected superficially or scratched into the skin and the reaction is observed. Another test is a provocative challenge, which is performed by putting an extract of the suspected allergen onto the conjunctiva of the eye or in the nose or lungs. When such direct skin testing is not possible, various methods of testing the blood may be used. Other conditions causing rhinitis, such as infection, may have to be ruled out by a nasal smear, in which a sample of mucus is taken on a swab for examination.

Treatment

Alternative treatments for hay fever often focus on modulation of the body's immune response. They frequently focus on diet and lifestyle adjustments. A healthy diet high in fiber and whole foods, including generous amounts of vegetables, grains, nuts, and raw seeds should be maintained. Plenty of fluids should be consumed. Six to eight glasses of water daily are recommended, along with plenty of herbal teas. Raw vegetable juices are also beneficial, particularly carrot, celery, beet, cucumber, spinach, and **parsley**. Meat, dairy, and foods high in saturated fats may aggravate a hay fever condition and should be limited in the diet. It is also best to avoid dairy products, wheat, eggs, citrus fruits, chocolate, peanuts, shellfish, food colorings, and preservatives, especially sulfites. These foods all contain common food allergens that may worsen hay fever symptoms. **Caffeine**, alcohol, tobacco, and sugar should be avoided, as well.

Beneficial supplements for treating hay fever include vitamins A, E, and B complex. **Vitamin C**, especially the buffered type, is a natural antihistamine. In substantial amounts it can help stabilize the mucous membrane response to allergens. **Bioflavonoids** prevent the release of histamine and can be taken in combination with vitamin C. **Essential fatty acids**, contained in **evening primrose oil**, **fish oil**, or **flaxseed** oil, are also recommended as a daily supplement. **Glutathione** peroxidase is an enzyme that blocks a key inflammatory reaction in the hay fever cycle. It can play a key role in neutralizing the allergic reactions of hay fever. **Selenium** is a trace mineral that may help stop the inflammation due to allergens and reduce other allergy symptoms.

For symptomatic relief, nettles (*Urtica dioica*) have been reported to have the ability to clear the sinuses and to greatly reduce other symptoms. Tincture of **licorice** (*Glycerrhiza glabra*) is also recommended. A good tincture combination for hay fever is comprised of equal parts of **black cohosh** (*Cimicifuga racemosa*), Chinese **skullcap** (*Scutellaria baicalensis*), **pleurisy** root, or butterflyweed (*Asclepias tuberosa*), **catnip** (*Nepeta cataria*), and **cayenne** pepper (*Capsicum frutescens*). In western herbal remedies other herbs found to be effective include **ginger** root (*Zingiber officinale*), **eyebright** (*Euphrasia officinalis*), **goldenseal** (*Hydrastis canadensis*), horseradish (*Amoracia rusticana*), and **mullein** (*Verbascum thapsus*). **Bee pollen** may also be effective in alleviating or eliminating hay fever symptoms. Bee pollen should be taken a few months before the hay fever season starts. It desensitizes the body and can dramatically reduce hay fever symptoms.

Acute attacks of hay fever often respond to homeopathic remedies. Possible hay fever remedies include **Allium cepa**, **Arsenicum album**, **euphrasia**, Ferrum phosphoricum, **gelsemium**, Natrum muriaticum, Nux vomica, sabadilla, and wyethia, depending on the associated symptoms. Since hay fever is often associated with deep-seated health problems, it is often best addressed with a constitutional remedy and the guidance of an experienced homeopathic practitioner.

Indoor allergens can cause increased sensitivity to outdoor allergens. Therefore, allergy testing for allergens other than pollen should be conducted, and those allergens should be removed from the diet or the environment to the greatest extent possible.

Allopathic treatment

The goal of most medical approaches to hay fever treatment is reduction of symptoms. Avoidance of the allergens is best, but this step is often not possible. When it is not possible, drug therapy is the major form of medical treatment used. Care should be taken, however, since a wide variety of antihistamines are available, and they all have potential side effects that affect function. These side effects may include drowsiness, heart problems, and harmful interactions with other medications and medical conditions. The extended use of topical decongestants can cause rebound congestion that is worse than the original problem.

Antihistamines block the action of histamine. They are most effective when used preventively, before symptoms appear. Over-the-counter antihistamines are often sufficient to provide relief for hay fever symptoms. People with severe or frequent symptoms, however, may need stronger prescription antihistamines. Azelastine, an antihistamine nasal spray, is effective and causes fewer side effects than oral antihistamines. When antihistamines do not relieve nasal symptoms, a nasal spray of cromolyn **sodium** is sometimes used. It works by preventing the release of histamine and similar chemicals.

Decongestants constrict blood vessels and counteract the effects of histamine. They may also be helpful in reducing symptoms such as nasal congestion. Nasal sprays are available that can be applied directly inside the nose. Oral decongestants are available as well. Phenylpropanolamine, phenylephrine, or pseudoephedrine are available in many preparations combined with antihistamines to increase the effectiveness of the drugs. Some components of nasal sprays traditionally used to combat the symptoms of hay fever are, however, no longer available as of 2008 without a prescription because of their potential use in the illegal manufacture of methamphetamine and related drugs. Decongestants are stimulants and may cause increased heart rate and blood pressure, headaches, and agitation.

Corticosteroids may be prescribed to reduce severe symptoms. An intranasal corticosteroid spray can be quite useful in reducing inflammation of the mucous membranes. Severe symptoms that do not respond to other treatment may require a course of oral corticosteroids, which are best started before allergy season begins. They are especially effective because they work more slowly and last longer than most other types of medication.

Late in 2001, researchers reported the first of many new drugs that may change treatment of hay fever and **asthma**: omalizumab. A monoclonal antibody, omalizumab works by blocking immunoglobulin E (IgE), an antibody produced in excess in people suffering from hay fever. The U.S. Food and Drug Administration approved the use of omalizumab for the treatment of mild to severe asthma and related disorders in June 2003.

Expected results

Some individuals are able to outgrow hay fever if their immune systems become less sensitive to the pollen that causes their problem. However, while hay fever may improve over time, it may also get worse or even lead to the development of new allergies. Hay fever treatment may sometimes cause uncomfortable and even dangerous side effects. However, most people can achieve acceptable hay fever relief with a combination of preventive strategies and treatment.

KEY TERMS

Allergen—A substance that provokes an allergic response.

Anaphylaxis—A possibly life-threatening allergic reaction causing increased sensitivity to an allergen. It can result in a sharp drop in blood pressure and difficulty breathing.

Antigen—A foreign protein to which the body reacts by making antibodies.

Granules—Small packets of reactive chemicals stored within cells.

Histamine—A chemical released by mast cells that activates pain receptors and causes cells to become leaky.

Mast cells—A type of immune system cell that is found in the lining of the nasal passages and eyelids, displays a type of antibody called immunoglobulin type E (IgE) on its cell surface, and participates in the allergic response by releasing histamine from intracellular granules.

Pollen count—The amount of pollen in the air; often broadcast on the daily news during allergy season. It tends to be lower after a heavy rain that washes the pollen out of the air and higher on warm, dry, windy days.

Prevention

As of the late 2000s there was no known way to prevent development of hay fever, but subsequent attacks may be reduced or prevented. Immunotherapy, also known as desensitization or allergy shots, involves injections of very small but gradually increasing amounts of an allergen over several weeks or months, with periodic boosters. This procedure serves to acclimatize, or familiarize, the body to encountering the allergen without having a major allergic response. Individuals receiving allergy shots are monitored closely following each shot because of the small risk of anaphylaxis. Full benefits of the shots may take up to several years to achieve, and even then about one person in five does not receive any benefit from the immunotherapy.

Reducing exposure to pollen may reduce symptoms of hay fever. Most trees produce pollen in the spring, while most grasses and flowers produce pollen during the summer, and ragweed and other late-blooming plants produce pollen during late summer and early autumn. People with hay fever should be aware of their particular pollen season and remain indoors whenever possible during that time. A pollen count can be used as a general guide for when it is most advisable to stay indoors to avoid contact with the pollen. Unfortunately, moving to a region with consistently low pollen counts is rarely effective, since new allergies to the local flora often develop.

Further strategies to prevent or reduce hay fever attacks include the following:

- Remain indoors with windows closed during the morning hours, when pollen levels are highest.
- Keep car windows rolled up while traveling by car.
- Wear a surgical facemask while outside.
- Forests and fields of grasses should be avoided, especially at the height of the pollen season.
- Wash clothes and hair after being outside.
- Air conditioners or air filters should be used in the home, and their filters should be changed regularly.

Headache

Description

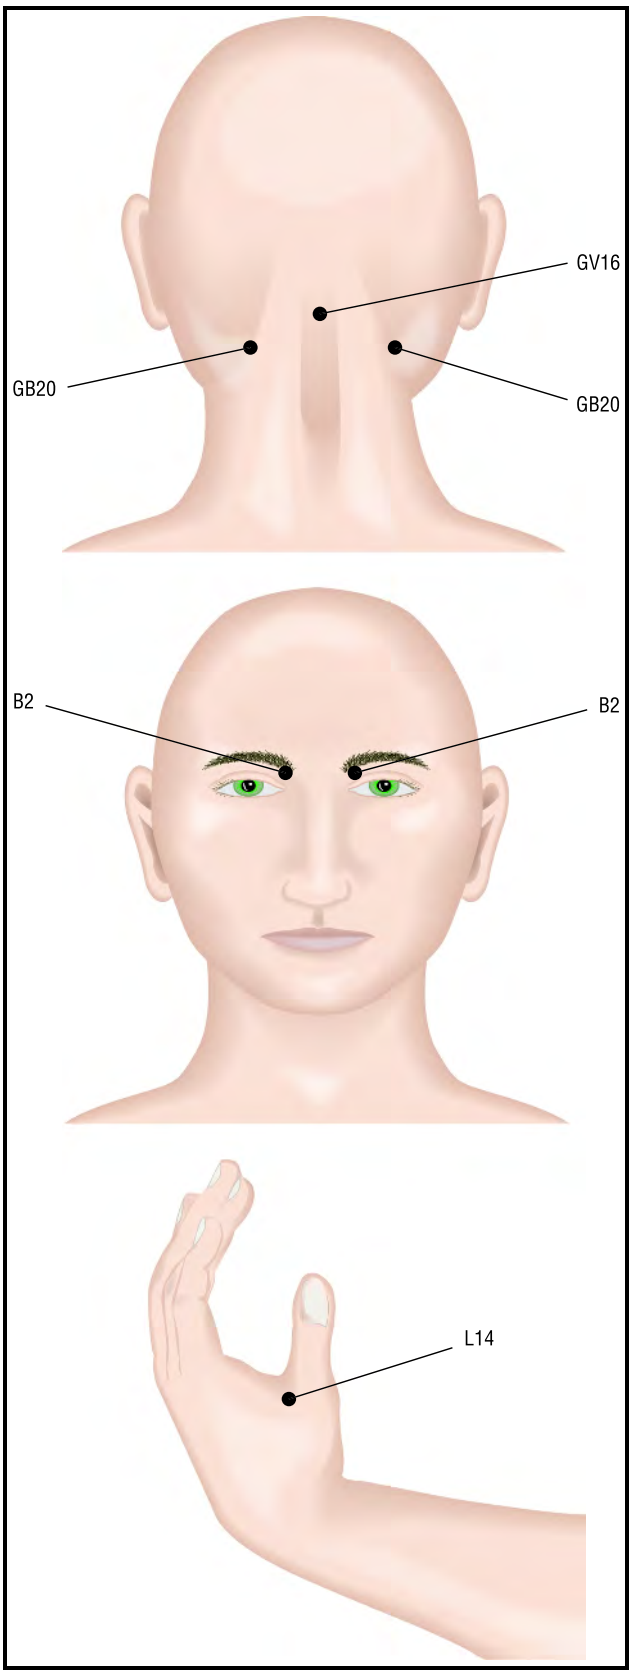
Headaches are divided into two large categories, primary and secondary, according to guidelines established by the International Headache Society (IHS). Primary headaches—accounting for more than 90% of all headaches— are not caused by an underlying medical condition. There are three major types of primary headaches: migraine, cluster, and tension. Secondary headaches are caused by another disease or medical condition and account for fewer than 10% of headaches.

Rebound headaches, also known as analgesic abuse headaches, are a subtype of primary headache caused by overuse of headache drugs. They may be associated with medications taken for tension or migraine headaches.

Secondary headaches are classified as either traction or inflammatory headaches. Traction headaches result from the pulling, pushing, or stretching of pain-sensitive structures, such as a brain tumor pressing upon the outer layer of tissue that covers the brain. Inflammatory headaches are caused by infectious diseases of the ears, teeth, sinuses, or other parts of the head.

Headaches are very common in the North American adult population. The American Council for Headache Education (ACHE) estimates that 95% of women and 90% of men in the United States and Canada have had at least one headache in the past 12 months. Most of these are tension headaches. Migraine headaches are less common, affecting about 11% of the population in the United States and 15% in Canada. Several studies indicate that doctors tend to underdiagnose migraine headaches; thus the true number of patients with migraines may be considerably higher than the reported statistics. Cluster headaches are the least common type of primary headaches, affecting about 0.4% of adult males in the United States and 0.08% of adult females. Cluster headaches occur most commonly in adults between the ages of 20 and 40. An estimated 45 million Americans suffer from chronic headaches each year. About 25% of adolescents aged 16–18 in the United States experience either severe or migraine headaches, according to the American Academy of Neurology. In the United States, 10 million doctor visits a year are for headaches.

It is possible for patients to suffer from more than one type of headache. For example, patients with chronic tension headaches often have migraine headaches as well.



Acupressure points that help relieve headaches. *(Illustration by GGS Information Services, Inc. Cengage Learning, Gale)*

Headache therapies

	Description	Type
Acupressure	Press pointer fingers beneath cheekbones and parallel to pupils (Stomach 3) for one minute. Squeeze fleshy area between thumb and pointer finger (Large Intestine 4) for one minute.	Sinus
Acupuncture	Practitioners treat using very thin needles.	Tension
Aromatherapy	Message mixture of lavender oil and sunflower oil in temples, sides of eyes, behind ears, and on the neck. Do same using eucalyptus.	Migraine, tension, and sinus
Chiropractic	Spinal or cervical manipulation to realign posture.	Tension
Diet and exercise	Avoid chocolate, cheeses, citrus, red wine, and foods containing sodium nitrates or MSG. Exercise regularly	Migraine
Herbal remedies	Feverfew, hawthorn, skullcap, ginger, goldenseal, valerian, passionflower, and cayenne.	Migraine and tension
Homeopathy	Belladonna, bryonia, kali bichromicum, and nux vomica	Sinus and tension
Home remedies	Simultaneous ice pack/warm foot soak; drink three cold glasses of water; inhale pure oxygen.	Migraine and cluster
Massage	Scalp massage	All
Mind/body	Mediation and relaxation and biofeedback	Migraine
Osteopathy	Neuromuscular manipulatin and massage of head, neck, and shoulders.	All

Causes and symptoms

Causes

A person feels headache **pain** when specialized nerve endings, known as nociceptors, are stimulated by pressure on or injury to any of the pain-sensitive structures of the head. Most nociceptors in humans are located in the skin or on the walls of blood vessels and internal organs. The bones of the skull and the brain itself do not contain these specialized pain receptors. The parts of the head that are sensitive to pain include the skin that covers the skull and upper spine; the fifth, ninth, and tenth cranial nerves, and the nerves that supply the upper part of the neck; and the large arteries located at the base of the brain, as well as those that supply the membranes covering the brain and spinal cord.

Tension headaches typically result from tightening of the face, neck, and scalp muscles as a result of emotional **stress**; physical postures that cause the head and neck muscles to tense (e.g., holding a phone against the ear with one's shoulder); emotional **depression** or **anxiety**; temporomandibular joint (TMJ) dysfunction; or arthritis of the neck. The tense muscles put pressure on the walls of the blood vessels that supply the neck and head, which stimulates the nociceptors in the tissues that line the blood vessels.

The causes of migraine headaches have been debated since the 1940s. Some researchers think that migraines are the end result of a **magnesium** deficiency in the brain or of hypersensitivity to a neurotransmitter (brain chemical) known as dopamine. Another theory is that certain nerve cells in the brain become unusually excitable, setting off a chain reaction that leads to changes in the amount of blood flowing through the blood vessels and stimulation of their nociceptors. Specific genes associated with migraines have been discovered. This finding suggested that genetic mutations may be responsible for the abnormal excitability of the nerve cells in the brains of patients with migraine headaches.

Little is known about the causes of cluster headaches or changes in the central nervous system that produce them. Patients with cluster headaches are advised to quit **smoking** and minimize their use of alcohol because nicotine and alcohol appear to trigger these headaches. The precise connection between these chemicals and cluster attacks was as of 2008 not completely understood.

Symptoms

Tension headaches are less severe than other types of primary headache. They rarely last more than a few hours; 82% resolve in less than a day. Patients usually describe the pain of a tension headache as mild to moderate. Doctor do not find anything abnormal in the course of a general physical examination, although they may detect sore or tense areas (trigger points) in the muscles of the patient's forehead, neck, or upper shoulder area.

Migraine headaches are characterized by throbbing or pulsating pain of moderate or severe intensity lasting from four hours to as long as three days. The pain is typically felt on one side of the head; in fact, the English word "migraine" is a combination of two Greek words that mean "half" and "head." Migraine headaches worsen with physical activity and are often accompanied by **nausea** and **vomiting**. Patients with migraine headaches are hypersensitive to lights, sounds, and odors.

Cluster headaches are recurrent brief attacks of sudden and severe pain on one side of the head. The pain is usually most intense in the area around the eye. Cluster headaches may last between five minutes and three hours and may occur once every other day or as often as eight times per day. Some patients describe it as severe enough to make them consider suicide. Patients may pace the floor, weep, rock back and forth, or bang their heads against a wall in desperate attempts to stop the pain. In addition to severe pain, patients often have a runny or congested nose, watery or inflamed eyes, drooping eyelids, swelling in the area of the eyebrows, and heavy facial perspiration. Because of the nasal symptoms and the relative rarity of cluster headaches, they are sometimes misdiagnosed as sinusitis.

Diagnosis

Patient history

The differential diagnosis of headaches begins with a careful patient history that includes information about head injuries or surgery on the head; eye problems or disorders; sinus **infections**; dental problems or extensive oral surgery; and medications that the patient takes regularly. Some primary care physicians give the patient a printed questionnaire that consists of 50–55 brief questions covering such matters as the timing and frequency of the headaches, family history of the same type of headache, signs of depression, and correlation between headaches and weather changes. The doctor may also ask the patient to keep a headache diary to help identify foods, stress, lack of sleep, weather, and other factors that may trigger the pain.

Physical examination

A physical examination helps the doctor identify signs and symptoms that may be relevant to the diagnosis such as **fever**, difficulty breathing, nausea or vomiting, stiff neck, changes in vision or hearing, watering or inflammation of the nose and eyes, evidence of head trauma, skin **rashes** or other indications of an infectious disease, and abnormalities in the structure or alignment of the spinal column, teeth or jaw. In some cases, the doctor may refer the patient to a dentist or oral surgeon for a more detailed evaluation of the mouth and jaw.

Special tests and imaging studies

Laboratory tests are useful in identifying headaches caused by infections, **anemia**, or thyroid disease. These tests include a complete blood count (CBC), erythrocyte sedimentation rate (ESR), and blood serum chemistry profile. Patients who report visual disturbances and other neurologic symptoms may be given visual field tests and screened for **glaucoma** (a condition involving high fluid pressure inside the eye). Imaging studies may include x rays of the sinuses to check for infections, and CT or MRI scans, which can rule out brain tumors and cerebral aneurysms. Patients whose symptoms cannot be fully explained by the results of physical examinations and tests may

be referred to a psychiatrist for evaluation of psychological factors related to their headaches.

Warning symptoms

There are warning signs associated with headache that indicate the need for prompt medical attention. Patients with any of the following symptoms should see a physician immediately:

- Three or more headaches per week
- Need for a headache pain reliever every day or almost every day
- Need for greater than recommended doses of over-the-counter (OTC) headache medications
- Headache accompanied by one-sided weakness, numbness, visual loss, speech difficulty, or other signs
- Headache that becomes worse over a period of six months, especially if most prominent in the morning or if accompanied by neurological symptoms
- Sudden onset of headache accompanied by fever and stiff neck
- Change in the character of the headaches—for example, persistent severe headaches in a person who has previously had only mild headaches of brief duration
- Recurrent headaches in a child
- Recurrent severe headaches beginning after age 50

Treatment

Alternative remedies can lessen the frequency and severity of headaches. Common treatments include:

- Acupressure. The stomach 3 and large intestine 4 points relieve sinus headaches.
- Acupuncture. A National Institutes of Health (NIH) panel concluded that acupuncture may be a useful treatment for headache.
- Aerobic exercise. Regular aerobic exercise reduces the frequency and intensity of headaches.
- Aromatherapy. Massage using the essential oils of lavender, rosemary, or peppermint relieves headache.
- Autogenic therapy. Headache may be relieved by learning to put oneself in a semi-hypnotic state.
- Biofeedback. Several types of biofeedback help relieve headaches, including electromyography (EMG) therapy, thermal hand-warming, and neurofeedback (EEG).
- Chiropractic. Cervical manipulation may relieve tension headaches.
- General exercise. Moderate exercise, such as a brisk daily walk for 20–30 minutes, can help fight migraines since it lowers stress, brings more oxygen to the body and brain, and relaxes tense muscles. Neck exercises are good for relieving tension headaches.
- Heat and/or cold. A hot shower or bath can ease tension headaches. Vascular headache may be relieved by placing an ice pack on the forehead or the feet in hot water and a cold pack on the forehead (hydrotherapy treatment).
- Herbals. Feverfew (*Chrysanthemum parthenium*) can be used for migraine; goldenseal (*Hydrastis canadensis*) for sinus headache; valerian (*Valeriana officinalis*), skullcap (*Scutellaria lateriflora*), or passionflower (*Passiflora incarnata*) for tension headache; and cayenne (in nostrils) for cluster headache. A German remedy made from butterbur root (*Petasites hybridus*) is available in the United States under the brand name Petadolex. The herb, Brahmi (*Bacopa monnieri*) is used in Ayurvedic medicine to treat headaches related to anxiety.
- Holistic medicine. Headaches may be caused by constipation and liver malfunction. Apple-spinach juice relieves constipation, and a blend of carrot, beet, celery, and parsley juices treats the liver.
- Homeopathy. Remedies are chosen for each patient and may include Belladonna (throbbing headache), Bryonia (splitting headache), Kali bichromicum (sinus headache), feverfew and butterbur (migraine headaches),and Nux vomica (tension headache with nausea and vomiting).
- Massage. Firm massage of the forehead, neck, and scalp may relieve headache. Tension headaches respond particularly well to massage.
- Osteopathy. Headache is treated with neuromuscular manipulation and massage of the head, neck, and upper back.
- Pressure. A headband tied tightly around the head may relieve migraines in some patients.
- Reflexology. Headache is treated using the solar plexus, ear, eye, and head points.
- Relaxation techniques. Meditation has been shown to help headache sufferers.
- Supplements. Vitamins B_2 and B_{12}, niacin, and magnesium (a mineral) may help treat or prevent headache.
- Transcutaneous electrical nerve stimulation (TENS). This effective headache treatment electrically stimulates nerves and blocks pain transmission.
- Visualization. This relaxation technique controls the images in the mind, replacing negative thoughts and images with positive ones that enhance relaxation.
- Yoga. Yoga is particularly good for tension headaches, since it quiets the nervous system and reduces stress.

Allopathic treatment

Medical

Tension headaches are usually relieved fairly rapidly by such over-the-counter analgesics as aspirin (300–600 mg every four hours), acetaminophen (650 mg every four hours), or other nonsteroidal anti-inflammatory drugs (NSAIDs) such as ibuprofen (brands include Advil or Motrin) or naproxen (brands such as Naprosyn or Aleve). For patients with chronic tension headaches, the doctor may prescribe a tricyclic antidepressant or benzodiazepine tranquilizer in addition to a pain reliever. One treatment for chronic tension headaches botulinum toxin (Botox type A) appears to work quite well for some patients.

Nonsteroidal anti-inflammatory drugs, including acetaminophen (e.g. Tylenol), ibuprofen, and naproxen are helpful for early or mild migraines. More severe attacks may be treated with dihydroergotamine, a group of drugs known as triptans, beta-blockers and **calcium** channel-blockers, antiseizure drugs, antidepressants (SSRIs), meperidine (Demerol), or metoclopramide (Reglan). Some of these medications are also available as nasal sprays, intramuscular injections, or rectal suppositories for patients with severe vomiting.

Sumatriptan (known as the brand Imitrex) or indomethacin (Indameth or Indocin) may be prescribed to suppress a cluster headache.

Surgical

Headaches that are caused by brain tumors, head trauma, dental problems, or disorders affecting the spinal discs usually require surgical treatment. In addition, some plastic surgeons have reported success in treating chronic migraine patients by removing some muscle tissue near the eyebrows, cutting a branch of the trigeminal nerve, and repositioning the soft tissue around the temples (sides of the head).

Psychotherapy

Psychotherapy may be helpful to patients with chronic headaches by interrupting the feedback loop between emotional upset and the physical symptoms of headaches.

Expected results

The prognosis for primary headaches varies. Episodic tension headaches usually resolve completely in less than a day without affecting the patient's overall health. The long-term outlook for patients with migraines depends on whether they have one or more of the other disorders associated with migraine. These disorders include Tourette's syndrome, **epilepsy**, ischemic **stroke**, hereditary essential **tremor**, depression, and anxiety. For example, migraine with aura increases a person's risk of ischemic stroke (when an artery to the brain is blocked) by a factor of six.

The prognosis for secondary headaches depends on the seriousness and severity of the cause.

KEY TERMS

Analgesics—A class of pain-relieving medicines, including aspirin and acetaminophen.

Biofeedback—A technique in which a person is taught to consciously control the body's response to a stimulus.

Cephalalgia—The medical term for headache.

Chronic—A condition that occurs frequently or continuously.

Neurotransmitter—Any of a group of chemicals that transmit nerve impulses across the gap (synapse) between two nerve cells.

Nociceptor—A specialized type of nerve cell that senses pain.

Primary headache—A headache that is not caused by another disease or medical condition.

Prophylactic—Treatment that prevents a disorder's symptoms from occurring.

Secondary headache—A headache that is caused by another disease or disorder.

Transcutaneous electrical nerve stimulation (TENS)—A treatment in which a mild electrical current is passed through electrodes on the skin to stimulate nerves and block pain signals.

Prevention

Lifestyle modification is one measure that people can take to lower their risk of tension headaches. They should get enough sleep and eat nutritious meals at regular times. Skipping meals, using unbalanced fad **diets** to lose weight, and insufficient or poor-quality sleep can bring on tension headaches.

Some headaches may be prevented by avoiding substances and situations that trigger them or by employing alternative therapies, such as **yoga** and regular **exercise**. Proper lighting may prevent headaches caused by eyestrain. Because food **allergies** are often linked with headaches, especially cluster strain headaches and migraines, identification and elimination of

the allergy-causing food(s) from the diet can be an important preventive measure. Women with migraines often benefit by switching from oral contraceptives to another method of birth control or by discontinuing estrogen replacement therapy. Prophylactic treatments for migraine include prednisone, calcium channel blockers such as amlodipine (Norvasc), diltiazem (Cardizem), and nifedipine (Adalat, Procardia), and synthetic ergot alkaloids such as methysergide (Sansert).

Hearing loss

Definition

Hearing loss is any degree of impairment of the ability to apprehend sound.

Description

Sound can be measured accurately. The term decibel (dB) is a measure of loudness and refers to a unit for expressing the relative intensity of sound on a scale from zero, for a nearly imperceptible sound, to 130, which is the level at which sound causes **pain** in the average person. A drop of more than 10 dB in the level of sound a person can hear is significant.

Sound travels as waves through a medium like air or water. These waves are collected by the external ear and cause the tympanic membrane (eardrum) to vibrate. The chain of ossicles (tiny bones) connected to the eardrum—the incus, malleus, and stapes—carries the vibration to the oval window (an opening to the inner ear), increasing its amplitude 20 times on the way. There, the energy causes a standing wave in the watery liquid (endolymph) inside the organ of Corti. (A standing wave is one that does not move.) The frequency of the sound determines the configuration of the standing wave. Many thousands of tiny nerve fibers detect the highs and lows of the standing wave and transmit their findings to the brain, which interprets the signals as sound.

To summarize, sound energy passes through the air of the external ear, the bones of the middle ear, and the liquid of the inner ear. It is then translated into nerve impulses, sent to the brain through nerves, and understood there as sound. It follows that there are five steps in the hearing process:

- air conduction through the external ear to the eardrum
- bone conduction through the middle ear to the inner ear
- water conduction to the organ of Corti
- nerve conduction into the brain
- interpretation by the brain

Hearing can be interrupted in a variety of ways at each of the five steps.

The external ear canal can be blocked with ear wax, foreign objects, infection, and tumors. Overgrowth of the bone can also narrow the passageway, making blockage and infection more likely. This condition can occur when the ear canal has been flushed with cold water repeatedly for years, as is the case with surfers, for whom the condition called "surfer's ear" is named.

Decibel ratings and hazardous levels of noise

Decibel Level	Example of Sounds
30	Soft whisper, quiet library
35	Noise may prevent the listener from falling asleep
40	Quiet office noise level
50	Quiet conversation, moderate rainfall
60	Average television volume, sewing machine, lively conversation
70	Busy traffic, noisy restaurant, vacuum cleaner
80	Heavy city traffic, factory noise, alarm clock
90	Cocktail party, lawn mower, shop tools, subway
100	Pneumatic drill, snowmobile, chain saw
120	Sandblasting, thunder, amplified rock music
140	Jet airplane, firearms, air raid siren
180	Rocket launching pad

Above 110 decibels, hearing may become painful

Above 120 decibels is considered deafening

Above 135 decibels, hearing will become extremely painful and hearing loss may result if exposure is prolonged

Above 180 decibels, hearing loss is almost certain with any exposure

(Illustration by Corey Light. Cengage Learning, Gale)

The eardrum is so thin a physician can see through it into the middle ear. It can be ruptured by sharp objects, pressure from an infection in the middle ear, or even a firm cuffing or slapping of the ear. The eardrum is also susceptible to pressure changes during scuba diving.

Several conditions can diminish the mobility of the small bones (ossicles) in the middle ear. Otitis media, an infection in the middle ear, occurs when fluid cannot escape into the throat because the eustachian tube is blocked. The fluid (pus or mucus) that accumulates prevents the ossicles from moving as efficiently as they normally do, thus dampening the sound waves. In a disease called otosclerosis, spongy tissue grows around the bones of the inner ear. This growth sometimes binds the stapes in the oval window, which interferes with its normal vibration and causes deafness. All the conditions mentioned so far–those that occur in the external and middle ear–are causes of what is known as *conductive* hearing loss.

The second category, sensory hearing loss, refers to damage to the organ of Corti and the acoustic nerve. Prolonged exposure to loud noise is the leading cause of sensory hearing loss. A million people have this condition, many identified during the military draft and rejected as being unfit for duty. The cause is often believed to be prolonged exposure to loud music. Occupational noise exposure is the other leading cause of noise-induced hearing loss (NIHL) and is ample reason for wearing ear protection on the job.

More unusual, but often undetected, is low-frequency hearing loss. Scientists discovered in 2001

KEY TERMS

Cochlea—A snail-shaped structure inside the inner ear, which contains the organ of Corti as well as fluid-filled compartments through which sound waves travel.

Decibel—A unit of the intensity of sound, a measure of loudness.

Meniere's disease—The combination of vertigo and decreased hearing caused by abnormalities in the inner ear.

Organ of Corti—A spiral structure inside the cochlea that converts vibration to signals that are passed to the brain.

Ossicles—A group of tiny bones in the middle ear that conduct sound through vibration. The bones are the malleus (or anvil), incus (or hammer), and stapes (or stirrup).

Otosclerosis—A disease that scars and limits the motion of the small conducting bones in the middle ear.

that people with a particular gene mutation gradually lose their abilities to hear low-frequency sounds. Since those people with this type of hearing loss can still distinguish speech, they often remain unaware of the low-frequency changes in their hearing. The scientists believe that the same gene mutations might make some people more susceptible to high-frequency hearing loss, but further study is needed.

One-third of people older than 65 have presbycusis, which is sensory hearing loss due to **aging**. Both NIHL and presbycusis are primarily loss of the ability to hear high-frequency sounds. In speech, consonants generally have a higher frequency than vowels. Yet in most languages, consonants provide us the clues needed for determining what a person is saying. So these people hear plenty of noise, they just cannot easily make out what it means. They have particular trouble differentiating speech from background noise.

Brain **infections** such as **meningitis**, drugs such as the aminoglycoside antibiotics (streptomycin, gentamycin, kanamycin, tobramycin), and Meniere's disease can also cause permanent sensory hearing loss. Meniere's disease combines attacks of hearing loss with attacks of vertigo. The symptoms may occur together or separately. High doses of salicylates such as aspirin and quinine can cause a temporary high-frequency loss, and prolonged high doses can lead to permanent deafness. There is also a hereditary form of sensory deafness and a congenital form most often caused by **rubella** (German **measles**).

Sudden hearing loss of at least 30 dB in less than three days is most commonly caused by cochleitis, a mysterious viral infection.

The final category of hearing loss is *neural* hearing loss. Permanent neural hearing loss most often results from damage to the acoustic nerve and the parts of the brain that control hearing. Strokes, **multiple sclerosis**, and acoustic neuromas are all possible causes of neural hearing loss.

Hearing can also be diminished by **tinnitus**, which is characterized by extra sounds generated by the ear. These sounds are referred to as tinnitus, and can be ringing, blowing, clicking, or anything else that no one but the patient hears. Tinnitus may be caused by loud noises, medication, **allergies**, or medical conditions—from the same kinds of disorders that can cause diminished hearing.

Diagnosis

Many common causes of hearing loss can be detected through an examination of the ears and nose combined with simple hearing tests performed in the physician's office. An audiogram (a test of hearing at a range of sound frequencies) often concludes the evaluation. These simple tests often produce a diagnosis. If the defect is in the brain or the acoustic nerve, further neurological testing and imaging will be required.

The audiogram has many uses in diagnosing hearing deficits. The pattern of hearing loss across the audible frequencies gives clues to the cause. Several alterations in the testing procedure can give additional information. For example, speech is perceived differently than pure tones. Adequate perception of sound combined with inability to recognize words points to a brain problem rather than a sensory or conductive deficit. Loudness perception is distorted by disease in certain areas but not in others. Acoustic neuromas often distort the perception of loudness.

Treatment

Conductive hearing loss can be treated with alternative therapies that are specific to the particular condition.

Nutritional therapy

The following dietary changes may help improve certain hearing impairment conditions:

- Alleviate accumulated wax in the ear by taking oral supplements with essential fatty acids such as flax oil and omega-3 oil.
- Identify and avoid potential allergenic foods. Children who are allergic to foods have an increased risk of getting chronic ear infections.
- Take nutritional supplements. B-complex vitamins and iron supplements may be helpful in preventing protein deficiency and anemia. These conditions depress immune function and increase the risk of chronic ear infections. Children suffering from frequent ear infections may need supplementation with strong antioxidants such as vitamins A and C, zinc, and bioflavonoids. High-potency multivitamin and mineral supplements should contain most of these helpful nutrients as well as other essential vitamins and minerals.

Herbal therapy

There are several effective herbal treatments for hearing impairments. They include:

- Ginkgo biloba. Ginkgo may be effective in patients with hearing loss who often complain of ringing in the ears.
- Natural antibiotics such as echinacea and goldenseal can help prevent or treat ear infections.
- Certain Chinese herbal combinations can help alleviate tinnitus, ear infections, and chronic sinus infections that can lead to hearing loss.

Homeopathy

Homeopathic therapies may help patients who have sensory hearing loss. An experienced homeopathic physician will prescribe specific remedies based on knowledge of the underlying cause.

Acupuncture

Acupuncture may be able to improve hearing in some patients with sensory-neural deafness. It may be used to improve the circulation of fluids in the head that lead to chronic congestion and noises.

Other therapies

Other therapies that may help improve hearing in some patients include **Ayurvedic medicine**, **craniosacral therapy**, and **auditory integration training**.

Allopathic treatment

Conductive hearing loss can almost always be restored to some degree, if not completely.

- Matter in the ear canal can easily be removed, with a dramatic improvement in hearing.
- Surfer's ear gradually regresses if the patient avoids cold water or uses a special ear plug. In advanced cases, surgeons can grind away the excess bone.
- A middle-ear infection involving fluid is also simple to treat. If medications do not work, fluid may be surgically drained through the eardrum, which heals completely after treatment.
- Traumatically damaged eardrums can be repaired with a tiny skin graft.
- Otosclerosis may be surgically repaired through an operating microscope. In this intricate procedure, tiny artificial parts are substituted for the original ossicles.

Now available for complete conductive hearing loss are bone conduction hearing aids and even devices that can be surgically implanted in the cochlea.

Sensory and neural hearing loss, on the other hand, cannot readily be cured. Fortunately such hearing loss is rarely complete, and hearing aids can fill the deficit. In-the-ear hearing aids can boost the volume of sound by up to 70 dB. (Normal speech is about 60 dB.) Federal law now requires that aids be dispensed only by prescription.

Tinnitus can sometimes be relieved by adding white noise (such as the sound of wind or waves crashing on the shore) to the environment.

Decreased hearing is such a common problem that there are legions of organizations to provide assistance. Special language training, both in lip reading and signing, is available in most regions of the United States, as well as special schools and camps for children.

Prevention

Prompt treatment and attentive follow-up of middle-ear infections in children will prevent this cause of conductive hearing loss. Sensory hearing loss as a complication of epidemic disease has been greatly reduced by control of infectious childhood diseases, such as measles. Laws that require protection from loud noise in the workplace have substantially reduced incidences of noise-induced hearing loss. Surfers, cold-water fishermen, and other people who are regularly exposed to frigid water should use the right kind of ear plugs.

Heart attack

Definition

A heart attack is the death of, or damage to, part of the heart muscle because its blood supply is severely reduced or stopped.

Description

Heart attack is the leading cause of death in the United States. Approximately every 29 seconds one American will have a heart attack, and once a minute one American will die from a heart attack. More than 1.5 million Americans suffer a heart attack every year, and almost half a million die, according to the American Heart Association. Most heart attacks are the end result of years of silent but progressive coronary artery disease, which can be prevented in many people. A heart attack is often the first symptom of coronary artery disease. According to the American Heart Association, 63% of women and 48% of men who died suddenly of coronary artery disease had no previous symptoms. Heart attacks are also called myocardial infarctions (MIs).

A heart attack occurs when one or more of the coronary arteries that supply blood to the heart are completely blocked and blood to the heart muscle is cut off. The blockage is usually caused by **atherosclerosis**, the build-up of plaque in the artery walls, and/or by a blood clot in a coronary artery. Sometimes, a healthy or atherosclerotic coronary artery has a spasm and the blood flow to part of the heart decreases or stops. Why this happens is unclear, but it can result in a heart attack.

About half of all heart attack victims wait at least two hours before seeking help. This increases their chance of sudden death or being disabled. The longer the artery remains blocked during a heart attack, the more damage will be done to the heart. That is why it is important to recognize the signs of a heart attack and seek prompt medical attention at the nearest hospital with 24-hour emergency cardiac care.

About one fifth of all heart attacks are silent, that is, the victim does not know one has occurred. Although the victim feels no **pain**, silent heart attacks can still damage the heart.

The outcome of a heart attack also depends on where the blockage is, whether the heart rhythm is disturbed, and whether another coronary artery supplies blood to that part of the heart. Blockages in the left coronary artery are usually more serious than in the right coronary artery. Blockages that cause an arrhythmia, an irregular heartbeat, can cause sudden death.

Causes and symptoms

Heart attacks are generally caused by severe coronary artery disease. Most heart attacks are caused by **blood clots** that form on atherosclerotic plaque. This blocks a coronary artery from supplying oxygen-rich blood to part of the heart. A number of factors increase the risk of developing coronary artery disease.

Major risk factors significantly increase the risk of coronary artery disease. Those that cannot be changed are:

KEY TERMS

Angina—Chest pain that happens when diseased blood vessels restrict the flow of blood to the heart. Angina is often the first symptom of coronary artery disease.

Atherosclerosis—A process in which the walls of the coronary arteries thicken due to the accumulation of plaque in the blood vessels. Atherosclerosis is the cause of coronary artery disease.

Coronary arteries—The two arteries that provide blood to the heart. The coronary arteries surround the heart like a crown, coming out of the aorta, arching down over the top of the heart, and dividing into two branches. These are the arteries where coronary artery disease occurs.

Myocardial infarction—The technical term for heart attack. Myocardial means heart muscle and infarction means death of tissue from lack of oxygen.

Plaque—A deposit of fatty and other substances that accumulate in the lining of the artery wall.

- Heredity. People whose parents have coronary artery disease are more likely to develop it as well. African Americans are also at increased risk, due to their higher rate of severe hypertension than whites.
- Gender. Men under the age of 60 years of age are more likely to have heart attacks than women of the same age.
- Age. Men over the age of 45 and women over the age of 55 are considered at risk. Older people (those over 65) are more likely to die of a heart attack. Older women are twice as likely to die within a few weeks of a heart attack than men. This may be because of other co-existing medical problems.

Major risk factors that can be changed are:

- Smoking. Smoking greatly increases both the chance of developing coronary artery disease and the chance of dying from it. Smokers have two to four times the risk of non-smokers of sudden cardiac death and are more than twice as likely to have a heart attack. They are also more likely to die within an hour of a heart attack.
- High cholesterol. Cholesterol is a soft, waxy substance that is produced by the body, as well as obtained from eating foods such as meat, eggs, and other animal products. Cholesterol level is affected by age, sex, heredity, and diet. Risk of developing coronary artery disease increases as blood cholesterol levels increase. Total cholesterol of 240 mg/dL and over poses a high risk, and 200–239 mg/dL a borderline high risk. In LDL cholesterol, high risk starts at 130–159 mg/dL, depending on other risk factors. HDL (healthy cholesterol) can also lower or raise the coronary risk.
- High blood pressure. High blood pressure makes the heart work harder, and over time, weakens it. It increases the risk of heart attack, stroke, kidney failure, and congestive heart failure. A blood pressure of 140 over 90 or above is considered high. As the numbers increase, high blood pressure goes from Stage 1 (mild) to Stage 4 (very severe). When combined with obesity, smoking, high cholesterol, or diabetes, the risk of heart attack or stroke increases several times.
- Lack of physical activity. This increases the risk of coronary artery disease. Even modest physical activity is beneficial if done regularly.
- Use of certain drugs or supplements. Extreme caution is advised in the use of the herbal supplement ephedra. The supplement, which was marketed for weight loss and to improve athletic performance, was found to contribute to heart attack, seizure, stoke and death. In April 2003, the U.S. Food and Drug Administration (FDA) investigated controlling or banning the substance. While it was once believed that hormone replacement therapy (HRT) helped prevent heart disease in women, a large clinical trial called the Women's Health Initiative found the opposite to be true. In 2003, the FDA began requiring manufacturers of HRT to place warnings on the box listing adverse effects of estrogen, including increased risk of heart attack, stroke and blood clots. The labels also must mention that HRT should not be used as a preventive medicine for heart disease.

Contributing risk factors

Contributing risk factors have been linked to coronary artery disease, but their significance and prevalence are not known yet. Contributing risk factors are:

- Diabetes mellitus. The risk of developing coronary artery disease is seriously increased for diabetics. More than 80% of diabetics die of some type of heart or blood vessel disease.
- Obesity. Excess weight increases the strain on the heart, increases blood pressure and blood cholesterol, and increases the risk of developing coronary artery disease, even if no other risk factors are present. In fact, research in 2002 shows that losing weight also reduces inflammation of the arteries in obese women, which is a risk factor equal to that of high cholesterol.

- Stress and anger. Some scientists believe that stress and anger can contribute to the development of coronary artery disease. Stress increases the heart rate and blood pressure, and can injure the lining of the arteries.

More than 60% of heart attack victims experience symptoms before the heart attack occurs. These sometimes occur days or weeks before the heart attack. Sometimes, people do not recognize the symptoms of a heart attack or are in denial that they are having one. Symptoms are:

- Uncomfortable pressure, fullness, squeezing, or pain in the center of the chest. This lasts more than a few minutes, or may go away and return.
- Pain that spreads to the shoulders, neck, or arms.
- Chest discomfort accompanied by lightheadedness, fainting, sweating, nausea, or shortness of breath.

All of these symptoms do not occur with every heart attack. Sometimes, symptoms disappear and then reappear. A person with any of these symptoms should immediately call an emergency rescue service or be driven to the nearest hospital emergency room.

Diagnosis

Experienced emergency care personnel can usually diagnose a heart attack simply by looking at the patient. To confirm this diagnosis, they talk with the patient, check heart rate and blood pressure, perform an electrocardiogram, and take a blood sample. The electrocardiogram shows which coronary artery is blocked. Electrodes covered with conductive jelly are placed on the patient's chest, arms, and legs. They send impulses of the heart's activity through an oscilloscope (a monitor) to a recorder, which traces them on paper. The blood test shows the leak of enzymes or other biochemical markers from damaged cells in the heart muscle. In 2003, the FDA cleared a new test for ruling out heart attacks in people who come to emergency rooms with severe chest pains. It is the first new blood test for evaluation of heart attacks since 1994 and is used along with an electrocardiogram.

Treatment

Heart attacks are treated with cardiopulmonary resuscitation (CPR) when necessary to start and keep the patient breathing and his heart beating. Upon arrival at the hospital, the patient is closely monitored. An electrical-shock device called a defibrillator may be used to restore a normal rhythm if the heartbeat is fluttering uncontrollably. Oxygen is often used to ease the heart's workload or to help a victim of a severe heart attack breathe easier. If oxygen is used within hours of the heart attack, it may help limit damage to the heart.

Alternative therapies aim at preventing the progression of **heart disease** that leads to a heart attack. Changes in lifestyle can also prevent second heart attacks.

Herbal medicine offers a variety of remedies that may have a beneficial effect on coronary artery disease. Oats (*Avena sativa*), **garlic** (*Allium sativum*), and guggul(*Commiphora mukul*) may help reduce **cholesterol**; linden (*Tilia europaea*) and **hawthorn** (*Crataegus spp.*) are sometimes recommended to control high blood pressure, a risk factor for heart disease. Tea (*Camellia sinensis*), especially **green tea**, is high in **antioxidants**, which studies have shown may have a preventative effect against atherosclerosis. A 2003 study found that black tea may reduce the risk of a heart attack by as much as 43% and that black tea's protective effects are even greater in women than in men.

Nutritional therapies have been shown to prevent coronary artery disease and stop, or even reverse, the progression of atherosclerosis. A low-fat, **high-fiber diet** is often recommended. It is essential to reduce the amount of meat and animal products consumed, as they are high in saturated fats. Whole grains, fresh fruits and vegetables, legumes, and nuts are recommended. Vitamin and mineral supplements that reduce, reverse, or protect against coronary artery disease include **chromium**; **calcium** and **magnesium**; B complex vitamins; the antioxidant vitamins B and E; L-carnitine; and **zinc**. These protective effects even work in the elderly, according to a 2003 report. A study revealed that those age 65 and older who ate the most cereal and bread fiber were 21% less likely to develop heart disease than those who ate the least. They also were less likely to have a heart attack or **stroke**.

Yoga and other bodywork, massage, **relaxation** therapies, **aromatherapy**, and **music therapy** may also help by reducing **stress** and promoting physical and mental well-being. A 1996 study in the United Kingdom found that participants who practiced **t'ai chi** had a resulting lowering in blood pressure. By evoking the body's relaxation response through **meditation** and deep breathing, blood pressure, metabolic rate, and hearth rate can all be reduced.

Allopathic treatment

Additional treatment after a heart attack can include close monitoring, electric shock, drug therapy, revascularization procedures, percutaneous transluminal coronary angioplasty and coronary artery bypass surgery.

Drugs to stabilize the patient and limit damage to the heart include thrombolytics, aspirin, anticoagulants, painkillers and tranquilizers, beta-blockers, ace-inhibitors, nitrates, rhythm-stabilizing drugs, and diuretics. Thrombolytic drugs that break up blood clots and enable oxygen-rich blood to flow through the blocked artery increase the patient's chance of survival if given as soon as possible after the heart attack. These include anisoylated plasminogen streptokinase activator complex (APSAC) or anistreplase (Eminase), recombinant tissue-type plasminogen activator (r-tPA, Retevase, or Activase), and streptokinase (Streptase, Kabikinase).

To prevent additional heart attacks, aspirin and an anticoagulant drug often follow the thrombolytic drug. These prevent new blood clots from forming and existing blood clots from growing. Anticoagulant drugs help prevent the blood from clotting. The most common anticoagulants are heparin and warfarin. Heparin is given intravenously while the patient is in the hospital; warfarin, taken orally, is often given later. Aspirin helps to prevent the dissolved blood clots from reforming.

To relieve pain, a nitroglycerine tablet taken under the tongue may be given. If the pain continues, morphine sulfate may be prescribed. Tranquilizers such as diazepam (Valium) and alprazolam (Ativan) may be prescribed to lessen the trauma of a heart attack.

Percutaneous transluminal coronary angioplasty and coronary artery bypass surgery are invasive revascularization procedures which open blocked coronary arteries and improve blood flow. They are usually performed only on patients for whom clot-dissolving drugs do not work, or who have poor **exercise** stress tests, poor left ventricular function, or **ischemia**. Generally, angioplasty is performed before coronary artery bypass surgery.

Percutaneous transluminal coronary angioplasty, usually called coronary angioplasty, is a non-surgical procedure in which a catheter (a tiny plastic tube) tipped with a balloon is threaded from a blood vessel in the thigh or arm into the blocked artery. The balloon is inflated and compresses the plaque to enlarge the blood vessel and open the blocked artery. The balloon is then deflated and the catheter is removed. Coronary angioplasty is successful about 90% of the time. For one third of patients, the artery narrows again within six months after the procedure. The procedure can be repeated. It is less invasive and less expensive than coronary artery bypass surgery.

In coronary artery bypass surgery, called bypass surgery, a detour is built around the coronary artery blockage with a healthy leg or chest wall artery or vein. The healthy vein then supplies oxygen-rich blood to the heart. Bypass surgery is major surgery appropriate for patients with blockages in two or three major coronary arteries or severely narrowed left main coronary arteries, as well as those who have not responded to other treatments. About 70% of patients who have bypass surgery experience full relief from **angina**; about 20% experience partial relief. Long term, symptoms recur in only about three or four percent of patients per year. Five years after bypass surgery, survival expectancy is 90%, at 10 years it is about 80%, at 15 years it is about 55%, and at 20 years it is about 40%.

Expected results

The aftermath of a heart attack is often severe. Two-thirds of heart attack patients never recover fully. Within one year, 27% of men and 44% of women die. Within six years, 23% of men and 31% of women have another heart attack, 13% of men and 6% of women experience sudden death, and about 20% have heart failure. People who survive a heart attack have a chance of sudden death that is four to six times greater than others and a chance of illness and death that is two to nine times greater. Older women are more likely than men to die within a few weeks of a heart attack.

Statistics released in early 2002 revealed that about half of all deaths from heart disease happen before the patient can get to the hospital. Women were slightly more likely than men to die quickly after cardiac arrest and the risk of dying quickly from heart disease increased with age, to 61% of those over age 85. The study authors said that improved prevention and recognition of the warning symptoms of heart attack could lower the number of sudden deaths.

Prevention

Many heart attacks can be prevented through a healthy lifestyle, which can reduce the risk of developing coronary artery disease. For patients who have already had a heart attack, a healthy lifestyle and carefully following doctor's orders can prevent another heart attack. A heart healthy lifestyle includes eating right, regular exercise, maintaining a healthy weight, no **smoking**, moderate drinking, no illegal drugs, controlling **hypertension**, and managing stress.

A healthy diet includes a variety of foods that are low in fat (especially saturated fat), low in cholesterol, and high in fiber; plenty of fruits and vegetables; and

limited **sodium**. Saturated fat raises cholesterol, and, in excessive amounts, it increases the amount of the proteins in blood that form blood clots. Polyunsaturated and monounsaturated fats are relatively good for the heart. Fat should comprise no more than 30 percent of total daily calories. Evidence suggests that a diet rich in **lutein**, the pigment found in dark green leafy vegetables, helps artery walls fight plaque and lessens risk of heart attack.

Cholesterol should be limited to about 300 mg per day. Many popular lipid-lowering drugs can reduce LDL-cholesterol by an average of 25–30% when combined with a low-fat, low-cholesterol diet. Soluble fiber can also help lower cholesterol. Fruits and vegetables are rich in fiber, vitamins, and minerals, and they are low calorie and nearly fat free. **Vitamin C** and beta-carotene, found in many fruits and vegetables, keep LDL-cholesterol from turning into a form that damages coronary arteries. Excess sodium can increase the risk of high blood pressure, and daily intake should be limited to 2,400 mg—about the amount in a teaspoon of salt.

Regular aerobic exercise can lower blood pressure, help control weight, and increase HDL ("good") cholesterol. Moderate intensity aerobic exercise lasting about 30 minutes four or more times per week is recommended for maximum heart health, according to the Centers for Disease Control and Prevention and the American College of Sports Medicine. Three 10-minute exercise periods are also beneficial. Aerobic exercise—activities such as walking, jogging, and cycling—uses the large muscle groups and forces the body to use oxygen more efficiently. It can also include everyday activities such as active gardening, climbing stairs, or brisk housework.

Maintaining a desirable body weight is also important. About one quarter of all Americans are overweight, and nearly one-tenth are obese, according to the Surgeon General's Report on **Nutrition** and Health. People who are 20% or more over their ideal body weight have an increased risk of developing coronary artery disease. Losing weight can help reduce total and LDL cholesterol, reduce triglycerides, and boost relative levels of HDL cholesterol.

Smoking has many adverse effects on the heart. It increases the heart rate, constricts major arteries, and can create irregular heartbeats. It also raises blood pressure, contributes to the development of plaque, increases the formation of blood clots, and causes blood platelets to cluster and impede blood flow. Heart damage caused by smoking can be repaired by quitting—even heavy smokers can return to heart health. Several studies have shown that ex-smokers face the same risk of heart disease as non-smokers within five to 10 years of quitting.

Drinking should be done in moderation. Modest consumption of alcohol can actually protect against coronary artery disease. This is believed to be because alcohol raises HDL ("good") cholesterol levels in some patients. The American Heart Association defines moderate consumption as one ounce of alcohol per day—roughly one cocktail, one 8-ounce glass of wine, or two 12-ounce glasses of beer. Excessive drinking is always bad for the heart. It usually raises blood pressure, and can poison the heart and cause abnormal heart rhythms or even heart failure. Illegal drugs, like cocaine, can seriously harm the heart and should never be used.

High blood pressure, one of the most common and serious risk factors for coronary artery disease, can be completely controlled through lifestyle changes and medication. People with moderate hypertension may be able to control it through lifestyle changes and medication.

Stress management means controlling mental and physical reactions to life's irritations and challenges. Techniques for controlling stress include thinking positively, getting enough sleep, exercising, and practicing relaxation techniques.

Daily aspirin therapy has been proven to help prevent blood clots associated with atherosclerosis. It can also prevent heart attacks from recurring, prevent heart attacks from being fatal, and lower the risk of strokes. Surprisingly, a 2002 study found that aspirin therapy is underused by people at risk for heart attacks. Patients should consult their doctors before taking aspirin regularly.

Heart disease

Definition

Heart disease is the narrowing or blockage of the arteries and vessels that provide oxygen and nutrient-rich blood to the heart. It is caused by **atherosclerosis**, an accumulation of fatty materials on the inner linings of arteries that restricts blood flow. When the blood flow to the heart is completely cut off, the result is a **heart attack** because the heart is starved of oxygen.

Description

Heart disease, also called coronary heart disease or coronary artery disease, is the leading cause of death for both men and women in the United States. According to the American Heart Association, deaths from coronary heart disease in the United States declined 33 percent from 1994 to 2004, but more than 450,000 people still died from the disease in 2004. About 16 million Americans have active symptoms of coronary artery disease.

Heart disease occurs when the coronary arteries become partially blocked or clogged. This blockage limits the flow of blood through the coronary arteries, the major arteries supplying oxygen-rich blood to the heart. The coronary arteries expand when the heart is working harder and needs more oxygen. If the arteries are unable to expand, the heart is deprived of oxygen (myocardial **ischemia**). When the blockage is limited, chest **pain** or pressure called **angina** may occur. When the blockage **cuts** off the blood flow, the result is heart attack (myocardial infarction or heart muscle death).

Heart healthy diets

	Heart Healthy diet guidelines	Therapeutic Lifestyle Changes diet guidelines	American Heart Association diet guidelines
Saturated fat	8–10% of the day's total calories	Less than 7% of the day's total calories	Less than 7% of the day's total calories
Total fat	30% or less of the day's total calories	25–35% or less of the day's total calories from fat	25–35% or less of the day's total calories from fat
Dietary cholesterol	Less than 300 milligrams a day	Less than 200 milligrams a day	Less than 300 milligrams a day
Sodium	Less than 2,400 milligrams a day	Less than 2,400 milligrams a day	Less than 2,400 milligrams a day
Calories	Enough calories to achieve or maintain a healthy weight and reduce blood cholesterol level	Enough calories to achieve or maintain a healthy weight and reduce blood cholesterol level	Number of calories based on age, gender, height, weight, and physical activity level, and whether trying to lose, gain or maintain weight

A comparison of the dietary guidelines of the Healthy Heart diet, the Therapeutic Lifestyle Changes diet, and the American Heart Association diet. *(Illustration by GGS Information Services. Cengage Learning, Gale)*

Risk factors for heart disease

- Male greater than 45 years of age
- Female greater than 55 years of age
- Female with premature menopause without estrogen replacement
- Family history of premature coronary heart disease having definite myocardial infarction or sudden death before age 55 in father or first-degree male relative, or mother before age 65 years of age
- Currently smoking or history of cigarette smoking
- Blood pressure greater than 140/90 mmHg or on antihypertensive medication
- HDL cholesterol less than 35 mg/dl
- LDL cholesterol greater than 130 mg/dl
- Diabetes mellitus

(Illustration by Corey Light. Cengage Learning, Gale)

Healthy coronary arteries are open, elastic, smooth, and slick. The artery walls are flexible and expand to let more blood through when the heart needs to work harder. The disease process is thought to begin with an injury to the linings and walls of the arteries. This injury makes them susceptible to atherosclerosis and production of **blood clots** (thrombosis).

Causes and symptoms

Heart disease is usually caused by atherosclerosis. **Cholesterol** and other fatty substances accumulate on the inner wall of the arteries. They attract fibrous tissue, blood components, and **calcium**. They then harden into artery-clogging plaques. Atherosclerotic plaques often form blood clots that can also block the coronary arteries (coronary thrombosis). Congenital defects and **muscle spasms** of arteries or heart muscles also block blood flow. Some research indicates that infection from organisms such as **chlamydia** bacteria may be responsible for some cases of heart disease.

A number of major contributing risk factors increase the chance of developing heart disease. Some of these can be changed and some cannot. The greater the number of risk factors, the greater the chance of developing heart disease.

Major risk factors

Major risk factors significantly increase the chance of developing heart disease. These include:

- Heredity. People whose parents have heart disease are more likely to develop it. African Americans are also at increased risk because they experience a high rate of severe hypertension.
- Gender. Men are more likely to have heart attacks than women and to have them at a younger age. Above the age of 60, however, women have heart disease at a rate equal to that of men.
- Age. Men who are 45 years of age and older, and women who are 55 years of age and older are more likely to have heart disease. Occasionally, heart disease may strike men or women in their 30s. People more than 65 years old are more likely to die from a heart attack. Older women are twice as likely as older men to die within a few weeks of a heart attack.
- Smoking. Smoking increases both the chance of developing heart disease and the chance of dying from it. Smokers are more than twice as likely as non-smokers to have a heart attack and are two to four times more likely die from it.
- High cholesterol levels. Dietary sources of cholesterol are meat, dairy food, eggs, and other animal-fat products. Cholesterol is also produced by the body. Age, body fat, diet, exercise, heredity, and sex affect one's blood cholesterol. For typical, healthy patients, the American Heart Association recommends a total blood cholesterol below 200 mg/dL, which puts the person at a comparatively low risk for coronary heart disease. For these individuals, a total cholesterol level of 200–239 mg/dL is considered borderline high-risk, and a level of 240 mg/dL or above is considered high risk and doubles the risk for coronary heart disease. Persons with such risk factors as elevated low-density lipoprotein (LDL cholesterol, or "bad" cholesterol) levels, low high-density lipoprotein (HDL or "good" cholesterol) levels, or high triglyceride levels should consult with their doctor about what their target cholesterol level should be.
- High blood pressure. High blood pressure makes the heart work harder and weakens it over time. It increases the risk of heart attack, stroke, kidney failure, and congestive heart failure. A blood pressure of 140 over 90 or above is considered high. The risk of heart attack or stroke is raised several times for people with high blood pressure combined with

obesity, smoking, high cholesterol levels, or diabetes. Nearly one-third of American adults have high blood pressure.

- Lack of physical activity. Lack of exercise increases the risk of heart disease. Even modest physical activity, such as walking, is beneficial if done regularly.
- Diabetes mellitus. The risk of developing heart disease is seriously increased for diabetics. About two-thirds of people who have type I or type II diabetes die as the result of a heart attack or stroke.

Contributing risk factors

Contributing risk factors have been linked to heart disease, but their significance was not known as of 2008. Contributing risk factors are:

- Obesity. Excess weight increases the strain on the heart and increases the risk of developing heart disease even if no other risk factors are present. Obesity increases blood pressure and blood cholesterol and can lead to diabetes.
- Hormone replacement therapy (HRT). Even though physicians once believed that HRT could help prevent heart disease in women, the Women's Health Initiative (WHI) released information in 2002 and 2003 showing that use of combined hormones (estrogen and progestin) is harmful in women who already have coronary artery disease. As of 2008, it continued to be debated if HRT, and estrogen in particular, can provide some protection against heart disease when a woman takes it soon after going through menopause.
- Stress and anger. Some scientists believe that poorly managed stress and anger can contribute to the development of heart disease and increase the blood's tendency to form clots (thrombosis). Stress increases the heart rate and blood pressure and can injure the lining of the arteries.
- Chest pain (angina). Angina is the main symptom of coronary heart disease, but it is not always present. Other symptoms include shortness of breath, chest heaviness, tightness, pain, a burning sensation, squeezing, or pressure either behind the breastbone or in the left arm, neck, or jaws. According to the American Heart Association, 64 percent of women and 50 percent of men who died suddenly of heart disease had no previous symptoms of the disease.

Diagnosis

Diagnosis begins with a doctor's review of the medical history, discussion of symptoms, listening to the heart, and performing basic screening tests. These tests measure blood lipid levels, blood pressure, **fasting** blood-glucose levels, weight, and other indicators. Other diagnostic tests include resting and **exercise** electrocardiograms, echocardiography, radionuclide scans, and coronary angiography. The treadmill exercise (**stress**) test is an appropriate screening test for those with high risk factors even though they feel well.

An electrocardiogram (ECG) shows the heart's activity and may reveal a lack of oxygen (ischemia). Electrodes covered with conducting jelly are placed on the patient's chest, arms, and legs. They send impulses of the heart's activity through an oscilloscope (a monitor) to a recorder that traces them on paper. Another type of electrocardiogram, known as the exercise stress test, measures how the heart and blood vessels respond to exertion when the patient is exercising on a treadmill or a stationary bike. Both tests can be performed in a physician's office or outpatient facility.

Echocardiography, or cardiac ultrasound, uses sound waves to create an image of the heart's chambers and valves. A technician applies gel to a handheld transducer and then presses it against the patient's chest. The heart's sound waves are converted into an image that can be displayed on a monitor. It does not reveal the coronary arteries themselves but can detect abnormalities in the heart wall caused by heart disease. Typically performed in a doctor's office or outpatient facility, the test takes 30 to 60 minutes.

Radionuclide angiography enables physicians to see the blood flow of the coronary arteries. Nuclear scans are performed by injecting a small amount of radiopharmaceutical, such as thallium, into the bloodstream. As the patient lies on a table, a camera that uses gamma rays to produce an image of the radioactive material passes over the patient and records pictures of the heart. Radionuclide angiography is usually performed in a hospital's nuclear medicine department. The radiation exposure is about the same as that in a chest x ray.

Coronary angiography is considered the most accurate method for making a diagnosis of heart disease, but it is also the most invasive. During coronary angiography the patient is awake but sedated. The cardiologist inserts a catheter into a blood vessel and guides it into the heart. A contrast dye (a radiopaque substance that is visible on x ray) is injected into the catheter and x rays are taken. Coronary angiography is performed in a cardiac catheterization laboratory in either an outpatient or an inpatient surgery unit.

Treatment

Herbal-medicine practitioners recommend a variety of remedies that may have a beneficial effect on

heart disease. They may suggest **garlic** (*Allium sativum*), **myrrh** (*Commiphora molmol*), and oats (*Avena sativa*) to help reduce cholesterol, and **hawthorn** (*Crataegus* spp.), linden (*Tilia europaea*), and **yarrow** (*Achillea millefolium*) to control high blood pressure, a risk factor for heart disease. Tea, especially **green tea** (*Camellia sinensis*), is high in **antioxidants** and studies have shown that it may have a preventative effect against atherosclerosis. Coenzyme Q10 has been shown to be beneficial for patients with congestive heart failure. Taurine, an amino acid found in meat and fish proteins, has also been suggested as a way to treat heart arrhythmia.

Some alternative-medicine practitioners believe that **yoga** and other bodywork, massage, **relaxation**, **aromatherapy**, and music therapies may also help prevent heart disease and stop, or even reverse, the progression of atherosclerosis. Vitamin and mineral supplements that are believed to reduce, reverse, or protect against heart disease include B-complex vitamins, calcium, **chromium**, **magnesium**, L-carnitine, **zinc**, and the antioxidant vitamins C and E. Notably, a study in 2004 showed a relationship between high doses of supplemental **vitamin C** and reduced coronary heart disease but found little risk reduction with supplemental **vitamin E**.

Traditional Chinese medicine (TCM) may recommend herbal remedies, massage, **acupuncture**, and dietary modification. A healthy diet (including cold water fish as a source of **essential fatty acids**) and exercise are important components of both alternative and conventional prevention and treatment strategies.

New reports on diet and heart disease have answered some questions, but others remain unclear. While one study concludes that four servings per day of fruit and vegetables are associated with a slight drop in risk of heart disease, eight or more servings per day can produce a significant drop in risk. Another study showed that consuming legumes at least four times per week lowered risk of heart disease from 11 percent to 22 percent compared with consuming legumes less than once a week. Research on antioxidants continued as of 2008 to produce mixed findings, with some reports showing that vitamins E, C, and other antioxidants can help prevent heart disease, and other studies showing they have no effect. Although scientists and medical professionals had not reached a consensus about the benefits of antioxidants as of 2008, the American Heart Association reported that up to 30 percent of Americans take antioxidant supplements. As of 2008, however, the association did not recommend supplements. Instead, it advised a diet containing a variety of nutrient-rich foods, including fruits, vegetables, whole grains, and nuts.

Allopathic treatment

Heart disease can be treated many ways. The choice of treatment depends on the patient and the severity of the disease. Treatments include lifestyle changes and drug therapy and coronary artery bypass surgery. (Recommendations for persons with coronary artery disease are available through the American Heart Association Web site at http://www.americanheart.org/presenter.jhtml?identifier=3039477.) These, however, are not a cure. Heart disease is a chronic disease requiring lifelong care.

Another treatment option is percutaneous transluminal coronary angioplasty, usually called coronary angioplasty, which is a non-surgical procedure. A catheter tipped with a balloon is threaded from a blood vessel in the thigh into the blocked artery. The balloon is inflated, compressing the plaque and opening the blocked artery. The balloon is then deflated and the catheter removed.

People with moderate heart disease may gain adequate control through lifestyle changes and drug therapy. Drugs such as nitrates, beta-blockers, and calcium channel blockers relieve chest pain and complications of heart disease, but they cannot clear blocked arteries. Nitrates improve blood flow to the heart, and beta-blockers reduce the amount of oxygen required by the heart during stress. Calcium channel blockers help keep the arteries open and reduce blood pressure.

Aspirin helps prevent blood clots from forming on plaques, reducing the likelihood of a heart attack and **stroke**. Cholesterol-lowering medications are also indicated in many cases.

Coronary angioplasty is successful about 90 percent of the time, but for about one-third of patients, the artery narrows again within six months. The procedure can be repeated. It is less invasive and less expensive than coronary artery bypass surgery.

In coronary artery bypass surgery, a healthy vein from an arm, leg, or chest wall is used to build a bypass around the coronary artery blockage. The healthy vessel then supplies oxygen-rich blood to the heart. Bypass surgery is major surgery. It is appropriate for those patients with blockages in two or three major coronary arteries, those with severely narrowed left main coronary arteries, and those who have not responded to other treatments. The majority of patients who have bypass surgery experience full relief from angina, and many of the remainder experience partial relief. A study in 2004 also noted that patients who had serious coronary artery disease had better

five-year survival rates with a bypass than they did with balloon angioplasty or stent procedures.

Three other surgical procedures for unblocking coronary arteries are available. Atherectomy is a procedure in which the cardiologist shaves off and removes strips of plaque from the blocked artery. In laser angioplasty, a catheter with a laser tip is inserted into the affected artery to burn or break down the plaque. A metal coil called a stent can be implanted permanently to keep a blocked artery open. As of 2008, stenting was becoming more common.

Expected results

Advances in medicine and the adoption of healthier lifestyles have caused a substantial decline in death rates from heart disease since the mid-1980s. New diagnostic techniques enable doctors to identify and treat heart disease in its earliest stages. New technologies and surgical procedures have extended the lives of many patients who would have otherwise died. Research on heart disease continued as of 2008.

Prevention

A healthy lifestyle can help prevent heart disease and slow its progress. A heart-healthy lifestyle includes maintaining a healthy diet and weight, performing regular exercise, refraining from **smoking**, engaging in moderate drinking, controlling **hypertension**, and managing stress. Cardiac rehabilitation programs are excellent ways to help prevent recurring coronary problems for people who are at risk and who have had coronary events and procedures.

Eating right

A healthy diet includes a variety of foods that are low in fat, especially saturated fat, low in cholesterol, and high in fiber. It includes plenty of fruits and vegetables and limited salt. According to the American Heart Association, fats should comprise no more than 25 to 35 percent of the total daily calories and should total less than 7 percent saturated fats, less than 1 percent trans fats, and the remainder as monounsaturated and polyunsaturated fats from such sources as nuts, seeds, fish and vegetable oils. Cholesterol intake should be limited to 300 mg per day for the average person. Those individuals who have coronary heart disease or who have an LDL cholesterol level of 100 mg/dL or more, should lower their daily cholesterol intake to less than 200 mg per day. Eating cold-water fish or taking comparable omega-3 polyunsaturated fatty acid supplements can help prevent cardiac death. The American Heart Association advocates eating fish (particularly fatty fish) at least twice a week. It also recommends adding soybeans (including tofu), canola, walnut, and **flaxseed**, and their oils to the diet because these contain alpha-linolenic acid than can transform into omega-3 fatty acid in the body. The association also notes that individuals consult with their doctor before taking omega-3 fatty acid supplements in excess of 3 grams per day because of the potential for bleeding.

Cholesterol, a waxy substance containing fats, is found in foods such as meat, dairy, eggs, and other animal products. It is also produced in the liver. Soluble fiber can help lower cholesterol. Dietary cholesterol should be below 300 milligrams per day. Many popular lipid-lowering drugs can reduce LDL cholesterol by an average of 25 to 30 percent, or more, when used with a low-fat, low-cholesterol diet.

Antioxidants are chemical compounds in plant foods. When people eat antioxidant-rich foods, they may improve the function of the arteries and prevent arterial plaque formation and reduce their risk of **cancer**. Colorful vegetables and fruits are sources of antioxidants and are rich in fiber, vitamins, and minerals. They are low in calories and nearly fat-free. Vitamin C and beta-carotene, found in many fruits and vegetables, keep LDL-cholesterol from turning into a form that damages coronary arteries. Whole grains, especially whole oats and oat bran, reduce cholesterol.

Excess **sodium** can increase the risk of high blood pressure. Many processed foods contain large amounts of sodium. Daily intake should be limited to about 2,300 milligrams, about the amount in a teaspoon of salt.

The Food Guide Pyramid developed by the Center for **Nutrition** Policy and Promotion, an organization of the U.S. Department of Agriculture, provides easy-to-follow guidelines for daily heart-healthy eating.

Exercising regularly

Aerobic exercise can lower blood pressure, help control weight, and increase HDL (good) cholesterol. It also may keep the blood vessels more flexible. The American Heart Association recommends moderate-to-vigorous intensity aerobic activity (50 to 85 percent of the maximum heart rate) for at least 30 minutes on most days of the week. Those 30 minutes can be divided into two 15-minute or three 10-minute sessions throughout the day. People with heart disease or risk factors should consult a doctor before beginning an exercise program.

Maintaining a desirable body weight

People who are 20 percent or more above their ideal body weight have an increased risk of developing heart disease. Losing weight can help decrease total and LDL cholesterol, reduce triglycerides, and boost HDL cholesterol. It may also reduce blood pressure. Eating right and exercising are two essential components of losing weight.

Quitting smoking

Smoking has many adverse effects on the heart. It increases the heart rate, constricts major arteries, and can create irregular heartbeats. It also raises blood pressure, contributes to the development of plaque, increases the formation of blood clots, and causes blood platelets to cluster and impede blood flow. When smokers quit the habit, heart damage can be repaired. Several studies have shown that ex-smokers face the same risk of heart disease as non-smokers within 5 to 10 years after they quit.

Drinking in moderation

Modest consumption of alcohol may actually protect against heart disease because alcohol appears to raise levels of HDL cholesterol. The American Heart Association defines moderate consumption as one to two daily drinks for men and one daily drink for women, or one ounce of alcohol per day. The association defines one drink as 4 ounces of wine, 12 ounces of beer, 1.5 ounces of 80-proof spirits, or 1 ounce of 100-proof spirits.

Seeking diagnosis and treatment for hypertension

High blood pressure, one of the most common and serious risk factors for heart disease, can be completely controlled through lifestyle changes and medication. Seeking diagnosis and treatment is critical because hypertension often exhibits no symptoms, so many people do not know they have it. Moderate hypertension can be controlled by reducing dietary intake of sodium and fat, exercising regularly, managing stress, abstaining from smoking, and drinking alcohol in moderation.

Managing stress

Everyone experiences stress. Stress can sometimes be avoided and, when it is inevitable, it can be managed through relaxation techniques, exercise, and other methods.

KEY TERMS

Angina—Chest pain that occurs when diseased blood vessels restrict the flow of blood to the heart. Angina is often the first symptom of heart disease.

Atherosclerosis—A process in which the openings in the coronary arteries narrow due to the accumulation of plaque on the linings of the blood vessels. Atherosclerosis is the cause of heart disease.

Beta-blocker—A drug that blocks some of the effects of fight-or-flight hormone adrenaline (epinephrine and norepinephrine), slowing the heart rate and lowering the blood pressure.

Calcium channel blocker—A drug that blocks the entry of calcium into the muscle cells of small blood vessels (arterioles) and keeps them from narrowing.

Coronary arteries—The main arteries that provide blood to the heart. The coronary arteries surround the heart like a crown, coming out of the aorta, arching down over the top of the heart, and dividing into two branches. These are the arteries in which heart disease occurs.

HDL cholesterol—High-density lipoprotein cholesterol is a component of cholesterol that helps protect against heart disease. HDL is nicknamed "good cholesterol."

LDL cholesterol—Low-density lipoprotein cholesterol is the primary cholesterol molecule. High levels of LDL increase the risk of coronary heart disease. LDL is nicknamed "bad cholesterol."

Plaque—A deposit of fatty and calcium substances that can accumulate dangerously in the lining of the artery wall.

Triglyceride—A fat that comes from food or is made from other energy sources in the body. Elevated triglyceride levels contribute to the development of atherosclerosis.

Heartburn

Definition

Heartburn is a burning sensation in the chest that can extend to the neck, throat, and face. It usually occurs after eating and is worsened by bending, lifting, or lying down.

Description

Heartburn, sometimes called acid **indigestion** or gastroesophageal reflux, is very common. More than one third of the population suffers from occasional heartburn, as do about one half of pregnant women. Some 50 million adult Americans complain of frequent heartburn. The occurrence of heartburn generally increases with age; however, it is common—and often overlooked—in infants and children.

Heartburn occurs when digestive juices from the stomach move back up into the esophagus, the tube connecting the throat to the stomach. The upper third of the esophagus consists of skeletal muscle that propels the food downward. The lower two-thirds of the esophagus is smooth muscle. The lower esophageal sphincter (LES) is a thick band of muscle that encircles the esophagus just above the uppermost part of the stomach. This sphincter is usually tightly closed—opening only when food passes from the esophagus into the stomach—and prevents the contents of the stomach from moving back into the delicate esophageal tissue. The stomach has a thick mucous coating that protects it from the strong hydrochloric acid it secretes to digest food. However the much-thinner esophageal mucous coating does not protect against stomach acid. Thus, if the LES opens inappropriately or fails to close completely, stomach acids can back up and burn the esophagus, causing heartburn.

Occasional heartburn is usually harmless. However, frequent or chronic heartburn (recurring more than twice per week) is called gastroesophageal reflux disease (GERD) and requires early management. Repeated episodes of GERD can lead to esophageal inflammation (esophagitis). If the esophagus is repeatedly subjected to stomach acid and **digestive enzymes**, ulcerations, scarring, and thickening of the esophageal walls can result. This causes a narrowing of the interior of the esophagus that can affect swallowing and the peristaltic movements that send food downward. Repeated esophageal irritation also can result in Barrett's syndrome—changes in the types of cells lining the esophagus. Barrett's esophagus can develop into esophageal **cancer**.

Nighttime heartburn, affecting about 80% of heartburn sufferers, is more damaging to the esophagus than daytime heartburn. It often interferes with sleep and may trigger symptoms in **asthma** sufferers.

Gastroesophageal reflux may occur in children under age one, particularly pre-term babies or those with **cerebral palsy**. It also may be a cause of some migraine headaches. In addition, chronic heartburn can be a symptom of a gastric ulcer or coronary artery disease.

Causes and symptoms

Causes

Heartburn is caused by:

- a relaxed LES that does not close properly
- over-production of stomach acid
- increased stomach pressure
- a damaged esophagus with increased acid sensitivity

Many factors can contribute to LES malfunction:

- irregular eating, skipping meals
- smoking
- caffeine
- stress
- some medications, including diazepam (Valium), meperidine (Demerol), theophylline, morphine, prostaglandins, calcium channel blockers, nitrate heart medications, progesterone, and anticholinergic and adrenergic drugs (drugs that limit nerve reactions)
- paralysis and scleroderma (an autoimmune disease that hardens body organs)

KEY TERMS

Antacid—Common medication that neutralizes stomach acid for the short-term treatment of heartburn.

Barrett's esophagus or Barrett's syndrome—Changes in the type of cells lining the esophagus. Sometimes associated with the development of esophageal cancer.

Digestive enzymes—Proteins that catalyze the breakdown of large molecules (usually food) into smaller molecules.

Endoscopy—Procedure in which a thin, flexible scope is placed down the esophagus to examine, biopsy, and/or suture the tissue.

Esophagitis—Inflammation of the esophagus.

Esophagus—Muscular tube, about 10 in (25 cm) long, connecting the throat to the stomach.

Fundoplication—Surgical procedure that increases pressure on the LES (lower esophageal sphincter), reducing reflux.

Gastroesophageal reflux—Upward flow of stomach contents into the esophagus, causing heartburn.

Gastroesophageal reflux disease (GERD)—Frequent (more than twice a week) gastroesophageal reflux.

Hiatal hernia—Protrusion of part of the stomach through the diaphragm to a position next to the esophagus.

Hiatus—Opening in the diaphragm through which the stomach connects to the esophagus.

Histamine receptor 2 (H2) blocker—Heartburn medication that reduces the production of stomach acid.

Lower esophageal sphincter (LES)—Muscle at the base of the esophagus that opens to allow food to enter the stomach and closes to prevent reflux back into the esophagus.

Manometry—Procedure that measures pressure. In esophageal manometry, a thin, flexible catheter is placed down the esophagus to measure pressure at various points.

Peristalsis—Sequence of muscle contractions that progressively squeezes the digestive tract to push food along.

Proton pump inhibitor (PPI)—Medication that inhibits stomach acid production in severe heartburn.

Ulceration—Wound or abrasion of surface tissue.

- large meals that distend the stomach and prevent the LES from closing
- alcohol, which lowers the pressure on the LES, allowing it to relax and open. Alcohol also may irritate the esophageal lining
- weakening LES and loss of LES muscle tone with increasing age

Hiatal hernias are common among pregnant women, smokers, the obese, and those over age 50. The hiatus is an opening in the diaphragm (the large muscle that separates the chest cavity and the abdomen) through which the esophagus connects to the stomach. If the hiatus loses its tautness and shape, the stomach may protrude through, forming a pocket just below the LES where stomach acid can be trapped. These hiatal hernias can cause the LES to relax and open. Hiatal hernias may result in frequent and severe heartburn and GERD.

Various factors can increase stomach pressure, causing gastroesophageal reflux:

- obesity
- lying down within one or two hours of eating
- tight clothing
- Pregnancy causing the enlarged uterus to displace the stomach, delaying the removal of stomach contents

Eating too fast, chewing insufficiently, and **smoking** all increase stomach acid production. Smoking also dries up saliva that protects the esophagus from acid.

Many foods are known to contribute to heartburn:

- greasy, fried, or fatty foods
- spicy foods
- black pepper
- acidic foods such as tomatoes, pickles, and vinegar
- chocolate
- coffee with or without caffeine
- Peppermint or other mints

Symptoms

Heartburn itself is a symptom of gastroesophageal reflux and GERD. Heartburn sufferers may salivate excessively or regurgitate stomach contents into their mouths, leaving a sour or bitter taste.

Other symptoms of GERD include:

- difficult or painful swallowing
- sore throat
- hoarseness, laryngitis, wheezing, coughing
- pneumonia
- gingivitis, bad breath
- earache

Diagnosis

Heartburn usually is diagnosed by patient histories, symptoms, and clinical assessments. Additional procedures may be used to confirm the diagnosis, assess damage to the esophagus, and monitor the healing progress. The following diagnostic procedures are appropriate for anyone with frequent, chronic, or difficult-to-treat heartburn, or complicating GERD symptoms as listed above.

Esophageal manometry uses a thin, flexible catheter placed down the esophagus. Small openings in the catheter sense pressure at various points on the esophagus while the muscle is at rest and during swallowing. The pressures are transmitted to a computer that analyzes the wave patterns.

An upper gastrointestinal (GI) series, or "barium swallow," can reveal esophageal narrowing, ulcerations, tumors, **hiatal hernia**, or reflux episodes as they occur. X rays are taken after a patient swallows a barium (a chemical element) suspension. This procedure takes about 15 minutes. However it cannot detect structural changes associated with different degrees of esophagitis.

Upper GI endoscopy uses a thin, flexible tube to view the inside of the esophagus directly. It is performed by a gastroenterologist, a physician specializing in diagnosis and treatment of disorders of the gastrointestinal tract, or by a gastrointestinal endoscopist. Upper GI endoscopy enables the physician to distinguish the degree of esophagitis and provides an accurate profile of esophageal damage. This procedure may include a biopsy—the removal of a small piece of tissue—to examine for Barrett's syndrome or malignancies. Patients with Barrett's esophagus may have frequent examinations of the esophageal lining for early detection of precancerous cells.

Other diagnostic tests include measurements of esophageal acidity (pH), usually over a 24-hour period, using an ambulatory acid probe. The patient is given a large capsule containing an acid-sensing probe, a battery, and a transmitter. Acid in the esophagus is measured by the probe, which then transmits the information to a recorder that the patient is wearing on his belt.

Note: A burning sensation in the chest is usually heartburn and is not associated with the heart itself. About 15 percent of the annual six million U. S. emergency room visits for chest **pain** are due to heartburn. However, **angina** (one type of temporary chest pain, pressure, or discomfort) sometimes is mistaken for severe heartburn. Chest pain that radiates into the arms and is not accompanied by regurgitation is a warning sign of a possible serious heart problem. Persistent chest pain should always be evaluated by a physician.

Treatment

Herbal remedies

These herbal remedies may be used to treat heartburn:

- ginger (*Zingiber officinalis*) as a tea or candied. (Ginger may cause heartburn in some people.)
- chamomile (*Matricaria chamomilla*) tea
- slippery elm (*Ulmus fulva*) tea
- cinnamon tea
- anise (*Pimpinella anisum*), caraway, dill, and/or fennel seed tea
- cardamom (*Elettaria cardamomum*) on buttered raisin toast
- turmeric (*Curcuma domestica*) added to warm water
- marsh mallow root (*Althaea officinalis*)
- licorice (*Glycyrrhiza glabra*), especially deglycyrrhizinated licorice (DGL) (The capsules or tablets may be dissolved in the mouth or in tea or two to four chewable 380-mg wafers are taken about 20 minutes before eating. DGL should not be used more than three times per week, as repeated use can be toxic.)
- peppermint tea (Peppermint also can cause heartburn by relaxing the LES.)
- Ayurvedic (traditional East Indian) herbs

Homeopathic remedies

Homeopathic remedies for heartburn include:

- *Calcarea carbonica*
- *Nux vomica* after eating spicy foods
- *Carbo vegetalis* after eating rich foods
- *Arsenicum album* for burning pain
- *Natrum muriaticum* for nervousness, tension, and pain
- *Zinc metallicum* after eating too fast

Other remedies

A variety of other remedies and therapies may be used to treat heartburn:

- Sodium bicarbonate (baking soda) reduces esophageal acidity immediately. However, its effect is short-lived and it should not be used by people on sodium-restricted diets.
- Nutritional remedies include carrots, celery, angelica, fennel, and/or parsley. These can be combined in a juice taken before meals.
- Acupressure points Stomach 36, Spleen 6, Pericardium 6, and Conception Vessel 12. CV 12 should not be pressed just after eating or during pregnancy.
- In Chinese medicine, foods and herbs that balance and cool the qi (Chinese term for universal life energy), including radishes, radish seed, citrus fruit peels, and cardamom.
- Walking after a meal.
- Chewing gum after eating to help produce saliva for soothing the esophagus and washing acid back into the stomach.
- Relaxation therapy, visualization, and deep breathing.

Allopathic treatment

Drugs

Occasional heartburn is commonly treated with nonprescription antacids that neutralize the pH of stomach acid. The neutralized acid does not burn the esophagus. Antacids usually work within 15 minutes and their effects last one to two hours. Liquid or dissolving antacids usually are faster acting than tablets. However, antacids, if taken for too long, can cause side effects including **diarrhea** or **constipation**.

Some antacids interfere with medications for kidney or **heart disease**. Heartburn sufferers with two or more episodes per week, or with an episode lasting longer than three weeks, should not rely on antacids as the sole treatment, since they may be at risk of kidney damage or other metabolic changes.

Common antacids include Maalox, Mylanta, Alka-Seltzer, Pepto-Bismol, Riopan, and Rolaids. The active ingredient in antacids such as Tums is **calcium** carbonate. Alginate (Gaviscon) is a foaming agent that coats the esophagus and the stomach to help prevent reflux. Other antacids are made from aluminum hydroxide, magaldrate, or **magnesium** hydroxide. Some antacids contain baking soda (**sodium** bicarbonate), which may interfere with vitamin and mineral absorption during **pregnancy**.

Histamine receptor (H2) blockers, such as famotidine (Pepcid), ranitidine (Zantac), nizatidine (Axid), and cimetidine (Tagamet), decrease stomach acid secretion. They relieve heartburn in about 75% of users. However, they take 30 to 45 minutes to act and usually are taken two to four times daily for several weeks. H2 blockers are both over-the-counter (OTC) and prescription medicines. They may have side effects or interactions with other medications.

Proton pump inhibitors (PPI) are for severe heartburn. They are the most effective drugs for inhibiting acid production and allowing the esophagus to heal in GERD. It may take up to five days for PPIs to take effect. They cannot be used by people with kidney or liver problems. Although it appears safe to take PPIs for at least 10 years, the lowest effective dosage reduces the risk of side effects that may include **headache**, diarrhea, stomach pain, and interactions with other medications. Common PPIs include lansoprazole (Prevacid), omeprazole (Prilosec), rabeprazole (Aciphex), pantoprazole (Protonix), and esomeprazole (Nexium). Prilosec OTC is available in 20-milligram doses to be taken once a day for 14 days to treat frequent heartburn.

Prokinetics are drugs that strengthen the LES (lower esophageal sphincter) and increase the rate of stomach emptying. These include metoclopramide (Reglan) and bethanechol (Urecholine). These drugs frequently have side effects.

Surgery

Laparoscopic Nissen fundoplication is a surgical procedure to increase pressure on the LES by stretching and wrapping the upper part of the stomach around it. It is performed under a general anesthetic and takes one to two hours. The complete recovery period is less than two weeks.

GERD (gastroesophageal reflux disease) may be treated successfully by endoscopic suturing of the weakened LES to stop acid reflux. Studies have shown that symptoms usually improve with this procedure and the use of medications declines. Another procedure involves using electrodes to make tiny **cuts** in the LES tissues. The resulting scarring tightens the LES. These outpatient procedures take less than an hour. They are not used in cases of hiatal hernia or Barrett's esophagus.

If the esophagus has become narrowed and badly scarred from stomach acid, a procedure that stretches and widens the esophageal tissue may be used along with acid-suppressing medication. Enteryx is a liquid

that can be injected into the LES where it forms a spongy muscle implant that strengthens the LES.

Prognosis

Occasional heartburn, without esophageal damage, has an excellent prognosis. Esophageal damage that is treated with a program that promotes healing also has an excellent prognosis. Infants usually outgrow gastroesophageal reflux by age one.

Untreated heartburn and GERD may lead to bleeding, esophageal ulcers, and **infections**. With treatment, the damaged tissue that forms ulcers can heal. About ten percent of patients with GERD experience esophageal narrowing from acid damage that leads to the formation of scar tissue in the lower esophagus. GERD also can cause **laryngitis**, **bronchitis**, and aspiration **pneumonia**. After five years of heartburn, the risk of developing Barrett's esophagus increases. About five percent of GERD patients have Barrett's syndrome. This condition is incurable and may lead to cancer. The prognosis for esophageal cancer is very poor. There is a strong likelihood of painful illness and a less than five percent chance of survival for more than five years.

Prevention

Due to the risk of GERD, Barrett's syndrome, and esophageal cancer, prevention of heartburn is very important. Heartburn usually is preventable with dietary and lifestyle changes.

Dietary adjustments to eliminate many causes of heartburn include:

- eating smaller, more frequent meals to reduce pressure on the LES
- eating slowly, chew thoroughly, and take deep breaths between bites
- avoiding caffeine, chocolate, onions, spicy foods, and mint, all of which tend to increase stomach acid and relax the LES
- avoiding fatty, fried, and greasy foods. Fatty foods relax the LES and slow stomach emptying, and fat consumption has been linked to GERD
- avoiding milk, garlic, peppers, and carbonated beverages
- avoiding nicotine
- avoiding citrus fruits and juices and tomato-based foods, which are acidic and can irritate an inflamed esophagus
- replacing meat at dinner with carbohydrates and easier-to-digest proteins such as rice, beans, and pastas
- avoiding alcohol
- adding the spice annato (*Bix orellana*) or bouquet garni to foods
- drinking tea made with crushed caraway seeds with meals
- controlling body weight

Lifestyle changes that can alleviate heartburn include:

- avoiding drugs known to contribute to heartburn, including aspirin or other nonsteroidal anti-inflammatories
- avoiding clothing that fits tightly around the abdomen
- not lying down until the stomach is empty—within about three hours of eating
- elevating the head of the bed six to nine inches to prevent nighttime heartburn
- avoiding strenuous exercise for two to three hours after a meal

Heavy metal poisoning

Definition

Heavy metal poisoning is the toxic accumulation of heavy metals in the soft tissues of the body.

Description

The term "heavy metal" has been defined in a number of ways. By one definition, a heavy metal is any chemical element with a specific gravity (a measure of density) greater than 4.0. Any toxic metal, no matter what its specific gravity, may also be called a heavy metal. The heavy metals most often implicated in human poisoning are lead, mercury, arsenic, and cadmium. Some heavy metals, such as **zinc**, **copper**, **chromium**, **iron**, and **manganese**, are required by the body in small amounts but can be toxic in larger quantities. Heavy metals may enter the body through food, water, or air, or by absorption through the skin. Once in the body, they compete with and displace essential minerals such as zinc, copper, **magnesium**, and **calcium**, and interfere with organ system function. People may come in contact with heavy metals in industrial work, pharmaceutical manufacturing, and agriculture. Children may be poisoned as a result of playing in contaminated soil.

Sources of exposure for some heavy metals include the following:

- lead: old paint, leaded gasoline, old pipes
- mercury: contaminated fish and industrial and agricultural wastes
- cadmium: industrial waste, insecticides, old galvanized pipes
- arsenic: insecticides and industrial processes, even drinking water

Causes and symptoms

Symptoms of heavy metal poisoning vary, depending on the nature and quantity of the heavy metal and whether it was ingested or inhaled. Patients who ingest a heavy metal may complain of cramps, **nausea**, **vomiting**, **diarrhea**, stomach **pain**, **headache**, sweating, and a metallic taste in the mouth. Mercury can cause skin **burns** if it has touched the skin, and inhaled mercury vapor can cause severe inflammation of the lungs. If lead is inhaled in the form of lead dust, **insomnia**, headache, mania, and convulsions may occur. In severe cases of heavy metal poisoning, patients exhibit obvious impairment of cognitive, motor, and language skills. The expression "mad as a hatter" comes from the **mercury poisoning** prevalent in seventeenth-century France among hatmakers who soaked animal hides in a solution of mercuric nitrate to soften the hair.

Diagnosis

Heavy metal poisoning may be detected using blood, urine, and stool tests, hair and tissue analysis, or x rays. In children, blood lead levels above 80 mcg/dL generally indicate **lead poisoning**. However, significantly lower levels (30 mcg/dL) can cause mental retardation and other cognitive and behavioral problems in chronically exposed children. The Centers for Disease Control and Prevention considers a blood lead level of 10 mcg/dL or higher in children a cause for concern. In adults, symptoms of lead poisoning are usually seen when blood lead levels exceed 80 mcg/dL for a number of weeks. Blood levels of mercury should not exceed 3.6 mcg/dL, whereas urine levels should not exceed 15 mcg/dL. Symptoms of mercury poisoning may appear when mercury levels exceed 20 mcg/dL in blood and 60 mcg/dL in urine. Some authorities have recommended testing of hair to determine mercury levels in the body. As of 2008, however, such tests were believed to have questionable value at best.

Since arsenic is rapidly cleared from the blood, blood arsenic levels may not be very useful in diagnosis. Arsenic in the urine (measured in a 24-hour collection following 48 hours without eating seafood) may exceed 50 mcg/dL in people with arsenic poisoning. If

acute arsenic poisoning is suspected, an x ray may reveal ingested arsenic in the abdomen (since arsenic is opaque to x rays). Arsenic may also be detected in the hair and nails for months following exposure. Cadmium toxicity is generally indicated when urine levels exceed 10 mcg/dL of creatinine and blood levels exceed 5 mcg/dL.

Treatment

Emergency treatment for acute poisoning, especially in children, can be handled by calling a poison control line at (800) 222-1222, or by dialing 911. Alternative practitioners often rely on the same chelating agents used by medical doctors to treat heavy metal poisoning, but they also use natural supplements and additional techniques to assist the body's own **detoxification** processes. One highly contested issue between alternative medicine and mainstream dentistry concerns mercury poisoning. Alternative practitioners believe that there is a large body of evidence suggesting that silver amalgam tooth fillings, which contain mercury, are a major factor in mercury poisoning. For individuals with high mercury levels in their bodies, they recommend that all mercury-containing tooth fillings be removed by a holistic dentist. A large number of studies have been conducted on the relationship of mercury from dental amalgams and human health. A comprehensive review of such studies conducted between 1996 and 2004 found "little evidence to support a causal relationship between mercury fillings and human health problems." Authors of the report noted, however, that further research was needed to obtain a definitive answer about the issue.

Dietary changes are used to support the treatment of heavy metal poisoning. Detoxification **diets** are predominantly vegetarian and reduce or avoid foods that may **stress** the immune system, such as processed foods, fried foods, sugar, fat, alcohol, **caffeine**, meat, and dairy products. Organic foods are recommended to avoid exposure to pesticides and chemicals. Detoxification diets include plenty of high-fiber foods, including oat bran and **psyllium** seeds, to help cleanse the digestive tract. Apples, pears, and legumes are high in pectins, which are believed to have chelating effects on heavy metals. Foods high in **antioxidants** are recommended, such as fruits, vegetables, and fresh juices. Sulfur-containing foods such as **garlic**, onions, and eggs (organically produced) are utilized, as are dark-green leafy vegetables that contain high amounts of chlorophyll. Foods that may contain heavy metals are avoided, including many fish and shellfish. Factory-farmed chicken and eggs are avoided as well because chickens are often fed fish meal. There is some evidence that eating tofu may reduce lead levels in the blood. Tofu is rich in calcium, which may help reduce the blood's ability to absorb and retain lead.

Nutritional supplements include antioxidant vitamins A, C, and E, and multimineral supplements that contain calcium, iron, magnesium, copper, chromium, **selenium**, and zinc. Cysteine, **methionine**, L-glutathione, and DMSA (dimethyl succinate) are other supplements. Herbal support includes herbs that have detoxification effects, such as **milk thistle**, burdock, and numerous others. **Spirulina** and **chlorella** sea algae are used as well, and **acidophilus** helps rebuild the digestive tract.

Homeopathic remedies, which prompt the body's detoxification mechanisms, have shown success with heavy metal poisoning. Detoxification therapies are also highly recommended, including **fasting**, sweating, colonics, and therapeutic vomiting. **Ayurvedic medicine** has an intensive detoxification and healing program called **panchakarma**.

Allopathic treatment

In an emergency, patients should call 911 or a poison control hotline at (800) 222-1222. The treatment for most heavy metal poisoning is **chelation therapy**. A chelating agent specific to the metal involved is given orally, intramuscularly, or intravenously. The three most common chelating agents are edetate calcium disodium (CaEDTA), dimercaprol (BAL), and penicillamine. Succimer (DMSA) is used for children suffering from lead poisoning. The chelating agent encircles and binds to the metal in the body's tissues, forming a complex, which is then released from the tissue and travels in the bloodstream. The complex is filtered out of the blood by the kidneys and excreted in the urine. This process may be lengthy and painful and typically requires hospitalization. Chelation therapy is effective in treating lead, mercury, and arsenic poisoning, but it is not useful in treating **cadmium poisoning**. To date, no treatment has been proven effective for cadmium poisoning. In cases of acute mercury or arsenic ingestion, vomiting may be induced. Washing out the stomach (gastric lavage) may also be useful. The patient may also require treatment such as intravenous fluids for complications of poisoning such as shock, **anemia**, and kidney failure.

Expected results

The chelation process can only halt further effects of the poisoning; it cannot reverse neurological damage already sustained.

KEY TERMS

Chelation—The process by which a molecule encircles and binds to a metal and removes it from tissue.

Heavy metals—Chemical elements that have a specific gravity (a measure of density) at least four times that of water, generally with harmful effects on the human body.

Prevention

Because exposure to heavy metals is often an occupational hazard, protective clothing and respirators should be provided and worn on the job. Protective clothing should then be left at the work site and not worn home, where it could transfer toxic dust to family members. Industries are urged to reduce or replace the heavy metals in their processes wherever possible. Exposure to environmental sources of lead, including lead-based paints, plumbing fixtures, vehicle exhaust, and contaminated soil, should be reduced or eliminated. In the late 2000s, the use of lead was banned in most applications in the United States, such as in leaded fuels and most types of paints.

Heel spurs

Definition

A heel spur is a bony projection on the sole (bottom) of the heel bone. This condition may accompany or result from severe cases of inflammation to the structure called *plantar fascia*. The plantar fascia is a fibrous band of connective tissue on the sole of the foot, extending from the heel to the toes.

Description

Heel spurs are a common foot problem resulting from excess bone growth on the heel bone. The bone growth is usually located on the underside of the heel bone, and may extend forward toward the toes. A painful tear in the plantar fascia between the toes and heel can produce a heel spur and/or inflammation of the plantar fascia. Because this condition is often correlated to a decrease in the arch of the foot, it is more prevalent after the ages of six to eight years, when the arch is fully developed.

Causes and symptoms

One frequent cause of injury to the plantar fascia is *pronation*. Pronation is defined as the inward and downward action of the foot that occurs while walking, so that the foot's arch flattens toward the ground (fallen arch). A condition known as excessive pronation creates a mechanical problem in the foot, and the portion of the plantar fascia attached to the heel bone can stretch and pull away from the bone. This can occur especially while walking and during athletic activities.

Some symptoms at the beginning of this condition include **pain** and swelling, and discomfort when pushing off with the toes during walking. This movement of the

KEY TERMS

Genu valgus—Deformity in which the legs are curved inward so that the knees are close together, nearly or actually knocking as a person walks with ankles widely apart.

Plantar fascia—A tough fibrous band of tissue surrounding the muscles of the sole of the foot.

Plantar fascitis—Inflammation of the plantar fascia.

Pronation—The lowering or descending of the inner edge of the foot while walking.

foot stretches the fascia that is already irritated and inflamed. If this condition is not treated, pain will be noticed in the heel when a heel spur develops in response to the **stress**. This is a common condition among athletes and others who run and jump a significant amount.

An individual with the lower legs turning inward, a condition called *genu valgus* or "knock knees," can have a tendency toward excessive pronation. This can lead to a fallen arch and problems with the plantar fascia and heel spurs. Women tend to suffer from this condition more than men. Heel spurs can also result from an abnormally high arch.

Other factors leading to heel spurs include a sudden increase in daily activities, an increase in weight, or less cushion on the bottom of the heel due to old age. A significant increase in training intensity or duration may cause inflammation of the plantar fascia. High heel shoes, improperly fitted shoes, and shoes that are too flexible in the middle of the arch or bend before the toe joints will cause problems with the plantar fascia and possibly lead to heel spurs.

Bone spurs may cause sudden, severe pain when putting weight on the affected foot. Individuals may try to walk on their toes or ball of the foot to avoid painful pressure on the heel spur. This compensation during walking or running can cause additional problems in the ankle, knee, hip, or back.

Diagnosis

A thorough history and physical exam is always necessary for the proper diagnosis of heel spurs and other foot conditions. X rays of the heel area are helpful, as excess bone production will be visible.

Treatment

Acupuncture and **acupressure** can be used to address the pain of heel spurs, in addition to using friction massage to help break up scar tissue and delay onset of bony formations. Physical therapy may help relieve pain and improve movement. **Feldenkrais** method could be especially helpful for retraining some of the compensation movements caused by the pain from the spur. **Guided imagery** or a light massage on the foot may help to relieve some of the pain. Other treatments include low-gear cycling and pool running. Some chiropractors approve of moderate use of aspirin or ibuprofen, or other appropriate anti-inflammatory drugs. **Chiropractic** manipulation is not recommended, although chiropractors may offer custom-fitted shoe orthotics and other allopathic-type treatments outlined below.

Allopathic treatment

Heel spurs and plantar fascitis (inflammation of the plantar fascia) are usually controlled with conservative treatment. Early intervention includes stretching the calf muscles while avoiding reinjury to the plantar fascia. Decreasing or changing activities, losing excess weight, and improving the fit of shoes are all important measures to decrease foot pain. Modification of footwear includes well padded shoes with a raised heel and better arch support. Shoe inserts recommended by a healthcare professional are often very helpful when used with exercises to increase the strength of the foot muscles and arch. The inserts prevent excessive pronation and continued tearing of the plantar fascia.

To aid in the reduction of inflammation, applying ice for 10–15 minutes after activities and the use of anti-inflammatory medications, such as aspirin or ibuprofen, can be helpful. Corticosteroid injections may also be used to reduce pain and inflammation. Physical therapy can be beneficial with the use of heat modalities, such as ultrasound, that create a deep heat and reduce inflammation. If the pain caused by inflammation is constant, keeping the foot raised above the heart and/or compressed by wrapping with a bandage will help. Taping can help speed the healing process by protecting the fascia from reinjury, especially during stretching and walking.

In 2000, a number of U.S. podiatrists experimented with a new technology known as Extracorporeal Pressure Wave Treatment (EPWT). This technology is similar to lithotripsy, which uses sound waves to break up **kidney stones**. Cost of EPWT was roughly comparable to that of surgery. Initial reports from practitioners using the treatment were positive.

Heel surgery

When chronic heel pain fails to respond to conservative treatment, surgical treatment may be necessary.

Heel surgery can provide pain relief and restore mobility. The type of procedure used is based on examination and usually consists of releasing the excessive tightness of the plantar fascia, called a plantar fascia release. The procedure may also include removal of heel spurs.

Expected results

Usually, heel spurs are curable with conservative treatment. If not, heel spurs are curable with surgery, although there is the possibility of them growing back. About 10% of those who continue to see a physician for plantar fascitis have it for more than a year. If there is limited success after approximately one year of conservative treatment, patients are often advised to have surgery.

Prevention

To prevent this condition, wearing properly fitted shoes with good arch support is very important. If a person is overweight, weight loss can help diminish stress on the feet and help prevent foot problems. For those who **exercise** frequently and intensely, proper stretching is always necessary, especially when there is an increase in activities or a change in running technique. It is not recommended to attempt to work through the pain, as this can change a mild case of heel spurs and plantar fascitis into a long-lasting and painful condition.

In 2002, researchers attempted to compare the effects of various running techniques on pronation and resulting injuries like stress **fractures** and heel spurs. They suggested that it is possible to teach runners to stride in such a way as to minimize impact forces. One way is to lower running speed. Another is to take longer rest periods following a run.

Hellerwork

Definition

Hellerwork is a system of bodywork that combines deep tissue massage, body movement education, and verbal dialogue. It is designed to realign the body's structure for overall health, improvement of posture, and reduction of physical and mental **stress**.

Origins

Joseph Heller (1940–) developed Hellerwork, a system of structural integration patterned after **Rolfing**. Although Heller received a degree in engineering and worked for NASA's Jet Propulsion Laboratory in Pasadena, CA, he became interested in humanistic psychology in the 1970s. He spent two years studying bioenergetics and Gestalt therapy as well as studying under architect and futurist Buckminster Fuller (1895–1983), flotation tank therapy developer John Lilly, family therapist Virginia Satir, and body movement pioneer Judith Aston.

During this period, he trained for six years with Dr. Ida P. Rolf (1896-1979), the founder of Rolfing, and became a certified Rolfer in 1972. After Heller developed his own system of bodywork, he founded Hellerwork in 1979 and established a training facility in Mt. Shasta, California, where he continues his work.

Benefits

Hellerwork improves posture and brings the body's natural structure into proper balance and alignment. This realignment can bring relief from general aches and pains; improve breathing; and relieve physical and mental stress. Hellerwork has also been used to treat such specific physical problems as chronic back, neck, shoulder, and joint **pain** as well as repetitive stress injuries, including **carpal tunnel**

KEY TERMS

Bioenergetics—A system of therapy that combines breathing and body exercises, psychological therapy, and the free expression of emotions to release blocked physical and psychic energy.

Bodywork—A term that covers a variety of therapies that include massage, realignment of the body, and similar techniques to treat deeply ingrained stresses and traumas carried in the tissues of the body.

Chronic—A disease or condition that progresses slowly but persists or reoccurs over time.

Fascia—The sheet of connective tissue that covers the body under the skin and envelops the muscles and various organs.

Gestalt therapy—A form of therapy that focuses on helping patients reconnect with their bodies and their feelings directly, as contrasted with verbal intellectual analysis.

Kinesiology—The study of the anatomy and physiology of body movement, particularly in relation to therapy.

Rolfing—A deep-tissue therapy that involves manipulating the body's fascia to realign and balance the body's structure.

syndrome. Hellerwork is also used to treat and prevent athletic injuries.

Description

Hellerwork is based largely on the principles of Rolfing, in which the body's connective tissue is manipulated or massaged to realign and balance the body's structure. Because Heller believes that physical realignment is insufficient, however, he expanded his system to include movement education and verbal dialogue as well as deep tissue massage.

Connective tissue massage

The **massage therapy** aspect of Hellerwork is designed to release the tension that exists in the deep connective tissue, called fascia, and return it to a normal alignment. The fascia is plastic and highly adaptable; it can tighten and harden in response to the general effects of gravity on the body, other ongoing physical stresses, negative attitudes and emotions, and periodic physical traumas. One example of ongoing physical stress is carrying a briefcase, which pulls down the shoulder on one side of the body. Over time, the connective tissue becomes hard and stiff; the body becomes adapted to that position even when the person is not carrying a briefcase. In trying to adjust to the uneven weight distribution, the rest of the body becomes unbalanced and out of proper alignment.

Heller believes that as people age, more of these stress and trauma patterns become ingrained in the connective tissue, further throwing the body out of alignment. As stress accumulates, the body shortens and stiffens, a process commonly attributed to **aging**. Hellerwork seeks to recondition the body and make the connective tissue less rigid.

Movement education

The second component of Hellerwork, movement education, trains patients in the proper physical movements needed to keep the body balanced and correctly aligned. Movement education focuses on common actions, such as sitting, standing, and walking. Hellerwork practitioners also teach better patterns of movement for activities that are specific to each individual, such as their job and favorite sports or social activities.

Verbal dialogue

Verbal dialogue is the third aspect of Hellerwork. It is designed to teach awareness of the relationships among emotions, life attitudes, and the body. Hellerwork practitioners believe that as patients become responsible for their attitudes, their body movements and patterns of self-expression improve. Dialogue focuses on the theme of each session and the area of the body that is worked on during that session.

Hellerwork consists of eleven 90-minute sessions costing about $90–100 each. The first three sessions focus on the surface layers of the fascia and on developmental issues of infancy and childhood. The next four sessions are the core sessions and work on the deep layers and on adolescent developmental issues. The final four treatments are the integrative sessions, and build upon all the previous ones, while also looking at questions of maturity.

Preparations

No advance preparations are required to begin Hellerwork treatment. The treatment is usually done on a massage table with the patient wearing only undergarments.

Precautions

Since Hellerwork involves vigorous deep tissue massage, it is often described as uncomfortable and

sometimes painful, especially during the first several sessions. As it requires the use of hands, it may be a problem for people who do not like or are afraid of being touched. It is not recommended as a treatment for any disease or a chronic inflammatory condition such as arthritis, and can worsen such a condition. Anyone with a serious medical condition, including **heart disease**, diabetes, or respiratory problems, should consult a medical practitioner before undergoing Hellerwork.

Side effects

There are no reported serious side effects associated with Hellerwork when delivered by a certified practitioner to adults and juveniles.

Research and general acceptance

As most alternative or holistic treatments, there is little mainstream scientific research documenting the effectiveness of Hellerwork therapy. Since the deep tissue massage aspect of Hellerwork is similar to Rolfing, however, several scientific studies of Rolfing may be useful in evaluating Hellerwork. A 1988 study published in the *Journal of the American Physical Therapy Association* indicated that Rolfing stimulates the parasympathetic nervous system, which can help speed the recovery of damaged tissue. A 1997 article in *The Journal of Orthopaedic and Sports Physical Therapy* reported that Rolfing can provide effective and sustained pain relief from lower back problems.

Training and certification

Hellerwork practitioners are certified by Hellerwork and must complete 1,250 hours of training, including courses in anatomy, psychology, massage, and kinesiology.

Hemorrhoids

Definition

Hemorrhoids, which are also called piles, is a condition of weakened and swollen veins in the anus or lower rectum. They often go unnoticed and usually clear up after a few days, but can also cause long-lasting discomfort of the rectum such as **pain**, **itching**, and bleeding. Hemorrhoids can be divided into two types: Internal hemorrhoids lie inside the anus or lower rectum; external hemorrhoids lie outside the anal opening. Both can be present at the same time. Sometimes a blood clot forms in an external hemorrhoid and inflammation and a painful lump develops. This condition is called a thrombosed hemorrhoid.

Description

Hemorrhoids are a very common medical complaint. More than 75% of Americans have hemorrhoids at some point in their lives, typically after age 30. Men are more likely than women to suffer from hemorrhoids that are serious enough to require professional treatment.

During a bowel movement, veins in the anus are protected from damage by expanding to drain blood away from the area. The veins are normally somewhat elastic, and they snap back to their regular size after defecation is finished. However, repeated straining due to **constipation** or hardened stools causes the veins to be swollen and stretched out of shape. The swelling also triggers nerves in the area, causing itchiness and a sensation of fullness in the bowel. In addition, straining may cause the rupture of blood vessels and bleeding at the anus.

Causes and symptoms

Aging, **obesity**, **pregnancy**, chronic constipation or chronic **diarrhea**, excessive use of enemas or laxatives, straining during bowel movements, and spending too much time on the toilet are all factors that can

contribute to the development of hemorrhoids. In some people there is also a genetic tendency to have fragile veins that are prone to developing hemorrhoids and **varicose veins**.

The most common symptom of internal hemorrhoids is bright red blood in the toilet bowl or on one's feces or toilet paper. When hemorrhoids remain inside the anus they are almost never painful, but they can protrude outside the anus and become irritated and sore. Such hemorrhoids are called prolapsed hemorrhoids. These sometimes move back into the anal canal on their own or can be pushed back inside; however, they may remain permanently outside the anus until treated by a doctor. Small external hemorrhoids usually do not produce symptoms. Larger ones, however, can be painful and interfere with sitting, walking, defecating, and cleaning the anal area after a bowel movement.

Diagnosis

Diagnosis of hemorrhoids begins with a visual examination of the anus, followed by an internal manual examination. The doctor may also insert an anoscope, a small tube with a light that can be used to view the anal canal. More serious problems may be ruled out using a sigmoidoscope or colonoscope to inspect the colon.

Treatment

An herbal sitz bath using **witch hazel**, *Hamamelis virginiana,* may shrink hemorrhoids and ease discomfort. A strong infusion should be prepared by adding a gallon of boiling water to eight ounces of the dry herb, and then letting this mixture steep overnight. The infusion can be used several times as a 15-minute soak. Witch hazel can also be wiped directly over external hemorrhoids. In addition, an ointment formulated of **plantain**, *Plantago* spp. and **yarrow**, *Achillea millefolium,* will reportedly reduce pain and swelling.

Chinese herbal medicine may be formulated to treat Spleen Qi deficiency or heat in the lower burner. Hemp seeds are recommended for constipation. Daily helpings of foods that soften the stools and make them easier to pass is recommended by **traditional Chinese medicine** (TCM); examples of these include carrots, broccoli, dried persimmons and unripe figs. **Acupuncture** and **acupressure** are also recommended.

Homeopathy offers a gentle treatment solution for hemorrhoids. It is, therefore, especially appropriate for use during pregnancy. Suggested remedies include Aesculus hippocastanum 30c, Hamamelis virginiana 6c, and Calcarea fluorica 6c. Homeopathic and herbal rectal suppositories are available.

KEY TERMS

Anus—The opening at the lower end of the rectum. The anus and rectum are both part of the large intestine.

Constipation—Difficulty passing stools, infrequent stools, or insufficient stools.

Defecate—Pass feces through the anus for elimination.

Heat—In traditional Chinese medicine (TCM), a disease condition characterized by intolerance for cold, deficient fluids, and irritability, among other things.

Ligation—Tying off a blood vessels or other tube with wire or suture, usually during surgery.

Lower burner—A TCM term for the kidneys.

Prolapsed—Referring to an organ fallen down from its normal body position.

Qi—In TCM, the vital energy that is the foundation for all physical and mental activity.

Rectum—The lower section of the large intestine. After food has passed through the stomach and intestines and been digested, the leftover material, in the form of feces, enters the rectum, where it stays until defecation.

Sitz bath—A warm water bath, sometimes including medications or herbs, that is taken in the sitting position, with water covering only the hips and buttocks.

Spleen—In TCM, all the organs considered necessary for extracting and using nutrients.

Varicose veins—Swollen veins that can no longer maintain proper blood pressure.

Allopathic treatment

Hemorrhoids can often be effectively dealt with by dietary and lifestyle changes. Avoiding constipation is important, therefore adding fiber to the diet is recommended. Bulk laxatives and fiber supplements such as Metamucil or Citrucel may be suggested. After each bowel movement, wiping with a moistened tissue or pad sold for that purpose helps lessen irritation. A warm sitz bath for about 10 or 15 minutes two to four times a day can ease hemorrhoid pain. A cool compress or ice pack to reduce swelling is also recommended. Many people

find temporary relief using over-the-counter hemorrhoid creams and foams. These products, however are not receommended during pregnancy.

When painful hemorrhoids do not respond to home-based remedies, professional medical treatment is necessary. Rubber band ligation is probably the most widely used of the many treatments for internal hemorrhoids. It is also the least costly for the patient. This procedure is performed on an outpatient basis. An applicator is used to place one or two small rubber bands around the base of the hemorrhoid, cutting off the blood supply. After 3 to 10 days in the bands, the hemorrhoid falls off, leaving a sore that heals in a week or two. Because internal hemorrhoids are located in a part of the anus that does not sense pain, anesthesia is unnecessary and the procedure is painless in most cases. The procedure may need to be repeated a few weeks later. After five years, 15–20% of patients experience a recurrence of internal hemorrhoids, but in most cases all that is needed is another banding.

External hemorrhoids, and some prolapsed internal hemorrhoids, are removed by conventional surgery in a hospital. Depending on the circumstances, this may require anesthesia. Full healing takes two to four weeks, but most people are able to resume normal activities at the end of a week. Hemorrhoids seldom return after surgery.

Expected results

Hemorrhoids are rarely life-threatening. Most clear up after a few days without medical treatment. However, because **colorectal cancer** and other digestive system diseases can cause anal bleeding and other hemorrhoid symptoms, people should always consult a healthcare practitioner when hemorrhoid symptoms occur.

Prevention

A **high-fiber diet**, daily **exercise**, and losing excess weight are recommended to maintain healthy digestion and elimination. To prevent hemorrhoids by strengthening the veins of the anus, rectum, and colon and increasing circulation, blackberries, blueberries, cherries and **vitamin C** are recommended. Tinctures of **butcher's broom** (*Ruscus aculeatus*, and **horse chestnut** (*Aesculus hippocastanum*), plant pigments (called flavonoids) found in fruit and fruit products, tea, and soy also are recommended. It should be noted that horse chestnut, along with commercial hemorrhoid preparations, is contraindicated during pregnancy.

Drinking water with a high-fiber meal or supplement will cause the stools to be softer and easier to pass, reducing straining. Constipation should be avoided, and good toilet habits should be cultivated. Promptly responding to the urge to defecate will help encourage regular bowel movements. Defecation should be done without rushing or straining. A squatting position over the toilet or having the feet raised on a small bench or footstool will also improve elimination. Reading, working or watching television are discouraged, because they entail prolonged sitting on the toilet, which increases the strain placed on anal and rectal veins. Perfumed soaps or toilet waters may irritate the anal area and should be avoided, as should excessive cleaning, rubbing, or wiping.

Patience Paradox

Hepar sulphuris

Description

Hepar sulphuris is a homeopathic remedy that was created by Samuel Hahnemann, the father of **homeopathy**. Hahnemann combined the inner layer of oyster shells (*Calcium carbonica*) with flowers of **sulfur** and burned them to create *Hepar sulphuris calcareum*, or *Hepar sulph*. as it is commonly called. It is also known as **calcium** sulfide or Hahnemann's calcium sulfide. *Hepar* is the Latin word for liver, and as certain compounds of sulfur had the color of liver, the remedy was so named.

Calcium sulfide was once used as a treatment for **mercury poisoning**, **gout**, **itching**, rheumatism, goiter, and swellings from **tuberculosis**. Now it is used in veterinary medicine, and in the manufacture of medicine, luminous paint, and hair removal products.

Although *Hepar sulph.* has the chemical properties of two other remedies, *Calcium carbonica* and sulfur, the actions of the remedies are different.

General use

Homeopaths prescribe *Hepar sulph.* for colds, coughs, sore throats, **croup**, abscesses, earaches, inflamed **cuts** and **wounds**, **asthma**, arthritis, **emphysema**, herpes, **constipation**, conjunctivitis, *Candida albicans* **infections**, **syphilis**, sinusitis, and skin infections.

The main indications for *Hepar sulph.* are as follows. The patient is overly sensitive to **pain**, touch, and cold. Pains are sharp, as if a splinter or piece of glass were being poked into the skin. A **sore throat** may feel like a fish bone is stuck in it and the pain increases upon swallowing. The slightest pressure causes much pain and the patient may faint from the pain. The patient cannot tolerate the cold and any exposure to cold air causes **chills**. If a hand or foot slips outside the bedcovers the patient will become chilled. Any slight exertion will cause the patient to perspire. The patient's sweat is cold and profuse and smells sour and offensive, like rotten cheese. Bodily discharges are yellow and thick and also smell offensive. If a **cough** is present, it is a dry, hacking cough with rattling of mucus in the chest.

The typical *Hepar sulph.* patients are delicate, oversensitive persons who tend to be scrawny in build and have enlarged glands. They are slow persons with flabby muscles, and often have light hair. They catch cold easily, dislike the cold, crave sour foods such as pickles and vinegar, and may dislike fats.

Mentally they are irritable, impulsive, angry, obstinate, anxious, fearful, impatient, sad, and depressed. They are very hard to get along with. Nothing pleases them and they dislike company. Often the desire to commit violence is present. They have poor memories. The *Hepar sulph.* patient is usually in a hurry—he drinks and eats fast and talks rapidly.

Hepar sulph. ailments generally arise from exposure to cold dry wind, suppression of perspiration and skin eruptions. Typical patients suffer from a lack of internal warmth, so all symptoms are made worse from exposure to cold conditions: cold air, cold weather, and cold wind. Fresh air, lying on the painful side, any pressure or touch, or being uncovered also aggravate the symptoms. Symptoms are worse in the morning and at night. Bed warmth and heat tend to make the symptoms better. The patient craves warmth and can often be found wrapped up in the bedcovers or wearing several layers of clothing.

Specific indications

The action of *Hepar sulph.* prevents the formation of pus and hastens healing of abscesses. In fact, *Hepar sulph.* is one of the best remedies for abscesses, but is useful only before the **abscess** is open. The *Hepar sulph.* abscess is swollen and painful, with needle-like pains.

Hepar sulph. colds are frequently brought on by exposure to cold, dry weather. A cold wind causes **sneezing** and a runny nose. At first the mucus is watery, then it becomes thick, yellow, and offensive smelling. The nose is swollen, red, and tender and the sense of smell may be lost. A hoarse voice, sore throat, and cough may develop. The patient may also be constipated.

The *Hepar sulph.* cough is of a dry, barking nature with thick, sticky, yellow mucus. The chest becomes sore from coughing. The cough is worse in the evening, and the patient may cough straight through to midnight or sometimes all night long. The patient may gag or choke while coughing. *Hepar sulph.* may be used in the treatment of croup when the symptoms for cough are exhibited. Croup coughs are generally worse in the morning, and the patient may have difficulty bringing up mucus.

The sore throat is accompanied by a splinter-like pain and swollen tonsils. The patient may feel as if there were a fish bone caught in the throat. The throat becomes worse from coughing or swallowing cold drinks.

Fevers are hot and often are accompanied by chills. A cold, sour sweat may be present, although it doesn't give any relief to the patient. If **diarrhea** is present, it is accompanied by a rumbling sensation in the abdomen.

Earaches with sharp, tearing pains may occur suddenly and be accompanied by abscesses in the ears. If the eardrum ruptures there may be a bloody, offensive discharge.

Eye irritations may indicate this remedy. The eyes are red and inflamed and may discharge a fluid. Toothaches are accompanied by bleeding gums and mouth abscesses.

Slow-to-heal cuts and wounds may be cured by *Hepar sulph.* The tissues surrounding the wound are inflamed and the pain is splinter-like.

Pains in the finger, hip, and shoulder joints are caused by exposure to the cold and are of a sore, bruised nature.

Hepar sulph. has a positive effect on many skin problems such as **eczema**, **boils**, and herpes. The eczema is crusty, scabby, and oozing and generally appears in the bends of joints. Other eruptions may be moist, dry, itchy, and filled with pus. The boils are red, inflamed, and sore.

This remedy is often indicated in liver problems. Symptoms include stitching pains in the right side, a soreness that is aggravated by pressing on the area, sensitive **hemorrhoids**, and constipation.

A burning in the bladder or frequent urge to urinate may be present. The urine flows in a slow stream or in drops.

Preparations

Finely powdered oyster shell is mixed with flowers of sulfur and heated in an airtight container. The resulting white powder is dissolved in hot hydrochloric acid, mixed with milk sugar and diluted.

Hepar sulph. is available at health food and drug stores in various potencies in the form of tinctures, tablets, and pellets.

Precautions

If symptoms do not improve after the recommended time period, the patient should consult a homeopath or health-care practitioner. Do not exceed the recommended dose.

Side effects

There are no side effects, but individual aggravations may occur.

Interactions

When taking any homeopathic remedy, the patient should not use **peppermint** products, coffee, or alcohol. These products are known as antidotes in homeopathy. They counteract the homeopathic remedies.

Hepatitis

Definition

Hepatitis is inflammation of the liver. Infectious or viral hepatitis is caused by a viral infection. The three most common forms of viral hepatitis recognized to cause liver disease are hepatitis A, hepatitis B, and hepatitis C (previously called hepatitis non-A, non-B). Other recognized types of hepatitis are hepatitis D, hepatitis E, and hepatitis G. A hepatitis F virus was reported in the 1990s, but its existence had not been confirmed as of the late 2000s.

Description

Hepatitis A

Hepatitis A is an inflammation of the liver caused by the hepatitis A virus (HAV). It is usually not very severe, generally starting within two to six weeks after contact with the virus and lasting no longer than two months.

Hepatitis A is commonly known as infectious hepatitis because it spreads relatively easily from those infected to close contacts. Once the infection ends, there is no lasting, chronic phase of illness. However, it is not uncommon to have a second episode or relapse of symptoms about a month after the first.

Epidemics of HAV infection can infect dozens and even hundreds of persons. Major outbreaks of hepatitis A have been linked to infected food handlers contaminating prepared foods. Many types of food also can be infected by sewage containing HAV, and shellfish is a common culprit.

Certain groups have an increased risk of contracting hepatitis A. These include:

- children and employees at daycare centers
- individuals living in crowded and/or unsanitary conditions
- sexually active individuals
- tourists visiting an area where hepatitis A is common

Hepatitis B

More than 300 million people throughout the world are infected by the hepatitis B virus (HBV). Hepatitis B occurs in both rapidly developing (acute) and long-lasting (chronic) forms and is one of the most frequent chronic infectious diseases worldwide. Commonly called serum hepatitis, hepatitis B ranges from mild to very severe. Some people who are infected by HBV develop no symptoms, but they may carry HBV

in their blood and pass the infection on to others. In its chronic form, HBV infection may destroy the liver through a scarring process, called **cirrhosis**.

When a person is infected by HBV, the virus enters the bloodstream and body fluids and is able to pass through tiny breaks in the skin, mouth, or the genital area. This infection can occur during birth, when a mother with hepatitis B may pass HBV on to her infant. The virus also may be transmitted through contaminated needles and through unprotected sex with an HBV-infected individual. Casual contact cannot transmit hepatitis B.

Hepatitis C

Hepatitis C, or HCV, causes a rapidly developing, and often long-lasting disease. Spread mainly by contact with infected blood, HCV is the major cause of transfusion hepatitis, which can develop in patients who are given blood, although today, donated blood is regularly tested for hepatitis C. The existence of a third hepatitis virus (in addition to the A and B viruses) became clear in 1974, but HCV was first identified in 1989.

Hepatitis C is generally mild in its early, acute stage, but it is much more likely to produce chronic liver disease than hepatitis B. About two of every three persons who are infected by HCV may continue to have the virus in their blood and become carriers, who can transmit the infection to others.

The most common way of transmitting hepatitis C is when blood containing the virus enters another person's bloodstream through a break in the skin or the mucosa (inner lining) of the mouth or genitals. HCV may be passed from an infected mother to the infant she is carrying (however, the risk of infection from breast milk is very low). It also can be spread through sexual intercourse, especially if one partner is acutely infected at the time.

Hepatitis D

Hepatitis D (or delta) occurs only in patients who also are infected by the hepatitis B virus. Infection by the hepatitis delta virus (HDV) either occurs at the same time as hepatitis B or develops later when infection by HBV has entered the chronic stage.

Delta hepatitis can be quite severe, but it is seen only in patients already infected with HBV. In the late 1970s, Italian physicians discovered that some patients with hepatitis B had another type of infectious agent in their liver cells. Later the new virus, HDV, was confirmed by experimentally infecting chimpanzees. When both viruses are present, acute infection tends to be more serious. Furthermore, patients with both **infections** are more likely to develop chronic liver disease than those with HBV alone, and, when it occurs, it is more severe.

Hepatitis E

Hepatitis E also is known as epidemic non-A, non-B hepatitis. Like hepatitis A, it is an acute and short-lived illness that sometimes can cause liver failure. HEV, discovered in 1987, is spread by the fecal-oral route. It is present in countries where human waste has contaminated the drinking water supply. Large outbreaks (epidemics) have occurred in Asian and South American countries where there is poor sanitation. In the United States and Canada no outbreaks have been reported as of the late 2000s, but persons traveling to a region where it is present may return with HEV.

Hepatitis G

The hepatitis G virus was first described in early 1996. It has been designated as GBV-C by the International Commmittee on Taxonomy of Viruses. As of 2008, little was known about the frequency of GBV-C infection, the nature of the illness, or how to prevent it. What is known is that transfused blood containing GBV-C has caused some cases of hepatitis. For this reason, patients with hemophilia and other bleeding conditions who require large amounts of blood or blood products are at risk of hepatitis G. GBV-C has been identified in 1-2% of blood donors in the United States. Also at risk are patients with kidney disease who undergo hemodialysis treatments and those who use intravenous drugs. It is possible that an infected mother can pass on the virus to her newborn infant or that sexual transmission can occur.

Often patients with hepatitis G are infected at the same time by the hepatitis B or C virus, or both. In about three of every thousand patients with acute viral hepatitis, GBV-C is the only virus present. There is some indication that patients with hepatitis G may continue to carry the virus in their blood for many years, and so they might be a source of infection for others.

Causes and symptoms

Hepatitis A

The time between exposure to HAV and the onset of symptoms ranges from two to seven weeks and averages about one month. The virus is passed in the feces, especially late in the incubation period, before symptoms first appear. It can live for several hours on

the skin surface and during this time may be transmitted to others. Infected persons are most contagious starting about a week before symptoms develop and remain contagious until the time **jaundice** (yellowing of the skin and/or eyes) is noted.

Often the first symptoms to appear are **fatigue**, muscle and joint aches, **nausea**, and a loss of appetite. Low grade **fever** is common, and the liver often enlarges, causing **pain** or tenderness in the right upper part of the abdomen. Jaundice then develops, typically lasting seven to ten days.

Hepatitis B

In the United States, a majority of acute HBV infections occur in teenagers and young adults. Half of these youth never develop symptoms, and only about 20% of infected patients develop severe symptoms and jaundice. The remaining 30% of patients have only flu-like symptoms and will probably not even be diagnosed as having hepatitis unless certain tests are done. Acute hepatitis B is characterized by loss of appetite, nausea, and pain or tenderness in the right upper part of the abdomen. Compared to patients with hepatitis A or C, those with HBV infection require more bed rest.

An HBV infection lasting longer than six months is said to be chronic. After this time it is much less likely for the infection to disappear. Not all carriers of the virus develop chronic liver disease; in fact, most have no symptoms. However, about one in every four HBV carriers develop cirrhosis. Patients are also likely to have an enlarged liver and spleen. The most serious complication of chronic HBV infection is liver **cancer**.

Hepatitis C

More than half of all patients who develop hepatitis C have no symptoms or signs of liver disease. Some, however, may have a minor illness with flu-like symptoms. About one in four patients with hepatitis C will develop jaundice, and some patients lose their appetite and frequently feel tired. Patients also may experience nausea.

In most patients, HCV can still be found in the blood six months after the start of acute infection, and these patients are considered carriers. If the virus persists for one year, it is unlikely to disappear completely. About 20% of chronic carriers develop cirrhosis (scarring) of the liver when the virus damages or destroys large numbers of liver cells, which are then replaced by scar tissue. Cirrhosis may develop only after a long period of time—as long as 20 years—has passed. Many patients will not develop cirrhosis and instead have a mild, chronic form of infection called chronic persistent hepatitis.

Hepatitis D

The delta virus is a small and incomplete viral particle. Perhaps this is why it cannot cause infection on its own. Its companion virus, HBV, actually forms a covering over the HDV particle. In chronically ill patients (those whose virus persists longer than six months), cirrhosis typically occurs.

When HBV and HDV infections develop at the same time—a condition called coinfection—recovery is the rule. Only 2–5% of patients become chronic carriers (the virus remains in their blood more than six months after infection). It may be that HDV actually keeps HBV from reproducing as rapidly as it would if it were alone, making chronic infection less likely.

When HBV infection occurs first and is followed by HDV infection, the condition is called superinfection. Between one-half and two-thirds of patients with superinfection develop severe acute hepatitis. Once the liver cells contain large numbers of HBV viruses, HDV tends to reproduce more actively. Massive infection and liver failure are more common in superinfection. The risk of liver cancer, however, is no greater than from hepatitis B alone.

As with other forms of hepatitis, the earliest symptoms are nausea, loss of appetite, joint pains, and fatigue. There may be fever and an enlarged liver may cause discomfort or pain in the right upper part of the abdomen. Jaundice may develop later.

Hepatitis E

There are at least two strains of HEV, one found in Asia and another in Mexico. The virus may start dividing in the gastrointestinal tract, but it grows mostly in the liver. After an incubation period of two to eight weeks, infected persons develop jaundice, fever, nausea, a loss of appetite, and discomfort or pain in the right upper part of the abdomen. Most often the illness is mild and disappears within a few weeks with no lasting effects.

Hepatitis E never becomes a chronic illness, but on rare occasions the acute illness damages and destroys so many liver cells that the liver can no longer function. This condition, called fulminant liver failure, may cause death. The great majority of patients who recover from acute infection do not continue to carry HEV and cannot pass the infection on to others. The most serious outbreaks of hepatitis E occurred in

China (100,000 cases between 1986 and 1988) and India (79,000 cases in 1991).

Hepatitis G

Some researchers believe that there may be a group of GBV-C viruses, rather than just one. Others remain doubtful that GBV-C actually causes illness. If it does, the type of acute or chronic illness that results is not clear. When diagnosed, acute GBV-C infection has usually been mild and brief. There is no evidence of serious complications, but it is possible that, like other hepatitis viruses, GBV-C can cause severe liver damage, resulting in liver failure. The virus has been identified in as many as 20% of patients with long-lasting viral hepatitis, some of whom also have hepatitis C.

Diagnosis

A healthcare professional takes a thorough medical history and performs a physical examination of the patient when hepatitis is suspected. Blood tests for specific antigens and antibodies that are present in the different subtypes of hepatitis confirm the diagnosis, although these tests cannot detect all types of hepatitis. Liver function tests that measure enzyme levels may also be performed.

Treatment

Once symptoms appear, no antibiotics or other medicines will shorten the course of infectious hepatitis. Patients should rest in bed as needed, follow a healthy diet, and avoid drinking alcohol or taking any medications that could further damage the liver. Any medication that can cause liver damage should be avoided, and non-critical surgery should be postponed.

An herbalist or naturopathic healthcare professional may recommend a preparation of **milk thistle** (*Silybum marianum*) for the treatment of hepatitis. Milk thistle is thought to promote the growth of new liver cells and to prevent toxins from penetrating through healthy liver cells by binding itself to the cell membranes. It is frequently prescribed by herbalists for the treatment of cirrhosis, hepatitis, and other liver disorders. As of 2008, the National Center for Complementary and Alternative Medicine (NCCAM) reported that studies with laboratory animals suggested that milk thistle may have various benefits for the liver, although those studies did not examine the effects of the product specifically on hepatitis C. Studies on humans had, as of 2008, shown no beneficial effects of milk thistle on hepatitis C. The NCCAM also found mixed results for the use of **licorice** (*Glycyrriza glabra*), ginseng, and other herbal remedies in the treatment of hepatitis. In general, these products may show benefits in studies with cell cultures and experimental animals, although they have limited or no effects in the treatment of hepatitis in humans.

Vitamin C may be taken as a nutritional supplement, and it has been shown to help diminish acute hepatitis and help prevent hepatitis in hospitalized patients. Liver extracts are effective in liver regeneration and were used throughout the twentieth century. Thymus extracts enhance the immune system, which may help the body fight a hepatitis virus.

A practitioner of Chinese herbal medicine may recommend Fructus Schisandrae Chinensis, which improves liver function; Fructus Citrulli Vulgaris, which helps to expel jaundice; or other herbs for hepatitis symptoms.

Allopathic treatment

The U.S. Food and Drug Administration (FDA) has approved a class of genetically engineered products called recombinant alpha interferons for the treatment of hepatitis B and C. These drugs are sold under trade names such as Intron A, Roferon, Infergen, Pegasys, and Peg-Intron. They tend to lessen the symptoms of infection and improve liver function. Approximately half of all patients respond positively to the drugs, although only about 20% receive lasting effects. Fever and flu-like symptoms, fatigue and low energy levels, nausea, lack of appetite, **vomiting**, **diarrhea**, **depression**, and hair thinning (alopecia) are frequent side effects of the drugs. A variety of other antiviral medications, including telbivudine (Tyzeka), entecavir (Baraclude), lamivudine (Epivir-HBV), and adefovir dipivoxil (Hepsera) may also be effective in treating chronic HBV infection. Most cases of hepatitis A and acute hepatitis B are treated on an outpatient basis in which patients are encouraged to have as much bed rest as possible and remain hydrated by drinking as much liquid as possible. When hepatitis destroys most or all of the liver, the only hope may be a liver transplant. However, even when the procedure is successful, disease often recurs and cirrhosis may actually develop more rapidly than before.

Expected results

Hepatitis A

Most patients with acute hepatitis A, even when severe, begin feeling better in two to three weeks and recover completely in four to eight weeks. After recovering from hepatitis A, a person no longer carries the

virus and remains immune for life. In the United States, serious complications are infrequent and deaths are rare. In the United States, as many as 75% of adults over the age of 50 have blood test evidence of previous hepatitis A.

Hepatitis B

Each year an estimated 150,000 persons in the United States get hepatitis B. More than 10,000 require hospital care, and as many as 5,000 die from complications of the infection. About 90% of those infected have only acute disease. A large majority of these patients recover within three months. It is the remaining 10%, with chronic infection, who account for most serious complications and deaths from HBV infection. In the United States, perhaps only 2% of all infected individuals become chronically ill. People infected with both HIV and hepatitis B are most likely to die than from either disease alone. Even when no symptoms of liver disease develop, chronic carriers remain a threat to others by serving as a source of infection.

Hepatitis C

In roughly one-fifth of patients who develop hepatitis C, the acute infection subsides, and they recover completely within four to eight weeks and have no later problems. Other patients face two risks: they themselves may develop chronic liver infection and possibly serious complications such as liver cancer, and they continue carrying the virus and may pass it on to others. The overall risk of developing cirrhosis is about 15% for all patients infected by HCV. Liver failure is less frequent in patients with chronic hepatitis C than it is for those with other forms of hepatitis. In those people who also have **AIDS**, hepatitis C infection increases the chance for liver cancer.

Hepatitis D

A large majority of patients with coinfection of HBV and HDV recover from an episode of acute hepatitis. However, about two-thirds of patients chronically infected by HDV go on to develop cirrhosis of the liver. If severe liver failure develops, the chance of a patient surviving is no better than 50%. A liver transplant may improve this figure to 70%.

Hepatitis E

In the United States hepatitis E is not a fatal illness, but elsewhere 1–2% of those infected die of advanced liver failure. In pregnant women the death rate is as high as 20%. It is not clear whether having hepatitis E once guarantees against future HEV infection.

KEY TERMS

Antibody—A substance made by the body in response to a foreign body, such as a virus, which is able to attack and destroy the invading body.

Antigen—Part of an invading microorganism, which causes tissue damage and which also stimulates the body's immune system to produce antibodies.

Cirrhosis—The end result of many forms of liver disease, the condition of the liver when its cells have been damaged or destroyed and are replaced by scar tissue.

Jaundice—Yellowing of the skin and whites of the eyes when pigments normally eliminated by the liver collect in high amounts in the blood.

Vaccine—A substance prepared from a weakened or killed virus which, when injected, helps the body to form antibodies that attack an invading virus and may prevent infection altogether.

Hepatitis G

What little is known about the course of hepatitis G suggests that illness is mild and does not last long. When more patients have been followed up after the acute phase, it will become clear whether GBV-C can cause severe liver damage.

Prevention

The best way to prevent any form of viral hepatitis is to avoid contact with blood and other body fluids of infected individuals. The use of condoms during sex is advisable. Travelers should avoid water and ice if unsure of their purity, or they can boil water before drinking it. All foods eaten should be packaged, well cooked, or, in the case of fresh fruit, peeled. Caution should be exercised when getting tattoos or body piercing, since a 2003 report stated that only about one-half of tattoo and piercing shops follow governmental guidelines concerning infection control. These practices can pass hepatitis and HIV infection.

Two vaccines are available for protection against hepatitis A and hepatitis B. The hepatitis A vaccine, distributed under the trade name Havrix, consists of inactivated HAV viruses. The hepatitis B vaccine, Engerix-B, is a recombinant (genetically modified) product containing a surface antigen of the HBV virus. Individuals in a high risk group and travelers should be vaccinated for hepatitis A, and much of the general population can be vaccinated for hepatitis B.

Herbalism, traditional Chinese

Definition

Chinese herbalism is one of the major components of **traditional Chinese medicine** (TCM), or Oriental medicine (OM). In TCM, herbs are often used in conjunction with other techniques, such as **acupuncture** or massage. Chinese herbalism is a holistic medical system, meaning that it looks at treating a patient as a whole person, looking at the mental and spiritual health, as well as the physical health, of the individual. Illness is seen as a disharmony or imbalance among these aspects of the individual. Chinese herbalism has been practiced for over 4,000 years.

One of the earliest and certainly the most important Chinese herbal text is the *Huang Ti Nei Ching*, or *Yellow Emperor's Classic of Internal Medicine*. It is believed to have been authored by Huang Ti during his reign over China, which started about 2697 B.C. Since that time, herbal practices have been more extensively documented and refined. In modern China, traditional Chinese herbalism is taught alongside conventional Western pharmacology. Chinese herbal remedies have been used in the West only relatively recently, over the past two decades. These remedies are more gentle and natural than conventional medicines. In addition, they have fewer unpleasant side effects. Individuals with chronic disorders in particular are increasingly drawn to the holistic aspect of Chinese herbalism and TCM in general.

Origins

Historical background

Traditional Chinese medicine originated in the region of eastern Asia that today includes China, Tibet, Vietnam, Korea, and Japan. Tribal shamans and holy men who lived as hermits in the mountains of China as early as 3500 B.C. practiced what was called the "Way of Long Life." This regimen included a diet based on herbs and other plants; kung-fu exercises; and special breathing techniques that were thought to improve vitality and life expectancy.

After the Han dynasty, the next great age of Chinese medicine was under the Tang emperors, who ruled from A.D. 608–906. The first Tang emperor established China's first medical school in A.D. 629. Under the Song (A.D. 960–1279) and Ming (A.D. 1368–1644) dynasties, new medical schools were established, their curricula and qualifying examinations were standardized, and the traditional herbal prescriptions

KEY TERMS

Absorption spectrometry—A scientific procedure to determine the chemical composition of an unknown substance.

Interferon—A substance proved to be necessary in the body to help fight cancer cells.

Immune function—The body's defense system against bacteria, viruses and fungi, and any malfunction of the organism.

Pharmacodynamics—The study of the relationships and interactions of herbs.

Platelet aggregation—The clumping together of blood cells, possibly forming a clot.

Qi—The Chinese term for life force or vital energy.

Thrombocyte—Another name for platelet.

were written down and collected into encyclopedias. One important difference between the development of medicine in China and in the West is the greater interest in the West in surgical procedures and techniques.

Philosophical background: the cosmic and natural order

In Taoist thought, the Tao, or universal first principle, generated a duality of opposing principles that underlie all the patterns of nature. These principles, yin and yang, are mutually dependent as well as polar opposites. They are basic concepts in traditional Chinese medicine. Yin represents everything that is cold, moist, dim, passive, slow, heavy, and moving downward or inward; while yang represents heat, dryness, brightness, activity, rapidity, lightness, and upward or outward motion. Both forces are equally necessary in nature and in human well-being, and neither force can exist without the other. The dynamic interaction of these two principles is reflected in the cycles of the seasons, the human life cycle, and other natural phenomena. One objective of traditional Chinese medicine is to keep yin and yang in harmonious balance within a person.

In addition to yin and yang, Taoist teachers also believed that the Tao produced a third force, primordial energy or qi (also spelled chi or ki). The interplay between yin, yang, and qi gave rise to the Five Elements of water, metal, earth, wood, and fire. These entities are all reflected in the structure and functioning of the human body.

The human being

Traditional Chinese physicians did not learn about the structures of the human body from dissection because they thought that cutting open a body insulted the person's ancestors. Instead they built up an understanding of the location and functions of the major organs over centuries of observation, and then correlated them with the principles of yin, yang, qi, and the Five Elements. Thus wood is related to the liver (yin) and the gall bladder (yang); fire to the heart (yin) and the small intestine (yang); earth to the spleen (yin) and the stomach (yang); metal to the lungs (yin) and the large intestine (yang); and water to the kidneys (yin) and the bladder (yang). The Chinese also believed that the body contains Five Essential Substances, which include blood, spirit, vital essence (a principle of growth and development produced by the body from qi and blood), fluids (all body fluids other than blood, such as saliva, spinal fluid, sweat, etc.), and qi.

Benefits

Because it is a safe and inexpensive solution to health problems of all kinds, Chinese herbalism is very popular in China. In recent years, herbalism has been modernized with the introduction of quality control. For example, herbs are subjected to absorption spectrometry to determine levels of heavy metals found in some. Because they are standardized, Chinese herbs are safer for self-treatment. This approach puts the individual, not the physician, in charge of the individual's health; that is a basic goal of Chinese herbalism.

Chinese herbalism offers unique advice regarding what foods can help and what can hinder, and a herbalist can help an individual discover what he is allergic to. In addition, Chinese herbs stimulate the immune system and provide beneficial nutrients, aside from their role in curing illness.

At M.D. Anderson Hospital in Texas, medical research has confirmed that patients undergoing chemotherapy were shown to have an improved degree of immune function when they took the tonic herb **astragalus** (*huang qi*). (It is well known that chemotherapy suppresses the immune system.) Research also showed that T-cell and macrophage activity and interferon production was increased in patients using the Chinese herbs **ganoderma**, lentinus, and polyporus, helping the body fight **cancer** cells. Agents also found in ganoderma were found to inhibit platelet aggregation

and thrombocyte formation, which would be helpful to counter circulation and heart problems.

An ingredient of ginseng was found to promote adrenal function, which would give the herb properties of enhancing many hormone functions in the body.

Description

Chinese herbal treatment differs from **Western herbalism** in several respects. In Chinese practice, several different herbs may be used, according to each plant's effect on the individual's Qi and the Five Elements. There are many formulas used within traditional Chinese medicine to treat certain common imbalance patterns. These formulas can be modified to fit specific individuals more closely.

A traditional Chinese herbal formula typically contains four classes of ingredients, arranged in a hierarchical order: a chief (the principal ingredient, chosen for the patient's specific illness); a deputy (to reinforce the chief's action or treat a coexisting condition); an assistant (to counteract side effects of the first two ingredients); and an envoy (to harmonize all the other ingredients and convey them to the parts of the body that they are to treat).

Methods of diagnosis

A Chinese herbalist will not prescribe a particular herb on the strength of symptoms only, but will take into consideration the physical condition, emotional health, and mental state of the patient. He or she may look at the condition of the patient's hair, skin, and tongue, as well as the appearance of the eyes, lips, and general complexion. The practitioner then listens to the sounds the body makes when breathing. He or she may smell the breath, **body odor**, or sputum in diagnosis.

TCM practitioners take an extensive medical history of a patient. He or she may ask about dietary habits, lifestyle, and sleep patterns. The patient will be questioned about chief medical complaints, as well as on his or her particular emotional state and sexual practices.

Chinese herbalists employ touch as a diagnostic tool. They may palpate the body or use light massage to assess the patient's physical health. Another chief component of Chinese medical diagnosis is **pulse diagnosis**, or sphygmology. This is a very refined art that takes practitioners years to master. Some practitioners can detect 12 different pulse points that correspond to the 12 major organs in Chinese medicine. There are over 30 pulse qualities that practitioners are able to detect on each point. The strength, speed, quality, and rhythm of the pulse, to name a few, will be determined before a diagnosis is given.

Herbs

Chinese herbs may be used alone or in combination. Relatively few are used alone for medicinal purposes. Practitioners believe that illness can be effectively treated by combining herbs based on their various characteristics and the patient's overall health. Every herb has four basic healing properties: nature, taste, affinity, and effect.

An herb's nature is described according to its yin or yang characteristics. Yang, or warming, herbs treat cold deficiencies. They are frequently used in the treatment of the upper respiratory tract, skin, or extremities. Yin, or cooling, herbs, treat hot excess conditions. They are most often used to treat internal conditions and problems with organs. Herbs can also be neutral in nature.

An herb's taste does not refer to its flavor, but to its effect on qi, blood, fluids, and phlegm. Sour herbs have a concentrating action. They are prescribed to treat bodily excess conditions, such as **diarrhea**, and concentrate qi. Bitter herbs have an eliminating or moving downward action. They are used to treat coughs, **constipation**, and heart problems. Sweet or bland herbs have a harmonizing action. They are used as restorative herbs and to treat **pain**. Spicy herbs have a stimulating action. They are prescribed to improve blood and qi circulation. Salty herbs have a softening action. They are used to treat constipation and other digestion problems.

An herb's affinity describes its action on a specific bodily Organ. (Note that Chinese medicine does not have the anatomical correlation for organ names. They correspond more closely to the organ's function.) Sour herbs have an affinity for the Liver and Gallbladder. Bitter herbs act on the Heart and Small Intestine. Sweet and bland herbs affect the Stomach and Spleen. Spicy herbs have an affinity for Lungs and Large Intestine, whereas salty herbs act on the Kidneys and Bladder.

Chinese herbs are lastly classified according to their specific actions, which are divided into four effects. Herbs that dispel are used to treat an accumulation, sluggishness, or spasm by relaxing or redistributing. Herbs with an astringent action are used to consolidate or restrain a condition characterized by discharge or excessive elimination. Herbs that purge treat an obstruction or "poison" by encouraging elimination and **detoxification**. Tonifying herbs nourish, support, and calm where there is a deficiency.

Treatment of diabetes

The incidence of diabetes has increased quite dramatically in recent years, especially in the United States, where in general people take less **exercise**, and food is taken in greater quantity with a general reduction in quality. This increase has led to a scramble to find new solutions to the problem, and many researchers have focused their interest on Chinese herbal remedies. In the search for more effective and more convenient treatments, the alkaloid berberine has come under close scrutiny for its many uses, among them the treatment of diabetes. In trials, rats given a mixture of berberine and alloxan showed less likelihood of incurring a rise in blood sugar. Patients suffering from type II diabetes who were given between 300 and 600 mg of berberine daily for between one and three months, showed a reduction in blood sugar levels, when taken in conjunction with a controlled diet.

Treatment of AIDS and cancer

Independent researchers are investigating indications that Chinese herbalism can reduce the toxicity of chemotherapy and other medications, in addition to stimulating immune responses.

Treatment of diarrhea associated with cholera

A team of researchers in Japan has found that some traditional Chinese herbal formulations inhibit the toxin produced by *Vibrio cholerae*, the microorganism that causes cholera. These preparations appear to be helpful when given in addition to oral rehydration treatment for diarrhea associated with cholera.

Treatment of atopic dermatitis

Some physicians have found Chinese herbal remedies useful in relieving the symptoms of atopic **dermatitis**, a chronic disorder of the skin that is difficult to treat. Herbal remedies have the advantage of relieving the **itching** and inflammation associated with atopic dermatitis without the long-term toxic side effects of conventional medications.

Preparations

Those who are unfamiliar with Chinese herbs and their uses should consult a practitioner before starting any treatment. Once a remedy is prescribed, it may be purchased at Oriental markets or health food stores. Most Chinese remedies prepared for Western markets are standardized and sold in ready-to-use formulations, with instructions for dosage. A Chinese herbalist may prescribe herbs to be made into tea, or taken as capsules.

Precautions

It is best to avoid Chinese herbs that are not sold in a standardized form. Herbs can vary considerably in potency, depending on the time and place of their harvesting. In addition, cases have been reported in Europe as well as the United States of dried Chinese herbs contaminated by sewage or other forms of pollution.

When treating a patient, the herbalist will aim to gently "nudge" the system into shape, rather than producing any immediate reaction. A return to health, therefore, may take time, and it is important that the patient realizes the principles underlying the treatment. Some practitioners estimate that treatment will take a month for every year that a chronic condition has existed. The advantage of the slow pace is that if there is a bad reaction to any herb, which is rare, it will be mild because the treatment itself is gentle.

As with most naturopathic therapies, Chinese herbal remedies work best when taken in conjunction with a healthy lifestyle and program of exercise.

Side effects

Some Chinese herbs are incompatible with certain prescription drugs or foods. Others should not be taken during **pregnancy**. Because of possible interactions, persons who are interested in taking traditional Chinese herbal remedies should not try to diagnose or treat themselves with these preparations.

Recent studies indicate that some herbs used in Chinese medicines may cause liver damage. Women appear to be more susceptible to such reactions than men. Damage to the liver may range from minor problems involving higher levels of certain enzymes called transaminases, to chronic **hepatitis**, **cirrhosis**, and acute liver failure requiring transplantation. Because of these risks, persons considering Chinese herbal treatments should consult a medical doctor before going to the herbalist. It is essential for patients to inform their doctors about all medications or preparations they are taking, including alternative and over-the-counter remedies as well as prescription drugs.

Research and general acceptance

At present, there is renewed interest in the West in traditional Chinese medicine and Chinese herbalism. Of the 700 herbal remedies used by traditional Chinese practitioners, over 100 have been tested and found effective by the standards of Western science. Several United States agencies, including the National Institutes of Health, the Office of Alternative Medicine,

and the Food and Drug Administration are currently investigating Chinese herbal medicine as well as acupuncture and *Tui na* massage. In general, however, Western studies of Chinese medicine focus on the effects of traditional treatments and the reasons for those effects, thus attempting to fit traditional Chinese medicine within the Western framework of precise physical measurements and scientific hypotheses.

Training and certification

Practitioners of Oriental medicine can obtain certification in Chinese herbalism through the National Commission for the Certification of Acupuncture and Oriental Medicine, (NCCAOM). Some states have adopted the NCCAOM examination as all or part of their criteria for licensing. In California, the standards are higher, and these qualifications are not accepted. The licensing titles given by states varies, but herbalists are required to be a doctor of oriental medicine (OMD or DOMO). In 1990, the U.S. Secretary of Education recognized the National Accreditation Commission for Schools and Colleges of Acupuncture and Oriental Medicine as an accrediting agency.

Herbal cold remedies

Definition

Herbal cold remedies are over-the-counter medications that contain herbs in their formulas, sometimes along with vitamins and minerals.

Description

Colds have been around for centuries; yet as of 2008, there was no cure for a cold or a vaccine to prevent them. However, walk into any pharmacy or chain supermarket and there is almost certain to be an entire section devoted to over-the-counter (OTC) products that claim to treat or prevent colds. Many of these are herbal formulas or individual herbs. OTC **cough** and cold medications accounted for nearly $3 billion in sales in the United States in 2007. Homeopathic cold remedies, many of which are herbal, account for more than $100 million in annual sales and are growing each year.

Herbal cold remedies took on an increased significance when in January 2008, the U.S. Food and Drug Administration (FDA) banned the use of OTC cold medications in children under the age of 2, and was considering raising the age limit to 5 and younger. The FDA also said it would issue recommendations on OTC cold products for children 12 and younger, which was expected in late 2008. In enacting the ban, the FDA said there was no scientific evidence that OTC cold products provided any relief to infants and that they may actually be harmful, citing reports of increased heart rates, unconsciousness, convulsions, and even death associated with their use. The ban prompted drug makers to discontinue all cold medications with the word "infant" or pictures of babies on their packaging. There were about 800 children's cold products marketed in the United States and dozens were affected by the ban. The ban specifically targeted cold products for children that contain one or more of certain types of drugs, including decongestants, expectorants, antihistamines, and antitussives. Several months before the ban, a number of drug makers voluntarily withdrew products from the market, including such brand names as Dimetapp, Little Colds, Pediacare, Robitussin, Triaminic, and Tylenol.

More than 200 different viruses are known to cause the symptoms of the **common cold**. Some, such as the rhinoviruses, seldom produce serious illnesses. Others, such as parainfluenza and respiratory syncytial virus, produce mild **infections** in adults but can cause severe lower respiratory infections in young

children. The causes of 30 to 50% of adult colds, presumed to be viral, remain unidentified as of 2008. Although the common cold is usually mild, with symptoms lasting one to two weeks, it is a leading cause of doctor visits and of school and job absenteeism, according to the National Institute of Allergy and Infectious Diseases (NIAID). Colds are most prevalent among children, and seem to be related to youngsters' relative lack of resistance to infection and to contacts with other children in day-care centers and schools. Children have about six to ten colds a year. In families with children in school, the number of colds per child can be as high as 12 a year. Adults average about two to four colds a year, although the range varies widely. Women, especially those aged 20 to 30 years, have more colds than men, possibly because of their closer contact with children. On average, individuals older than 60 have fewer than one cold a year, according to the NIAID.

Among the most popular herbal/homeopathic cold remedy formulas are Zicam, Airborne, and Cold-Eeze. Airborne received a huge boost in 2004 when it was featured on Oprah Winfrey's television talk show. Airborne is an effervescent (like an Alka-Seltzer tablet) dietary supplement that was allegedly created by a school teacher as an immune system booster to help ward off colds. Airborne claims to contain 17 ingredients, including seven herbal extracts, **antioxidants**, electrolytes, and **amino acids**. It costs $7 to $8 for a tube of 10 tablets. One critic of Airborne is Mark Crislip, a specialist in internal medicine and infectious disease and an outspoken skeptic of alternative and complementary medicine. In a very carefully worded article in the March 2007 issue of *Pediatrics for Parents*, Crislip questions the legitimacy and effectiveness of Airborne. He lists seven warning signs that indicate a product, such as Airborne, is "not worth your hard-earned money." One is when a product is advertised directly to the public and not through the medical community. He notes that Airborne is not subject to FDA regulation and has not been proven in clinical studies to be safe or effective. He also wrote that Airborne makes conflicting statements about its product's ability to boost the immune system and reduce the duration of cold symptoms. He claims that Airborne's ingredients—with the exception of zinc—do nothing to treat or prevent a cold. He also questions the legitimacy of a cold remedy created by a school teacher rather than a physician or scientist.

Another Airborne critic is James Steckelberg, an infectious disease specialist at the Mayo Clinic. In an April 19, 2007, article on the Mayo Clinic Web site (http://www.mayoclinic.com), Steckelberg wrote: "there's no conclusive evidence that this product (Airborne) or any of its ingredients prevent colds or shorten their duration." Both Zicam and Airborne state that they have clinical studies that show the products are safe and effective. However, critics note that the studies were paid for by Zicam and Airborne and that their safety and effectiveness have not been determined by the FDA. Cold-Eeze, Zicam, and Airborne can be marketed as homeopathic remedies simply because they contain small amounts of **zinc**, which has been shown in some clinical trials to reduce cold symptoms. However, other clinical trials have concluded that zinc showed no benefit in reducing cold symptoms, according to a 2008 report from researchers at the Mayo Clinic.

General use

Most herbal cold remedies were not affected by the FDA ban. There are dozens of herbs that are used in herbal cold formulas. Among them are **andrographis**, ashwa ghanda, ginseng, **echinacea**, eleuthero, **astragalus**, cat's claw, **garlic**, fo-ti, black cumin, **green tea**, ligustrum, **maitake**, **noni**, white cedar, wild indigo, and black elderberry. Herbal cold remedies treat single or multiple cold symptoms, such as coughing, **fever**, nasal congestion, **sore throat**, **headache**, and **sneezing**.

Preparations

The most popular herb to prevent and treat cold and flu is echinacea, which has been shown in some studies to bolster the immune system. It has been used for centuries by Native Americans for a variety of health conditions. A number of studies reported it is effective in treating and preventing colds. Garlic and onions both have antiviral chemicals and have been used to counteract the effects of colds. Cinnamon is another natural cold remedy that has been used for centuries to treat colds, flu, and sinus conditions. Another herbal cold remedy, **ginger**, has a dozen antiviral compounds and is a powerful digestive herb. Ginger root is a plant native to southeast Asia and is also grown in the United States and other countries. It fights colds by relieving congestion and soothing sinus **pain** and sore throats. Herbal cold remedies also include inhaling the steam from **chamomile**, **thyme**, or **eucalyptus** teas, which are known to loosen mucus and help soothe the throat, nasal passages, and bronchial tubes. Many herbal formulas also contain **vitamin C** and zinc.

Recommended dosage

There are few, if any, standard dosing recommendations for herbs and herbal cold formulas. However, some general dosing guidelines for several of the most popular herbs are as follows:

- Echinacea—As a powdered extract, take at least 2,000 milligrams (mg) a day in three doses; as a liquid, take three to four milliliters (ml) three times daily.
- Andrographis—A common dose is an extract of 400 mg three times a day. Some alternative medicine practitioners recommend it be used with eleutherococcus, a Chinese herb.
- Black elderberry—As an extract or in capsules, take 15 ml four times a day for five days to treat a cold.
- Maitake—An extract from the maitake mushroom, the suggested dose is 1,800 mg once a day as a treatment and preventative.
- Black cumin—An extract, the usual dosage is 50 to 75 mg once a day as a preventative and three times a day as a treatment.
- Chamomile, thyme, and eucalyptus—Steep one to two teaspoons in hot or boiling water for three to five minutes. Inhale the steam for 15 minutes three times a day in the acute stage of a cold and in the evening before bed in the end stage of a cold to help the bronchial passages heal.

Precautions

The primary precautions are that not all herbal cold remedies contain the ingredients that are listed on the package, that they contain ingredients not listed, or they do not contain the dosage listed on the package or insert. In 2007, the non-profit consumer research group ConsumerLab.com (http://www.consumerlab.com) tested 66 herbal cold remedy products and found that only 44% contained the correct dosages and four were contaminated with lead, a toxic substance that in high amounts can cause serious illness and even death. Only one of six echinacea products tested had the correct ingredients and one had lead. Only six of 14 cold prevention products with garlic had the correct ingredients and two had lead contamination. Of the 13 ginseng cold remedies tested, only seven contained the correct ingredients and two contained lead. Recommendations by ConsumerLab.com for people purchasing herbal cold remedies are:

- Cold remedies with echinacea—Look for products that contain at least 1% of phenols and at least 2,000 mg of echinacea and as a treatment, use for one to two weeks.

KEY TERMS

Antihistamine—A drug that blocks the action of histamine (a substance that produces an allergic reaction) and is used to control allergies.

Antitussive—A drug that is used to control coughing.

Decongestant—A drug that relieves nasal congestion.

Expectorant—A medicine that stimulates the production of mucus and is used to treat coughing.

Over-the-counter (OTC)—A medication that does not require a doctor's prescription.

- Cold remedies with garlic—Buy products that contain at least 3,600 micrograms (mcg) of allicin (garlic extract) per day. Garlic does not treat cold symptoms, but as a preventative, it reduces the number of colds by 66% if used regularly.
- Cold remedies with ginseng—Use products with at least 1.5 to 2% total ginsenosides (3 to 4% for extracts). Take 400 mg per day regularly to reduce the number of colds during the winter.

Side effects

Most herbs and herbal formulas have no adverse side effects when taken in normal or usual doses. People with concerns should check with their doctor or pharmacist before taking any herbal cold remedy.

Interactions

Interactions are rare but can occur. Products containing garlic should not be used with blood thinners. Ginseng can affect blood glucose (sugar) levels. It is best to check with a doctor or pharmacist for possible interactions between herbs or between herbs and other OTC or prescription medications the patient is taking.

Herbalism, Western

Definition

Western herbalism is a form of the healing arts that draws from herbal traditions of Europe and the Americas, and that emphasizes the study and use of European and Native American herbs in the treatment and prevention of illness. Western herbalism is based on physicians' and herbalists' clinical experience and traditional knowledge of medicinal plant remedies preserved by oral tradition and in written records over thousands of years. Western herbalism, like the much older system of **traditional Chinese medicine**, relies on the synergistic and curative properties of the plant to treat symptoms and disease and maintain health.

Western herbalism is based upon pharmocognosy, the study of natural products. Pharmocognosy includes the identification, extraction methods, and applications of specific plant constituents responsible for specific therapeutic actions, such as the use of digoxin from **Digitalis** leaf for heart failure. These constituents are extracted, purified and studied in clinical research. They may be concentrated to deliver standardized, set doses. Sometimes, the natural constituent can be synthesized in the lab, or changed and patented. Practitioners may choose to use fresh medicinal plants, simple extracts, or standardized extracts.

In standardized extracts, a specific quantity of a constituent is called a marker compound, and it may or may not be the active constituent(s) in the plant medicine. The products should be produced under good manufacturing processes and according to the traditional *National Formulary U. S. Dispensatory* or *U. S. Pharmacopeia*.

Origins

Over 2,500 years ago Hippocrates wrote, "In medicine one must pay attention not to plausible theorizing but to experience and reason together." This Greek physician and herbalist from the fourth century B.C. is considered the father of western medicine. He stressed the importance of diet, water quality, climate, and social environment in the development of disease. Hippocrates believed in treating the whole person, rather than merely isolating and treating symptoms. He recognized the innate capacity of the body to heal itself, and emphasized the importance of keen observation in the medical practice. He recommended simple herbal remedies to assist the body in restoring health.

Ancient Greek medicine around the fifth century B.C. was a fertile ground for contrasting philosophies and religions. Greek physicians were influenced by the accumulated medical knowledge from Egypt, Persia, and Babylon. Medical advances flourished and practitioners and scholars were free to study and practice without religious and secular constraints. In the fourth century B.C., Theophrastus wrote the *Historia Plantarum*, considered to be the founding text in the science of botany.

During the first century A.D. Dioscorides, a Greek physician who traveled with the Roman legions, produced five medical texts. His herbal text, known as the *De Materia Medica* is considered to be among the most influential of all western herbal texts. It became a standard reference for practitioners for the next

KEY TERMS

Phyto-, as in phytochemical, phytomedicinal, and phytotherapy—Meaning, or pertaining to, a plant or plants.

Wildcrafting—Gathering of herbs or other natural materials.

1,500 years. This influential book also included information on medicinal herbs and treatments that had been used for centuries in Indian **Ayurvedic medicine**. Galen of Pergamum, who also lived in the first century A.D., was a Roman physician and student of anatomy and physiology. He authored a recipe book containing 130 antidotes and medicinal preparations. These elaborate mixtures, known as galenicals, sometimes included up to 100 herbs and other substances. This complex approach to herbal medicine was a dramatic change from the simple remedies recommended by Hippocrates and employed by traditional folk healers. Galen developed a rigid system of medicine in which the physician, with his specialized knowledge of complex medical formulas, was considered the ultimate authority in matters of health care. The Galenic system, relying on theory and scholarship rather than observation, persisted throughout the Middle Ages. The galenical compounds, along with bloodletting, and purging, were among the drastic techniques practiced by the medical professionals during those times; however, traditional herbal healers persisted outside the mainstream medical system.

During the eighth century a medical school was established in Salerno, Italy, where the herbal knowledge accumulated by Arab physicians was preserved. The Arabian Muslims conducted extensive research on medicinal herbs found in Europe, Persia, India, and the Far East. Arab businessmen opened the first herbal pharmacies early in the ninth century. The *Leech Book of Bald*, the work of a Christian monk, was compiled in the tenth century. It preserved important medical writings that had survived from the work of physicians in ancient Greece and Rome.

The Middle Ages in Europe were a time of widespread death by plagues and pestilence. The Black Plague of 1348, particularly, and other health catastrophes in later years, claimed so many lives that survivors began to lose faith in the dominant Galenic medical system. Fortunately, the knowledge of traditional herbal medicine had not been lost. Medieval monks who cultivated extensive medicinal gardens on the monastery grounds, also patiently copied the ancient herbal and medical texts. Folk medicine as practiced in Europe by traditional healers persisted, even though many women herbalists were persecuted as witches and enemies of the Catholic Church and their herbal arts were suppressed.

The growing spice trade and explorations to the New World introduced exotic plants, and a whole new realm of botanical medicines became available to Europeans. Following the invention of the printing press in the fifteenth century, a large number of herbal texts, also simply called herbals, became available for popular use. Among them were the beautifully illustrated works of the German botanists Otto Brunfels and Leonhard Fuchs published in 1530, and the Dutch herbal of Belgian physician Rembert Dodoens, a popular work that was later reproduced in English. In 1597, the physician and gardener John Gerard published one of the most famous of the English herbals, still in print today. Gerard's herbal, known as *The Herball or General Historie of Plantes* was not an original work. Much of the content was taken from the translated text of his Belgian predecessor Dodoens. Gerard did, however, include descriptions of some of the more than one thousand species of rare and exotic plants and English flora from his own garden.

The correspondence of astrology with herbs was taught by Arab physicians who regarded astrology as a science helpful in the selection of medicines and in the treatment of diseases. This approach to Western herbalism was particularly evident in the herbal texts published in the sixteenth and seventeenth centuries. One of the most popular and controversial English herbals is *The English Physician Enlarged* published in 1653. The author, Nicholas Culpeper, was an apothecary by trade. He also published a translation of the Latin language *London Pharmacopoeia* into English. Culpeper was a nonconformist in loyalist England, and was determined to make medical knowledge more accessible to the apothecaries, the tradesmen who prescribed most of the herbal remedies. Culpeper's herbal was criticized by the medical establishment for its mix of magic and astrology with **botanical medicine**, but it became one of the most popular compendia of botanical medicine of its day. Culpeper also accepted the so-called "Doctrine of Signatures," practiced by medieval monks in their medicinal gardens. This theory teaches that the appearance of plants is the clue to their curative powers. Plants were chosen for treatment of particular medical conditions based on their associations with the four natural elements and with a planet or sign. The place where the plant grows, its dominant physical feature, and the

smell and taste of an herb determined the plant's signature. Culpeper's herbal is still in print in facsimile copies, and some pharmocognosists and herbalists in the twenty-first century voice the same criticisms that Culpeper's early critics did.

European colonists brought their herbal knowledge and plant specimens to settlements in North America where they learned from the indigenous Americans how to make use of numerous nutritive and medicinal plants, native to the New World. Many European medicinal plants escaped cultivation from the early settlements and have become naturalized throughout North America. The first record of Native American herbalism is found in the manuscript of the native Mexican Indian physician, Juan Badianus published in 1552. The American Folk tradition of herbalism developed as a blend of traditional European medicine and Native American herbalism. The pioneer necessity for self-reliance contributed to the perseverance of folk medicine well into the twentieth century.

In Europe in the seventeenth century, the alchemist Paracelsus changed the direction of Western medicine with the introduction of chemical and mineral medicines. He was the son of a Swiss chemist and physician. Paracelsus began to apply chemicals, such as arsenic, mercury, **sulfur**, **iron**, and **copper** sulfate to treat disease. His chemical approach to the treatment of disease was a forerunner to the reliance in the twentieth century on chemical medicine as the orthodox treatment prescribed in mainstream medical practice.

The nineteenth and twentieth centuries brought a renewed interest in the practice of Wwestern herbalism and the development of natural therapies and health care systems that ran counter to the mainstream methods of combating disease symptoms with synthetic pharmaceuticals.

In the late eighteenth century, the German physician Samuel Hahnemann developed a system of medicine known as **homeopathy**. This approach to healing embraces the philosophy of "like cures like."homeopathy uses extremely diluted solutions of herbs, animal products, and chemicals that are believed to hold a "trace memory" or energetic imprint of the substance used. Homeopathic remedies are used to amplify the patient's symptoms with remedies that would act to produce the same symptom in a healthy person. Homeopathy holds that the symptoms of illness are evidence of the body's natural process of healing and eliminating the cause of the disease.

In 1895, the European medical system known as naturopathy was introduced to North America. Like homeopathy, this medical approach is based on the Hippocratic idea of eliminating disease by assisting the body's natural healing abilities. The naturopath uses nontoxic methods to assist the body's natural healing processes, including nutritional supplements, herbal remedies, proper diet, and **exercise** to restore health.

Western herbalism is regaining popularity at a time when the world faces the **stress** of overpopulation and development that threatens the natural biodiversity necessary for these valuable medicinal plants to survive. The American herb market is growing rapidly and increasing numbers of individuals are choosing alternative therapies over mainstream allopathic Western medicine.

Though research into the efficacy and safety of traditional herbal remedies is increasing, it has been limited by the high costs of clinical studies and laboratory research, and by the fact that whole plants and their constituents are not generally patentable (therefore, there is no drug profit after market introduction). Outside the United States, herbalism has successfully combined with conventional medicine, and in some countries is fully integrated into the nations' health care systems. At the beginning of the twenty-first century, 80% of the world's population continues to rely on herbal treatments. The World Health Organization promotes traditional herbal medicine for treatment of many local health problems, particularly in the Third World where it is affordable and already well integrated into the cultural fabric.

In the United States, the re-emergence in interest in holistic approaches to health care is evident. Citizens are demanding access to effective, safe, low-cost, natural medicine. Legislative and societal change is needed, however, before natural therapies can be fully integrated into the allopathic health care system and provide citizens with a wide range of choices for treatment. If the current trend continues, U. S. citizens will benefit from a choice among a variety of safe and effective medical treatments.

Benefits

The benefits of botanical medicine may be subtle or dramatic, depending on the remedy used and the symptom or problem being addressed. Herbal remedies usually have a much slower effect than pharmaceutical drugs. Some herbal remedies have a cumulative effect and work slowly over time to restore balance, and

others are indicated for short-term treatment of acute symptoms. When compared to pharmaceutical drugs, herbal remedies prepared from the whole plant have relatively few side effects. This is due to the complex chemistry and synergistic action of the full range of phytochemicals present in the whole plant, and the relatively lower concentrations. They are generally safe when used in properly designated therapeutic dosages, and less costly than the isolated chemicals or synthetic prescription drugs available from Western pharmaceutical corporations.

Description

Herbs are generally defined as any plant or plant part that may be used for medicinal, nutritional, culinary, or other beneficial purposes. The active constituents of plants (if known) may be found in varying amounts in the root, stem, leaf, flower, and fruit, etc. of the plant. Herbs may be classified into many different categories. Some Western herbalists categorize herbal remedies according to their strength, action, and characteristics. Categories may include sedatives, stimulants, laxatives, febrifuges (to reduce **fever**), and many others. One system of classification is based on a principle in traditional Chinese medicine that categorizes herbs into four classes: tonics, specifics, heroics, or cleansers and protectors. Within these broad classifications are the numerous medicinal actions of the whole herb which may be due to a specific chemical or combination of chemicals in the plant.

- Tonics. Herbs in this classification are also known as alteratives in Western herbalism. They are generally mild in their action and act slowly in the body, providing gentle stimulation and nutrition to specific organs and systems. Tonic herbs act over time to strengthen and nourish the whole body. These herbs are generally safe and may be used regularly, even in large quantities. These tonic herbs are known as "superior" remedies in traditional Chinese medicine. The therapeutic dose of tonic remedies is far removed from the possible toxic dose. American ginseng is an example of a tonic herb.
- Specifics. Herbs in this classification are strong and specific in their therapeutic action. They are generally used for short periods of time in smaller dosages to treat acute conditions. Herbs classified as specifics are not used beyond the therapeutic treatment period. Echinacea is a specific herb.
- Heroic. These herbs offer high potency but are potentially toxic, and should not be used in self-treatment. Because the therapeutic dosage may be close to the lethal dosage, these herbs are presented cautiously and closely monitored or avoided by trained clinicians. They should not be used continuously or without expert supervision. Poke (*Phytolacca americana*) is an example of a heroic remedy.
- Cleansers and protectors. These herbs, plants, and plant tissues remove wastes and pollutants, while minimally affecting regular body processes. An example of a cleanser is pectin. Pectins are the water-soluble substances that bind cell walls in plant tissues, and some believe that they help remove heavy metals and environmental toxins from the body.

Preparations

Herbal preparations are commercially available in a variety of forms including tablets or capsules, tinctures, teas, fluid extracts, douches, washes, suppositories, dried herbs, and many other forms. The medicinal properties of herbs are extracted from the fresh or dried plant parts by the use of solvents appropriate to the particular herb. Alcohol, oil, water, vinegar, glycerin, and propylene glycol are some of the solvents used to extract and concentrate the medicinal properties. Steam distillation and cold-pressing techniques are used to extract the **essential oils**. The quality of any herbal remedy and the potency of the phytochemicals found in the herb depends greatly on the conditions of weather and soil where the herb was grown, the timing and care in harvesting, and the manner of preparation and storage.

Precautions

Herbal remedies prepared by infusion, decoction, or alcohol tincture from the appropriate plant part, such as the leaf, root, or flower are generally safe when ingested in properly designated therapeutic dosages. However, many herbs have specific contraindications for use when certain medical conditions are present. Not all herbal remedies may be safely administered to infants or small children. Many herbs are not safe for use by pregnant or lactating women. Some herbs are toxic, even deadly, in large amounts, and there is little research on the chronic toxicity that may result from prolonged use. Herbal remedies are sold in the United States as dietary supplements and are not regulated for content or efficacy. Self-diagnosis and treatment with botanical medicinals may be risky. A consultation with a clinical herbalist, Naturopathic physician, or certified clinical herbalist is prudent before undertaking a course of treatment.

Essential oils are highly concentrated and should not be ingested as a general rule. They should also be diluted in water or in a non-toxic carrier oil before application to the skin to prevent **contact dermatitis**

or photo-sensitization. The toxicity of the concentrated essential oil varies depending on the chemical constituents of the herb.

The American Professor of Pharmacognosy, Varro E. Tyler, believes that "herbal chaos" prevails in the United States with regard to herbs and phytomedicinals. In part he blames the herb producers and marketers of crude herbs and remedies for what he terms unproven hyperbole, poor quality control, deceptive labeling, resistance to standardization of dosage forms, and continued sale of herbs determined to be harmful.

A new warning about Western herbalism has been made necessary by technology. The Internet has a number of sites available with unregulated and often unhealthy advice about use of herbal remedies. Many herbalists and allopathic physicians urge patients to use caution when seeking Internet information on herbal treatments. One cancer-related study found that only 36% of the web sites found in a search offered information that complied with regulatory guidelines about unsubstantiated claims about treatment or cure of disease.

Side effects

Herbs contain a variety of complex phytochemicals that act on the body as a whole or on specific organs and systems. Some of these chemical constituents are mild and safe, even in large doses. Other herbs contain chemicals that act more strongly and may be toxic in large doses or when taken continuously. Drug interactions are possible with certain herbs when combined with certain pharmaceutical drugs. Some herbs are tonic in a small amount and toxic in larger dosages.

In 2002, a report to the American Academy of Pediatrics cautioned members to watch for signs of adverse effects to the cardiovascular system of children from certain herbal remedies that are often not revealed by their families. For example, **ephedra** causes increases in heart rate and blood pressure. Other examples of child and adolescent patients with heart complications from herbs given to them that their parents assumed would be harmless were given by the presenter. Another report said that even adult patients fail to inform their physicians about herbal products they are using, and that patients do not think of them as medicines. Yet many herbal products can interact with allopathic medicines and either cancel their effects or cause adverse effects. For example, **garlic**, ginseng, ginkgo, **feverfew**, **licorice**, and other common remedies have anticoagulant properties that can put patients as risk of bleeding during surgery.

Research and general acceptance

Western herbalism is experiencing a revival of popular and professional interest. The number of training schools and qualified herbal practitioners is growing to meet the demand. Western herbalism is incorporated into the medical practice of licensed Naturopathic doctors, who receive special training in clinical herbalism. Folk herbalists, heir to the continuing oral traditions passed from generation to generation in many rural areas, as well as amateur, self-taught herbalists, keep the practice of botanical medicine alive at the grassroots level. Traditional Western herbalism relies on traditional use and materia medica, folk wisdom, and recent clinical research and advances in the extraction processes. These advances provide increased quality control on the concentration and potency of the active ingredients. Western physicians, educated in allopathic medicine, typically receive no training in the use of herbs. These doctors rely on pharmaceutical drugs for their patients, and some cite the following reasons for continuing to do so: lack of standardized dosages, lack of quality control in the preparation of herbal medicinals, and the dearth of clinical research verifying the safety and effectiveness of many traditional herbal remedies.

Herbalism is widely practiced throughout Europe, particularly in England, France, Italy, and Germany where phytomedicinals are available in prescription form and as over-the-counter remedies. In Germany, plant medicines are regulated by a special government body known as the Commission E. In the United States, however, despite increasing popularity, traditional herbalism is not integrated into the allopathic medical system. Phytomedicinals are sold as dietary supplements rather than being adequately researched and recognized as safe and effective drugs. The Dietary Supplement Health and Education Act of 1994 circumvented a U. S. Food and Drug Administration (FDA) effort to effectively remove botanicals from the marketplace and implement regulations restricting sale. Massive popular outcry against the proposed regulations on the sale of herbs and phytomedicinals resulted in this Congressional action. In 2000, U.S. President Bill Clinton, by executive order, created the White House Commission on Alternative Medicine in an effort to hold alternative medicine therapies "to the same standard of scientific rigor as more traditional health care interventions." That Commission is charged with recommending federal guidelines and legislation regarding the use of alternative medical therapies in the twenty-first century.

Training and certification

In the United States, courses of study in Western herbalism are available in almost all 50 states. The study of traditional herbalism is part of the course curriculum in Naturopathic medical colleges that offer four-year degree programs leading to licensure as a Doctor of Naturopathy. The oldest of these institutions is the National College of **Naturopathic Medicine**, established in 1956. Western clinical herbalism is taught through a growing number of institutions and organizations offering training and certification through residential and apprenticeship programs, and by correspondence. Some programs are comprehensive, with curricula in physiology, clinical diagnosis and treatment, ethnobotany, pharmacognosy, phytotherapy, plant identification, ethical wildcrafting and cultivation, and preparation and application of herbal remedies. Other programs are brief, geared more to the amateur herbalist and gardener. The Southwest School of Botanical Medicine in Bisbee, Arizona, is one of the oldest herbal schools, established in 1978. No licensing body yet exists in the United States to regulate the practice of herbal medicine.

In the United States herbal remedies are sold as dietary supplements. They are not regulated as to content and efficacy, and few are prepared in standardized dosages. Many of the supplements commercially available base claims for efficacy on traditional use and anecdotal evidence that has not been duplicated by clinical studies. In Germany, Commission E evaluates the safety and efficacy of the 300 herbs and herb combinations sold in that country. No equivalent regulatory commission exists in the United States. Permits are required in some states for the wildcrafting of rare and endangered herbs, such as **goldenseal** and **American ginseng**, two commercially valuable herbs in high demand in the growing medical botanicals industry.

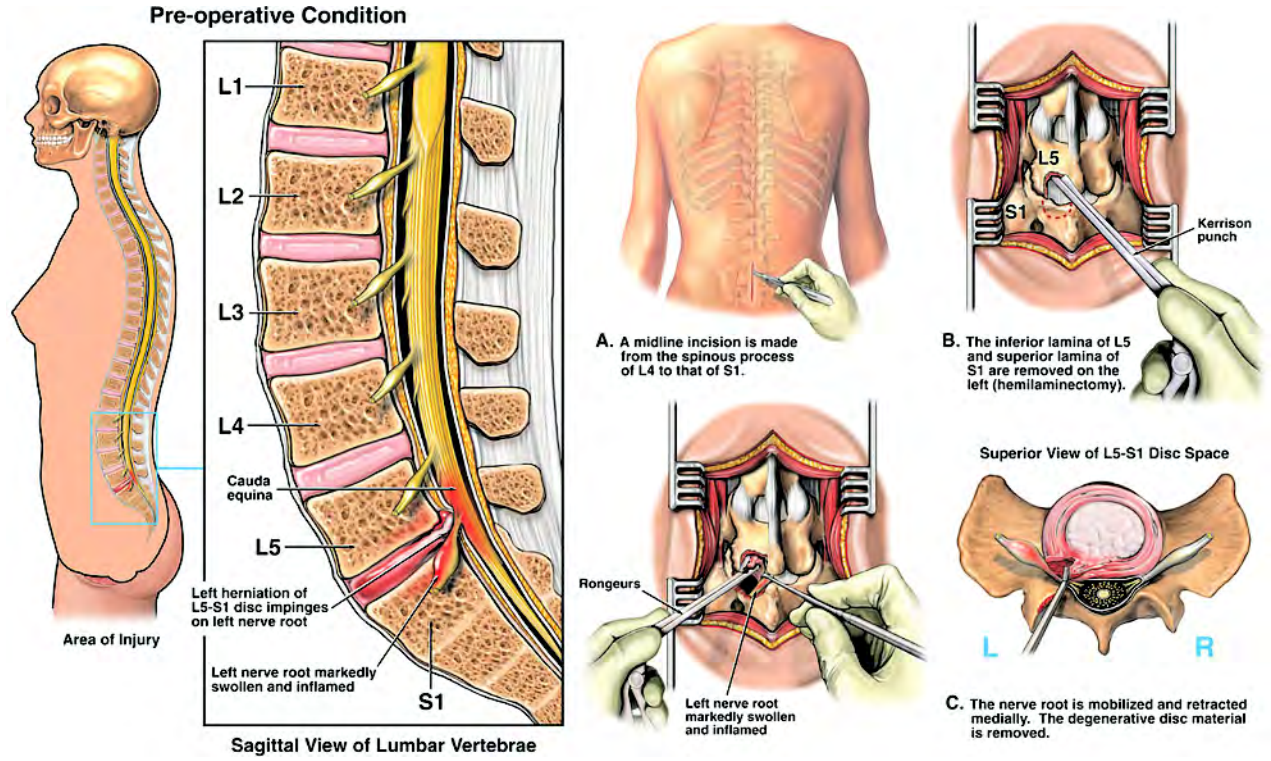
Herniated disk

Definition

Disk herniation is a breakdown of a fibrous cartilage material (annulus fibrosus) that makes up the intervertebral disk. The annulus fibrosus surrounds a soft gel-like substance in the center of the disk called the nucleus pulposus. Pressure from the vertebra above and below may cause the nucleus pulposus to be forced against the sides of the annulus. The constant pressure of the nucleus against the sides of the annulus will cause the fibers of the annulus to break down. As the fibers of the annulus breakdown, the nucleus will push toward



Back surgery, Disk Herniation with Hemilaminectomy and Discectomy. *(© Nucleus Medical Art, Inc. / Alamy)*

the outside of the annulus and cause the disk to bulge in the direction of the pressure. This condition most frequently occurs in the lumbar region and is also commonly called a herniated nucleus pulposus, prolapsed disk, ruptured disk, or a slipped disk.

Description

The spinal column is made up of 24 vertebrae that are joined together and permit forward and backward bending, side bending, and rotation of the spine. There are seven cervical (neck), twelve thoracic (chest region), and five lumbar (low back) vertebrae. There are intervertebral disks between each of the 24 vertebrae as well as a disk between the lowest lumbar vertebrae and the large bone at the base of the spine called the sacrum.

Disk herniation most commonly affects the lumbar region. However, disk herniation can also occur in the cervical spine. The incidence of cervical disk herniation is most common between the fifth and sixth cervical vertebrae. The second most common area for cervical disk herniation occurs between the sixth and seventh cervical vertebrae. Disk herniation is uncommon in the thoracic region.

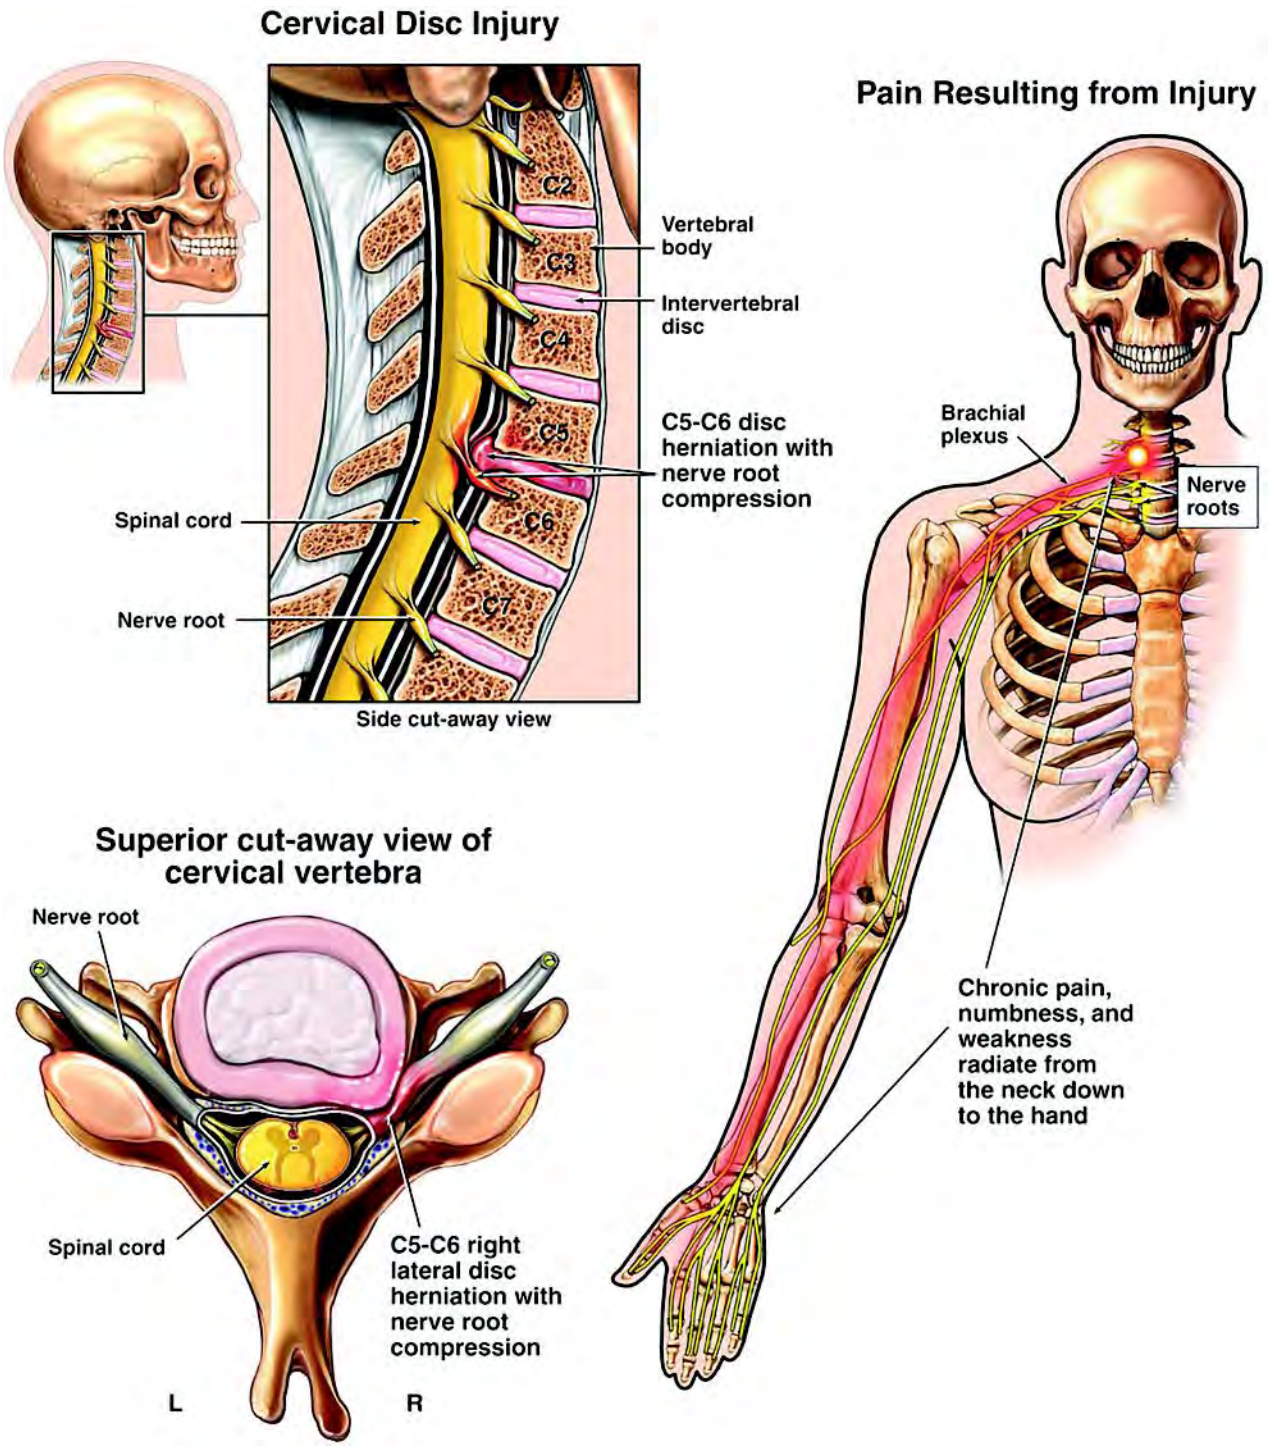
The peak age for occurrence of disk herniation is between 20 and 45 years of age. Studies have shown that males are more commonly affected than females in lumbar disk herniation by a 3:2 ratio. Long periods of sitting or a bent-forward work posture may lead to an increased incidence of disk herniation.

There are four classifications of disk pathology:

- A protrusion occurs when a disk bulges without rupturing the annulus fibrosus.
- A prolapse occurs when the nucleus pulposus pushes to the outermost fibers of the annulus fibrosus but does not break through them.
- An extrusion occurs when the outermost layer of the annulus fibrosus is torn and the material of the nucleus moves into the epidural space.
- A sequestration occurs when fragments from the annulus fibrosus or the nucleus pulposus have broken free and are outside the confines of the disk.

Causes and symptoms

Any direct or forcefulpressure on the disks in a vertical directioncan cause the disk to push its nucleus into the fibers of the annulus or into the intervertebral canal. A herniated disk may occur suddenly from lifting, twisting, or direct injury, but more often it will occur from constant compressive loads over time. There may be a single incident that causes symptoms



Herniated disk. *(© Nucleus Medical Art, Inc. / Alamy)*

to be felt, but very often the disk was already damaged and bulging prior to any one particular incident.

Depending on the location of the herniation, the herniated material can also press directly on nerve roots or on the spinal cord. Pressure on the nerve roots or spinal cord may cause a shock-like **pain** sensation down the arms if the herniation is in the cervical vertebrae or down the legs if the herniation is in the lumbar region.

KEY TERMS

Annulus fibrosis—The outer portion of the intervertebral disk made primarily of fibrocartilage rings.

Epidural space—The space immediately surrounding the outer most membrane of the spinal cord.

Excision—The process of excising, removing, or amputating.

Fibrocartilage—Cartilage that consists of dense fibers.

Nucleus pulposus—The center portion of the intervertebral disk that is made up of a gelatinous substance.

In the lumbar region a herniation that presses on the nerve roots or the spinal cord may also cause weakness, numbness, or problems with bowels, bladder, or sexual function. It is unclear if a herniated disk causes pain by itself without pressing on neurological structures. It is likely that irritation of the disk or the adjacent nerve roots may cause muscle spasm and pain in the region of the disk pathology.

Diagnosis

Several radiographic tests are useful for confirming a diagnosis of disk herniation and locating the source of pain. X rays show structural changes of the lumbar spine. Myelography is a special x ray of the spine in which a dye or air is injected into the patient's spinal canal. The patient lies strapped to a table as the table tilts in various directions and spot x rays are taken. X rays showing a narrowed dye column in the intervertebral disk area indicate possible disk herniation.

Computed tomography scan (CT scans) exhibit the details of pathology necessary to obtain consistently good treatment results. Magnetic resonance imaging (MRI) analysis of the disks can accurately detect the early stages of disk **aging** and degeneration. Electromyograms (EMGs) measure the electrical activity of the muscle contractions and possibly show evidence of nerve damage.

A number of physical examination procedures may be used to determine if a herniated disk is pressing on a nerve root. While these tests may not identify the definitive presence of a herniated disk, they are very useful for indicating if there is pressure on a nerve root from some structure such as a herniated disk. The straight leg raise test may be used to identify pressure on nerve roots in the lumbar region while the Spurling's test (involving neck motion) may be used to identify compression of nerve roots in the cervical region. Compression of nerve roots in the cervical, thoracic, or lumbar regions may be apparent with the slump test.

Treatment

It is unclear if herniated disks cause pain themselves, or if they must be pressing on a nerve root to cause pain. Pain may also occur with herniated disks as a result of mechanical or neurological irritation of surrounding structures such as muscles, tendons, ligaments, or joint capsules. Therefore, many treatment strategies will be primarily focused on managing symptoms that occur in conjunction with a herniated disk. Unless a serious neurological problem exists, most symptoms of a herniated disk will resolve on their own. Yet, the interventions listed below may greatly speed the time required to resolve symptoms associated with a herniated disk.

Chiropractic manipulations are often used to treat herniated disks. There is often significant joint restriction that accompanies a herniated disk and the manipulative therapy is effective at helping to mobilize movement restrictions in the spine. Mobilizing the spine will help the patient get back to moderate activity levels sooner and the earlier an individual can return to moderate activity levels, the quicker they can expect a resolution of their symptoms. Chiropractic manipulations are generally done with a greater frequency when a condition is in an acute stage. The frequency of treatments will be reduced as the condition progresses.

Osteopathic therapy, considered by some to be an alternative treatment, may use manipulations or manual therapy techniques very similar to chiropractors. However, osteopathic physicians often employ more manual therapy techniques that focus on the role of the muscles and other soft tissues in producing pain sensations with herniated disks. Osteopathic physicians may also recommend use of the same medications prescribed by allopathic physicians. Some osteopaths also perform surgery for herniated disks.

Acupuncture involves the use of fine needles inserted along the pathway of the pain to move energy through the body and relieve the pain. Neurological irritation is considered to be a frequent source of pain with a herniated disk. Many believe acupuncture is particularly effective for pain management and addressing this neurological irritation. Acupuncture can also help break the cycle of pain and muscle spasm that often accompanies a herniated disk.

Massage therapists focus on muscular reactions to the herniated disk. Neurological irritation that comes with a herniated disk will often cause excessive **muscle spasms** in the lower back muscles. These spasms will perpetuate dysfunctional movements in the joints of the spine and may exaggerate compressive forces on the intervertebral disk. By relaxing the muscles, massage therapists will attempt to manage the symptoms of disk herniation until proper movement can be restored. Proper movement and avoidance of aggravating postures, like sitting for long periods, will often be a great help in completely resolving the symptoms.

Allopathic treatment

Unless serious neurologic symptoms occur, herniated disks can initially be treated with pain medication. Pain medications, including anti-inflammatories, muscle relaxers, or in severe cases, narcotics, may be used if needed. Bed rest is sometimes prescribed. However, bed rest is frequently discouraged as a treatment for herniated disks unless movement is severely painful. It has become apparent that prolonged periods of bed rest may aggravate symptoms, slow down the healing time, and cause other complications.

Epidural steroid injections have been used to decrease pain by injecting an anti-inflammatory drug, usually a corticosteroid, around the nerve root to reduce inflammation and **edema** (swelling). This partly relieves the pressure on the nerve root as well as resolves the inflammation.

Physical therapists are skilled in treating acute back pain caused by disk herniation. The physical therapist can provide noninvasive therapies, such as ultrasound or **diathermy** to project heat deep into the tissues of the back or administer manual therapy, if mobility of the spine is impaired. They may help improve posture and develop an **exercise** program for recovery and long-term protection. Traction can be used to try to decrease pressure on the disk. A lumbar support can be helpful for a herniated disk at this level as a temporary measure to reduce pain and improve posture.

Surgery may be used for conditions that do not improve with conservative treatment. There are several surgical approaches to treating a herniated disk. A number of surgical procedures may be used to remove a portion of the intervertebral disk that may be pressing on a nerve root. When a portion of the disk is removed through a surgical procedure it is called a discectomy. Sometimes a spinal fusion will be performed after disk material has been removed. In this process a portion of bone is taken from the pelvis and placed between the bodies of the vertebrae. A spinal fusion will limit motion at that vertebral segment, but may be helpful in the event that significant disk material has been removed.

Chemonucleolysis is an alternative to surgical removal of the disk. Chymopapain, a purified enzyme derived from the papaya plant, is injected into the disk space to reduce the size of the herniated disks. The reduction in size of the disk relieves pressure on the nerve root. In 2002, Tokyo doctors produced evidence that a growth factor called vascular endothelial growth factor (VEGF) could speed up the process of injured disk resorption.

In September 2002, a noted orthopedic and spine authority named John Engelhardt became the first American to receive an artificial disk replacement (using the Bristol disk) in an operation in Switzerland. The artificial disk technology was still in clinical trials in the United States.

Expected results

Only a small percentage of patients with unrelenting neurological involvement, leading to chronic pain of the spine, need to have a surgical procedure performed. This strongly suggests that many patients with herniated disks respond well to conservative treatment. Alternative therapies can play a significant role in managing the pain and discomfort for the majority of patients with a herniated disk. In fact, magnetic resonance imaging (MRI) studies of the lumbar spine have indicated that many people without any back pain at all have herniated disks. This means it is unclear what role the herniated disk plays in many back pain cases. For many of these patients, proper symptom management of pain and improvement in joint motion and mobility through manual therapies will be enough to fully resolve their symptoms. For those patients who do require surgery, options are available for newer, less invasive procedures that will allow a quicker healing time.

Prevention

Proper exercises to strengthen the lower back and abdominal muscles are key in preventing excess **stress** and compressive forces on lumbar disks. Good posture will help prevent problems on cervical, thoracic, and lumbar disks. A good flexibility program is critical for prevention of muscle spasm that can cause an increase in compressive forces on disks at any level. Proper lifting of heavy objects is important for all muscles and levels of the individual disks. Good posture in sitting, standing, and lying down is helpful for the spine. Losing weight, if needed, can prevent weakness and unnecessary stress on the disks caused by **obesity**.

Alternative treatments such as chiropractic, **massage therapy**, or acupuncture may play a very important role in prevention of herniated disk problems. Regular use of these approaches may help maintain proper muscular tone and reduce the cumulative effects of postural strain that may lead to the development of disk problems.

Hesperidin

Definition

Hespiridin is a citrus flavonoid found primarily in orange, lemon, and grapefruit peel.

Description

Flavonoids, also called **bioflavonoids**, are a type of antioxidant found primarily in fruits, vegetables, and other plant-based foods, including teas and wines. More than 5,000 individual flavonoids have been identified in plants, and several hundreds are known to occur in frequently consumed foods. Flavonoids are the most common subgroup of polyphenol phytochemicals, or natural bioactive compounds in plant-based foods that have a variety of health maintenance and disease-fighting properties.

Because of the antioxidant properties of flavonoids, these phytochemicals are thought to reduce the risk of **cancer** and **heart disease** by repairing cellular damage and protecting the body from environmental toxins. Ultraviolet (UV) wavelengths can generate molecules called free radicals that can damage living cells. Free radicals are molecules, or fragments of molecules, that are unstable and highly reactive. Free radicals are produced as the result of a normal molecule losing or gaining an electron. In normal, stable molecules, electrons associate in pairs. However, radiation from the sun can result in the removal of an electron from a molecule and the formation of free radical. Flavonoids as **antioxidants** limit free radical damage by donating electrons to quench, or neutralize, the oxidant radicals.

In human **nutrition**, the antioxidant properties of flavonoids serve to protect cells from the danger of free radicals that may be produced by the body during metabolism or by cigarette smoke, sunlight, radiation, pollutants, or even **stress**. Tens of thousands of free radicals are created in the body every second. When a free radical captures an electron from another molecule, a new free radical is created as the second molecule has a lone, unpaired electron. This new free radical seeks to capture another electron and become normal again. This continual process of forming free radicals becomes a chain reaction. Unless quenched, these free radicals can damage DNA, fats, and proteins. However, the body has a defense against these free radicals. With proper nourishment, the body can make sufficient quantities of antioxidant enzymes and substrates for those enzymes that can facilitate the quenching of free radical reactions by antioxidants. These enzymes include superoxide dismutase, catalase, and **glutathione** peroxidase. In addition to these enzymes produced by the body, antioxidant nutrients taken into the body through foods or through dietary supplements also can surrender electrons to the free radicals without adding to the chain reaction, thus terminating the free radical reactions. Antioxidant nutrients include bioflavonoids; vitamins A, C, and E; lipoic acid; and **carotenoids**.

General use

Several research studies have reported a reduced risk of heart disease associated with flavonoid intake.

In one 2007 study, daily treatment with 270 mg citrus flavonoids plus 30 mg tocotrienols improved cardiovascular parameters compared to placebo, with significant reductions in total **cholesterol**, LDL, apolipoprotein B, and trigilycerides. The exact cardioprotective properties of flavonoids were still being defined in the medical literature as of 2008, but these actions are thought to aid in the defense against cardiovascular disease:

- reduce oxidation of LDL cholesterol
- inhibit platelet activation, which may affect the relaxation capabilities of blood vessels
- balance levels of eicosanoids

Other published benefits of citrus flavonoids, particularly diosmin, include improvement of venous tone, increased **lymphatic drainage**, inhibition of inflammatory reactions, and protection against microcirculatory damage, making it a promising and effective treatment for peripheral vascular and venous diseases, such as chronic venous insufficiency and venous ulceration. Additionally, hespiridin and ascorbic acid combination has been shown to reduce symptoms of **hot flashes** in menopausal women.

Preparations

Although not classified as essential nutrients, flavonoids are important substances in human food sources, especially in citrus fruits, vegetables, nuts, and wine, that provide many health benefits. A diet that includes many types of fruits, vegetables, and nuts supplies the essential flavonoids and their associated health benefits. Five servings of a variety of fruits and vegetables is the recommended daily intake. The more common flavonoids are also available as dietary supplements.

Diosmin is a hespiridin-derivitive extracted from citrus rinds, although it has different molecular properties than hespiridin.

While preliminary research shows promise for the health benefits of flavonoids, more research is needed to quantify the amount of supplementation that yields health benefits. There are no recommended daily allowances for flavonoid supplements, but 500 mg two to three times per day is the suggested daily dosage. When taken with **vitamin C**, flavonoids help to increase the absorption of this vitamin and prolong its effects.

Precautions

Daily dosage on the product label should not be exceeded.

In the United States, dietary supplements are not required to be standardized. Although regulated under the 1994 Dietary Supplement Health and Education Act (DSHEA), there are no safety reviews or approved therapeutic uses for citrus flavonoid supplements by the U.S. Food and Drug Administration (FDA). After the product is marketed, the FDA must prove the dietary supplement unsafe before it can be removed from the shelves.

Manufacturing guidelines for herbal remedies are not standardized; therefore, preparations can vary widely from one brand to another and within the same brand from one purchase to the next, making inconsistency in the concentration of ingredients a potential risk. Anyone using herbal products should be careful and try to use well-known brands because these products are largely unregulated.

Many people associate the term "natural" with "safe," yet that is not always the case. Anyone taking herbal products of any kind should be certain to read labels carefully and discuss the products with a physician to evaluate potential interactions with other medical conditions and/or prescription medications.

Side effects

Citrus flavonoid dietary supplements are generally safe and do not produce side effects when taken according to proper dosing guidelines.

Interactions

There are no documented interactions between citrus flavonoid supplements and other herbal remedies. Citrus flavonoid supplements derived from grapefruit may interfere with the action of anticoagulant medications such as warfarin (Coumadin) and other pharmaceutical preparations. Patients should discuss their interest in using citrus flavonoid supplements with their doctor to identify any potential interactions with current prescription medications.

Flavonoids seem to work best together in a complementary and synergistic manner to provide antioxidant and other health benefits; they also seem to work well with other antioxidants. Therefore, the use of a mixed citrus flavonoid supplement in combination with a multi-antioxidant formula, along with a diet rich in a variety of fruits, vegetables, and nuts is most desirable. As of 2008 research was ongoing to gain a better understanding of potential interactions.

KEY TERMS

Antioxidant—A substance that protects against the oxidative processes that may lead to cellular damage. Antioxidants are associated with a reduced risk of cancer, cardiovascular disease, and other medical conditions. Flavonoids are a type of antioxidant.

Eicosanoids—Hormone-like compounds thought to protect against cardiovascular disease.

Free radicals—Molecules, or fragments of molecules, that are unstable and highly reactive. Antioxidants appear to provide protection against free radicals.

Hiatal hernia

Definition

A hiatal hernia is an abnormal protrusion of the stomach up through the diaphragm and into the chest cavity.

Description

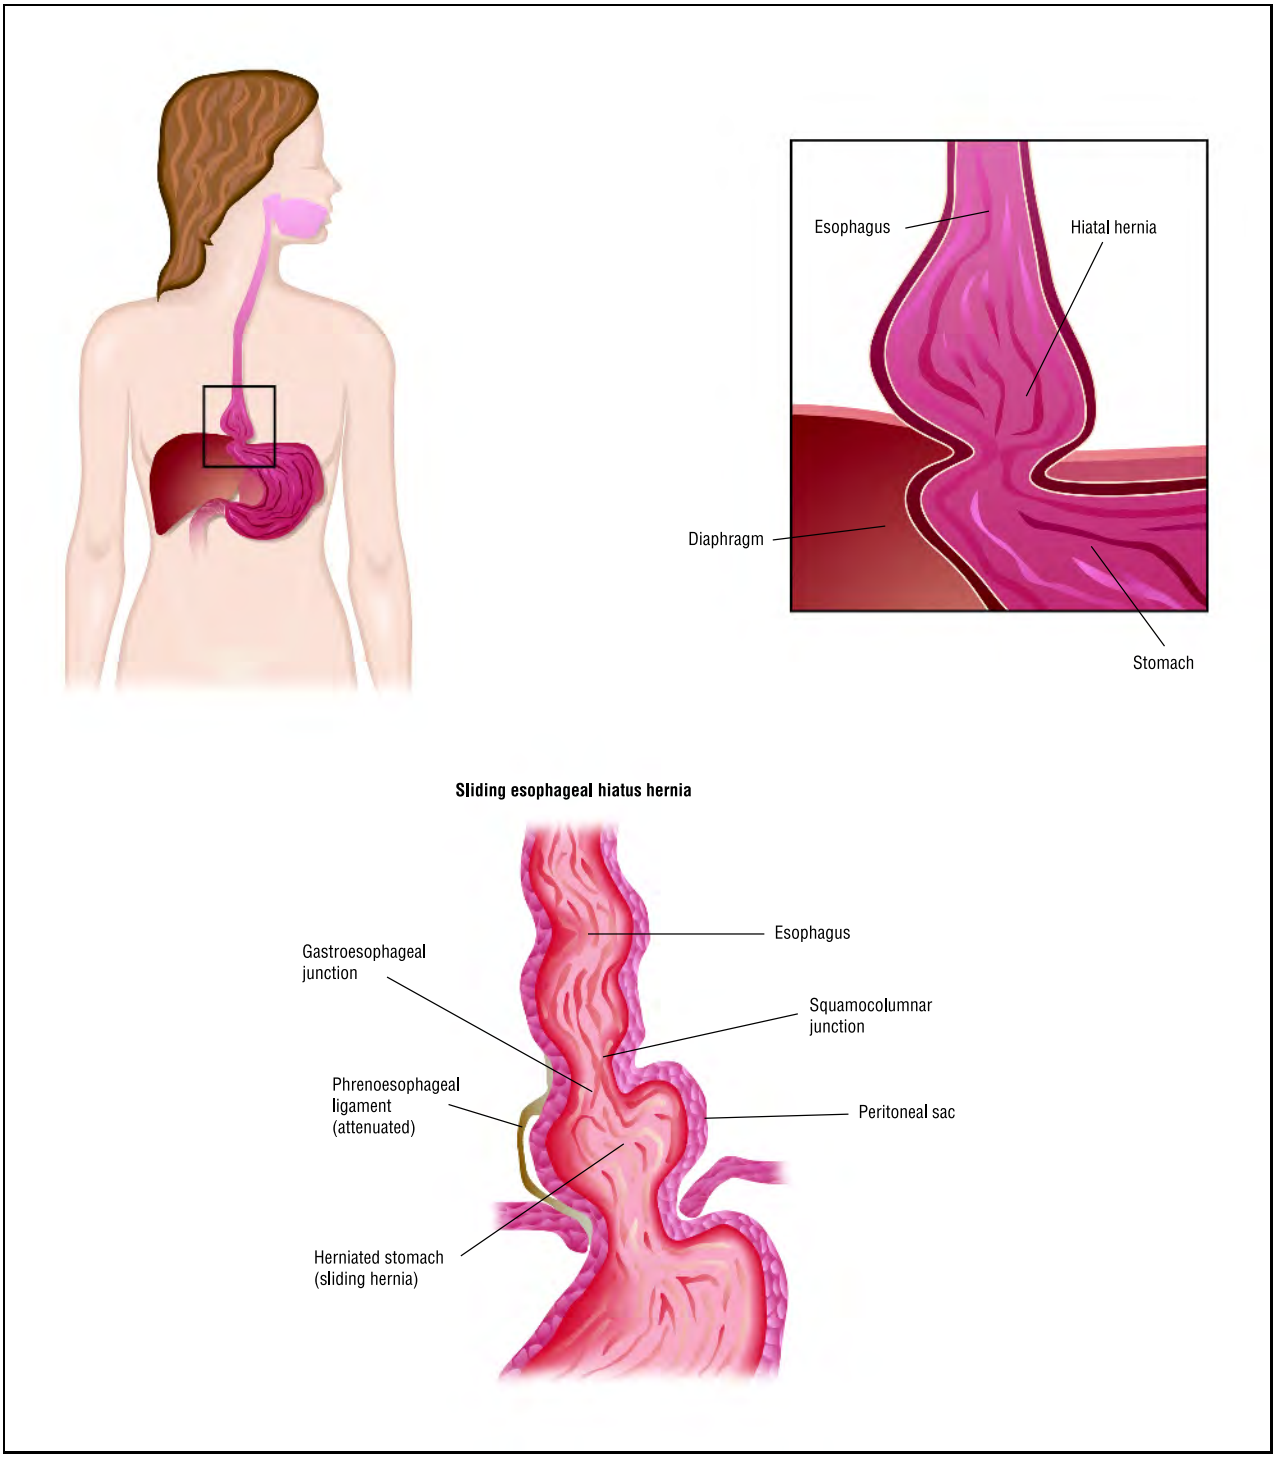
A hiatal or diaphragmatic hernia is different from abdominal hernias in that it is not visible on the outside of the body. With a hiatal hernia, the stomach bulges upward through the esophageal hiatus (the hole through which the esophagus passes) of the diaphragm. This type of hernia occurs more often in women than in men, and it is treated differently from other types of hernias.

Causes and symptoms

A hiatal hernia may be caused by **obesity**, **pregnancy**, **aging**, or previous surgery. About half of all people with hiatal hernias do not have any symptoms. For those who do, symptoms include **heartburn**, usually 30 to 60 minutes after a meal, or mid-chest **pain** due to gastric acid from the stomach being pushed up into the esophagus (gastroesophageal reflux disease, or GERD). The pain and heartburn are usually worse when lying down. Frequent belching and feelings of abdominal fullness may also occur.

Diagnosis

The diagnosis for a hiatal hernia is based on a person's reported symptoms. The doctor may then order tests to confirm the diagnosis. If a barium swallow is ordered, the person drinks a chalky white barium solution that helps any protrusion through the diaphragm to show up more clearly on the x ray



View and position of hiatal hernia in the body. *(Illustration by GGS Information Services, Inc. Cengage Learning, Gale)*

that follows. As of 2008, a diagnosis of hiatal hernia was more frequently made by endoscopy. This procedure is done by a gastroenterologist (a specialist in digestive diseases). During an endoscopy the person is given an intravenous sedative and a narrow tube is inserted through the mouth and esophagus, into the stomach where the doctor can visualize the hernia. The procedure takes about 30 minutes and may cause

some discomfort, but usually no pain. It is done on an outpatient basis.

Treatment

Dietary and lifestyle adjustments to control a hiatal hernia include:

- avoiding reclining after meals
- avoiding spicy foods, acidic foods, alcohol, and tobacco
- eating small, frequent, bland meals to keep pressure on the esophageal sphincter
- eating a high-fiber diet
- raising the head of the bed several inches with blocks to improve both the quality and quantity of sleep

Visceral manipulation, done by a trained therapist, can help return the stomach to its proper position. **Deglycyrrhizinated licorice** (DGL) helps balance stomach acid by improving the protective substances that line the stomach and intestines and by improving blood supply to these tissues. DGL does not interrupt the normal function of stomach acid.

Allopathic treatment

There are several types of medications that help to manage the symptoms of a hiatal hernia. Antacids are used to neutralize gastric acid and decrease heartburn. Drugs that reduce the amount of acid produced in the stomach (H2 blockers) are also used. This class of drugs includes famotidine (sold under the name Pepcid), cimetidine (Tagamet), and ranitidine (Zantac). Omeprazole (Prilosec) is not an H2 blocker, but is another drug that suppresses gastric acid secretion and is used to treat symptoms caused by hiatal hernias. Another option may be metoclopramide (Reglan), a drug that increases the tone of the muscle around the esophagus and causes the stomach to empty more quickly.

Expected results

Hiatal hernias are treated successfully with medication and diet modifications 85% of the time. The prognosis remains excellent even if surgery is required in adults who are otherwise in good health.

Prevention

Some hernias can be prevented by maintaining a reasonable weight, avoiding heavy lifting and **constipation**, and following a moderate **exercise** program to maintain good abdominal muscle tone.

KEY TERMS

Endoscopy—A diagnostic procedure in which a tube is inserted through the mouth, into the esophagus and stomach. It is used to visualize various digestive disorders, including hiatal hernias.

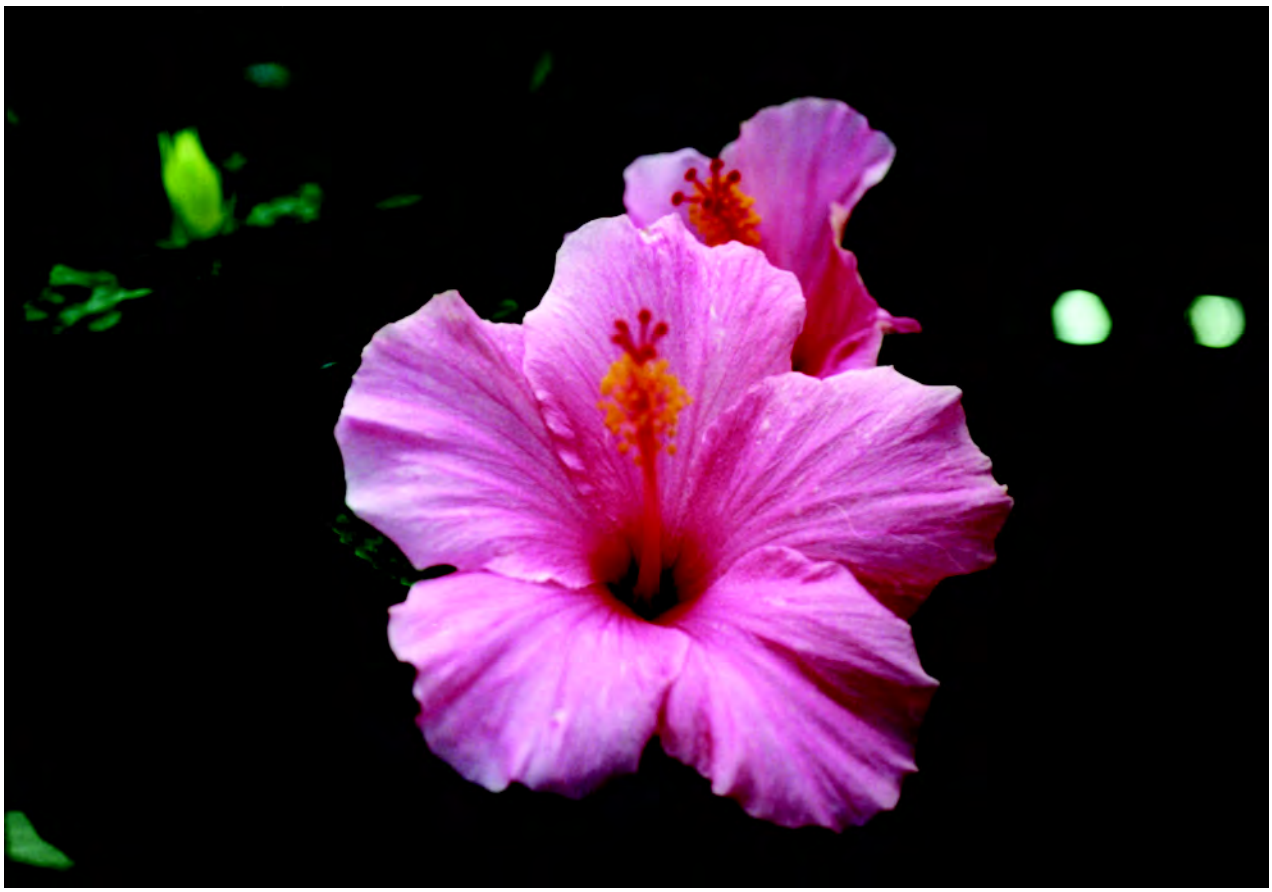
Hibiscus

Description

Hibiscus is the name given to more than 250 species of herbs, shrubs, and trees of the mallow or Malvaceae family. The most commonly used species



Hibiscus flower. *(Photo by Kelly Quinn. Reproduced by permission.)*

of hibiscus for medicinal purposes are *Hibiscus sabdariffa*, commonly known as the roselle; *Hibiscus rosa-sinensis*, also called China rose and common hibiscus; and *Hibiscus syriacus*, known as the Rose of Sharon. These three shrubs are native to tropical climates, but are now grown around the world. Hibiscus is renowned for its beauty as well as its medicinal uses, and gardeners cultivate the plant for its showy flowers.

General use

Hibiscus is used for a variety of ailments partly because there are so many species. Roselle lowers fevers and high blood pressure, increases urination, relieves coughs, and has been found to have antibacterial properties. All parts of the plant are used, from the seeds to the roots. Common hibiscus is used mainly for respiratory problems, but is also widely used for skin disorders or to treat fevers. Rose of Sharon is used externally as an emollient, but is also taken internally for gastrointestinal disorders.

Fever

As a natural febrifuge, roselle contains citric acid which is a natural coolant. In Pakistan and Nepal, it is the flowers that are used as a treatment for **fever**. Common hibiscus has been found to be particularly useful for children's fevers.

Respiratory disorders

Common hibiscus is used to treat coughs by placing extracts from the plant in the patient's bath or in water used for steam inhalations. Hibiscus is often combined with other herbs to make a **cough** syrup. Hibiscus is used widely in Cuba, where the tropical climate contributes to respiratory illnesses, and where hibiscus is readily found.

Hypertensive conditions

Roselle and rose of Sharon contain hypotensive compounds that lower the blood pressure. Roselle's ability to lower blood pressure may be due to its

KEY TERMS

Abortifacient—A substance that induces abortions.

Anthelminthic—A medication that destroys or expels parasitic worms from the digestive tract.

Antispasmodic—A medication that prevents or relieves involuntary muscular cramps.

Emollient—A substance that softens and smoothes the skin.

Febrifuge—A substance or medication that lowers or dispels fevers.

diuretic and laxative effects. The plant contains ascorbic and glycolic acid, which increase urination.

Skin conditions

Hibiscus is a natural emollient, used for softening or healing the skin. The leaves and flowers of the roselle are used all around the world for their emollient qualities. When the leaves are heated, they can be placed on cracked feet or on **boils** and ulcers to promote healing. Since the herb is a cooling herb, when applied externally it cools the surface of the skin by increasing blood flow to the epidermis and dilating the pores of the skin. A lotion made from a decoction of hibiscus leaves can be used to soothe **hemorrhoids**, **sunburn**, open sores, and **wounds**.

Other conditions

Hibiscus has been credited with a wide range of healing properties. In Colombia, the plant is used to treat **hair loss** and scurvy; in Samoa, it is commonly given to women who are suffering from menstrual cramps or who are in **childbirth**, as the leaves ease labor pains. In the Cook Islands and the Philippines, the flowers are used to induce abortions. In a 1962 study, hibiscus was confirmed to be hypotensive, as well as antispasmodic, anthelminthic, and antibacterial. In subsequent studies, the plant was found to effectively work against such diseases as ascariasis and **tuberculosis**. Studies in France, Malaysia, and Egypt have found that the plant has anticarcinogenic effects.

Preparations

A decoction of hibuscus can be made by pouring 1 cup of boiling water over 2 tsp of dried blossoms or 1 tsp of crumbled blossom. Steep for 10 minutes. In addition, many commercial herbal teas contain hibiscus.

Precautions

Since there are over 250 species of hibiscus, it is essential to identify the species of the herb before taking it. Since some species of hibiscus are used as abortifacients, the plant should not be used by women who are pregnant or nursing.

Side effects

Some drinks made from roselle can have alcoholic effects. The plant can also be mildly hallucinogenic.

Interactions

There are no known interactions between hibiscus and standard pharmaceutical preparations. Because it is a tart plant, however, it may not mix harmoniously with other tannic herbs. Mint leaves or rose hips are good to blend with hibiscus.

Hiccups

Definition

Hiccups are the result of an involuntary, spasmodic contraction of the diaphragm followed by the closing of the throat.

Description

Virtually everyone experiences hiccups, but they rarely last long or require a doctor's care. Occasionally, a bout of hiccups will last longer than two days, earning it the name "persistent hiccups." Very few people will experience intractable hiccups, in which hiccups last longer than one month.

A hiccup involves the coordinated action of the diaphragm and the muscles that close off the windpipe (trachea). The diaphragm is a dome-shaped muscle separating the chest and abdomen. It is normally responsible for expanding the chest cavity for inhalation. Sensation from the diaphragm travels to the spinal cord through the phrenic nerve and the vagus

KEY TERMS

Innervate—To supply a part of the body with nerves. For example, the vagus nerve supplies nerve function to the eardrum; therefore, we say that the eardrum is innervated by the vagus nerve.

Nerve—Fibers that carry sensory information, movement stimuli, or both from the brain and spinal cord to other parts of the body and back again. Some nerves, including the vagus nerve, innervate distantly separated parts of the body.

nerve, which pass through the chest cavity and the neck. Within the spinal cord, nerve fibers from the brain monitor sensory information and adjust the outgoing messages that control contraction. These messages travel along the phrenic nerve.

Irritation of any of the nerves involved in this loop can cause the diaphragm to undergo involuntary contraction, or spasm, pulling air into the lungs. When this occurs, it triggers a reflex in the throat muscles. Less than a tenth of a second afterward, the trachea is closed off, making the characteristic "hic" sound.

Causes and symptoms

Hiccups can be caused by disorders of the central nervous system, by injury or irritation to the phrenic and vagus nerves, and by toxic or metabolic disorders affecting the central or peripheral nervous systems. They may be of unknown cause or may be a symptom of psychological **stress**. Hiccups often occur after drinking carbonated beverages or alcohol. They may also follow overeating or rapid temperature changes. Persistent or intractable hiccups may be caused by any condition that irritates or damages the relevant nerves, including:

- overstretching of the neck
- laryngitis
- heartburn (gastroesophageal reflux)
- irritation of the eardrum (which is innervated by the vagus nerve)
- general anesthesia
- surgery
- bloating
- tumor
- infection
- diabetes

Diagnosis

Hiccups are diagnosed by observation and by hearing the characteristic sound. Diagnosing the cause of intractable hiccups may require imaging studies, blood tests, pH monitoring in the esophagus, and other tests.

Treatment

Most cases of hiccups will disappear on their own. Home remedies, which interrupt or override the spasmodic nerve circuitry, are often effective. Such remedies include:

- Holding one's breath for as long as possible.
- Breathing into a paper bag.
- Swallowing a spoonful of sugar or peanut butter.
- Bending forward from the waist and drinking water from the wrong side of a glass.

Acupressure techniques can also be helpful in eliminating hiccups. Acupressure is a Chinese medicine treatment that involves placing pressure on different points of the body, called acupoints. It is based on the premise that good health is based on a harmony of energy flow, or *qi*, throughout the body. By placing pressure on acupoints, qi is balanced and harmony—and health—is restored to the patient.

To treat hiccups through acupressure, rest the heels of the palms on both cheekbones while placing hands over the eyes. Massage the temples by pulling the thumbs in towards the palm. After massaging, remove the hands from the eyes and lightly press the tip of the nose with a fingertip.

Allopathic treatment

Treating any underlying disorder will usually cure the associated hiccups. Chlorpromazine (Thorazine) relieves intractable hiccups in 80% of cases. Metoclopramide (Reglan), carbamazepam, valproic acid (Depakene), and phenobarbital are also used. As a last resort, surgery to block the phrenic nerve may be performed, although it may lead to significant impairment of respiration.

Expected results

Most cases of hiccups last no longer than several hours, with or without treatment.

Prevention

Some cases of hiccups can be avoided by drinking in moderation, avoiding very hot or very cold food, and avoiding cold showers. When carbonated beverages are

drunk through a straw, more **gas** is delivered to the stomach than when they are sipped from a container; therefore, avoid using straws.

High-fiber diet

Definition

Fiber is the material that gives plants texture and support. Dietary fiber is found in many plant foods such as fruits, vegetables, beans, nuts, and whole grains. Although it is primarily made up of carbohydrates, it does not have a lot of calories and usually is not broken down by the body for energy. Fiber is sometimes called roughage.

Dietary fiber belongs to one of two types, depending on whether or not it is able to dissolve in water. Fiber that dissolves in water is called *soluble*, while fiber that cannot be dissolved in water is known as *insoluble*. Upon ingestion, soluble fiber dissolves in the fluids secreted by the digestive tract, forming a gel. This gel moves slowly through the digestive tract, thus slowing the rate of digestion and absorption. **Diets** containing large amounts of soluble fiber have been shown to stabilize blood sugar levels in people with diabetes, and have been shown to reduce blood levels of unhealthy (LDL) **cholesterol**. Foods high in soluble fiber include beans, lentils, oats, **psyllium**, citrus fruits, barley and apples. In contrast, insoluble fiber acts as roughage. It contributes to stool bulk and promotes regularity. Foods rich in insoluble fiber include wheat bran, whole grains, dried beans, nuts, seeds, and those fruits and vegetables with an edible outer skin or seeds.

Adequate intake of fiber

Age	g/day
Children > 1 yr.	Not established

Origins

High-fiber diet therapy is actually a return to nature and the plant-based diets used by our ancestors since the beginning of time. In fact, our ancestors consumed large quantities of fiber-containing foods such as fruits, vegetables and whole grain products every day. As technology advanced, however, people began to turn away from these unprocessed healthful foods and began eating more highly processed and fat-

laden foods. As a result, the incidence of coronary **heart disease**, diabetes and cancers has steadily risen.

No single person developed the high-fiber diet. Over the years, researchers have compared the rate of various chronic diseases in populations that had high-fiber diets with those that had lower dietary fiber intake. They found, for example, that native Africans who ate a high-fiber, plant-based diet are rarely bothered **constipation**. However, in industrialized countries where a lot of animal products are consumed, constipation is common. Observations like this encouraged researchers to look at other roles that dietary fiber might play in health. From their findings came a consensus that a high-fiber diet is a healthy diet. This is reflected in the Dietary Guidelines for Americans 2005, which encourage people to eat more high-fiber foods such as whole grains.

Benefits

A high-fiber diet helps prevent or treat the following health conditions:

- High blood cholesterol levels. Fiber effectively lowers blood cholesterol levels. It appears that soluble fiber binds to the cholesterol molecule and moves it through the digestive tract so that it can be excreted from the body. This mechanism prevents cholesterol from being reabsorbed into the bloodstream.
- Constipation. A high-fiber diet is a useful non-drug treatment for constipation. Fiber in the diet adds more bulk to the stools, making them softer. Fiber also shortens the length of time that foods remain in the digestive tract. It is important, however, for people increasing their fiber intake to drink more water as well, in order to get the benefit of using dietary fiber to relieve constipation.
- Hemorrhoids. Fiber in the diet adds more bulk and softens the stool, thus reducing the pain and bleeding associated with hemorrhoids.
- Diabetes. A common problem for diabetics is the rapid rise of insulin levels following meals. Soluble fiber in the diet delays the emptying of the stomach contents into the intestines. This delay helps to slow the rise of blood sugar levels following a meal and thus gives diabetics greater control over their condition.
- Obesity. Dietary fiber makes a person feel full more rapidly. It can thus help a person lose weight by making the appetite easier to control.
- Colon cancer. Claims have been made that a diet high in fiber reduces the risk of colon cancer. The theory is that fiber speeds up the elimination of waste from the colon. This decreases the time that cells lining the intestinal wall are exposed to potential cancer-causing agents. However, in the mid-2000s, a study that followed 80,000 nurses for 16 years found no relationship between dietary fiber and colon cancer. More research remains to be done in this area.
- Breast cancer. A high dietary consumption of fats is associated with an increased risk of breast cancer. Because fiber reduces fat absorption in the digestive tract, it may prevent breast cancer. In 2003, a study confirmed these findings and showed that women who consumed more fiber and vitamin E also had a lower risk of developing benign breast disease, a condition which can lead to breast cancer.
- Prostate cancer. Though research is still relatively new, Dr. Dean Ornish presented data in April 2002 on a study that showed how a high-fiber vegan diet could slow or even stop prostate cancer for men in early stages of the disease. Men who submitted to an extremely low-fat, vegan diet consisting of fruits, vegetables, whole grains, beans and soy products instead of dairy, and who gave up alcohol and agreed to exercise three hours a week, relax and meditate one hour a day showed improvements in markers for prostate cancer indicators. Patients should not try this regimen unless they first discuss it with their doctors and it should complement other physician–ordered treatments.

Description

The United States Institute of Medicine (IOM) of the National Academy of Sciences has set dietary reference intakes (DRIs) for fiber based on research data that applies to American and Canadian populations. DRIs provide **nutrition** guidance to both health professionals and consumers. The current daily DRIs for fiber are as follows:

- children ages 1–3 years: 19 grams
- children ages 4–8 years: 25 grams
- men ages 14–50: 38 grams
- men age 51 and older: 30 grams
- girls ages 9–18: 26 grams
- adult women ages 19–50: 25 grams
- women age 51 and older: 21 grams
- pregnant women: 28 grams
- breastfeeding women: 29 grams

An individual can generally get 25–35 g of fiber daily by eating two to three servings of fruits and three to five servings of vegetables every day. To increase fiber intake, an individual should eat more of the following high-fiber foods: whole grains, beans, fruits (preferably with skins on), roots and leafy vegetables,

broccoli or carrots. As an added bonus, he or she will also receive other health benefits provided by the vitamins, minerals, **antioxidants** and cancer-fighting phytochemicals in these foods.

Preparations

For the greatest benefit to health, people should have both soluble and insoluble fiber in their diet, preferably in a 50:50 ratio. The following foods are good sources of insoluble fiber:

- wheat bran
- whole wheat products
- cereals made from bran or shredded wheat
- crunchy vegetables
- barley
- grains
- whole wheat pasta
- rye flour

Good sources of soluble fiber include:

- oats
- oat bran
- oatmeal
- apples
- citrus fruits
- strawberries
- dried beans
- barley
- rye flour
- potatoes
- raw cabbage
- pasta

Precautions

Few risks are associated with a high-fiber diet in healthy individuals. However, in people with gastrointestinal disorders such as **irritable bowel syndrome** and **inflammatory bowel disease**, a high-fiber diet may irritate the bowel and worsen their symptoms. Likewise, people who have had a surgical weight-loss procedure may be unable to tolerate a high-fiber diet. Adding bran fiber to foods is not recommended due to the risk of poor intakes of some vitamins that bind with phytates and oxalates in many high-fiber foods.

High-fiber therapy must be part of a balanced diet that includes adequate water intake and also provides the proper amounts of essential vitamins and minerals, including **calcium**, **iron** and **zinc**.

KEY TERMS

Cellulose—The primary substance composing the cell walls or fibers of all plant tissues.

Hemorrhoid—A varicose vein in the area around the anus. Hemorrhoids sometimes cause pain and bleeding.

Naturopathy—A school of alternative medicine that focuses on natural healing. Therapies provided by practitioners of naturopathy often include diet, exercise, supplement and hydrotherapy and may also include osteopathic and chiropractic treatments.

Roughage—Another name for dietary fiber.

Fiber supplements such as psyllium may reduce the absorption of certain medications when taken at the same time. In general, medications should be taken at least one hour before or two hours after fiber supplements.

Side effects

Fiber should be increased in the diet gradually. If fiber intake increases suddenly, abdominal **pain**, **gas**, and **diarrhea** may result. Also, when eating a high-fiber diet, it is important to drink at least 8 glasses (64 oz or 2 L) of water or other fluids daily. People whose fluid intake must be restricted for medical reasons should avoid a high-fiber diet.

Research and general acceptance

As a result of the large volume of scientific evidence supporting the use of fiber in disease prevention and treatment, high-fiber diet treatments have been accepted and advocated by practitioners of alternative and conventional medicine alike. High-fiber diets have been endorsed by the American Heart Association, the American Dietetic Association, the National **Cancer** Institute, the National Research Council, and the United States Department of Health and Human Services.

High sensitivity C-reactive protein test

Definition

The high sensitivity C-reactive protein (CRP) test is a blood assay used to estimate an individual's risk for **heart disease** and **stroke**. The test also measures the presence of inflammation or infection.

Origins

In the late twentieth century, the primary methods of measuring a person's risk of heart disease included traditional factors such as age, family history of heart disease or stroke, past heart disease, **smoking**, **obesity**, and tests that measured lipids in the bloodstream, including low-density lipoprotein (LDL). Low-density lipoproteins ("bad" **cholesterol**) were previously considered the gold standard in risk factor prediction.

In the 1990s and early twenty-first century, several new tests came into widespread use. These tests are considered better predictors of heart disease risk. They include blood tests to measure the levels of homocysteine, lipoprotein(a), fibrinogen, and highly sensitive C-reactive protein. They are called emerging or non-traditional risk factors.

Benefits

Knowing one's highly sensitive C-reactive protein levels can help a person manage and lower his or her risk for heart disease. Factors that lower highly sensitive CRP levels include weight loss, regular **exercise**, a healthy diet, and smoking cessation. Medicines may also be needed. Medications include a class of drugs called statins, with brand names such as Lipitor, Zocor, Crestor, and Pravachol. Other interventions may include Zetia, a cholesterol absorption inhibitor, and a class of drugs called thiazoladinediones, such as the diabetes brand name medications, Avandia and Actos.

According the American Heart Association, the three risk levels associated with high sensitivity CRP levels are:

- Low risk: under 1 milligram per liter of blood.
- Average risk: 1 to 3 milligrams per liter of blood.
- High risk: More than 3 milligrams per liter of blood.

Description

C-reactive protein is produced by the liver, and is not normally found in the blood in high amounts. It is rapidly produced following an injury, bacterial or fungal infection, or inflammation. It disappears quickly once the injury, illness, or inflammation heals or resolves. High CRP levels following surgery or an injury are a good indication that an infection is present. Until early this century, the blood test used to detect CRP levels could only measure them down to 3 milligrams per liter of blood or higher. Improvements in technology have permitted more precise measurements of CRP levels ranging from less than 0.3 milligrams to 3 milligrams per liter of blood. The more precise measurement is called the high sensitivity C-reactive protein (hsCRP) test.

While levels under 3 milligrams per liter of blood do not necessarily indicate an infection, they do indicate the presence of an inflammatory reaction. Researchers found that these lower amounts of CRP in the body are extremely useful in predicting coronary

KEY TERMS

Anticoagulant— Medication that prevents blood clotting.

C-reactive protein—A protein produced in the liver that is not normally found in the blood in high amounts. It is elevated when infection or inflammation are present. A test that measures this substance in the bloodstream serves as a predictor of heart disease or stroke.

Centrifuge—A machine that rotates rapidly and uses centrifugal force to separate substances of different densities.

Cholesterol—A compound found in animal tissue and blood, of which high levels in the blood are linked to clogged arteries, heart disease, and gallstones.

Cholesterol absorption inhibitor—A substance that decreases the absorption of cholesterol in the intestines.

Diabetes—Several metabolic disorders in which the body produces insufficient insulin or is resistant to the insulin it does produce, causing glucose levels to rise in the blood.

Fasting—Avoiding food for a period of time.

Fibrinogen—A protein that is important in blood clotting.

Homocysteine—An amino acid, derived from protein in food, that can build up in the blood and contribute to the development of heart disease.

Lipids—Organic compounds that are greasy, insoluble in water, but soluble in alcohol. Fats, waxes, and oils are examples of lipids.

Lipoprotein(a)—A type of bad cholesterol that increases the risk of heart attack or stroke.

Low-density lipoprotein—LDL, the so-called bad cholesterol.

Plasma—A clear yellowish fluid that is a component of blood.

Statins—A class of drugs used primarily, but not exclusively, to treat high cholesterol.

Thiazoladinediones—A class of drugs typically used to treat diabetes and insulin resistance.

heart disease (CHD). However, since CRP levels vary on different days, at least two separate measurements are needed to adequately determine a person's CHD risk level.

To take the high sensitivity CRP test, a healthcare worker draws blood from a vein, and into a tube. In the laboratory, the tube of blood spins at high speed within a machine called a centrifuge. The blood cells sink to the bottom and the liquid stays on the top. This straw-colored liquid on the top is the plasma. To measure the high sensitivity CRP, a person's plasma is combined with other substances. From the resulting reaction, the amount of CRP in the plasma is determined.

A study released in 2003 by the College of American Pathologists found varying outcomes when it compared results from five different methods in identifying hsCRP. A 2001 study by several university medical departments found that six out of nine hsCRP testing methods did not produce results as accurate as the manufacturers claimed. In 2003, the Centers for Disease Control and Prevention announced it would attempt to address these issues.

Preparations

Unlike some blood tests that require **fasting**, the high sensitivity C-reactive protein test can be done either before or after eating. No other preparations are needed.

Each high sensitivity CRP test requires a 5-milliliter blood sample. A healthcare worker usually ties a tight band (tourniquet) on the person's upper arm. The blood is drawn from a vein in the arm, usually at the inside of the elbow or on the back of the hand. The needle insertion site is cleaned with antiseptic. A small needle is inserted through the skin and into the vein, allowing the blood sample to flow into a collection tube or syringe. Once the blood is collected, the needle is removed from the puncture site. Collecting the blood sample takes several minutes or less.

Precautions

The primary risk to the patient is a mild stinging or burning sensation during the drawing of blood, with minor swelling or bruising afterward. Some patients may feel faint or lightheaded when blood is drawn.

Side effects

There are generally no side effects associated with the test. Any weakness, fainting, sweating, or other unusual reaction should be immediately reported.

Research and general acceptance

Several large-scale scientific studies have shown that high sensitivity C-reactive protein levels are a strong predictor of future heart attacks and strokes among apparently healthy men and women. Research has also shown that hsCRP test will play an important role in preventing heart disease, according to an article in the March 2001 issue of *Circulation*. The Centers for Disease Control and Prevention, and the American Heart Association, recommend limited use of hsCRP testing for assessing heart disease risk. The two groups recommend the test only when a physician is undecided about a course of treatment for a patient who is considered at intermediate risk for CHD. According to an article in the February 2003 issue of the *Harvard Health Letter*, a growing number of physicians believe everyone should be tested, and this test may eventually supplant cholesterol testing as a predictor of CHD.

Training and certification

Nurses are usually the health care professionals that administer high sensitivity CRP tests. Nurses can also help educate patients regarding the role that a proper diet and regular exercise can play in reducing the risk of CHD. However, the physician that recommends specific treatment and prescribes needed medication.

HIV infection *see* **AIDS**

Hives

Definition

Hives are an allergic skin reaction causing localized redness, swelling, and **itching**.

Description

Hives are a reaction of the body's immune system that causes areas of the skin to swell, itch, and become reddened. (The areas are called wheals.) When the reaction is limited to small areas of the skin, it is called urticaria. Involvement of larger areas, such as whole sections of a limb, is called angioedema.

Causes and symptoms

Causes

Hives are an allergic reaction. The body's immune system is normally responsible for protection from foreign invaders. When it becomes sensitized to normally harmless substances, the resulting reaction is called an allergy. An attack of hives is set off when such a substance, called an allergen, is ingested, inhaled, or otherwise contacted. It interacts with immune cells called mast cells, which reside in the skin, airways, and digestive system. When mast cells encounter an allergen, they release histamine and other chemicals, both locally and into the bloodstream. These chemicals cause blood

KEY TERMS

Allergen—A substance capable of producing an immediate type of hypersensitivity, or allergy.

Wheal—A smooth, slightly elevated area on the body surface, which is redder or paler than the surrounding skin.

vessels to become more porous, allowing fluid to accumulate in tissue and leading to the swollen and reddish appearance of hives. Some of the chemicals released sensitize **pain** nerve endings, causing the affected area to become itchy and sensitive.

A wide variety of substances may cause hives in sensitive people. Common culprits include:

- prescription and nonprescription drugs (Aspirin and penicillin are the two most commonly known causes of allergic reactions in adults.)
- nuts, especially peanuts, walnuts, and Brazil nuts
- fish, mollusks, and shellfish
- eggs
- wheat
- milk
- strawberries
- food additives and preservatives
- flu vaccines
- tetanus toxoid vaccine
- gamma globulin
- bee, wasp, and hornet stings
- bites of mosquitoes, fleas, and scabies.

In addition, hives may also be the body's response to certain physical conditions such as emotional **stress**, rubbing, cold wind, heat contact (**prickly heat** rash), wearing tight clothing, or **exercise** after a heavy meal.

Symptoms

Urticaria is characterized by redness, swelling, and itching of small areas of the skin. These patches usually grow and recede in less than a day, but may be replaced by others in other locations. Angioedema is characterized by more diffuse swelling. Swelling of the airways may cause **wheezing** and respiratory distress. In severe cases, airway obstruction may occur.

Diagnosis

Hives are easily diagnosed by visual inspection. The cause of hives is usually apparent, but may require a careful medical history in some cases.

Treatment

Home remedies

To deal with the symptoms of hives, an oatmeal bath may help to relieve itching. **Chickweed**, (*Stellaria media*), applied as a poultice (crushed or chopped herbs applied directly to the skin) or added to bath water, may also help relieve itching.

Nutritional therapy

Naturopaths or nutritionists will try to determine what allergic substance is causing the reaction and help the patient eliminate or minimize its effects. They may also recommend **vitamin C**, **vitamin B_{12}**, and **quercetin** (a flavonoid) supplements to help control acute or chronic hives.

Homeopathic therapy

The following homeopathic remedies have been used to relieve itching, redness or swelling associated with hives:

- urtica urens
- apis (Apis mellifica)
- sulfur

Allopathic treatment

Mild cases of hives are treated with antihistamines, such as diphenhydramine (Benadryl). More severe cases may require oral corticosteroids, such as prednisone. Topical corticosteroids are not effective. In 2002, the Food and Drug Administration (FDA) approved the allergy drug Claritin for over-the-counter use for patients with urticaria. The drug comes in tablet and syrup form and carries low risks. Its release for over-the-counter use was delayed until the company that manufactures the drug could add instructions for patients about self-diagnosis of hives. They cautioned it should only be used for recurrent hives that had already been diagnosed by a physician, not for acute or severe urticaria. Airway swelling may require emergency injection of epinephrine (adrenaline).

Expected results

Most cases of hives clear up within one to seven days without treatment, provided the cause (allergen) is found and avoided.

Prevention

Preventing hives depends on avoiding the allergen causing them. Analysis of new items in the diet or new drugs taken may reveal the likely source of the reaction. Chronic hives may be aggravated by stress, **caffeine**, alcohol, or tobacco; avoiding these may reduce the frequency of reactions.

Hodgkin's disease

Definition

Hodgkin's disease, also called Hodgkin's lymphoma, is a type of **cancer** involving tissues of the lymphatic system, or lymph nodes. Its cause is unknown, although some interaction between individual genetic makeup, family history, environmental exposures, and infectious agents is suspected.

Description

Hodgkin's lymphoma can occur at any age, although the majority of these lymphomas occur in people age 15–34, and over the age of 60. Lymphoma is a cancer of the lymphatic system. Depending on the specific type, a lymphoma can have any or all of the characteristics of cancer: rapid multiplication of cells, abnormal cell types, loss of normal arrangement of cells with respect to each other, and invasive ability.

KEY TERMS

Biopsy—The removal of a small sample of tissue, in order to carefully examine it under a microscope. This helps in the diagnosis of cancer, and can also reveal infection or inflammation.

Chemotherapy—Treatment for a disease involving various chemical or drug preparations; this term tends to refer to treatment for forms of cancer in particular.

Constitutional—Involving the whole body. A constitutional symptom, for example, is one that is not focused entirely in the diseased organ system, but affects the whole system (such as fever).

Radiation therapy —Also called radiotherapy, the treatment for a disease involving carefully measured exposure to radiation.

Staging—Using various methods of diagnosis to determine the extent of disease present in an individual. Staging is important as a way of determining the appropriate type of treatment for a particular disease, as well as helping to predict an individual's chance for cure from a particular disease.

Causes and symptoms

Hodgkin's lymphoma usually begins in a lymph node. The node enlarges and—similar to enlarged lymph nodes due to infectious causes—may or may not cause any **pain**. Hodgkin's lymphoma progresses in a fairly predictable way, traveling from one group of lymph nodes to another, unless it is treated. More advanced cases of Hodgkin's involve the spleen, liver, and bone marrow.

The features and prognosis of patients with Hodgkin's disease and non-Hodgkin's lymphoma (NHL) differ significantly. However, research in 2001 found that among patients with human immunodeficiency virus (HIV), Hodgkin's disease appears very similar to HIV-related non-Hodgkin's lymphoma. NHL occurs much more often in patients with HIV, but in recent years, a small but significant increase in Hodgkin's disease has been seen in HIV-infected patients.

Constitutional symptoms—symptoms that affect the whole body—are common. They include **fever**, weight loss, heavy sweating at night, and **itching**. Some patients note pain after drinking alcoholic beverages.

As nodes swell, they may push against nearby structures, resulting in other local symptoms. These symptoms include pain from pressure on nerve roots,

as well as loss of function of specific muscle groups served by the compressed nerves. Kidney failure may result from compression of the ureters, the tubes which carry urine from the kidneys to the bladder. The face, neck, or arms may swell due to pressure slowing the flow in veins that should drain blood from those regions (superior vena cava syndrome). Pressure on the spinal cord can result in leg paralysis. Compression of the trachea and/or bronchi (airways) can cause **wheezing** and shortness of breath. Masses in the liver can cause the accumulation of certain chemicals in the blood, resulting in jaundice—a yellowish discoloration of the skin and the whites of the eyes.

As Hodgkin's lymphoma progresses, a patient's immune system becomes less and less effective at fighting infection. Thus, patients with Hodgkin's lymphoma become increasingly more susceptible to both common **infections** caused by bacteria and unusual (opportunistic) infections caused by viruses, fungi, and protozoa.

Diagnosis

Diagnosis of Hodgkin's lymphoma requires the removal of a sample of a suspicious lymph node (biopsy) and careful examination of the tissue under a microscope. In Hodgkin's lymphoma, certain characteristic cells—Reed-Sternberg cells—must be present in order to confirm the diagnosis. These cells usually contain two or more nuclei—oval, centrally-located structures within cells that house their genetic material. In addition to the identification of these Reed-Sternberg cells, other cells in the affected tissue sample are examined. The characteristics of these other cells help to classify the specific subtype of Hodgkin's lymphoma.

Once Hodgkin's disease has been diagnosed, staging is the next important step. This involves computed tomography (CT) scans of the abdomen, chest, and pelvis, to identify areas of lymph node involvement. In rare cases, a patient must undergo abdominal surgery so that lymph nodes in the abdominal area can be biopsied (staging laparotomy). Some patients have their spleens removed during this surgery, both to help with staging and to remove a focus of the disease. Bone marrow biopsy is also required unless there is obvious evidence of vital organ involvement. Some physicians also order a lymphangiogram—a radiograph of the lymphatic vessels.

Staging is important because it helps to determine what kind of treatment a patient should receive. On one hand, it is important to understand the stage of the disease so that the treatment chosen is sufficiently strong to provide the patient with a cure. On the other hand, all the available treatments have serious side effects, so staging allows the patient to have the type of treatment necessary to achieve a cure, and to minimize the severity of short and long-term side effects from which the patient may suffer.

Treatment

Hodgkin's disease is a life-threatening disease, and a correct diagnosis and appropriate treatment with surgery, chemotherapy, and/or radiation therapy is critical to controlling the illness.

Acupuncture, **hypnotherapy**, and **guided imagery** may be useful tools in treating pain symptoms associated with Hodgkin's. Acupuncture involves the placement of a series of thin needles into the skin at targeted locations on the body known as acupoints in order to harmonize the energy flow within the human body.

In guided imagery, the patient creates pleasant and comfortable mental images that promote **relaxation** and improve a patient's ability to cope with discomfort and pain symptoms. Other guided imagery techniques involve creating a visual mental image of pain. Once the pain can be visualized, the patient can adjust the image to make it more pleasing, and thus more manageable, to them.

A number of herbal remedies are also available to lessen pain symptoms and promote relaxation and healing. However, individuals should consult with their healthcare professionals before taking them. Depending on the preparation and the type of herb, these remedies may interact with or enhance the effects of other prescribed medications.

Allopathic treatment

Treatment of Hodgkin's lymphoma has become increasingly effective over the years. The type of treatment used for Hodgkin's depends on the information obtained by staging, and may include chemotherapy (treatment with a combination of drugs), and/or radiotherapy (treatment with radiation to kill cancer cells).

Both chemotherapy and radiation therapy have unfortunate side effects. Chemotherapy can result in **nausea**, **vomiting**, **hair loss**, and increased susceptibility to infection. Radiation therapy can cause **sore throat**, difficulty in swallowing, **diarrhea**, and growth abnormalities in children. Both forms of treatment, especially in combination, can result in sterility (the permanent inability to have offspring), as well as heart and lung damage. A 2003 study showed a link between radiation therapy for Hodgkin's disease and increased risk for later **breast cancer**. However, adding chemotherapy to

the regimen decreased the chance for breast cancer, perhaps by inducing premature **menopause**.

Expected results

Hodgkin's is one of the most curable forms of cancer. Current treatments are quite effective, especially with early diagnosis. Children have a particularly high rate of cure from the disease, with about 75% still living cancer-free 20 years after their original diagnosis. Adults with the most severe form of the disease have about a 50% cure rate. In 2003, research noted that even after complete remission, some patients showed signs of thyroid dysfunction, most likely from the immune problems caused by Hodgkin's disease. They recommended thyroid examinations every year during follow-up of the disease.

Prevention

While Hodgkin's disease cannot be prevented, researchers continue to study risk factors for the disease. In 2003, a study showed a possible link between exposure to the **measles** virus around the time of **pregnancy** or birth. As research continues, these and other discoveries may help people control certain risk factors for Hodgkin's disease and other cancers.

Holistic dentistry

Definition

Holistic dentistry, also referred to as biologic dentistry, is an alternative approach that focuses on the use of non-toxic restorative materials for dental work and emphasizes the unrecognized impact that dental toxins and dental **infections** may have on a person's overall health. While traditional dentistry focuses only on the areas above the neck, holistic dentistry looks at the patient as a whole system and how the mouth relates to the rest of the body.

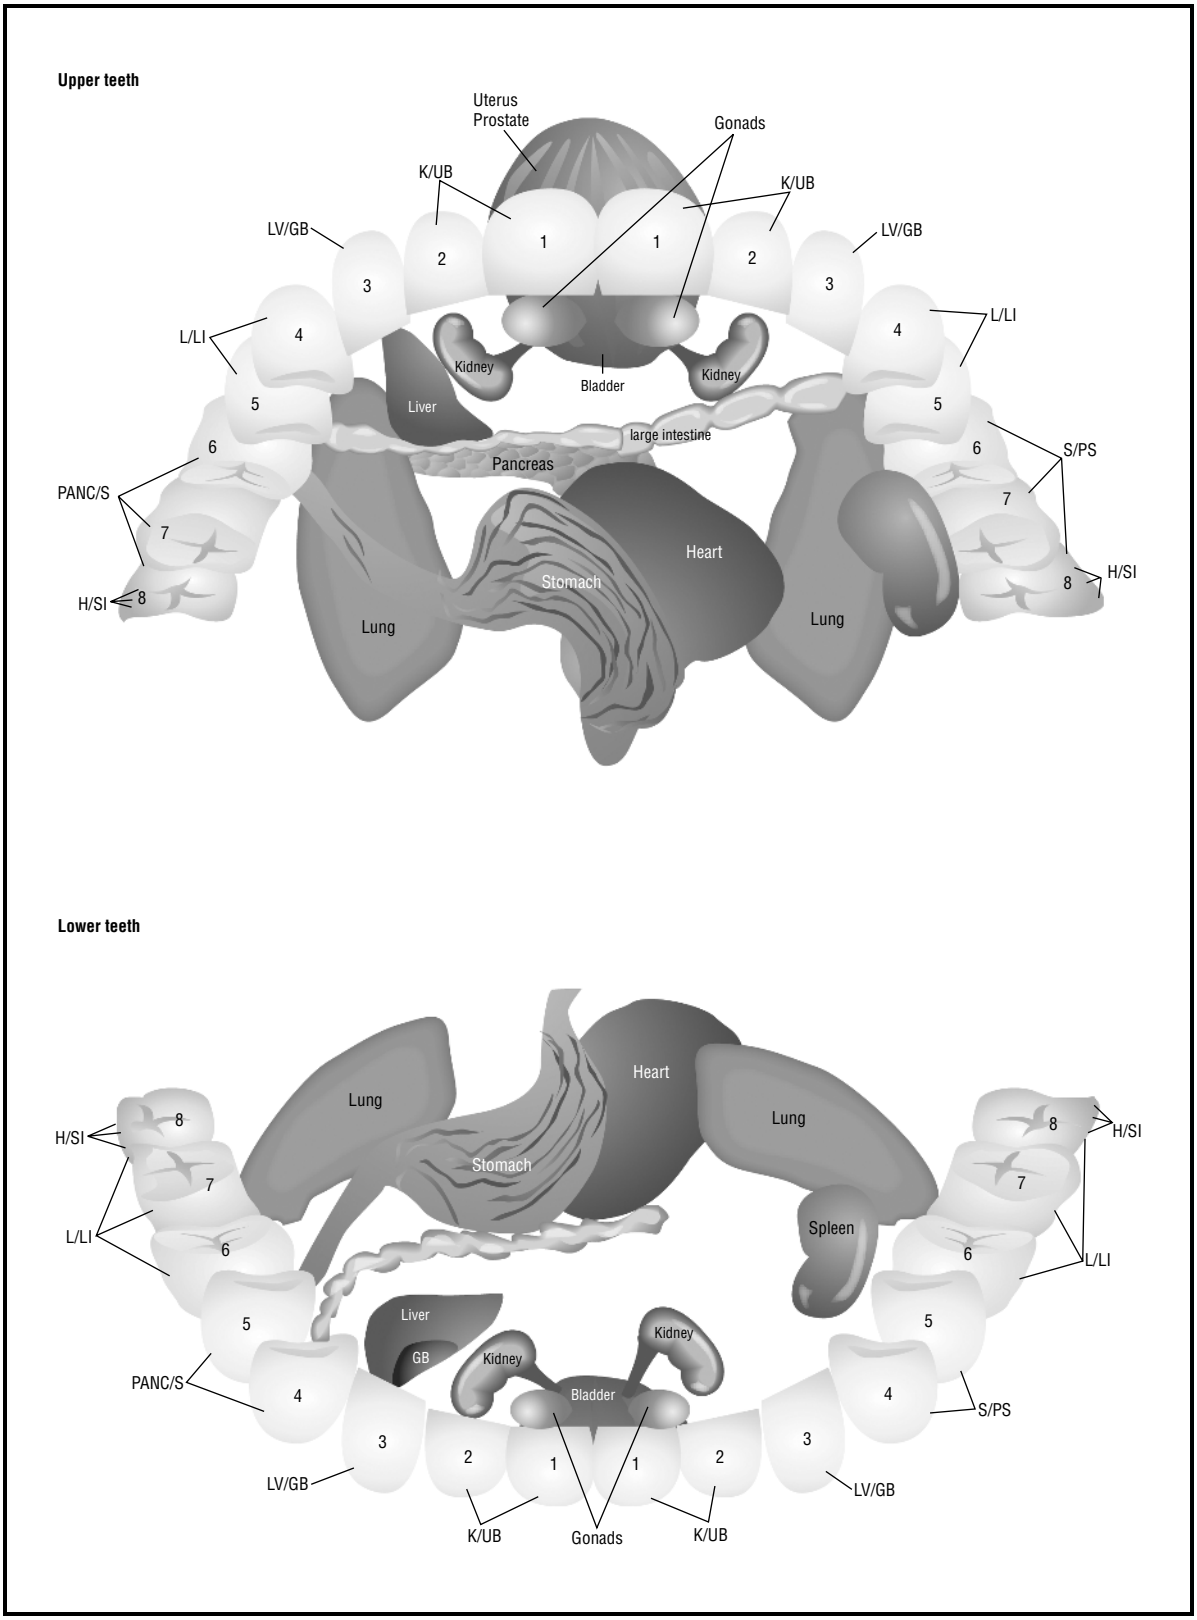
Origins

Applying a biological concept to the practice of dentistry began in the late 1800s when the National Dental Association recognized the harmful effects of mercury (amalgam) fillings and mandated that members of the association not use these on their patients. As of 1997, this warning had been recognized and acted upon by several foreign countries that have either banned the use of mercury fillings or were in the process of doing so. Supporters of holistic dentistry state that mercury in amalgam fillings causes ill effects when placed as an implant in the body.

Further beginnings of holistic dentistry are linked to a 1925 article by dentist Weston A. Price (1870–1948). A former director of research for the American Dental Association, Price claimed in an article for the *Journal of the American Medical Association* that degenerative diseases such as heart troubles, kidney and bladder disorders, arthritis, rheumatism, mental illness, lung problems, and several kinds of bacterial infections arise from root canal therapy, or endodontics. To come to this conclusion, Price conducted research that involved implanting teeth from root canals of individuals with symptoms such as severe heart problems and kidney disease under the skin of healthy rabbits. These same conditions arose in the rabbits, and within three days they died. Price then implanted the same tooth in another rabbit and found a similar response, but he also found that implanting a normal extracted tooth did not affect the rabbits.

Price's root canal research became known as the "focal infection" theory and because of its popularity, it led to the extraction of millions of endodontically treated teeth. Further research conducted during the 1930s ridiculed Price's theory calling it invalid, ending the once-recommended extractions.

Price also maintained that sugar causes not only tooth decay but is responsible for physical, mental,



Acupuncture points of teeth that correspond to major organs. *(Illustration by GGS Information Services, Inc. Cengage Learning, Gale)*

moral, and social decay. This judgment came about as he and anthropologist Francis Pottenger observed primitive areas throughout the world whose natives did not have cavities. Although concluding that the lack of sugar in their **diets** led to good oral health, critics have since pointed out that Price overlooked the fact that malnourished people do not typically get many dental cavities.

Support of Price's theories continued, especially from a dentist named Melvin Page. Page coined the phrase "balancing body chemistry" and considered tooth decay an "outstanding example of systemic chemical imbalances." In an attempt to aid these problems, Page marketed a mineral supplement with claims that widespread mineral deficiencies were an underlying cause of several health conditions, including goiter, heart trouble, **tuberculosis**, and diabetes. He also claimed that drinking cow's milk was unnatural and the underlying cause of colds, sinus infections, **colitis**, and cancer.There is no research supporting Price's statements, and his mineral supplement was never supported by the Federal Trade Commission (FTC).

The origins of holistic dentistry remain with Price's manuscripts and photographs at the Price-Pottenger **Nutrition** Foundation in La Mesa, California. Founded in 1965, the Foundation promotes nutrition, megavitamin therapy, **homeopathy**, and **chelation therapy**.

Founded in 1978, the Holistic Dental Association provides support to holistic dentists. Through a program of continuing education, the organization furthers the knowledge of alternative practices in dentistry. The International Academy of Biological Dentistry and Medicine supports the efforts of holistic dentists and medical doctors. The group was founded in 1985 by two California dentists and was renamed in 2005. Among its programs are professional educational seminars, presented to its members, covering topics related to holistic dentistry and medicine.

Since the late 1800s, supporters of holistic dentistry have continued to state their concerns regarding several procedures and recommendations of conventional dentistry, including the use of fluoride in drinking water and in teeth cleansers.

Benefits

Holistic dentistry is said to be an emerging new field of probiotic dental medicine—a type of medicine that supports the life process. Those who practice this form of biologic dentistry claim that it is aesthetic, relatively nontoxic, and individually biocompatible, or life supporting. A holistic dentist uses physiologic and electronic methods to locate areas of chronic disease that are difficult to locate by current standard methods.

The benefits of holistic dentistry are said to be the result of its incorporation of hypnosis, homeopathy, **aromatherapy**, nutrition, and herbology.

Hypnosis

When hypnosis is used, patients are able to relax their bodies and minds by concentrating on suggestions of **relaxation**. Patients are fully aware of what is happening during their treatment and no drugs are used. Many holistic dentists employ specialist hypnotherapists to provide treatment that is highly effective and cannot cause any harm or produce any side effects.

Homeopathy

Homeopathy is used by holistic dentists as a natural approach to their practice. The therapy is a safe and natural alternative that is nonaddictive and effective with both adults and children. Homeopathic remedies are used to improve the psychological or emotional condition of patients without the drugging effects of conventional tranquilizers. The three main remedies considered by holistic dentists are: **aconite** (**foxglove**); **gelsemium** (yellow jasmine); and *argentum nitricum* (silver nitrate).

Aromatherapy

Aromatherapy uses the pure oil essences from plants and flowers that act as hormone-like stimulants to improve a patient's health balance. Used because they are natural and gentle, oils such as **lavender**, bergamot, sandalwood, and basil are beneficial in their power to soothe, relax, and calm. Some holistic dentists use these oils to make their offices more inviting to patients.

Nutrition

Holistic dentists believe that **stress** and tension are often linked to diet. Dietary excesses or deficiencies increase the body's needs for essential vitamins and minerals, and the stress and tension accelerate any fears or **phobias** of the patient.

Botanical medicine & herbal medicine

Holistic dentistry may use herbs to promote relaxation. The sedative properties of **chamomile**, limeflower, vervain, **rosemary**, and **valerian** are relied upon in place of conventional drugs.

Holistic dentists may incorporate **acupuncture** and physical therapy into their use of clinical dentistry. The more modern sciences of **neural therapy**, hematology, immunology, and **electroacupuncture** may also be incorporated into a holistic dental practice.

Description

Biological dentistry's main concern is the toxicity of metals and their release from fillings and replacement appliances (such as metal partials and crowns that have nickel) used in dentistry. According to supporters of holistic dentistry, the metal ions separate from their original structures to diffuse, migrate to, and become absorbed in the tissues of the body, affecting the overall integrity of the immune system. An additional biological concern is what is called oral galvanism, or the direct electrical currents generated by separated metals throughout fluids and tissues in the body. Hidden or residual infection, or the abnormal changes in the soft connective tissue containing dental material that cannot be processed, is believed to cause local and general defenses that put the body in a continuous state of active conflict, often leading to chronic disease.

According to those who practice holistic dentistry, there may be several major types of dental problems that can cause illness or dysfunction in the body:

- silver (amalgam) fillings that typically contain 50% mercury silver
- root canals
- cavitations, or neuralgia-inducing cavitational osteonecrosis (NICO), a term coined by the oral pathologist J. E. Bouguot in the 1980s
- electro-oral galvanism from dissimilar metals
- temporomandibular joint syndrome (TMJ), a painful condition of the jaw and its supporting muscles used for chewing

The main goals of a holistic dentist are identifying areas that need treatment and providing treatment to patients that will not create stress. Holistic dentists work in conjunction with other healthcare providers to investigate whether a hidden infection of dental origin exists and whether it may be the source of or contributing factor to overall health problems. A biological approach to dentistry ensures the use of treatment and therapies that cause the least disturbance to the immune system. In order to determine the appropriate method of treatment, a holistic dentist must thoroughly review the patient's medical and dental background.

Preparations

While the method of biological dentistry varies for each holistic dentist, the keys to preparing their patients remain education and communication. Treatment is individualized.

A typical initial visit consists of an interview process, exam and x rays. Pictures of the patient's mouth are often collected with state-of-the-art equipment that uses film providing 50% less radiation than standard systems. The second meeting is typically called a Review of Findings appointment that educates the patient about the mouth and proactive treatment choices.

Precautions

Although proponents of holistic dentistry continue to increase, so do critics of these alternative methods. Believers in biologic dentistry claim that root canal-treated teeth cause NICO and other chronic systemic diseases and require removal of all these teeth and the healthy teeth surrounding them. Critics state that these extreme measures are bizarre and dangerous. According to a 1994 article in *Milwaukee Magazine*, a group of local patients filed suit against several holistic practitioners who had removed several of their perfectly healthy teeth after guaranteeing improvement of their diseases. These patients experienced no relief from their ongoing health problems after the extractions.

Side effects

Certain side effects have been reported as a result of treatments used by holistic dentists. Patients who were treated with **auriculotherapy**, or acupuncture of the ear, have experienced complications from unsterile needles.

When correcting a bad bite, holistic dentists often place a plastic appliance called a mandibular orthopedic repositioning appliance (MORA) between the teeth. The long-term use of MORAs has been reported to cause the patient's teeth to move out of proper alignment, leading to the need for orthodontics or facial reconstructive surgery to correct the deformity.

Since amalgam fillings are one of the main concerns of holistic dentists, many have turned to using nontoxic composite materials, but these too have come under scrutiny. The plastics used in the composites have been linked to leaching compounds that may be dangerous to health.

KEY TERMS

Homeopathy—The principal known as like cures like, the use of minute quantities of remedies that if used in large doses would produce the effects of the disease being treated.

Mercury—A metallic element appearing as a silver-colored liquid at ordinary temperatures.

Probiotic—Favoring the support of life; related to promoting life and life conditions.

Toxins—Poisonous substances of animal or plant origin having a protein structure.

Research and general acceptance

While dentistry has been reportedly undergoing a quiet revolution with the emergence of holistic dentists, their complementary methods remain under criticism. The nutritional supplements they prescribe to balance the body chemistry and the methods holistic dentists use to reach their recommended treatment continually attract negative comments. Hair analysis, computerized dietary analysis, or blood chemistry screening tests are used by some practitioners as a basis for recommending supplements. Critics state that hair analysis is not a reliable tool for measuring the body's nutritional state, and computer analysis, while useful for determining the composition of a person's diet, is being used by dentists who may not be qualified to perform dietary counseling. Blood chemistry screenings are processed in laboratories, but while the results may indicate a normal reading, holistic dentists use a narrower range to read the results, indicating to patients that their bodies are out of balance and need treatment.

Although supportive research is limited regarding the alternative methods used by holistic dentists, advocates of the complementary treatment continue to grow. With the formation of the Holistic Dental Association in 1978, a shift to treating the entire patient's health needs emerged from dentists, dental hygienists, and healthcare practitioners from all fields who endorse these ideas.

Many of the medical services provided by holistic dentists are paid for by healthcare insurance in the United States (excluding HMOs and Medicare). Insurance typically pays for what is termed usual and customary treatments, such as laboratory tests, doctor visits, medical treatment, and x rays, but it will not cover experimental drugs.

Training and certification

Holistic dentists are those who have been trained as authorized practitioners of dentistry through a school of medicine acquiring a degree as a doctor of dental surgery (DDS). Their focus is one that combines conventional teachings with new, complementary methods to treat their patients' health needs.

Holistic medicine

Definition

Holistic medicine is a term used to describe therapies that attempt to treat the patient as a whole person. That is, instead of treating an illness, as in orthodox allopathy, holistic medicine looks at an individual's overall physical, mental, spiritual, and emotional well-being before recommending treatment. A practitioner with a holistic approach treats the symptoms of illness as well as looking for the underlying cause of the

illness. Holistic medicine also attempts to prevent illness by placing a greater emphasis on optimizing health. The body's systems are seen as interdependent parts of the person's whole being. The body's natural state is one of health, and an illness or disease is an imbalance in the body's systems. Holistic therapies tend to emphasize proper **nutrition** and avoidance of substances—such as chemicals—that pollute the body. Their techniques are noninvasive.

Some of the world's health systems that are holistic in nature include **naturopathic medicine**, **homeopathy**, and **traditional Chinese medicine**. Many alternative or natural therapies have a holistic approach, although that is not always the case. The term complementary medicine is used to refer to the use of both allopathic and holistic treatments. It is more often used in Great Britain, but is gaining acceptance in the United States.

There are no limits to the range of diseases and disorders that can be treated in a holistic way, as the principle of holistic healing is to balance the body, mind, spirit, and emotions so that the person's whole being functions smoothly. When an individual seeks holistic treatment for a particular illness or condition, other health problems improve without direct treatment due to improvement in the performance of the immune system, which is one of the goals of holistic medicine.

Origins

The concept of holistic medicine is not new. In the 4th century B.C. Socrates warned that treating one part of the body only would not have good results. Hippocrates considered that many factors contribute to the health or otherwise of a human being, including weather, nutrition, emotional factors. In our time, a host of different sources of pollution can interfere with health. And of course, holistic medicine existed even before ancient Greece in some older healing traditions, such as those from India and China, which date back over 5,000 years. However, the term "holistic" only became part of everyday language in the 1970s, when Westerners began seeking an alternative to allopathic medicine.

Interestingly, it was only at the beginning of the twentieth century that the principles of holistic medicine fell out of favor in Western societies, with the advent of major advances in what we now call allopathic medicine. Paradoxically, many discoveries of the twentieth century have only served to confirm many natural medicine theories. In many cases, researchers have set out to debunk holistic medicine, only to find that their research confirms it, as has been the case, for example, with many herbal remedies.

KEY TERMS

Detoxification—Treating the body in such a way that it eliminates poisons accumulated in the cells.

Healing crisis—An uncomfortable condition that occurs When the body begins to eliminates toxins at an accelerated rate.

Benefits

Many people are now turning to holistic medicine, often when suffering from chronic ailments that have not been successfully treated by allopathic means. Although many wonderful advances and discoveries have been made in modern medicine, surgery and drugs alone have a very poor record for producing optimal health because they are designed to attack illness. Holistic medicine is particularly helpful in treating chronic illnesses and maintaining health through proper nutrition and **stress** management.

Description

There are a number of therapies that come under the umbrella of "holistic medicine." They all use basically the same principles, promoting not only physical health, but also mental, emotional, and spiritual health. Most emphasize quality nutrition. Refined foods typically eaten in modern America contain chemical additives and preservatives, are high in fat, **cholesterol**, and sugars, and promote disease. Alternative nutritionists counter refinded foods by recommending whole foods whenever possible and minimizing the amount of meat—especially red meat—that is consumed. Many alternative therapies promote **vegetarianism** as a method of **detoxification**.

The aim of holistic medicine is to bring all areas of an individual's life, and most particularly the energy flowing through the body, back into harmony. Ultimately, of course, only the patient can be responsible for this, for no practitioner can make the necessary adjustments to diet and lifestyle to achieve health. The practice of holistic medicine does not rule out the practice of allopathic medicine; the two can complement each other.

A properly balanced holistic health regimen, which takes into consideration all aspects of human health and includes noninvasive and nonpharmaceutical healing

methods, can often completely eradicate even acute health conditions safely. If a patient is being treated with allopathic medicine, holistic therapies may at least support the body during treatment, and alleviate the symptoms that often come with drug treatments and surgery. In addition, holistic therapies focus on the underlying source of the illness, to prevent recurrence.

Here are some of the major holistic therapies:

- herbal medicine
- homeopathy
- naturopathic medicine
- traditional Chinese medicine
- Ayurvedic medicine
- nutritional therapies
- chiropractic
- stress reduction
- psychotherapy
- massage.

Because holistic medicine aims to treat the whole person, holistic practitioners sometimes may advise treatment from more than one type of practitioner. This precaution ensures that all aspects of health are addressed. Some practitioners also specialize in more than one therapy and so may be able to offer more comprehensive assistance.

Preparations

To choose a holistic practitioner, a person should consider the following questions:

- How did you hear of this therapist? A personal referral can sometimes be more reliable than a professional one. What do other professionals say about this therapist? What qualifications, board certification, or affiliations does this practitioner have?
- How do you feel personally about this practitioner? Do you feel comfortable in his/her office and with his/her staff? Is your sense of well being increased? Are you kept waiting for appointments?
- Do you have confidence in this practitioner, does he/she respect you as a person? Does he/she show an interest in your family, lifestyle, and diet? Are various treatment options explained to you?
- Is your personal dignity respected?
- Do you feel that this practitioner is sensitive to your feelings and fears regarding treatment?
- Is this practitioner a good advertisement for his/her profession? Signs of stress or ill health may mean that you would be better off choosing another practitioner.
- Do you feel that you are rushed into decisions, or do you feel that you are allowed time to make an informed choice regarding treatment?
- Are future health goals outlined for you? And do you feel that the practitioner is taking your progress seriously?
- Do you feel unconditionally accepted by this practitioner?
- Would you send your loved ones to this practitioner?

If you answered yes to all the above, then you have found a suitable practitioner. The cost of treatment by a holistic therapist varies widely depending on the level of qualification and the discipline, so it is best to discuss how much treatment can be expected to cost with a practitioner before beginning a course of therapy. Some forms of holistic treatment may be covered by health insurance.

Precautions

Many people who try holistic therapies focus on one area of their health only, often detoxification and nutrition. However, practitioners stress that it is only when all areas of a person's potential well-being are tackled that total health and happiness can be achieved. They stress that the spiritual and emotional health contribute just as much as physical and mental health to a person's overall state of well-being.

When seeking treatment from a holistic practitioner, it is important to ensure that they are properly qualified. Credentials and reputation should always be checked. In addition, it is important that allopathic physicians and alternative physicians communicate with one another about a patient's care.

Side effects

One of the main advantages of holistic therapies is that they have few side effects when used correctly. If a reputable practitioner is chosen, and guidelines are adhered to, the worst that typically happens is that when lifestyle is changed, and fresh nutrients are provided, the body begins to eliminate toxins that may have accumulated in the cells over a lifetime.

Often holistic therapy results in what is known in alternative medicine circles as a "healing crisis." This comes about when the cells eliminate poisons into the blood stream all at the same time, throwing the system into a state of toxic overload until it can clear the "backlog." Symptoms such as **nausea**, headaches, or sensitivities to noise and other stimulations may be experienced.

The answer to most patients who are otherwise healthy patients is often just to lie quietly in a darkened room and take herbal teas. However, in the case of someone who has a serious illness, such as arthritis, **colitis**, diabetes, or **cancer**, it is strongly advised that they seek the help of a qualified practitioner. Therapists can help patients achieve detoxification in a way that causes the least stress to their bodies.

Research and general acceptance

Traditionally, holistic medicine, in all its different forms, has been regarded with mistrust and skepticism on the part of the allopathic medical profession. This situation is gradually changing. As of 2008, many insurance companies will provide for some form of alternative, or complementary treatment.

In addition, many allopathic physicians, recognizing the role alternative medicine can play in overall health and well being, are actually referring patients to reputable practitioners, particularly chiropractors and **relaxation** therapists, for help with a varied range of complaints.

Training and certification

Holistic or alternative medicine practitioners are usually affiliated with an organization in their field. Training varies widely with the category, and ranges from no qualifications at all—experience only—to holding a Ph.D. from an accredited university. Again, credentials and memberships should be checked by prospective patients.

An excellent source for qualified practitioners is the American Board of Holistic Medicine (AHBM), which was incorporated in 1996. Also, the American Holistic Medicine Association has a comprehensive list of practitioners in all types of therapies across the United States, which they call "the holistic doctor finder." However, these groups stress that it is the responsibility of the patient to check each practitioner's credentials prior to treatment.

The ABHM has established the core curriculum upon which board certification for holistic medicine will be based. It includes the following twelve categories:

Body

Physical and environmental health

- nutritional medicine
- exercise medicine
- environmental medicine

Mind

Mental and emotional health

- behavioral medicine

Spirit

Spiritual health

- spiritual attunement
- social health

The six specialized areas:

- biomolecular diagnosis and therapy
- botanical medicine
- energy medicine
- ethnomedicine—including traditional Chinese medicine, Ayurveda, and Native American medicine
- homeopathy
- manual medicine

Founded in 1978 for the purpose of uniting practitioners of holistic medicine, membership of the AHMA is open to licensed medical doctors (MDs) and doctors of osteopathic medicine (DOs) from every specialty, and to medical students studying for those degrees. Associate membership is open to health care practitioners who are certified, registered or licensed in the state in which they practice. The mission of the AHMA is to support practitioners in their personal and professional development as healers, and to educate physicians about holistic medicine.

Homeopathy

Definition

Homeopathy, or homeopathic medicine, is a holistic system of treatment that originated in the late eighteenth century. The name homeopathy is derived from two Greek words that mean "like disease." The system is based on the idea that substances that produce symptoms of sickness in healthy people will have a curative effect when given in very dilute quantities to sick people who exhibit those same symptoms. Homeopathic remedies are believed to stimulate the body's own healing processes. Homeopaths use the term "allopathy," or

Homeopathic remedies

Name	Description
Aconite	Commonly known as monkshood, aconite is highly toxic. A nontoxic, diluted extract of aconite is used in homeopathy to treat symptoms similar to that of poison.
Allium cepa	Commonly known as red onion, homeopathic physicians use a dilute extract of red onion to treat symptoms similar to that of hay fever - watery eyes, burning, etc.
Apis	Commonly known as the honeybee, apis as a homeopathic remedy is made from the body of the bee. It is used to treat symptoms similar to that of a bee sting - redness, swelling, etc.
Arnica	Commonly known as the mountain daisy, arnica is used by homeopathic physicians as an ingredient in anti-inflammatory preparations, mainly to treat bruises, sprains, and strains.
Arsenicum album	Also known as *ars alb*, *arsenicum album* is a diluted form of arsenic, a metallic poison. It is used by homeopathic physicians to treat symptoms similar to the effects of arsenic poisoning - dehydration, burning pain, etc.
Belladonna	Commonly known as deadly nightshade, belladonna is used in homeopathy to treat symptoms of dry mouth, nausea, delirium, etc., and is also thought to be an anti-spasmodic.
Bryonia	Commonly known as wild hops, bryonia is used in homeopathy to treat vomiting, diarrhea, inflammation, etc.
Calcarea carbonica	Also known as calcium carbonate or *calc carb*, it is used in homeopathy to treat symptoms of exhaustion, depression, and anxiety.
Cantharis	Commonly known as Spanish fly, cantharis is used in homeopathy to treat conditions with symptoms of abdominal cramps, vomiting, diarrhea, convulsions, etc.
Chamomilla	Derived from German chamomile, it is used in homeopathy to treat irritability, impatience, etc. It is most often prescribed to children.
Ferrum phosphoricum	Also known as *ferrum phos* or iron phosphate, it is used to treat symptoms of low energy and anemia.
Gelsemium	Also known as yellow jasmine, it is used to treat conditions that affect vision, balance, thought, and locomotion.
Hepar sulphuris	Derived from the inner layer of oyster shells, *hepar sulphuris* is used to treat infection.

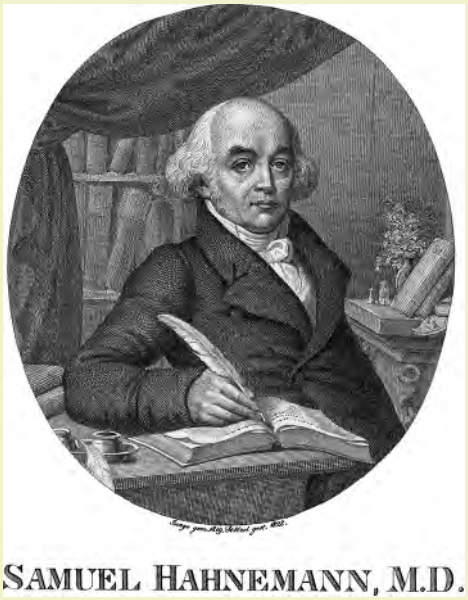
(Illustration by Corey Light. Cengage Learning, Gale)

Homeopathic remedies (CONTINUED)

Name	Description
Hypericum	Commonly known as St. John's wort, hypericum has historically been used to treat nerve damage and mental disorders, and is often used today to treat depression, anxiety, and sleep disorders.
Ignatia	Derived from seeds of a tree native to the Philippines, this homeopathic remedy is prescribed to treat conditions with symptoms such as headache, cramping, tremors, and nervous complaints.
Ipecac	Ipecac induces vomiting and causes gastrointestinal distress. Homeopaths prescribe it to treat similar symptoms.
Kali bichromicum	Commonly known as potassium bichromate, *kali bichromicum* is a poison used in textile dyes, wood stain, etc., as well as an oxidizing agent in photography. Homeopaths use it to treat localized pain.
Lachesis	Derived from the venom of the bushmaster snake, this homeopathic remedy is used to treat conditions that cause the same symptoms as the venom itself, which can include delirium tremen, tension and constriction, pressure, or even paralysis.
Ledum	Also known as marsh tea, ledum is used to treat infections, most often from animal bites, stings, cuts, etc.
Lycopodium	Commonly known as club moss, lycopodium is used to treat diarrhea, digestive upset, etc.
Mercurius vivus	Also known as quicksilver, it is used to treat symptoms of sweats, shaking, nausea, etc.
Natrum muriaticum	Commonly known as salt, it is used to treat conditions that cause excessive thirst and salt cravings.
Nux vomica	It is used to treat symptoms caused by overeating and too much caffeine or alcohol.
Phosphorus	It is used to treat symptoms of excessive thirst, fatigue, and nervousness.
Pulsatilla	It is used to treat conditions that are accompanied by discharge, such as bedwetting, sinusitis, etc.
Rhus toxicodendron	Commonly known as poison ivy, homeopaths use it to treat conditions with symptoms of fever, swollen glands, and restlessness.
Ruta	It is used to treat conditions with joint pain and tenderness and with bruising, such as tennis elbow, sciatica, etc. Also used to treat certain problems of the eyes and uterus, such as eyestrain and menstrual pain.
Sepia	Sepia is the discharge used by the cuttlefish to disappear from a predator. Homeopaths use sepia to treat symptoms of apathy and weakness.
Silica	Also called flint, silica is used by homeopaths to treat conditions that cause weakness, sweating, and sensitivity to cold.
Sulphur	It is used to treat conditions with symptoms of itching, burning pains, and odor.

(Illustration by Corey Light. Cengage Learning, Gale)

SAMUEL HAHNEMANN (1755–1833)



(Corbis Corporation. Reproduced by permission.)

Samuel Christian Hahnemann created and developed the system called homeopathy. It is also known as *similia similibus curentor* or like cures like. Although his new methods initially met with ridicule and criticism, by the time of his death they were accepted the world over as a result of the great success he had with his new cure.

Hahnemann was born in Meissen, Saxony (now part of Germany) into a financially challenged middle class family. His parents initially educated him at home, where his father taught him never to accept anything he learned without first questioning it. He graduated as a physician at Erlangen in 1779 after studying at Leipzig and Vienna. He was also fluent in English, German, Italian, French, Greek, Arabic, Latin and Hebrew.

At age 27 he married his first wife, Johanna Henriette Kuchler, the daughter of an apothecary, with whom he had 11 children.

Living in poverty, Hahnemann began practicing medicine in 1781 and translating scientific texts to supplement his income. However, disillusioned with medicine, he eventually gave it up entirely.

He discovered the concept of homeopathy when considering the effect of quinine on malaria, and went on to cure soldiers and then sufferers of a typhus epidemic with astounding success. He documented his discoveries in the *Organon*, a treatise on his work. Homeopathy also proved it's worth in 1831 when there was an outbreak of cholera. Hahnemann used homeopathic treatment with a 96% success rate, compared to the 41% of allopathic medicine. He also wrote his *Materia Medica Pura.*

In 1834, Hahnemann met his second wife, Marie Melanie d'Hervilly. Despite a great difference in age, they were happily married until his death in Paris on July 2, 1843, at the age of 88.

"different disease," to describe the use of drugs used in conventional medicine to oppose or counteract the symptom being treated.

Origins

Homeopathy was founded by the German physician Samuel Hahnemann (1755-1843), who was much disturbed by the medical system of his time, believing that its cures were crude and some of its strong drugs and treatments did more harm than good to patients. Hahnemann performed experiments on himself using Peruvian bark, which contains quinine, a **malaria** remedy. He concluded that in a healthy person, quinine creates the same symptoms as malaria, including fevers and **chills**, which is the reason why it is effective as a remedy. He then began to analyze the remedies available in nature by what he called provings. Provings of homeopathic remedies are still compiled by dosing healthy adults with various substances and documenting the results, in terms of the dose needed to produce the symptoms and the length of the dose's effectiveness. The provings are collected in large homeopathic references called *materia medica* or materials of medicine.

Hahnemann formulated these principles of homeopathy:

- Law of Similars (like cures like)
- Law of the Infinitesimal Dose (The more diluted a remedy is, the more potent it is.)
- Illness is specific to the individual.

Hahnemann's Law of Similars was based on thinking that dated back to Hippocrates in the fourth century B.C. It is the same thinking that provided the basis for the vaccines discovered by Edward Jenner and Louis Pasteur. These vaccines provoke a reaction in the individual that protects against the actual disease. Allergy treatments work the same way. By

KEY TERMS

Aggravation—Temporary increase in symptoms due to homeopathic remedy.

Antidote—Substance which cancels the effect of homeopathic remedies

Homeopath—A homeopathic physician.

Proving—Case study of the effect of a homeopathic medicine.

Repertory—Reference manual of homeopathic remedies.

Vital force—Innate wisdom and energy of the body.

exposing a person to minute quantities of the allergen, the person's tolerance levels are elevated.

The Law of the Infinitesimal Dose has always caused controversy among those outside the field of homeopathy. Hahnemann contended that as he diluted his remedies with water and alcohol and succussed, or shook, them, the remedies actually worked more effectively. In fact, diluted homeopathic remedies may have no chemical trace of the original substance. Practitioners believe that the electromagnetic energy of the original substance is retained in the dilution, but the toxic side effects of the remedy are not. It is this electrochemical "message" that stimulates the body to heal itself.

Homeopathic practitioners believe that illness is specific to an individual. In other words, two people with severe headaches may not receive the same remedies. The practitioner will ask the patient questions about lifestyle, dietary habits, and personality traits, as well as specific questions about the nature of the **headache** and when it occurs. This information gathering is called profiling or case-taking.

In the early 1900s, homeopathy was popular in America, with over 15 percent of all doctors being homeopaths. There were 22 major homeopathic medical schools, including Boston University and the University of Michigan. However, with the formation of the American Medical Association, which restricted and closed down alternative practices, homeopathy declined for half a century. When the 1960s revived back-to-nature trends and distrust of artificial drugs and treatments, homeopathy began to grow again dramatically through the next decades. In 1993, *The New England Journal of Medicine* reported that 2.5 million Americans used homeopathic remedies and 800,000 patients visited homeopaths in 1990, and homeopathy has continued to grow. Homeopathy is much more popular in Europe than in the United States. French pharmacies are required to make homeopathic remedies available along with conventional medications. Homeopathic hospitals and clinics are part of the national health system in Britain. Homeopathy is also practiced in India and Israel, among other countries.

Benefits

Homeopathic physicians seek to cure their patients on the physical, mental and emotional levels, and each treatment is tailored to a patient's individual needs. Homeopathy is generally a safe treatment, as it uses medicines in extremely diluted quantities, and there are usually minimal side effects. Its nontoxicity makes some consider it a good choice for the treatment of children. Another benefit of homeopathy is the cost of treatments; homeopathic remedies are inexpensive, often a fraction of the cost of conventional drugs.

Homeopathic treatment has been shown to be effective in treating many conditions. Colds and flu may be effectively treated with **aconite** and **bryonia**. **Influenza** sufferers in a double-blind study found that they were twice as likely to recover in 48 hours when they took homeopathic remedies. Studies have been published in British medical journals confirming the efficacy of homeopathic treatment for **rheumatoid arthritis**. Homeopathic remedies are considered effective in treating **infections**, circulatory problems, respiratory problems, **heart disease**, **depression** and nervous disorders, migraine headaches, **allergies**, arthritis, and diabetes. Homeopathy is a treatment to explore for acute and chronic illnesses, particularly if these are found in the early stages and where there is not severe damage. Homeopathy can be used to assist the healing process after surgery or chemotherapy.

Description

A visit to a homeopath is usually a different experience from a visit to a regular physician. Surveys have shown that homeopathic doctors spend much more time during initial consultations than conventional doctors spend. This is because a homeopath does a thorough case-taking to get a complete picture of a person's general health and lifestyle, as well as particular symptoms, on the physical, mental and emotional levels. Some symptoms can be so subtle that the patient is not always completely aware of them, and the doctor must spend time getting to know the patient.

The initial visit often includes a long questionnaire about a patient's medical and family history,

and then a long interview with the doctor, who prompts the patient with many questions. Sometimes a homeopathic doctor will use lab tests to establish a patient's general level of health. The initial interview usually lasts between one and two hours.

The purpose of homeopathy is the restoration of the body to homeostasis, or healthy balance, which is its natural state. The symptoms of a disease are regarded as the body's own defensive attempts to correct its imbalance, rather than as enemies to be defeated. Because a homeopath regards symptoms as positive evidence of the body's inner intelligence, he or she will prescribe a remedy designed to stimulate this internal curative process rather than suppress the symptoms.

In homeopathy, the curative process extends beyond the relief of immediate symptoms of illness. Healing may come in many stages, as the practitioner treats layers of symptoms that are remnants of traumas or chronic disease in the patient's past. The stages are related to Hering's Laws of Cure, named for Constantine Hering, the father of homeopathy in America. Hering believed that healing starts from the deepest parts of the body to the extremities, and from the upper parts of the body to the lower parts. Hering's Laws also state that homeopaths should treat disease symptoms in reverse chronological order, from the most recent to the oldest, restoring health in stages. Sometimes, the patient may feel worse before feeling better. This temporary worsening is called a healing crisis.

When prescribing a remedy, homeopaths will match a patient's symptoms with the proper remedy in a repertory or *materia medica* that has been compiled throughout the history of homeopathy. Classical homeopaths prescribe only one remedy at a time. However, it is becoming more common, especially in Europe, to use combination formulas of several remedies for the treatment of some combinations of symptoms.

The cost of homeopathic care can vary. The cost of visits will be comparable to conventional medicine, with initial visits ranging from $50 to $300. Non-M.D. homeopaths can charge from $50 to $250. Follow-up visits are less, at about $35 to $100. Homeopathic medicine is significantly cheaper than pharmaceuticals, and most remedies cost between $2 and $10. Some doctors provide remedies without charge. Homeopaths rarely use lab tests, which reduces the cost of treatment further. In general, homeopathy is much more economical than conventional medicine. In 1991, the French government did a study on the cost of homeopathic medicine, and found that it costs half as much to treat patients, considering all costs involved.

When homeopaths are licensed professionals, most insurance companies will pay for their fees. Consumers should consult their insurance policies to determine individual regulations. Insurance usually will not cover homeopathic medicine, because it is sold over-the-counter.

Precautions

Although homeopathic remedies sometimes use substances that are toxic, they are diluted and prescribed in nontoxic doses. Remedies should be prescribed by a homeopathic practitioner. Those preparing to take homeopathic remedies should also avoid taking antidotes, which are substances that homeopathic doctors believe cancel the effects of their remedies. These substances include alcohol, coffee, prescription drugs, **peppermint** (in toothpaste and mouthwash), camphor (in salves and lotions), and very spicy foods. Homeopathic medicine should also be handled with care, and should not be touched with the hands or fingers, which may contaminate it.

Side effects

A homeopathic aggravation sometimes occurs during initial treatment with homeopathic remedies. This term means that symptoms can temporarily worsen during the process of healing. Although this is usually mild, the aggravation can sometimes be severe. Homeopaths see aggravation as a positive sign that the remedy is a good match for the patient's symptoms. The healing crisis, which happens when the patient is undergoing treatment for layers of symptoms, may also cause the patient to feel worse before feeling better. Some patients can experience emotional disturbances like weeping or depression, if suppressed emotional problems led to the illness in the first place.

Research and general acceptance

Since the early 1900s, when the American Medical Association and pharmacists waged a battle against it, homeopathy has been neglected and sometimes ridiculed by mainstream medicine. Aside from politics, part of the reason for this hostility is that there are some aspects of homeopathy that have not been completely explained scientifically. For instance, homeopaths have found that the more they dilute and succuss a remedy, the greater effect it seems to have on the body. Some homeopathic remedies are so diluted that not even a single molecule of the active agent remains in a solution, yet it still works; studies have demonstrated this paradox, yet can't explain it. Also, homeopathy puts an emphasis on analyzing symptoms and then applying remedies to these symptoms, rather than

working by classifying diseases. Thus, some people with the same disease may require different homeopathic medicines and treatments. Furthermore, conventional medicine strives to find out how medicines work in the body before they use them; homeopathy is less concerned with the intricate biochemistry involved than with whether a remedy ultimately works and heals holistically. For all these reasons, conventional medicine claims that homeopathy is not scientific, but homeopaths are quick to reply that homeopathy has been scientifically developed and studied for centuries, with much documentation and success.

There continue to be many studies that affirm the effectiveness of homeopathic treatments. Among the most celebrated, the *British Medical Journal* in 1991 published a large analysis of homeopathic treatments that were given over the course of 25 years. This project involved more than 100 studies of patients with problems ranging from vascular diseases, respiratory problems, infections, stomach problems, allergies, recovery from surgeries, arthritis, trauma, psychological problems, diabetes, and others. The study found improvement with homeopathic treatment in most categories of problems, and concluded that the evidence was "sufficient for establishing homeopathy as a regular treatment for certain indications."

For example, a study in early 2002 was reported on in a pediatric journal that showed symptom improvement for children with uncomplicated acute otitis media (**ear infection**) who received individualized homeopathic remedies. Although the authors concluded that more research was needed, results were positive enough to justify a larger study.

Training and certification

The Council on Homeopathic Education is the only organization that accredits training programs in classical homeopathy. To date, it has accredited five institutions: Bastyr University of Natural Health Sciences in Seattle, Ontario College of **Naturopathic Medicine** in Toronto, Hahnemann Medical Clinic in Albany, California, the National College of Naturopathic Medicine in Portland, and the International Foundation for Homeopathy, also in Seattle. Other well-known training programs include the Pacific Academy of Homeopathic Medicine in Berkeley, California, and the New England School of Homeopathy in Amherst, Massachusetts.

There are several organizations that certify homeopathic practitioners:

- The National Center for Homeopathy is the largest homeopathic organization, with more than 7,000 members. It also runs the Council on Homeopathic Education, and provides a listing of all its members and their credentials. Address: 801 N. Fairfax St., #306, Alexandria, VA 22314, phone (703) 548-7790.
- The American Institute of Homeopathy is the oldest national medical body. It provides a list of D.Ht.s (Diplomate in Homeopathy) certified by the American Board of Homeotherapeutics. Address: 1585 Glencoe, Denver, CO 80220, phone (303) 898-5477.
- The Council for Homeopathic Certification was created in 1992 to establish a certification exam and a code of ethics. It confers upon qualified practitioners a C.C.H. (Certification in Classical Homeopathy). Address: P.O. Box 157, Corte Madera, CA 94976.
- The Homeopathic Academy of Naturopathic Physicians offers a certification based on a competency exam, the "Diplomate in the Homeopathic Academy of Naturopathic Physicians" (D.H.A.N.P.).
- The North American Society of Homeopaths certifies non-physician homeopaths. Address: 10700 Old County Rd. 15, #350, Minneapolis, MN 55441, phone (612) 593-9458.

Homeopathy, acute prescribing

Definition

Acute homeopathic prescribing is that part of **homeopathy** that treats illnesses of abrupt onset requiring immediate attention. In homeopathic medicine, acute refers primarily to the speed of onset and self-limiting character of the disorder rather than its seriousness. Colds, **influenza**, sore throats, insect **stings**, **cuts**, **bruises**, **vomiting**, **diarrhea**, **fever**, muscle aches, and short-term **insomnia** are all examples of conditions that are treated by acute prescribing. The remedies given in acute homeopathic prescribing are intended to stimulate the body's internal ability to heal itself; they do not kill germs or suppress symptoms. Acute prescribing can be done—within limits—by patients at home, as well as by homeopathic practitioners. Study courses, self-treatment guides, and homeopathic home medicine kits are now available by mail order from homeopathic pharmacies and educational services.

Origins

Homeopathy is a gentle, painless, holistic system of healing developed during the 1790s by Samuel Hahnemann, a German physician. Experimenting on himself with the anti-malarial drug quinine, Hahnemann noticed that large doses of the medicine actually caused malaria-like symptoms, while smaller doses cured the symptoms. From this, he advanced his concept of *Similia similibus curentur*, or "let like be cured with like." Hahnemann then developed an extensive system of medicine based on this concept. He named it homeopathy, from the Greek words *homoios* (the same) and *pathos* (suffering).

Homeopathic remedies are almost always made from natural materials—plant, animal, or mineral substances—that have been treated to form mother tinctures or nonsoluble powders. Liquid extracts are then potentized, or increased in power, by a series of dilutions and succussions, or shakings. It is thought that succussion is necessary to transfer the energy of the natural substance to the solution. In addition, the potency of the remedy is regarded as increasing with each dilution. After the tincture has been diluted to the prescribed potency, the resulting solution is added to a bottle of sucrose/lactose tablets, which are stored in a cool, dark place. If the remedy is not soluble in water, it is ground to a fine powder and triturated with powdered lactose to achieve the desired potency.

KEY TERMS

Acute prescribing—Homeopathic treatment for self-limiting illnesses with abrupt onset.

Allopathy—Conventional medical treatment of disease symptoms that uses substances or techniques to oppose or suppress the symptoms.

Law of similars—The basic principle of homeopathic medicine that governs the selection of a specific remedy. It holds that a substance of natural origin that produces certain symptoms in a healthy person will cure those same symptoms in a sick person.

Modalities—The factors and circumstances that cause a patient's symptoms to improve or worsen.

Mother tincture—The first stage in the preparation of a homeopathic remedy, made by soaking a plant, animal, or mineral product in a solution of alcohol.

Potentization—The process of increasing the power of homeopathic preparations by successive dilutions and succussions of a mother tincture.

Succussion—The act of shaking diluted homeopathic remedies as part of the process of potentization.

Trituration—The process of diluting a nonsoluble substance for homeopathic use by grinding it to a fine powder and mixing it with lactose powder.

Proponents of homeopathy over the years have included Louisa May Alcott, Charles Dickens, Benjamin Disraeli, Johann Wolfgang Goethe, Nathaniel Hawthorne, William James, Henry Wadsworth Longfellow, Pope Pius X, John D. Rockefeller, Harriet Beecher Stowe, William Thackeray, Daniel Webster, and W. B. Yeats. England's royal family has employed homeopathic practitioners since the 1830s.

Benefits

Homeopathic physicians seek to cure their patients on physical, mental, and emotional levels, and each treatment is tailored to a patient's individual needs. Homeopathy is generally a safe treatment, as it uses medicines in extremely diluted quantities, and there are usually minimal side effects. Its non-toxicity makes it a good choice for the treatment of children. Another benefit of homeopathy is the cost of treatments; homeopathic remedies are inexpensive, often a fraction of the cost of conventional drugs.

Acute homeopathic prescribing is thought to benefit a wide range of ailments. These include altitude sickness, Bell's palsy, the **common cold**, **allergies**,

coughing, dengue fever, dysentery, earaches, migraine headaches, fever, **food poisoning**, grief, influenza, **motion sickness**, shock, **sore throat**, surgical complications, and reactions to vaccinations and drug therapy. Acute remedies may also be prescribed for treat insect stings, animal **bites**, and problems related to poison **oak** and poison ivy. It may be further employed in treating injuries including black eyes, **burns**, bruises, concussions, cuts, damaged tendons and ligaments, dislocations, **fractures**, herniated discs, **nosebleeds**, puncture **wounds**, **sprains**, and **strains**.

Description

Homeopathic prescribing differs in general from allopathic medicine in its tailoring of remedies to the patient's overall personality type and totality of symptoms, rather than to the disease. Whereas a conventional physician would prescribe the same medication or treatment regimen to all patients with the common cold, for example, a homeopathic practitioner would ask detailed questions about each patient's symptoms and the modalities, or factors, that make them better or worse. As a result, the homeopath might prescribe six different remedies for six different patients with the same illness. In acute prescribing homeopathy, consultations are more brief compared to constitutional homeopathic prescribing. A typical patient might spend just 10–15 minutes with the practitioner, compared to more than an hour for constitutional prescribing.

Homeopathic classification of symptoms

Homeopathic practitioners use the word symptom in a more inclusive fashion than traditional medicine. In homeopathy, symptoms include any change that the patient experiences during the illness, including changes in emotional or mental patterns.

Homeopaths classify symptoms according to a hierarchy of four categories for purposes of acute prescribing:

- Peculiar symptoms. These are symptoms unique to the individual that do not occur in most persons with the acute disease. Homeopaths make note of peculiar symptoms because they often help to determine the remedy.
- Mental and emotional symptoms. These are important general symptoms that inform the homeopath about the patient's total experience of the disorder.
- Other general symptoms. These are physical symptoms felt throughout the patient's body, such as tiredness, changes in appetite, or restlessness.
- Particular symptoms. Particular symptoms are localized in the body; they include such symptoms as nausea, skin rashes, headache, etc.

During homeopathic case-taking, the practitioner will evaluate the intensity of the patient's symptoms, assess their depth within the patient's body, note any peculiar symptoms, evaluate the modalities of each symptom, and make a list of key symptoms to guide the selection of the proper medicine.

Homeopathic remedies

There are several hundred homeopathic remedies. Homeopathic medicines are usually formulated from diluted or triturated natural substances, including plants, minerals, or even venom from snakes or stinging insects. Some remedies may be given in a spray, ointment, or cream, but the most common forms of administration are liquid dilutions and two sizes of pellets, or cylindrical tablets (for triturated remedies). A dose consists of one drop of liquid; 10–20 small pellets; or 1–3 large pellets. Since the remedies are so dilute, the exact size of the dose is not of primary importance. The frequency of dosing is considered critical, however; patients are advised not to take further doses until the first has completed its effect.

Homeopathic remedies can be kept indefinitely with proper handling. Proper handling includes storing the remedies in the original bottles and discarding them if they become contaminated by sunlight or other intense light; temperatures over 100°F (37.8°C); vapors from camphor, mothballs, or perfume; or from other homeopathic remedies being opened in the same room at the same time.

Preparations

Case-taking

The first step in acute prescribing is a lengthy interview with the patient, known as case-taking. In addition to noting the character, location, and severity of the patient's symptoms, the homeopath will ask about their modalities. The modalities are the circumstances or factors (e.g., weather, time of day, body position, behavior or activity, etc.) that make the symptoms either better or worse. Case-taking can be done by the patient or a family member as well as by a homeopath.

Selection and administration of a remedy

The choice of a specific remedy is guided by the patient's total symptom profile rather than by the illness. Homeopathic remedies are prescribed according

to the law of similars, which holds that a substance that produces specific symptoms in healthy people cures those symptoms in sick people when given in highly diluted forms. For example, a patient with influenza who is irritable, headachy, and suffering from joint or muscle pains is likely to be given *bryonia* (wild **hops**), because this plant extract would cause this symptom cluster in a healthy individual.

Patients are instructed to avoid touching homeopathic medicines with their fingers. The dose can be poured onto a piece of white paper or the bottle's cap and tipped directly into the mouth. Homeopathic remedies are not taken with water; patients should not eat or drink anything for 15–20 minutes before or after taking the dose.

Precautions

Homeopathic acute prescribing is not recommended for the treatment of chronic conditions requiring constitutional prescribing, for severe **infections** requiring antibiotic treatment, or for conditions requiring major surgery. It is also not recommended for the treatment of mental health problems.

Persons who are treating themselves with homeopathic remedies should follow professional guidelines regarding the limitations of home treatment. Most homeopathic home treatment guides include necessary information regarding symptoms and disorders that require professional attention.

Homeopathic remedies may lose their potency if used at the same time as other products. Some homeopathic practitioners recommend the avoidance of mint and mentholated products (toothpastes, candies, chewing gum, mouth rinses), as well as camphor and camphorated products (including **eucalyptus** and Tiger Balm), patchouli and other **essential oils**, moth balls, strong perfumes, aftershaves, scented soaps, **stress**, x rays, coffee, nicotine, recreational drugs (**marijuana**) and certain therapeutic drugs (most notably cortisone and prednisone) during treatment. Patients are also advised to avoid electric blankets and dental work, as these are thought to adversely affect homeopathic therapy. Homeopathic remedies should never be placed near magnets.

Practitioners caution that high-potency preparations should be used only under the supervision of a homeopathic practitioner.

Side effects

Homeopathic medicines are so diluted that sometimes no trace of the original substance can be detected. These medicines are therefore considered non-toxic and generally free of harmful side effects. There may, however, be individual reactions to homeopathic medicine.

An intensified healing response may occur as treatment begins, which causes symptoms to worsen, but the phenomenon is temporary. In some patients, old symptoms may reappear from past conditions from which recovery was not complete. Such phenomena are taken as positive indications that the healing process has commenced.

Research and general acceptance

As Samuel Hahnemann's healing system grew in popularity during the 1800s, it quickly attracted vehement opposition from the medical and apothecary professions. Since the early 1900s, when the American Medical Association and pharmacists waged a battle against it, homeopathy has been neglected and sometimes ridiculed by mainstream medicine. Aside from politics, part of the reason for this hostility is that there are some aspects of homeopathy which have not been completely explained scientifically. For instance, homeopaths have found that the more they dilute and succuss a remedy, the greater effect it seems to have on the body. Some homeopathic remedies are so diluted that not even a single molecule of the active agent remains in a solution, yet homeopaths maintain it still works. Also, homeopathy puts an emphasis on analyzing symptoms and then applying remedies to these symptoms, rather than working by classifying diseases. Thus, some people with the same disease may require different homeopathic medicines and treatments. Furthermore, conventional physicians strive to find out how medicines work in the body before they use them; homeopathy is less concerned with the intricate biochemistry involved than with whether a remedy ultimately works and heals holistically. For all these reasons, conventional medicine claims that homeopathy is not scientific, while homeopaths are quick to reply that homeopathy has been scientifically developed and studied for centuries with much documentation and success.

There continue to be many studies on the effectiveness of homeopathic treatments. Among the most celebrated, the *British Medical Journal*, published a large analysis of homeopathic treatments in 1991 that were given over the course of 25 years. This project involved more than 100 studies of patients with problems ranging from vascular diseases, respiratory problems, infections, stomach problems, allergies, recovery from surgeries, arthritis, trauma, psychological problems, diabetes, and others. The study found improvement with homeopathic treatment in most categories of

problems, and concluded that the evidence was "sufficient for establishing homeopathy as a regular treatment for certain indications."

A 2002 pediatric journal article reported on a study that showed some individualized homeopathic remedies eased the symptoms of uncomplicated acute otitis media (ear infections) in children. While the authors admitted more research was needed, they said the positive results justified further study on homeopathic remedies for childhood ear infections.

In the United Kingdom and other countries where homeopathy is especially popular, some medical doctors incorporate aspects of acute prescribing homeopathy into their practices. Countries in which homeopathy is popular include France, India, Pakistan, Sri Lanka, Brazil, and Argentina. Large homeopathic hospitals exist in London and Glasgow, and homeopathic medical centers can be found in India and South America.

Training and certification

It takes three to four years of training to become a qualified homeopath. Naturopathic physicians study homeopathy during their four-year medical school programs, and other practitioners may study homeopathy in post-graduate courses. The Council on Homeopathic Education is the only organization that accredits training programs in classical homeopathy. To date, it has accredited five institutions: Bastyr University of Natural Health Sciences in Seattle, Washington; Ontario College of **Naturopathic Medicine** in Toronto; Hahnemann Medical Clinic in Albany, California; the National College of Naturopathic Medicine in Portland, Oregon; and the International Foundation for Homeopathy, also in Seattle. Other well-known training programs include the Pacific Academy of Homeopathic Medicine in Berkeley, California, and the New England School of Homeopathy in Amherst, Massachusetts.

There are several organizations that certify homeopathic practitioners:

- The National Center for Homeopathy is the largest homeopathic organization, with more than 7,000 members. It also runs the Council on Homeopathic Education, and provides a listing of all its members and their credentials.
- The American Institute of Homeopathy is the oldest national medical body. It provides a list of D.Ht.s (Diplomate in Homeopathy) certified by the American Board of Homeotherapeutics.
- The Council for Homeopathic Certification was created in 1992 to establish a certification exam and a code of ethics. It confers upon qualified practitioners a C.C.H. (Certification in Classical Homeopathy).
- The Homeopathic Academy of Naturopathic Physicians offers a certification based on a competency exam, the "Diplomate in the Homeopathic Academy of Naturopathic Physicians" (D.H.A.N.P.).
- The North American Society of Homeopaths certifies non-physician homeopaths.

Homeopathy, constitutional prescribing

Definition

Constitutional homeopathic prescribing, also called classical prescribing, is a holistic system of medicine that has been practiced for more than 200 years.

Unlike acute homeopathic prescribing, constitutional prescribing refers to the selection and administration of homeopathic preparations over a period of time for treatment related to what practitioners call miasmic disorders, those caused by an inherited predisposition to a disease. The term miasm comes from a Greek word meaning stain or pollution. As in acute prescribing, constitutional prescribing is holistic in that it is intended to treat the patient on the emotional and spiritual levels of his or her being as well as the physical. Constitutional prescribing is also aimed at eventual cure of the patient, not just suppression or relief of immediate symptoms.

Origins

Homeopathy was developed during the 1790s by Samuel Hahnemann, a German physician. Experimenting on himself with the antimalarial drug quinine, Hahnemann noticed that large doses of the medicine actually caused malaria-like symptoms, while smaller doses cured the symptoms. From this, he advanced his concept of *Similia similibus curentur*, or "let like be cured with like." Hahnemann then developed an extensive system of medicine based on this concept. He named it homeopathy, from the Greek words *homoios* (the same) and *pathos* (suffering).

There are several hundred homeopathic remedies. They are almost always made from natural materials—plant, animal, or mineral substances—that have been treated to form mother tinctures or nonsoluble powders. Liquid extracts are then potentized, or increased in power, by a series of dilutions and succussions, or shakings. It is thought that succussion is necessary to transfer the energy of the natural substance to the solution. In addition, the potency of the remedy is regarded as increasing with each dilution. After the tincture has been diluted to the prescribed potency, the resulting solution is added to a bottle of sucrose/lactose tablets, which are stored in a cool, dark place. If the remedy is not soluble in water, it is ground to a fine powder and triturated with powdered lactose to achieve the desired potency.

Proponents of homeopathy over the years have included Louisa May Alcott, Charles Dickens, Benjamin Disraeli, Johann Wolfgang Goethe, Nathaniel Hawthorne, William James, Henry Wadsworth Longfellow, Pope Pius X, John D. Rockefeller, Harriet Beecher Stowe, William Thackeray, Daniel Webster, and W. B. Yeats. England's royal family has employed homeopathic practitioners since the 1830s.

KEY TERMS

Aggravation—Another term used by homeopaths for the healing crisis.

Allopathy—Conventional medical treatment of disease symptoms that uses substances or techniques to oppose or suppress the symptoms.

Constitutional prescribing—Homeopathic treatment for long-term or chronic disorders related to inherited predispositions to certain types of illnesses.

Healing crisis—A temporary worsening of the patient's symptoms during successive stages of homeopathic treatment.

Law of similars—The basic principle of homeopathic medicine that governs the selection of a specific remedy. It holds that a substance of natural origin that produces certain symptoms in a healthy person will cure those same symptoms in a sick person.

Laws of cure—A set of three rules used by homeopaths to assess the progress of a patient's recovery.

Materia medica—In homeopathy, reference books compiled from provings of the various natural remedies.

Miasm—In homeopathic theory, a general weakness or predisposition to chronic disease that is transmitted down the generational chain.

Modalities—The factors and circumstances that cause a patient's symptoms to improve or worsen, including weather, time of day, effects of food, and similar factors.

Repertories—Homeopathic reference books consisting of descriptions of symptoms. The process of selecting a homeopathic remedy from the patient's symptom profile is called repertorizing.

Benefits

Homeopathic physicians seek to cure their patients on physical, mental, and emotional levels, and each treatment is tailored to a patient's individual needs. Homeopathy is generally a safe treatment, as it uses medicines in extremely diluted quantities, and there are usually minimal side effects. Its non-toxicity makes some consider it a good choice for the treatment of children. Another benefit of homeopathy is the cost of treatments; homeopathic remedies are inexpensive, often a fraction of the cost of conventional drugs.

Classical homeopathy has been used to treat a wide range of diseases and conditions, most of which tend to be long-term. These include: **alcoholism**, **allergies**, **anxiety**, arthritis, **asthma**, bladder conditions, **chronic fatigue syndrome**, **depression**, drug dependencies, gastrointestinal problems, Gulf War sickness, **headache**, hearing problems, herpes, hypersensitivity, immune disorders, **insomnia**, joint problems, kidney conditions, liver problems, **Lyme disease**, lower back problems, **malaria**, **menopause**, menstrual problems, migraine, **multiple sclerosis**, paralysis, **phobias**, **shingles**, sinus problems, skin disorders, repetitive **stress** injury, rheumatism, vertigo, vision problems, and yeast **infections**.

Description

Constitutional prescribing is based on the patient's symptom profile and specific aspects of homeopathic theory.

Homeopathic classification of symptoms

Homeopathic practitioners use the word symptom in a more inclusive fashion than traditional medicine. In homeopathy, symptoms include any change that the patient experiences during the illness, including changes in emotional or mental patterns.

Homeopaths classify symptoms according to a hierarchy of four categories:

- Peculiar symptoms. These are symptoms unique to the individual that do not occur in most persons. Homeopaths make note of peculiar symptoms because they often help to determine the remedy.
- Mental and emotional symptoms. These are important general symptoms that inform the homeopath about the patient's total experience of the disorder.
- Other general symptoms. These are physical symptoms felt throughout the patient's body, such as tiredness, changes in appetite, or restlessness.
- Particular symptoms. Particular symptoms are localized in the body; they include such symptoms as nausea, skin rashes, or headaches.

Miasms

Homeopaths regard the patient's symptom profile as a systemic manifestation of an underlying chronic disorder called a miasm. Miasms are serious disturbances of what homeopaths call the patient's vital force that are inherited from parents at the time of conception. Hahnemann believed that the parents' basic lifestyle, their emotional condition and habitual diet, and even the atmospheric conditions at the time of conception would affect the number and severity of miasms passed on to the child. Hahnemann himself distinguished three miasms: the psoric, which he considered the most universal source of chronic disease in humans; the syphilitic; and the sycotic, which he attributed to **gonorrhea**. Later homeopaths identified two additional miasms, the cancernic and the tuberculinic. The remaining major source of miasms is allopathic medicine. It is thought that specific allopathic treatments—particularly smallpox vaccinations, cortisone preparations, major tranquilizers, and antibiotics—can produce additional layers of miasms in the patient's constitution. Constitutional prescribing evaluates the person's current state or miasmic picture, and selects a remedy intended to correct or balance that state. The homeopath may prescribe a different remedy for each miasmic layer over time, but gives only one remedy at a time directed at the person's current state. The basic principle governing the prescription of each successive remedy is the law of similars, or "like cures like."

Hering's laws of cure

The homeopathic laws of cure were outlined by Constantine Hering, a student of Hahnemann who came to the United States in the 1830s. Hering enunciated three laws or principles of the patterns of healing that are used by homeopaths to evaluate the effectiveness of specific remedies and the overall progress of constitutional prescribing:

- Healing progresses from the deepest parts of the organism to the external parts. Homeopaths consider the person's mental and emotional dimensions, together with the brain, heart, and other vital organs, as a person's deepest parts. The skin, hands, and feet are considered the external parts.
- Symptoms appear or disappear in the reverse of their chronological order of appearance. In terms of constitutional treatment, this law means that miasms acquired later in life will resolve before earlier ones.
- Healing proceeds from the upper to the lower parts of the body.

Healing crises

Homeopaths use Hering's laws to explain the appearance of so-called healing crises, or aggravations, in the course of homeopathic treatment. It is not unusual for patients to experience temporary worsening of certain symptoms after taking their first doses of homeopathic treatment. For example, a person might notice that arthritic pains in the shoulders are better but that the hands feel worse.

Hering's third law would indicate that the remedy is working because the symptoms are moving downward in the body. In constitutional prescribing, a remedy that removes one of the patient's miasmic layers will then allow the symptoms of an older miasm to emerge. Thus the patient may find that a physical disease is followed by a different set of physical problems or by emotional symptoms.

Preparations

The most important aspects of preparation for constitutional prescribing are the taking of a complete patient history and careful patient education.

Case-taking

Homeopathic case-taking for constitutional prescribing is similar to that for acute prescribing, but more in-depth. The initial interview generally takes one to two hours. The practitioner is concerned with recording the totality of the patient's symptoms and the modalities that influence their severity. Also included are general characteristics about the patient and his or her lifestyle choices. For example, a practitioner might ask the patient if he or she likes being outside or is generally hot or cold. There is also an emphasis on the patient's lifetime medical history, particularly records of allopathic treatments.

Patient education

Homeopaths regard patients as equal partners in the process of recovery. They will take the time to explain the theories underlying constitutional prescribing to the patient as well as taking the history. Patient education is especially important in constitutional prescribing in order to emphasize the need for patience with the slowness of results and length of treatment, and to minimize the possibility of self-treatment with allopathic drugs if the patient has a healing crisis.

Homeopathic remedies

In constitutional prescribing, one dose of the selected remedy is given. Patients then wait two to six weeks before following up with the homeopath, while the body begins the healing process. At the follow-up visit, the remedy may be repeated, or a different remedy prescribed. The preparation, selection, administration, and storage of remedies for constitutional prescribing are the same as for acute prescribing. These procedures are described more fully in the article on acute prescribing.

Precautions

Constitutional homeopathic prescribing is not appropriate for diseases or health crises requiring emergency treatment, whether medical, surgical, or psychiatric. In addition, constitutional prescribing should not be self-administered. Although home treatment kits of homeopathic remedies are available for acute self-limited disorders, the knowledge of homeopathic theory and practice required for constitutional evaluation is beyond the scope of most patients.

Patients are instructed to avoid touching homeopathic medicines with their fingers. The dose can be poured onto a piece of white paper or the bottle's cap and tipped directly into the mouth. Homeopathic remedies are not taken with water; patients should not eat or drink anything for 15–20 minutes before or after taking the dose.

Homeopathic remedies may lose their potency if used at the same time as other products. Some homeopathic practitioners recommend the avoidance of mint and mentholated products (toothpastes, candies, chewing gum, mouth rinses), as well as camphor and camphorated products (including **eucalyptus** and Tiger Balm), patchouli and other **essential oils**, moth balls, strong perfumes, aftershaves, scented soaps, stress, x rays, coffee, nicotine, recreational drugs (**marijuana**) and certain therapeutic drugs (most notably cortisone and prednisone) during treatment. Patients are also advised to avoid electric blankets and dental work, as these are thought to adversely affect homeopathic therapy. Homeopathic remedies should never be placed near magnets.

Side effects

Homeopathic medicines are so diluted that sometimes no trace of the original substance can be detected. These medicines are therefore considered non-toxic and generally free of harmful side effects. The primary risks to the patient from constitutional homeopathic treatment are the symptoms of the healing crisis and individual reactions to homeopathic medicine. The complexity of constitutional prescribing requires homeopaths to have detailed knowledge of the *materia medica* and the repertories, and to take careful and extensive case notes.

An intensified healing response may occur as treatment begins, which causes symptoms to worsen, but the phenomenon is temporary. In some patients, old symptoms may reappear from past conditions from which recovery was not complete. Such phenomena are taken as positive indications that the healing process has commenced.

Research and general acceptance

As Samuel Hahnemann's healing system grew in popularity during the 1800s, it quickly attracted vehement opposition from the medical and apothecary professions. Since the early 1900s, when the American Medical Association and pharmacists waged a battle against it, homeopathy has been neglected and sometimes ridiculed by mainstream medicine. Aside from politics, part of the reason for this opposition is that there are some aspects of homeopathy which have not been completely explained scientifically. For instance, homeopaths have found that the more they dilute and succuss a remedy, the greater effect it seems to have on the body. Some homeopathic remedies are so diluted that not even a single molecule of the active agent remains in a solution, yet homeopaths maintain that it still works. Also, homeopathy puts an emphasis on analyzing symptoms and then applying remedies to these symptoms, rather than working by classifying diseases. Thus, some people with the same disease may require different homeopathic medicines and treatments. Furthermore, conventional medicine strives to find out how medicines work in the body before they use them; homeopathy is less concerned with the intricate biochemistry involved than with whether a remedy ultimately works and heals holistically. For all these reasons, conventional medicine claims that homeopathy is not scientific, while homeopaths are quick to reply that homeopathy has been scientifically developed and studied for centuries, with much documentation and success.

There continues to be many studies on the effectiveness of homeopathic treatments. Among the most celebrated, the *British Medical Journal* in 1991 published a large analysis of homeopathic treatments that were given over the course of 25 years. This project involved more than 100 studies of patients with problems ranging from vascular diseases, respiratory problems, infections, stomach problems, allergies, recovery from surgeries, arthritis, trauma, psychological problems, diabetes, and others. The study found improvement with homeopathic treatment in most categories of problems, and concluded that the evidence was "sufficient for establishing homeopathy as a regular treatment for certain indications."

In early 2002, a study in England sought to prove homeopathy's effect on treating chronic **fatigue** syndrome. Homeopathic consultations with patients took place monthly and the homeopaths in the study were allowed to choose any remedies they deemed appropriate and changed them as needed. Patients who received homeopathic treatments reported feeling more rested, less tired, and fitter than those in the placebo control group. Overall, nearly two-thirds of chronic fatigue patients reported some improvement.

In the United Kingdom and other countries where homeopathy is especially popular, some medical doctors incorporate aspects of **acute prescribing homeopathy** into their practices. Countries in which homeopathy is popular include France, India, Pakistan, Sri Lanka, Brazil, and Argentina. Large homeopathic hospitals exist in London and Glasgow, and homeopathic medical centers can be found in India and South America.

Training and certification

It takes three to four years of training to become a qualified homeopath. Naturopathic physicians study homeopathy during their four-year medical school programs, and other practitioners may study homeopathy in post-graduate courses. The Council on Homeopathic Education is the only organization that accredits training programs in classical homeopathy. As of 2005, it had accredited five institutions: Bastyr University of Natural Health Sciences in Seattle, Washington; Ontario College of **Naturopathic Medicine** in Toronto; Hahnemann Medical Clinic in Albany, California; the National College of Naturopathic Medicine in Portland, Oregon; and the International Foundation for Homeopathy, also in Seattle. Other well-known training programs include the Pacific Academy of Homeopathic Medicine in Berkeley, California, and the New England School of Homeopathy in Amherst, Massachusetts.

There are several organizations that certify homeopathic practitioners:

- The National Center for Homeopathy is the largest homeopathic organization, with over 7,000 members. It also runs the Council on Homeopathic Education, and provides a listing of all its members and their credentials.
- The American Institute of Homeopathy is the oldest national medical body. It provides a list of D.Ht.s (Diplomate in Homeopathy) certified by the American Board of Homeotherapeutics.
- The Council for Homeopathic Certification was created in 1992 to establish a certification exam and a code of ethics. It confers upon qualified practitioners a C.C.H. (Certification in Classical Homeopathy).
- The Homeopathic Academy of Naturopathic Physicians offers a certification based on a competency exam, the "Diplomate in the Homeopathic Academy of Naturopathic Physicians" (D.H.A.N.P.).
- The North American Society of Homeopaths certifies non-physician homeopaths.

Honeysuckle

Description

Honeysuckle is a large volubilate shrub of the genus *Lonicera*. There are more than 300 species of honeysuckle in the Caprifoliaceae family, found from Asia to North America. The shrub reaches heights of 20–30 ft (6–9 m), with thin, hairy branches. It has ovoid leaves that range 1.2–3.2 in (3–8 cm) long by 0.6–1.6 in (1.5–4.0 cm) wide. The plant flowers in late spring or early summer, depending on the species. Japanese honeysuckle (*Lonicera japonica*) blooms in the spring from April to May, with fragrant white flowers touched with a shade of purple that fade to yellow as they mature. The species of honeysuckle that is found in North America, the United Kingdom, and western Asia, *Lonicera caprifolium*, flowers in June. Generally, honeysuckle flowers are 1.2–1.6 in (3–4) cm long, with an inner tube of approximately the same length. All varieties of honeysuckle are famous for this tube, which is extracted and sucked for its sweet nectar. The shrub also produces a black berry. Despite the sweetness of its fragrance and nectar, the medicinal parts of the plant are bitter, due to the saponin in its stem, the 8% tannin in the leaves and the 1% insitol in its flowers.

Honeysuckle. *(©PlantaPhile, Germany. Reproduced by permission.)*

General use

Japanese honeysuckle (*L. japonica*, also called Japanese *jin yin hua*, which means gold and silver flower) and common honeysuckle (*L. caprifolium*, also called Italian honeysuckle, Dutch honeysuckle, and woodbine) are both widely used for their medicinal qualities. Although the Chinese most commonly use the bud of the flower in their medical practice, in other countries it is mostly the flowers and leaves that are used for their healing properties. Japanese honeysuckle works well as a detoxifier, and is best used for acute **infections** and inflammations. As an alterative, which cleanses and purifies the blood, and an antipyretic, which reduces **fever** with its cooling properties, Japanese honeysuckle is best used for such ailments as sore throats, swollen eyes, headaches, etc.

Acute infections and inflammations

Japanese honeysuckle is most useful in treating acute illnesses, infections and inflammations. At the onset of a cold, honeysuckle should be taken in combination with chrysanthemum flowers. Several popular Chinese formulas, such as *yin chaio* and *ganmaoling*, contain this herbal combination. Because it is a natural antibiotic, honeysuckle can also be used to treat infections caused by staphylococcal or streptococcal bacteria. Honeysuckle should be used for

KEY TERMS

Alterative—A substance that cleanses and purifies the blood.

Antipyretic—A substance or medication that combats fever with cooling properties.

Antispasmodic—A substance or medication that prevents spasms or cramps.

Vasodilatory—Having the effect of relaxing or widening the blood vessels.

acute conditions, and is not meant to be used in the treatment of chronic illnesses.

Skin infections

Honeysuckle works well against internal infections, and it can also be used externally for skin irritation and infections. Honeysuckle has been found useful in alleviating **rashes** ranging from skin diseases to poison **oak**. For these types of skin ailments, honeysuckle is best used as a poultice. For **cuts** and abrasions that may become infected, a honeysuckle infusion can be applied externally. It is in treating skin infections that the stems of honeysuckle are used.

Circulatory system

John Gerard, a master herbalist of the sixteenth century, said that honeysuckle's "floures, be steeped in oile, and set in the Sun, are good to annoint the body that is bennumed, and growne very cold." Indeed, *L. caprifolium* as a fixed oil is good for the circulatory system. When it is heated and smoothed onto the skin, it has been shown to have a vasodilatory effect, causing the blood to flow into the dermis, which is the thick layer of skin beneath the epidermis.

Asthma and coughs

L. caprifolium can be used for **asthma** on account of its antispasmodic properties. An herbal infusion of the leaves is the best method for treating asthma. A decoction of honeysuckle flowers can be used for coughs.

Other uses

The seeds of *L. caprifolium* can be used as a diuretic. *L. villosa*, also known as American honeysuckle, has been used as a kidney stimulant. *L. japonica* has been used to treat dysentery, and **diarrhea**.

Preparations

Three teaspoons of the leaf infusion can be taken three times a day. For skin irritation, honeysuckle should be made into an infusion or poultice and applied externally to the skin. When honeysuckle is compounded in capsule form, 10–17 g can be taken daily.

Precautions

Although honeysuckle poultices are used for skin irritations, there have been cases of contact dermititis reported from pulling up Japanese honeysuckle. A patient that had come into contact with *L. japonica* reported developing a line of itchy **blisters**. People often taste honeysuckle tubes for their nectar; however, several cases of plant poisoning have been reported in children. The symptoms include gastrointestinal discomfort and **muscle cramps**.

Side effects

There are no known side effects from using honeysuckle.

Interactions

No known adverse drug interactions have been reported with honeysuckle.

Hoodia

Description

Hoodia is a genus of succulent plants, native to the Namib Desert, along the Atlantic Coast of Namibia. Although the plant looks like a cactus, it is properly part of the *Apocynaceae* or *Dogbane* family. Common names are Bushman's Hat and Queen of the Nam. Although there are several species of hoodia, *Hoodia gordonii* has gained interest as an appetite suppressant. Other species have been traditionally used as ornamental plants. There is no evidence that species other than *gordonii* have appetite suppressant effects.

General use

Hoodia has a history of use in folk medicine by the San bushmen of Africa. According to the United States Department of Agriculture, wild hoodia is an endangered species, and international trade in hoodia is restricted under the Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES). In the 2000s, Phytopharm, a British firm which applied for patents for hoodia, reported that it was developing hoodia plantations to assure a sustainable supply.

Although hoodia has been widely promoted as an appetite suppressant, there have been no published human studies documenting the safety or efficacy of hoodia products. Although Phytopharm claimed to have completed a double blind study showing both safety and efficacy, the details of this study were not available as of 2008. According to documents submitted to the United States Food and Drug Administration, Phytopharm apparently considered these results to be proprietary information and was unwilling to release details.

One published study, sponsored by the Council for Scientific and Industrial Research (CSIR, South Africa), documented efficacy in rats. In this study, hoodia extracts fed to rats over an eight-day period resulted in reduction in caloric intake and loss of body mass. In a subsequent study, rats were given either hoodia extract or the weight loss drug *fenfluramine*. In this study, hoodia was more effective than the traditional drug. A 2004 publication from the Hallett Center for Diabetes and Endocrinology of Brown University Medical School reported that the active principle of hoodia, a glycoside commonly called P57, when injected into the brains of rats, induced biochemical changes resulting in appetite reduction.

In one widely publicized report, Lesley Stahl of the CBS television program *60 Minutes* went to Africa and tried the plant. Although she commented favorably on its safety and efficacy, her report was anecdotal, based on a single day's use and cannot be considered significant.

Preparations

Although there are many products claiming to contain hoodia in various forms, they do not appear to be standardized. Adulterants may be present.

Side effects

There are no established side effects associated with hoodia; however, this is due to lack of information and documentation rather than an evidence of safety. In a letter to the Editor of the *New York Times,* a researcher who had been working with Pfizer Laboratories to develop a commercial form of hoodia, wrote: "An early clinical trial indeed showed that hoodia could be a potent appetite suppressant. But there were indications of unwanted effects on the liver caused by other components, which could not be easily removed from the supplement. Clearly, hoodia has a long way to go before it can earn approval from the Food and Drug Administration. Until safer formulations are developed, dieters should be wary of using it."

KEY TERMS

Anorectic—A drug that reduces the appetite.

Fenfluramine—An anorectic drug, withdrawn from the United States market in 1997 due to toxic effects.

Succulent—Any plant with fleshy stems or leaves.

Interactions

There are no established interactions with hoodia. Because preparations labeled as hoodia may contain **chromium**, persons using insulin for diabetes control should show extra caution, since this adulterant may affect the activity of insulin.

Hops

Description

Hops derive from the large perennial vine *Humulus lupulus*. This plant is native to North America and Europe but is cultivated in many other places. The vine grows to a height of 25 ft (8 m). It has heart-shaped dark green leaves and yellowish green flowers. Each plant produces either male or female flowers. Only the female flowers, called strobiles, are used medicinally. Strobiles are picked in autumn and either used fresh or dried.

General use

Hops have been cultivated to be used in the brewing of beer since at least A. D. 1000, but they also have a mixed history of use in healing. Ancient Hebrews used hops to help ward off plague. In North America, several Native American tribes independently discovered the healing properties of hops and used it as a sedative and sleep aid, to relieve **toothache**, and to improve digestion. By the end of the 1800s, hops were being used routinely in mainstream medicine in the United States as a sedative and digestive tonic. Although hops were sometimes used as a sleep aid in Europe, until relatively recently their major use in Europe was in the brewing of beer, to which they add a bitter flavor and act as a preservative. In the mid-2000s, European herbalists were much more enthusiastic about the healing properties of hops. They are used in three ways: as a sedative, as an aid in digestion, and as an antibiotic.

The best-known medicinal function of hops is as a mild sedative and sleep aid. For centuries pillows filled with hops have been prescribed for people who have difficulty falling asleep. Hops extracts taken orally are also said to promote sleep. Hops are chemically complex and contain many different compounds. Scientists have separated out several components that are sedative in nature, although it is not clear whether hops contain enough of these compounds to actually make a person sleepy. Some modern studies have given support to hops as an effective treatment for **insomnia**. The German Federal Health Agency's Commission E, established in 1978 to independently review and evaluate scientific literature and case studies pertaining to herb and plant medications, has approved hops for sleep problems, restlessness, and **anxiety**. Hops belong to the same family of herbs as **marijuana**, and some people claim it produces a mild, relaxed, euphoric feeling when smoked. There is no scientific evidence for this claim.

The second major use of hops is as an aid to digestion. Hops have been used for centuries in both **traditional Chinese medicine** and Native American healing to stimulate the appetite, ease digestion, and aid in relieving **colic**. It is believed that hops stimulate the secretions of the stomach.

The German E Commission has also concluded that hops may act as a digestive aid. Scientists have isolated another extract from the plant that in the laboratory inhibits spasms in the digestive tract and other smooth muscle.

Chinese healers use hops to treat **tuberculosis** and as an antibiotic. Test-tube studies show that the bitter acids in hops inhibit the growth of certain bacteria and fungi, including the common bacteria *Staphylococcus aureus* (responsible for staph **infections**) and *Bacillus subtilis*, but they do not inhibit *Escherichia coli*, a bacterium that causes digestive upsets. This antibacterial action may account for the preservative effect of hops in brewed beer. A 1999 study also showed that some compounds isolated from hops were effective in test-tube studies in reducing the proliferation of certain types of human breast and **ovarian cancer** cells. As of 2007, hops extract was being studied as a possible **cancer** chemopreventive.

In the early 2000s, researchers confirmed that hops contain compounds called phytoestrogens that are related to or easily converted into estrogen, the main female hormone. Some herbalists believe that the presence of an estrogenic compound accounts for the dampening of male sexual arousal and the control of sexual nervous tension ascribed to ingesting fresh hops. Other herbalists disagree, maintaining that those effects are related to the relaxing or sedative properties of hops only.

In addition to their use in healing, hops are used as an ingredient in perfume and occasionally as a tobacco or food flavoring. Their main food use and commercial value is in beer.

Preparations

Fresh and dried hops have different properties and are used to treat different symptoms. Fresh or newly dried hops, usually dampened with glycerin to reduce the rustling noise, are used in sleep pillows to help ease a restless or anxious person into sleep. As the hops age, they change in chemical composition. For this reason, the hops in pillows should be changed every few months. Fresh hops can also be made into a tea that is taken to combat insomnia. The tea is made by steeping about two teaspoons of fresh hops in one cup (250 ml) of boiling water for five minutes.

KEY TERMS

Phytoestrogen—Any of several compounds found in plants that possess estrogen-like activity.

Tincture—An alcohol-based extract prepared by soaking plant parts.

Dried hops change in composition when exposed to light, heat, or moisture. They should be stored in a container that excludes moisture and light and should be kept at room temperature. Dried hops are used to treat digestive and other complaints. They can be prepared various ways. As a tincture, about 1/2 tsp (2 ml) can be taken three times a day. Capsules are available commercially to take before meals to aid digestion. Dry extract or powder can be added to boiling water to make a tea. Compresses are made by soaking a pad in the infusion or diluted tincture. An essential oil is produced by steam distillation. Hops are also used in combination with other herbs in commercially available remedies.

Precautions

Hops are not recommended for people suffering from **depression**. Their sedative action may accentuate depressive symptoms in these people. Some herbalists recommend that pregnant women and those with estrogen sensitive **breast cancer** avoid hops because of the possibility that they contain an estrogenic compound. Hops are included on the United States Food and Drug Administration's list of foods "Generally Recognized as Safe"(GRAS).

Side effects

There are no known side effects if hops are used in the recommended dosages. Some people who pick fresh hops may develop a skin rash (**contact dermatitis**).

Interactions

As of 2008, there had been little scientific study of the interaction of hops and pharmaceuticals. As noted above, however, people who are depressed or who are taking medications for depression should consult a doctor before using hops.

Horehound

Description

Horehound (*Marrubium vulgare L.*), commonly known as white horehound, is a European native of the Lamiaciae or mint family. Other names for this ancient remedy include houndsbane, marrubium, eye of the star, seed of Horus, marvel, bulls' blood, and houndsbane. Horehound is a hardy perennial that has naturalized throughout North America; it may be found in sunny, wayside places, thriving even in poor, dry soil. The common name horehound comes from the Old English words *har* and *hune*, meaning downy plant. This descriptive name refers to the white hairs that give this herb its distinctive hoary appearance. Another suggested derivation is from the name of the Egyptian god of sky and light, Horus. Horehound is one of the oldest known **cough** remedies. It was one of the herbs in the medicine chests of the Egyptian pharaohs. In Roman times, Caesar's

antidote for poison included horehound. The generic name is believed to be derived from the Hebrew word *marrob*, meaning bitter juice. Horehound is one of the bitter herbs used in the Jewish Passover rites. Throughout its long history, white horehound has been valued not only as a folk remedy for coughs and congested lungs, but also as a magic herb for protection against the spells attributed to witches.

Black horehound (*Ballota nigra*), also known as black stinking horehound, is the smelly relative of white horehound. It belongs to the same family of plants as white horehound and is credited with some of the same medicinal applications. Both black and white horehound have been used to treat the **bites** of snakes and mad dogs, to rid the system of intestinal **worms**, and as antidotes to vegetable poisons. Black horehound is considered to be especially useful in quelling the **nausea** associated with **motion sickness**, or to stop the **vomiting** brought on by nervous tension. It also acts as an emmenagogue, restoring a healthy balance to the menstrual cycle.

White horehound is a bushy plant that grows nearly 2 ft (61 cm) tall from a short, stout, and woody root. The small oval leaves are bitter to the taste, with a musky aroma. They are wrinkled and dark green on top, and pale with downy white hairs on the underside. The leaves are opposite and deeply veined, growing on hairy, square, branching stems also covered with downy white hairs. The lower leaves of white horehound have long stalks, while the upper leaves are smaller and stalkless. The small white flowers form dense whorls at the leaf axils, blooming in the second year of growth from June to August. Flowers are tubular with two lips. Four small shiny dark brown seeds are carried in each nutlet after flowering. Horehound seeds have tiny barbs to attach to animal fur and clothing, while horehound blossoms attract bees to the garden.

General use

White horehound is best known as a time-honored cough remedy, found in syrup, candy and tea preparations. The aerial parts of the plant are used medicinally. The active ingredients include sesquiterpene **bitters**, marrubin, volatile oil, tannins, flavonoids, and mucilage. White horehound is antiseptic. An infusion used as a wash, or a preparation of horehound salve is useful to disinfect **wounds**. A cold infusion of white horehound acts as a bitter digestive tonic and will stimulate the flow of bile from the gall bladder. It is diuretic and may also relieve flatulence and stimulate appetite. White horehound stimulates discharge of bronchial mucus, loosening and expelling phlegm. It is beneficial in the treatment of **croup**, **bronchitis**, and **whooping cough**, and has been used in the past in the treatment of **tuberculosis**, once known as consumption. White horehound is also said to normalize cardiac arrhythmias. A warm infusion is diaphoretic, meaning that it will promote sweating. It has been used to break fevers and to treat **jaundice** and typhoid **fever**. The finely chopped leaves, mixed with honey and chewed slowly, will ease a **sore throat** and relieve hoarseness. The herb was also used following **childbirth** to promote expulsion of the placenta. White horehound combines well with other herbs in medicinal infusions, including elecampane (*Inula helenium L.*) and **licorice** (*Glycyrrhiza glabra*).

KEY TERMS

Antioxidant—An enzyme or other organic substance that is able to counteract the damaging effects of oxidation in living tissue.

Diaphoretic—A medication given to induce sweating.

Emmenagogue—A substance or medication given to bring on a woman's menstrual period.

Infusion—The most potent form of extraction of an herb into water. Infusions are steeped for a longer period of time than teas.

Mucilage—A gummy or gelatinous substance found in some plants, including horehound.

Tincture—The extraction of an herb into an alcohol solution for either internal or external use.

Many of the time-tested traditional uses for this safe herbal remedy have not been clinically proven. White horehound has been approved for treatment of bronchial problems and as an appetite stimulant by the German E Commission—an advisory group on herbal medicines in that country. The U.S. Food and Drug Administration (FDA), however, has declared horehound ineffective for its traditional medicinal use as a sore throat remedy, while approving it as a safe food additive.

It is possible, however, that horehound may prove to be useful in herbal treatments for inflammation. In 2002, French researchers reported isolating new glycoside compounds in horehound, one of which has anti-inflammatory activity. In addition, a group of American researchers studying traditional Mexican herbal remedies for **headache**, **asthma**, arthritis, fever, and menstrual cramps found that horehound has a high

antioxidant content that may explain its inclusion in folk remedies for these conditions.

Preparations

Tincture: Combine 4 oz of finely-cut fresh horehound leaf (or 2 oz of dry powdered herb) with 1 pt of brandy, gin, or vodka in a glass container. There should be enough alcohol to cover the plant parts and have a 50/50 ratio of alcohol to water. Cover and store the mixture away from light for about two weeks, shaking several times each day. Strain and store in a tightly-capped dark glass bottle. A standard dose is 10–15 drops of the tincture in water, up to three times a day.

Infusion: Place 2 oz of fresh horehound leaves in a warmed glass container. Bring 2.5 cups of fresh, non-chlorinated water to the boiling point and add it to the herbs. Cover. Infuse the tea for about ten minutes. Strain and sweeten to taste. Drink warm or cold, depending on the intended results. The prepared tea will store for about two days in the refrigerator. Drink three cups a day.

Syrup: Using fresh leaves, prepare a strong infusion of horehound using twice the amount of fresh herb. Combine the infusion with a 50/50 mixture of honey and brown sugar. Use 24 oz of sweetener for each 2.5 cups of the herbal infusion. Heat the mixture in a glass or enamel pot and stir frequently as the mixture thickens. Cool and pour into clearly-labeled glass bottles. Refrigerate for storage. One teaspoonful of syrup may be taken three times a day, or every two hours if needed in acute illness.

Precautions

Pregnant women should not self-medicate with horehound herbal preparations. Lactating women should also consult with a qualified herbalist before using the herb internally. Infants and children under two years of age should not be given horehound. Do not use horehound medicinally if there is chronic disease of the gastrointestinal tract, such as ulcers, esophageal reflux, **colitis**, or diverticulosis. Large doses of horehound may have a purgative action. Very large doses may cause irregular heartbeat.

Side effects

When horehound is taken internally, it may interfere with the absorption of **iron** and other minerals.

Interactions

No interactions have been reported between horehound and standard pharmaceutical preparations. However, some anesthesiologists recommend that patients scheduled for any surgery requiring total anesthesia should discontinue all herbal preparations for 1–2 weeks before the operation. The reason for this precaution is that some herbal preparations appear to interfere with the action of inhaled anesthetics.

Horse chestnut

Description

The European horse chestnut, *Aesculus hippocastanum*, is the horse chestnut most frequently used in herbal medicine. It is a member of the Hippocastanaceae family. Horse chestnuts are in an entirely different botanical family from the well-known sweet chestnut tree, *Castanea vesca*. Horse chestnuts exist in nature as both a tree and a shrub, and are found in all temperate regions of Europe, Asia, and North America.

There are 15 recognized species of horse chestnut. The European horse chestnut is believed to have originated in the Balkan region of eastern Europe but is now grown in every country in the Northern Hemisphere.

The name *Aesculus* is actually a misnomer, coming originally from the word *esca*, meaning food. It was applied by ancient peoples to a certain species of oak; and somehow the name was transferred over the years to the horse chestnut. The name *hippocastanum* is thought to refer to the horse chestnut's ability to heal horses and cattle of respiratory illnesses. Another possibility may be that it is named for the small horseshoe-like markings that are present on the branches of the horse chestnut tree.

Horse chestnut trees grow in nearly any soil but seem to prefer a sandy loam. They grow very rapidly into tall straight trees that can reach heights of over 100 ft (approximately 30 m) tall, with widely spreading branches. The bark is grayish-green or grayish-brown in color, and the tree limbs are thick and have corky, elongated, wart-like eruptions that appear from a distance like ribbing. The interior of horse chestnut bark is pinkish-brown, with fine lines running its length. It is odorless and its taste is very bitter and astringent.

The characteristic horseshoe markings found on the branches are actually the scars from where leaves previously grew. Horse chestnut wood is seldom if ever used for lumber due to its soft and spongy character. Large leaf and flower buds are clearly visible even during winter months but are encased in a scaly, resinous protective covering that prevents damage from frost or damp. This thick sticky coating melts with the beginning of warm weather in spring, and flowers and leaves appear with remarkable rapidity, usually within three to four weeks.

The leaves are dark green, rough in texture, and large, with minutely serrated edges. Horse chestnut leaves can be nearly 1 ft (0.3 m) in length. They somewhat resemble a hand with five to nine leaf sections emerging from a palm-like base to form the finger-like projections. European horse chestnuts produce clusters of white flowers with a pale scarlet tinge at the throat or yellow mottling. American horse chestnut flowers can be white, pale pink, or yellow, depending upon the species. All types of horse chestnut trees, with their graceful wide limbs and showy flowers, are grown for their ornamental beauty.

The fruit of the horse chestnut is a dark brown smooth-surfaced nut approximately 2 in (5 cm) in diameter. It has a polished appearance except for the rounded dull tan-colored scar on the side that was attached to the seed vessel. Horse chestnuts are encased in a light green spine-covered coating that divides into three parts and drops away prior to the nut dropping from the tree. Horse chestnut nuts contain mostly carbohydrates which are generally indigestible until boiled. They also contain saponins, tannin, flavones, two glycosides, aesculin and fraxin, some crude protein, a fatty oil, ash and water.

Horse chestnuts native to North America are called buckeyes because of their large seeds resembling the eye of a buck, or male deer.

American horse chestnuts are divided into four types:

- Ohio buckeye, or *Aesculus glabra*, is a medium-sized tree which grows from the southern United States to the prairies of western Canada. It is the state tree of Ohio, hence the state's nickname of the Buckeye State.
- Yellow buckeye, *Aesculus octandra*, or *Aesculus flava*, is a tree that grows to heights of 40 ft (12 m) or more. It is fairly common across the central portion of the United States. Its leaves are somewhat smoother than those of other horse chestnuts.
- Red buckeye, or *Aesculus pavia*, is a shrub or small tree that generally is found in the southern United States. In early summer it develops brilliantly scarlet flowers in large clusters, and has dense foliage. The tree species of red buckeye grows to heights of between 15–20 ft (5–7 m) tall.
- California buckeye, or *Aesculus californica*, is a horse chestnut tree found all along the Pacific coast.

General use

Horse chestnuts have been used as fodder for feeding farm animals, and some Native American peoples have included them in their diet. However, the outer covering of the horse chestnut nut is toxic, and the nut itself has to be boiled prior to being eaten

safely. Its wood, which is too soft for furniture-making or construction, is used in building crates and other packing cases.

Both the bark and the fruit from horse chestnut trees are used medicinally to strengthen and tone the circulatory system, especially the venous system. It is used both internally and externally to treat varicose veins, **phlebitis**, and hemorrhoids. Horse chestnut preparations are particularly effective in treating varicose ulcers. Due to its ability to improve circulation, it is also helpful for the relief of leg cramps. Its bark also has narcotic and fever-reducing properties. A compound known as aescin, which is present in the horse chestnut fruit, is now often added to external creams and preparations used for the treatment of **varicose veins**, varicose ulcers, bruises, and sports injuries.

Horse chestnut preparations using the seed, bark, twigs, and leaves are all utilized in traditional Chinese medicine. Chinese herbalists consider horse chestnut to be a part of treatment not only for circulatory problems, but use it as an astringent, as a diuretic, for reduction of **edema** or swelling, to reduce inflammation, as an expectorant in respiratory problems, and to fight viruses.

Preparations

Horse chestnut bark is removed in the spring, in strips 4 or 5 in (10–13 cm) long, about 1 in (2.5 cm) thick and broad. The fruit of the horse chestnut is gathered in the autumn, when they fall from the tree. Both the bark and the fruit are dried in sunlight or with artificial heat, and are either kept whole or ground to a powder for storage. A decoction, made of 1 or 2 tsp of the dried, pulverized bark or fruit left to simmer for 15 minutes in 1 cup of water can be either taken internally three times a day or used externally as a lotion. Horse chestnut preparations are also available as tinctures, extracts, capsules, and external ointments and lotions.

Precautions

The outer husks of the horse chestnut fruit are poisonous. There are also reported cases of poisoning from eating raw horse chestnuts.

Side effects

There have been reported cases of gastrointestinal irritation, **nausea**, and **vomiting** from taking large doses of horse chestnut. There are also rare reports of rash and **itching**, and even rarer cases of kidney problems.

Interactions

Horse chestnut's ability to reduce blood coagulation, or clotting, indicates that it should not be given to those with bleeding disorders or who are taking anticoagulant drugs. It is known to add to the action of blood thinning drugs such as warfarin or aspirin.

Horsetail

Description

Horsetail is a perennial plant that is found in or near watery areas such as marshes, streams, or rivers. Horsetail grows in temperate northern hemisphere areas of Asia, Europe, North America, and North Africa. It flourishes where it can root in water or clay soil.

Horsetail is a derivative of larger plants that grew 270 million years ago during the carboniferous period. It belongs to the Equisetaceae family and is a relative of the fern.

There are over 20 species of horsetail. The species most commonly used medicinally is field horsetail (*Equisetum arvense*). *E. arvense* grows up to 1.5 ft (0.5 m) in corn fields and wet meadows. Wood horsetail (*E. sylvaticum*) grows in copses and on hedgebanks, usually to a height of 1-2 ft (0.3-0.6 m). This species is used as food for horses in parts of Sweden. River horsetail (*E. maximum*) is the largest of the European species of horsetail. Found in bogs, ditches,

KEY TERMS

Decoction—An herbal tea created by boiling herbs in water. Roots, bark, and seeds are used in decoctions; boiling the herbs brings out their medicinal properties.

Diuretic—A substance that promotes urination.

Edema—A condition that occurs when fluid accumulates in the tissues of the body.

Incontinence—The inability to control urination.

Infusion—An herbal tea created by steeping herbs in hot water. Generally, leaves and flowers are used in infusions.

Perennial—A plant that lives for many years and comes back yearly without replanting.

Sitz bath—A bath in which only the hips and buttocks are soaked.

and on banks of rivers and ponds, *E. maximum* grows to a height of 3-6 ft (1-2 m).

Horsetail has no leaves or flowers and grows in two stages. The first stage occurs during the early spring. At this time, a fertile hollow stem appears that resembles asparagus. After these stems have withered and died, the second stage begins. During this stage, which occurs during the summer months, thin green barren stems branch out from the plant. It is during this stage that horsetail is gathered for medicinal use.

Horsetail was named for its bristly appearance. The genus name *Equisetum* is derived from the Latin words *equus*, meaning horse, and *seta*, meaning bristle. Other names for horsetail include shave-grass, bottlebrush, and paddock-pipes.

Horsetail contains silicon, **potassium**, aluminum, **manganese**, saponins, phytosterols, phenolic acids, cafeic acids, alkaloids, and tannins. Fifteen types of **bioflavonoids** are also present. These bioflavonoids are believed to be responsible for horsetail's strong diuretic action. The high silicon content of the herb strengthens connective tissue, ligaments, bones, hair, and fingernails.

Origins

The medicinal use of horsetail dates back to ancient Roman and Greek times. The Greeks used horsetail as a wound healer, a diuretic, and an agent to stop bleeding. Nicholas Culpeper, a popular seventeenth-century herbalist, wrote of horsetail's beneficial properties in stopping bleeding, and treating ulcers, **kidney stones**, **wounds**, and skin inflammation. In the nineteenth century, horsetail was also used to treat **gonorrhea**, prostatitis, and **urinary incontinence**.

The North American native peoples used horsetail to treat a number of kidney and bladder ailments. The Cherokee used horsetail to aid the kidneys. Chippewa natives made a decoction out of horsetail stems and used it to treat painful or difficult urination. The Okanagan-Colville and Potowatami peoples made a horsetail infusion as a diuretic to aid kidney function.

Horsetail's reedy exterior and **silica** content have made it a popular metal polisher and natural abrasive cleanser. One species is so rich in silica that it was imported from Holland for the purpose of polishing metal, hence the nickname Dutch rushes. Another nickname is pewterwort, so named because it was used to scour pewter. Dairy maids of England used horsetail to scour their milk pails, while early Americans used it to scrub their metal pots and pans.

Horsetail has been used internally and externally as a folk medicine to treat rheumatism and **gout**, coughs and **asthma**, **acne**, brittle hair and fingernails, and as a blood purifier. Shoots of a larger species of horsetail were sometimes eaten by the poorer classes, although the food lacked taste and wasn't very nutritious.

General use

Herbalists still use horsetail to treat a variety of kidney and bladder problems. Horsetail has properties that help bladder and kidney tissue. Its tonifying effects help to reduce inflammation in conditions such as kidney stones, bladder and **kidney infections**, weak bladder, weak kidney, and urinary incontinence.

The German Commission E has approved horsetail as an effective treatment for kidney and bladder inflammations, **edema**, urinary tract **infections**, and bacterial infections. It is also used as a component in diuretic drugs.

Silica and horsetail

Horsetail is rich in minerals, particularly silica deposited in its stems. Silica helps to promote the body's absorption of **calcium**, an important component in tissue repair and bone and cartilage formation. Horsetail's silica and silicic acid content ranges from 5-8%, making it a good source for strengthening weak connective tissues, and healing bones, **fractures**, and torn ligaments. Horsetail is also used to treat arthritis and **osteoporosis**, as the silicon in horsetail may replace lost silicon in the affected bones.

Horsetail may be a possible remedy for senility. Senility often occurs when there is more aluminum in the blood than silica. One theory suggests that when the silicon and aluminum levels are balanced, the symptoms of senility will disappear.

Wound healer

Horsetail's ability to stop blood flow has made it useful in treating **nosebleeds**, internal bleeding, heavy menstrual bleeding, bleeding **hemorrhoids**, and bleeding wounds. Often a compress made from fresh horsetail juice is placed on the wound to stop the flow of blood. The healing effect may be strongest when horsetail is taken both internally and externally.

Other uses

Horsetail is also used to remedy brittle nails, bleeding wounds, **hair loss**, cystic ulcers, **rheumatoid arthritis**, gout, gonorrhea, digestive disturbances, **bronchitis**, lung disorders, **tuberculosis**, poor teeth and gums, **varicose veins**, and fallen arches. Skin ailments such as **sties**, **rashes**, itchy **eczema**, or eye inflammation may be treated with an external compress made from horsetail tea.

Preparations

Horsetail is gathered in the spring and early summer, after the fertile stems have died and the barren shoots have grown. The plant is cut above the root and the stems are used dried or fresh. Horsetail is available in dried bulk, powder, capsules, tablets, or tincture forms.

It is recommended that commercial preparations of horsetail contain no more than 3% blackish rhizome fragments and no more than 5% stems or branches from other horsetail species. Standard preparations generally contain 10% silicic acid and 7% silica.

Taken as a dietary supplement, horsetail is a good source of calcium and silica. Horsetail can be made into a tea (infusion or decoction) and consumed internally. Horsetail may also be used in full body baths, sitz baths, foot baths, compresses, hair rinses, and poultices.

For the capsule form, two capsules can be taken with water up to two times daily.

To make a tea, 1 cup of boiling water can be poured over 2 tsp of dried horsetail and steeped for 15 minutes. Up to 4 cups of the cold tea can be drunk daily for bladder or kidney ailments. The tea may be used externally as a hair rinse for **dandruff** or an oily scalp.

About 10-60 drops of the tincture can be used daily.

Precautions

Pregnant or nursing women and people with severe kidney or liver disease should consult their health practitioner before using horsetail. People with high blood pressure or heart problems should not take horsetail. Horsetail contains low levels of nicotine and may not be safe for young children. Horsetail shouldn't be taken internally for more than three days, and people should not take more than the normal dosage. Long-term use or high doses of horsetail have caused irreversible kidney damage due to too much silica. It is best to follow dosage guidelines and use properly harvested horsetail since the older shoots are higher in silica.

Commercial preparations that are processed at high temperatures are recommended since the heat destroys a potentially harmful enzyme, thiaminase, found in crude horsetail.

When horsetail is gathered for medicinal use, plants with brown spots aren't collected. Brown spots may indicate the presence of a toxic fungus. Horsetail that grows near an industrial or waste site or in heavily fertilized areas should not be harvested since it can pick up nitrates and **selenium** from the soil. The correct species of horsetail should be collected. Marsh horsetail (*E. palustre*) is poisonous.

Side effects

Mild side effects include **diarrhea**, upset stomach, and increased urination.

Severe side effects that may require medical attention are kidney **pain**, lower back pain, pain while urinating, **nausea**, or **vomiting**. These symptoms may signal kidney damage. Heart palpitations can occur if horsetail is overused. If this happens, immediate medical attention is required.

Interactions

People taking digitalis-type drugs should consult their health practitioner before taking horsetail.

Hot flashes

Definition

Hot flashes, experienced by large numbers of women and some men as a result of surgical, chemical, or age-induced changes in estrogen levels, are characterized by a rapid rise and discharge of heat with perspiration, discomfort, and possible redness. Ranging from mild to severe in intensity, they may be preceded by an aura-like experience and may be followed by a subsequent feeling of chill. With natural, age-related **menopause**, hot flashes may begin as early as two years prior to the cessation of menses and continue as long as five or more years afterward. Statistically, the average experience is approximately four years of varying intensities.

Description

Approximately 20% of women without **breast cancer** and 50 to 75% of women taking tamoxifen subsequent to breast **cancer** reportedly seek a doctor's advice for the management of hot flashes. For women without breast cancer, this seems to be a conservative estimate, given that another source notes that as many as 85% of women experience hot flashes at some time during menopause. Statistics are mixed with regard to overall duration. One study reported that only 20% of women reported still having hot flashes after four years, while another reported 25 to 50% of women continue having them as long as five years. Hot flashes appear to be more common among African American women than white, Japanese, Hispanic, or Chinese women, while Mayan Indian women report no symptoms associated with menopause at all.

Hot flashes may be preceded by a prodromal experience, or set of signs, of rapid heart rate, **anxiety**, and **dizziness** or weakness. There is considerable variation in the experience of hot flashes. As the flash comes on, there is a feeling of sudden heat that may produce as little as a beading of perspiration on the upper lip or a sudden and uncontrollable drenching. The sudden heat may be followed by a cold, clammy sensation and coldness, as evaporation of perspiration occurs. Hot flashes generally last from 30 seconds to five minutes, although in some cases they may last as long as half an hour. Although hot flashes can occur at any time, the most common time of onset is between six and eight in the morning and six and ten at night.

A stressful incident may precede the hot flash, and keeping a journal of these events as a means of identifying triggers may be helpful. Depending on the intensity, severity, and timing, embarrassment may also accompany the hot flash when others witness the sudden, unmistakable experience. Breast cancer, premature onset of menopause, faster onset rate of menopause, tamoxifen therapy in women and antiandrogenic therapies in women and men may contribute to more severe and longer durations of hot flashes. Each person's experience with hot flashes is different, and each person can experience a wide variation of symptoms over time.

Causes and symptoms

The exact cause and mechanism of hot flashes is not well understood. What is recognized is that as estrogen levels are depleted, whether due to surgical, chemical, or natural age-related changes, the hypothalamus in the brain, which regulates several functions, including body temperature, becomes confused. The core body temperature set point is lowered, and the threshold between acceptable and non-acceptable body heat levels is more easily crossed. When that occurs, signals are sent to the rest of the body of a sudden need to discharge heat, accomplished through the sudden release of perspiration from the sweat glands. Studies reveal measurable rises in skin temperature. Other hypothalamic signals cause awakenings from sleep, changes in blood pressure and heart rate, and anxiety states (alertness), as if the body is in fight-or-flight mode.

Common accompanying symptoms include:

- sleep disruptions
- fatigue
- night sweats
- heart palpitations
- irritability
- short-term memory loss
- attention span changes
- depression and weepiness
- uncharacteristic rage or impatience
- dryness of eyes and vagina
- reduced libido and interest in sex
- accelerated bone loss

Diagnosis

In most cases, diagnosis of hot flashes is not difficult. What may be difficult is assessing existing levels of hormones, anticipating the duration of menopause and menopausal symptoms, and finding safe, effective treatment options. Family history, personal medical history, including history of pregnancies and births, a physical examination, diagnostic assessments such as

blood tests for thyroid and adrenal (**stress** coping) function, and hormonal assays (blood or saliva) may be recommended. Bone density testing and, depending on history, more regular mammograms and Pap tests, though not diagnostic of hot flashes, may become advisable.

Treatment

Several alternative treatments are effective.

Phyto- (plant-derived) hormones

The most widely proclaimed remedies in this category include **black cohosh** (*Cimicifuga racemosa*), wild yam (*Dioscorea villosa*), **dong quai** (*Angelica sinensis*), **red clover** (*Trifollium pratense*), and **licorice** (*Glycyrrhiza glabra*). Also in this category are soy and two soy isoflavones: genistein and daidzein. Of all of these, black cohosh, wild yam, and soy have shown the greatest efficacy. They have also incited controversy.

Black cohosh may be the most well-studied of all the phyto-estrogens. In North America, Native American women have traditionally used it. The German Commission E, whose stamp of approval makes prescriptive use of black cohosh reimbursable, recommends, according to one source, use for no longer than six months at doses of 20 to 40 mg daily [of the concentrate]. Although black cohosh is a common alternative treatment for hot flashes, an extensive 2006 study funded by the National Institutes of Health, found no difference in effectiveness between black cohosh supplements and a placebo. However, many women continue to give personal testimony to its effectiveness.

A study examining the reduction of hot flashes from use of soy flour showed a 40% reduction, 15% greater than placebo. However, considerable controversy about an estrogen additive effect in women at risk or with a history of breast or **uterine cancer**, and in men at risk of **prostate cancer**, warrants caution. One study noted that the soy isoflavones stimulated tumor growth and opposed any beneficial effects tamoxifen might have.

Dong quai was reported to be equivalent to placebo with regard to hot flashes, with an advisory caution. Dong quai belongs to a family of herbs that contain warfarin (Coumadin)-like substances and is, therefore, contraindicated for use in persons on warfarin (Coumadin) or other blood thinning therapies.

Wild yam and licorice have both been used and recommended for their progesterone-like qualities. Many of the progesterone creams available without prescription have wild yam as a basic source ingredient. Many of these creams also contain pharmaceutical grade (concentrated and standardized) amounts of progesterone. Without monitoring use by saliva sampling a worsening of hot flashes may be provoked by progesterone's estrogen suppressive capacity. Licorice has been historically included in many combination herbals in **traditional Chinese medicine** as a synergistic (exponentially additive) element; however, caution is advised for persons with high blood pressure.

A red clover study of 252 women divided into three groups, two each using a separate red clover supplement for 12 weeks and one control group, reported a 40% improvement and no significant side effects. An average of eight hot flash episodes was reduced to an average of five in the two trial groups. Women who have had breast cancer should be cautious about the use of red clover because it has some effects that are similar to estrogen.

Traditional Chinese medicine (TCM)

TCM divides menopause into "hot" and "cold" menopause, on the basis of a thorough history taking and examination of the tongue and pulses (six different pulses). Both **acupuncture** and Chinese herbology may be employed to reduce stress, facilitate the movement of chi (or Xi—the body's internal energy flow), and balance body systems. While some critics claim TCM no more effective than placebo in controlling hot flashes or the symptoms of menopause, with few documented benefits, others point to the survival of this tradition in medicine for thousands of years and believe that something more than a **placebo effect** is shown.

Vitamins and vitamin E therapy

Vitamin E therapy is perhaps one of the most historically recommended therapies in North America for hot flashes, in a dosing range from 400 to 1,000 International Units (IU), daily. Since the 1940s, vitamin E has been believed to be useful in reducing hot flashes and another common symptom of estrogen deficiency: vaginal dryness. However, after rigorous scientific study vitamin E was found to be only as effective as placebo, and as of 2008 the Mayo Clinic reported that it was no longer recommended for use in treating hot flashes.

Dietary changes

Weight and fitness have been demonstrated to be factors in the management of hot flashes. Weight is recommended to be height proportionate. Women with less body fat may have as difficult a time as

women with too much body fat. Fitness is especially important, and **exercise** has been demonstrated to improve stamina and attitude, which contribute to tolerance.

Nuts, whole grains, apples, celery, **alfalfa**, and beans have all been recommended as useful dietary adjuncts. One source reports that a general, dietary "housecleaning back to basics," eliminating highly refined and processed foods, including fast foods and junk food, reducing or eliminating sugar and sugar-substitute products such as aspartame, eating more vegetables and fruit, and including in the diet **essential fatty acids** such as flax or fish oils, may go a long way toward stabilizing the nervous system and supporting more normal activity in the hypothalamus.

Natural hormone replacement therapy

Licensed practitioners and others in the healthcare community have recognized for some time that there is a relationship between high estrogen (estradiol or E2) levels and **fibrocystic breast disease**, **uterine fibroids**, **endometriosis**, and fertility dysfunction. Saliva sampling was developed as an alternate means of effectively monitoring not just the levels of circulating hormone but the amount of biologically active circulating hormone. The pioneer lab, DiagnosTechs, of Kent, Washington, developed a female hormone profile that tracks the interplay of estrogen and progesterone across the span of a menstruating woman's cycle. They also developed a postmenopausal panel to assess the more static balances of women after **menstruation** ceases, and a testosterone panel for men. Information from these kinds of tests are valuable aids in assessing an individual's existing hormone values, especially when compared to statistical data of physiologically effective ranges. This information allows for safer, more precise and individual—not one size fits all—use of hormone replacement therapy.

A special class of pharmacist, known as a compounding pharmacist, is able to formulate a hormone replacement of molecularly identical phyto-hormones (usually soy and wild yam), standardized to a calculated milligram strength, for use by prescription. These natural estrogen replacements make broadest use of the weakest, most gentle fraction of estrogen, estriol (E3). The other fractions are estradiol (E2)—the most potent—and estrone (E1). Although natural hormones are available in capsules, the most commonly recommended forms are sublingual (under the tongue) drops, or a topical cream or gel, in order to avoid adding further burden to the liver. The liver is responsible for metabolizing the chemistry of the body, and by the time hormone replacement therapy is usually needed, the liver has been hard at work for many years. Drops and creams also allow individual tailoring. **Natural hormone replacement therapy**, however, must be used with the same caution as pharmaceutical synthetics. But some people believe that because of their molecularly pure identity they may be safer and reduce the health risks that have become associated with synthetic hormone replacement therapy. Without clinical trials, statistical proof and good data remain unavailable. The International Academy of Compounding Pharmacists (IACP) maintains a Web site to help locate compounding pharmacists (http://www.iacprx.org/about_iacp/). The American Association of Naturopathic Physicians also maintains a Web site of licensed members (http://www.naturopathic.org).

Liver support and detoxification

Because the liver is the primary organ for metabolizing hormones, therapies that may include a liver support or **detoxification** may assist in a smooth transition through menopause. This might be especially important in persons whose hot flashes are surgically or chemically induced because the need for both of these kinds of interventions was likely preceded by hormone-related illness. Colon cleansing and increased intake of dietary and soluble fibers may also be recommended. Sources of dietary and soluble fiber include whole grains and grain brans, most vegetables, many fruits and fruit pectin, **psyllium**, and guar gum.

Allopathic treatment

Premarin and Prempro

For many years, the standard remedy for relief of hot flashes was premarin, a product derived from the urine of pregnant mares. During **pregnancy**, levels of the most potent fraction of estrogen, estradiol (E2), are down graded to a less potent fraction, estrone (E1). (Estrone is more potent than estriol, or E3.) Mares were kept pregnant, catheterized for urine collection, and dehydrated for more concentrated urine. That fact alone was enough to dissuade some women from using it. However, no other single remedy had been shown to have the efficacy (96%) of reducing or eliminating hot flashes like estrogen (as premarin) hormone replacement therapy.

Mares have similar but not identical estrogens compared to humans. One of the substances specific to mare estrogen is genetically toxic to humans. Furthermore, in

the normal female's physiology, estrogen is opposed by progesterone, another female reproductive hormone. Supplementing estrogen using premarin, unopposed by progesterone, resulted frequently in a condition known as hyperestrogenism and increased risks and rates of breast and uterine cancer. Ignoring a possible genetic toxicity of premarin, subsequent prescriptions for hormone replacement therapy concentrated on opposing Premarin's estrogen in a combination patented hormone drug called Prempro. In the summer of 2002, results of the Women's Health Initiative study were released; these data statistically demonstrated the increased health risks (breast cancer, **stroke**, and **heart attack**) of these modalities. Along with results of other studies suggesting that estrogen replacement therapy was also not as protective against **osteoporosis** as had once been believed, serious reconsideration of hot flashes management was prompted. As of 2008 the general recommendations for hot flash management are to reduce the hot flashes as much as possible using non-hormone therapies and if necessary to use the lowest dose of hormone replacement found to be effective for the shortest amount of time reasonable.

The progestins

Depomedroxyprogesterone acetate (MPA) has been reviewed and found, at doses of 150 mg every one to two months (as an injection), for women with endometrial cancer to be 85% effective in reducing hot flashes when compared with estrogen. Oral doses of 10 mg/day were 87% effective. Reported side effects included: irregular vaginal bleeding, weight gain and bloating, breast tenderness, and mood swings.

Blood pressure medications (antihypertensives)

Blood pressure medications—alpha-adrenergic agonist antihypertensives—that inhibit the stress trigger pathways involved in hot flashes, reduce hot flashes 20% to 65%. Drugs and dosages used include: clonidine (0.05–0.2 mg/day); lefoxidine (0.1 mg/day); and methyldopa (250 mg three times daily). Side effects of dizziness and **dry mouth** were reported.

Bellergal

The twice daily use of 40 mg of bellergal—a potent hypnotic-sedative combination of ergotamine tartrate, belladona alkaloids, and phenobarbitol—reduces hot flashes by 60% when compared to the placebo rate of 22%. This drug is one of the older synthetic remedies prescribed for hot flashes, due to its effects on the nervous system. It has the very undesirable effect of being addictive, and avoidance of alcohol is strongly advised.

Megestrol acetate

One of the newer drugs for relief of hot flashes, studied under rigorous clinical trial according to one source, in a 20 mg twice daily oral dose, megestrol acetate is considered to show high promise for use in both men and women. It is considered as a treatment for breast cancer in high continuous doses. Initial dosing is reported to start at 40 mg daily and then tapered up or down after a month with a maximum of 80 mg daily. Side effects noted were fluid retention and bloating.

Selective serotonin reuptake inhibitors (SSRIs)

As of 2008, attention was being paid to this class of drugs, especially to fluoxetine (Prozac), paroxetine (Paxil), and venlafaxine (Effexor). Venlafaxine is sometimes also notated as an norepinephrine serotonin reuptake inhibitor (NSRI). Norepinephrine is an adrenal hormone related to feelings of ambition and **depression**. By relieving deficits that may affect mood and hot flashes, these reuptake inhibitors were showing a 50% to 75% efficacy in decreasing hot flashes in 60% of women, making them better than trial placebo (22% to 30%) by about half. Eighty percent of the benefit was achieved in the first week. The noted dose on Paxil is 10 mg daily for the first week, followed by 20 mg daily thereafter. Dosing for Effexor was noted at 75 mg twice daily of a time released formula. The study using 75 mg followed studies using considerably less, 12.5 mg twice daily. Side effects include **sexual dysfunction**, and, according to one source, possible weight gain from increased carbohydrate craving.

Prognosis

Though some hot flashes for some women may be severe, occur over several years, be embarrassing, disruptive, mood altering, **fatigue** inducing, and correlated with other age-related deficiencies, they are not life threatening. The statistics, according to one source, that hot flashes respond to placebo in one-third to a half of all women, may mean that an average 40% reduction in hot flashes may be obtained by visiting a healthcare professional, allopathic or alternative, talking about concerns, and instituting lifestyle changes representing a kind of pampering or self care. In other words, hot flash sufferers may feel statistically justified in adopting new ways of living they might have been contemplating previously but have not yet adopted.

Prevention

Hot flashes may represent an invitation or opportunity to experiment with new modalities. Prevention, in the strictest sense, is not a likely option unless one is a Mayan Indian woman or healthy male. However, many suggestions offer significant improvements in quality of life that may be helpful, including the following:

- Saliva sampling: Consider working with a healthcare professional who can offer advice and hormone testing of the bio-available levels through saliva sampling and who may also be able to quantitatively advise and monitor natural hormone replacement therapy. A postmenopausal saliva panel may be covered by insurance. Sampling intervals may vary according to need.
- Obtaining and maintaining optimum body weight: Adipose (fat) tissue stores estrogen which may complicate safe hormone replacement therapy, while making heat distribution more difficult. A deficiency of adipose tissue may add to stress and a lower immunity.
- Exercising regularly: Exercise not only tones the muscles and improves distribution of all hormones, it also reduces stress, builds endorphins (hormones related to feeling well), and quiets the nervous system.
- Avoiding dietary triggers: Sugar, spicy foods, caffeine, and alcohol may all adversely affect the ability of the hypothalamus to more normally regulate temperature.
- Avoiding life style triggers: Diet pills, sauna, hot tubs, hot showers, and smoking are all advised to be avoided.
- Wearing layered cotton clothing and using cotton bed linens: Breathable natural fibers or sport fibers that wick away perspiration may help transfer heat; layering more easily allows quicker responses to flashing and chilling.
- Meditating and breathing deeply: Also included in this category are yoga, hypnosis, massage, biofeedback techniques, visualization, and relaxation exercises. These techniques reduce stress and oppose or quiet the nerve pathways involved in increased triggering of hot flashes.
- Air conditioning: One source suggested liberal use of the air conditioner and even the freezer (at home and supermarket) when a hot flash happens; turning down the thermostat of the furnace in winter, as possible, was also suggested.

KEY TERMS

Bellergal—A potent combination of ergotamine tartrate (a blood vessel constricting substance often used for migraines), belladona alkaloids (a potentially poisonous substance with sedative and antispasmodic effects), and phenobarbitol (an hypnotic, long-acting sedative and anti-convulsant). Bellergal is one of the early synthetic patented formulations prescribed for relief of hot flashes due to its actions on the central nervous system, but as of 2008, avoided due to its addictive capacity.

Estrogen—One of the primary reproductive hormones in women and present in men. Three fractions of estrogen have been identified: E1 or estrone is moderately active; E2 or estradiol is the most potent; and, E3 or estriol is the least potent and most often recommended for use in natural hormone replacement therapy, often in an 80% to 10% to 10% combination of E3 to E1 and E2.

Hormone replacement therapy (HRT)—A term used for the supplementation of hormones in the treatment of hormone deficiency related symptoms and illnesses. HRT often uses synthetic, patented hormonal drugs. Natural soy or wild yam based hormone replacement therapy is also available using hormones molecularly identical to human hormones and, therefore, unpatentable.

Progesterone—A primary reproductive hormone in women that has an estrogen suppressing and pregnancy term supporting role. Natural progesterone levels often decline long before declining estrogen levels may produce hot flashes. Prior to estrogen replacement therapy, progesterone therapy may be recommended to balance estrogen and reduce the risk of estrogen related health risks like fibroids of breast and uterus, and breast or endometrial cancer.

Standardized—A process by which active ingredients in compounds are quantified to insure a desired level of potency.

Synergy—A condition in which the action of a sum of parts is greater than the individual actions of those parts added together, something like "one plus one is greater than two."

Hoxsey formula

Definition

The Hoxsey formula is an herbal mixture named for the man who developed it and marketed it as a **cancer** cure during the 20th century. Harry Hoxsey developed a tonic that was taken internally and a powder that was applied to the skin. His treatment also included a special diet. Although supporters maintained that the Hoxsey treatment was effective, Hoxsey was sued by the American Medical Association for practicing medicine without a license. In addition, the United States Food and Drug Administration (FDA) in 1960 forced Hoxsey to stop selling the medicine and close his clinics in the United States. The treatment has been illegal in the United States since then but as of 2008 was offered at clinics in Tijuana, Mexico.

Origins

While Harry Hoxsey (1901–1974) is most associated with the herbal combination that bears his name. Hoxsey said that the formula was based on a remedy created by other family members. In 1840, his great-grandfather John Hoxsey observed the effect of wild plants on a horse that had a cancerous tumor on its leg. According to Harry, the horse ate wild plants, and the tumor disappeared in three months. The great-grandfather collected the herbs and mixed them with remedies that were used at the time to treat cancer. Those remedies included arsenic. Harry's father John was a veterinarian who began using the herbal formula to treat people for cancer.

Son Harry was a former coal miner with an eighth-grade education. During the 1920s, he began promoting the cancer remedy, a brown liquid tonic consisting of nine herbs and **potassium** iodide. Although he had no medical training, Hoxsey staged healing sessions and advertised the remedy in newspapers. He opened his first clinic in Taylorsville, Illinois, during the 1920s. In 1936, Hoxsey opened a clinic in Dallas, Texas. He also obtained a naturopath license. Dallas became the headquarters for the clinic that eventually operated branches in 17 states.

Cancer claims

Hoxsey claimed that the herbal combination worked well on **skin cancer** but was also effective on cancers affecting internal tumors in areas such as the lungs and bladder. The Hoxsey tonic supposedly eliminated toxins from the body, strengthened the immune system, and eliminated internal cancer. The powder applied to the skin was supposedly able to distinguish between malignant and nonmalignant skin. The treatment would come to include a diet that restricted foods that were said to interfere with the healing effects of the Hoxsey formula.

The Hoxsey formula was challenged for decades by organizations, including the American Medical Association (AMA). Criticism from the local AMA forced Hoxsey to close his first clinic in Illinois. The association was among the groups that accused Hoxsey of practicing medicine without a license. He closed the clinic and moved to another state. That set a pattern. Hoxsey was convicted and fined numerous times for practicing medicine without a license, according to the American Cancer Society.

Court cases

For decades, litigation pitted Hoxsey against what his supporters regarded as the establishment medical community. Some cases were dropped due to the testimony of people who said they were cured. Critics of the Hoxsey treatment pointed to cases in which reportedly cured people never had cancer. In a 1931 case, a man testified that he had received the treatment and learned later that he actually had barber's itch, according to *Time* magazine.

In 1949, Hoxsey responded to a negative article and sued the AMA, the editor of the *Journal of the American Medical Association*, and Hearst publications. Hoxsey

sued for libel and slander. Although Hoxsey won the suit claiming that his character was harmed, the judge only awarded $1 to him.

The FDA also challenged Hoxsey, who long refused to reveal the ingredients of his formula. In 1950, court decisions about labeling requirements gave the FDA power to block the interstate shipping of Hoxsey's products. During a court hearing, Hoxsey revealed the ingredients, which led to cases in which researchers said the treatment was not effective. Hoxsey supplied case histories, but these did not satisfy the courts or the medical community. They maintained that full clinical research was needed.

By 1960, Hoxsey faced FDA lawsuits in the states where he had clinics. He closed the U.S. clinics and gave the formula to Mildred Nelson, his nurse. Nelson said that the Hoxsey treatment cured her mother's cancer in 1946. In 1963, the nurse opened a Hoxsey cancer clinic, the Bio-Medical Center, in Tijuana, Mexico.

Hoxsey was diagnosed with **prostate cancer** in 1967. According to the American Cancer Society, Hoxsey did not respond to his treatment and underwent traditional surgery. He died seven years later.

Aftermath

During the 1990s, the Bio-Medical Center treated about 1,200 people each year for cancer and other conditions, according to the University of Texas M. D. Anderson Cancer Center.

The Hoxsey formula was again the subject of litigation in 2005 when authorities learned that Virginia teenager Starchild Abraham Cherrix refused chemotherapy for **Hodgkin's disease**. Instead, Cherrix's family took him to Mexico where he received the Hoxsey treatment. His father told the *Washington Post* that after several months of treatment that the teenager's tumor growth had slowed.

The court case charged the teenager's parents with neglect. For some people, the litigation became an issue about whether the parents and teenager had the right to decide on a treatment. During litigation that went from juvenile court to county circuit court, the teenager stopped the Hoxsey treatment. The circuit court in 2006 ruled that the teenager did not have to undergo chemotherapy. In 2007, a Mississippi radiation oncologist reported that a final small tumor in the boy's lung appeared to be gone, according to the Associated Press.

Benefits

Although supporters maintained that the Hoxsey formula was an effective treatment for cancer, organizations, including the American Cancer Society and the University of Texas M. D. Anderson Cancer Center cautioned that additional scientific research was needed to determine whether the treatment was safe and effective for treating cancer in people.

Description

The Hoxsey treatment consists of a tonic for internal cancer and a topical mixture for skin cancer. During treatment, people follow a special diet.

The herbal ingredients of the Hoxsey brown tonic are: **licorice**, **red clover**, **burdock root**, stillingia root, **barberry**, cascara, prickly ash bark, **buckthorn** bark, and pokeroot.

The skin cancer treatments include a paste made of antimony trisulfide, **zinc** chloride, and **bloodroot**. The powder applied to the skin contains **sulfur** and talc.

People undergoing the Hoxsey treatment eliminate certain items from their diet because they supposedly block the effectiveness of the formula. They are supposed to avoid pork, vinegar, tomatoes, flour, carbonated beverages, and alcohol.

Preparation

The type of preparation and treatment depend on the type of cancer. That would also determine the length of the treatment.

Precautions

No clinical trials have been performed to determine whether the Hoxsey formula is a safe and effective method for treating cancer. Some ingredients in the formula could produce side effects that include burning and **nausea**. The Hoxsey treatment is illegal in the United States, and organizations, including the American Cancer Society, warn people not to undergo it. Medical organizations in the United States caution that the treatment should not take the place of conventional treatment.

Furthermore, women who are pregnant and nursing mothers should not use any form of the Hoxsey treatment. Moreover, red clover has an estrogenic activity, meaning that it produces estrogen. Women with estrogen-positive **breast cancer** should not take red clover.

Side Effects

The ingredients in the Hoxsey formula may cause side effects ranging from the internal reaction of **diarrhea** to the external reaction of scarred skin.

Sloan-Kettering Memorial Hospital labeled buckthorn a "violent laxative" that could cause nausea, **vomiting**, diarrhea, abdominal **pain**, dehydration, **anxiety**, decreased respiration, and trembling.

Cascara is also a laxative that Sloan-Kettering cautioned may cause diarrhea, abdominal pain, cramping, vomiting, discoloration of urine, fluid and electrolyte imbalance, osteomalacia (softening of bones), steatorrhea (fat in feces), and vitamin and mineral deficiencies.

Licorice may interact with a person's hormones and cause imbalances in the retention of water, **sodium**, and potassium, according to Sloan-Kettering. This reaction leads to high blood pressure, **fatigue**, muscle pain, cardiac arrhythmia, low levels of potassium in the blood, and decreased libido, according to numerous reports in the scientific literature. Also, when taken regularly it can cause pregnant women to give birth too early.

Pokeweed is a poisonous plant that could cause nausea, vomiting, diarrhea, and stomach cramps, according to the American Cancer Society. Sloan-Kettering warned that consuming pokeweed has been associated with illnesses that required hospitalization. It also caused the deaths of children.

Red clover could increase the risk of bleeding for people who take blood-thinning medications.

Organizations, including the American Cancer Society, caution that the Hoxsey paste and powder are escharotics, substances that could burn, scar, or disfigure the skin.

High levels of **iodine** from potassium iodide may cause pimples, excessive secretion from the eyes of nose, **impotence**, and inflammation of the salivary glands, according to Sloan-Kettering.

Furthermore, ingredients in the Hoxsey formula may interact with medications. For example, potassium iodide could decrease the effectiveness of anticoagulant medications.

Research and general acceptance

As of February 2008, the American Cancer Society and Sloan-Kettering had pointed out that diet is an important component of preventing cancer. Currently, it is unknown if diet will reverse the course of cancer, according to Sloan-Kettering. Both organizations warned against the treatment.

The Hoxsey treatment has been the subject of study at the M. D. Anderson Cancer Center. That study includes the review of research and reports. The center pointed out that the congressional Officer of Technology Assessment (OTA) noted that animal research indicated that many herbs in the Hoxsey tonic had anti-tumor effects. However, the OTA and other organizations maintained that there was not sufficient acceptable scientific evidence that the Hoxsey treatment was effective as a cancer treatment for people. The OTA also cautioned about the side effects of some formula ingredients.

KEY TERMS

Escharotic—A corrosive or caustic substance.

Training and Certification

The Hoxsey treatment was illegal in the United States as of February 2008. As a result, there was no training and certification program in the United States for people who provide the treatment.

KEY TERMS

Aura—An energy field surrounding the human body, discernible by its various colors.

Gesundheit—A German expression wishing good health, usually used when a person sneezes.

Immunosuppressive—Anything that acts to suppress or weaken the body's immune system, thus making it more susceptible to disease.

Humor therapy

Definition

Humor therapy is the art of using humor and laughter to help heal people with physical or mental illness.

Origins

The benefits of humor therapy were acknowledged as far back as the book of Proverbs in the Old Testament, which contains verses like Prov. 17:22: "A cheerful heart is a good medicine, but a downcast spirit dries up the bones." The earliest historical reference to humor therapy is from the fourteenth century, when French surgeon Henri de Mondeville wrote, "Let the surgeon take care to regulate the whole regimen of the patient's life for joy and happiness, allowing his relatives and special friends to cheer him, and by having someone tell him jokes." In the sixteenth century, Martin Luther used a form of humor therapy as part of his pastoral counseling of depressed people. He advised them not to isolate themselves but to surround themselves with friends who could joke and make them laugh. Many of Luther's own letters to other people include playful or humorous remarks.

Modern humor therapy dates from the 1930s, when clowns were brought into hospitals to cheer up children hospitalized with polio. In his 1979 book, *Anatomy of an Illness*, author Norman Cousins brought the subject of humor therapy to the attention of the medical community. Cousins, himself a physician, details how he used laughter to help ease his **pain** while undergoing treatment for rheumatoid arthritis of the spine (ankylosing spondylitis.) The benefits of laughter in treating the sick captured the public's attention in the 1998 movie *Patch Adams*, starring Robin Williams as real-life doctor Hunter "Patch" Adams. The movie is based on Adams' experiences treating the poor in rural West Virginia as related in his 1983 book *Gesundheit!*

Benefits

It may seem difficult to measure the benefits of laughter in medicine but a number of clinical studies have helped verify the adage that laughter is the best medicine. In general, laughter improves the physical, mental, emotional, and spiritual health of individuals. Laughter appears to release tension in the diaphragm and relieve pressure on the liver and other internal organs. It stimulates the immune system, reduces stress, and helps balance the body's natural energy fields, or auras. People who have developed a strong sense of humor generally have a better sense of well-being and control in their lives.

A strong advocate of humor therapy is Dr. Michael R. Wasserman, president and chief medical officer of GeriMed Of America, Inc., a primary care physician management company for seniors. "A few years ago I came down with **pneumonia**, pulled out videotapes of *I Love Lucy* reruns and laughed myself back to good health," he said. "Clearly, humor and laughter have a positive effect on one's attitude and health overall. While we don't know all of the specifics, our immune system appears to benefit from these emotions."

Description

Humor therapy is used in both mainstream and alternative medicine. It can take many forms but generally it is simply the recognition by physicians, nurses, and other health care practitioners of the value of mixing humor and laughter with medication and treatment. It is especially important with children and the elderly. Patients can also help themselves to heal by adding more humor and laughter to their lives.

Hospitals, hospices, nursing homes, and other medical care facilities can also turn to professionals for help in bringing humor to their patients. One example is the Big Apple Circus Clown Care Unit, which has programs in hospitals throughout the New York metropolitan area and major children's hospitals throughout the United States, including Children's Hospital in Boston. Professional clowns perform three days a week at the bedsides of hospitalized children to help ease the **stress** of serious illnesses. The clowns use juggling, mime, magic tricks, music, and gags to promote the healing power of humor. Instead of stethoscopes, thermometers, and hypodermics, the "doctors of delight" make their "clown rounds" with Groucho Marx disguises, funny hats, and rubber chickens.

Preparations

No advance preparation is required, except possibly a good repertoire of jokes and gags for the therapist.

Precautions

Not everyone will appreciate humor therapy. Some people may consider humor for the sick or injured as inappropriate or harmful. Therefore, it is important to know or sense when humor will be therapeutic and when it will be inappropriate. It should be used cautiously at first in situations in which the sensitivity of the person it is directed at is uncertain or unknown.

Side effects

The only adverse side effects of humor therapy is that it can cause mental hurt, sadness, and alienation in persons who are not receptive to it, or if it is used insensitively.

Research and general acceptance

Humor therapy is widely accepted in the alternative health community and is finding growing acceptance with mainstream health practitioners, especially registered nurses. Numerous scientific studies done in a clinical setting support the benefits of humor therapy. Two 1989 studies done at the Loma Linda (CA) University School of Medicine showed that laughter stimulates the immune system, counteracting the immunosuppressive effects of stress. These findings have been supported by other studies at the UCLA Medical School Department of Behavioral Medicine, Ohio State University School of Medicine, and the VA Medical Center in San Diego.

While several studies have demonstrated that humor therapy raises the level of salivary immunoglobin A, they have also been challenged. Other research focuses on the effects of humor therapy on natural killer (NK) cell assays, which are considered to give clearer and more replicable results. The general conclusion is that laughter has the potential to reduce stress and stress hormone levels, consequently reducing their effects on the immune system. Humor therapy may well be a useful complementary therapy for oncology patients.

Training and certification

Although no official training or certification is required, there are a few institutions that teach humor therapy. Further information is available from the American Association for Therapeutic Humor listed below.

Ken R. Wells

Huna

Definition

Huna is an esoteric Polynesian psychology that claims to use the powers of the mind to accomplish healing and spiritual development. Max Freedom

Long, who rediscovered Huna in the 1920s, defined it as a system of religious psychiatry because it contains elements of religion, psychology, and psychic science.

Origins

Huna practitioners believe their teachings are ancient and sacred, although at least one writer has claimed they actually have modern origins. In the Hawaiian language, the word *huna* means "secret" or "that which is hidden," referring to a tradition of concealing these teachings. The word is also said to be taken from *kahuna*, a priest or teacher who was the "keeper of the secret." Huna has traditionally been passed on through oral communication and in chants rather than in writing.

Christian missionaries to the Hawaiian Islands outlawed Huna in the 19th century. Max Freedom Long, who founded the Huna Fellowship in 1945, spent years decoding the language of Huna knowledge. He published eight books on Huna between the 1920s and his death in 1971. Serge Kahili King, a non-Polynesian kahuna, founded One Order of Huna International in 1973.

Benefits

Huna claims to offer the following benefits to its adherents:

- Becoming a complete person psychologically.
- Solving personal problems, including financial or social issues.
- Having a higher level of physical, emotional, and spiritual energy.
- Handling the demands and stresses of daily life more effectively.
- Acquiring the ability to heal oneself and others.
- Learning how to accumulate mana (vital force) in order to attain personal goals.
- Growing spiritually.
- Changing one's future.

Description

The specific teachings and customs associated with Huna vary somewhat from island to island. All agree, however, on the concept of three spirits or minds in the human being. According to Huna, the complete being consists of a physical body inhabited by two of the three minds: the "low self" which is below the level of consciousness, and the "middle self" which is the conscious mind. The middle self is what others perceive as one's personality. The third spirit or mind, the High Self, is outside the body. Each person has a transparent shadow body that completely duplicates the physical body. This shadow body is called the aka. The aka is like a pattern or blueprint that connects the three selves. It has a sticky and stretchy quality that allows it to form connections between an individual and another person or object. When someone touches, looks at, or even thinks of something, a thread or cord from the aka attaches to it, forming an energy channel between the person and another person or object. Illness develops when a conflict exists between the conscious mind and the patterns of the aka.

The third mind or self, the High Self, is not God but a person's divine connection with God. Ideally all three selves or minds in a person are in continual contact with one another. The low self is the communication link between the middle self and the High Self. It obtains information directly from the senses and is the seat of the emotions. It has a limited ability to reason and reacts to events only on the basis of previous programming, even if this programming has been incorrect or negative. Fear, anger, or negative programming can lead to blockages in the low self, and this can interrupt communication with the High Self. The function of the kahuna is to remove these interferences. Kahunas use a wide range of techniques including telepathy, rituals, massage, body stroking, herbs, dream work to clear the mind of limiting beliefs and fears, meditative movements known as *kalana hula,* and a variety of other self-development techniques to establish harmony among people, objects, locations, and circumstances. One such self-development technique is *Ho'oponopono*, which refers to counseling and mediation to balance relationships.

The three minds or selves use a form of subtle energy called mana, which is stored in the aka. The low self takes energy from food and turns it into mana, or basic life energy. The kahunas, who serve as conduits for the healing qualities of mana, use breathing techniques to increase a person's mana. The basic breathing technique involves drawing a deep breath, holding it, and willing the mana into a body part that needs healing, into the hands, or into an object like a crystal or talisman. A person can also increase his or her mana by living correctly. Huna emphasizes the importance of living and speaking positively, and of doing no harm to others.

Practitioners of Huna also emphasize that their way of life is accessible to and may be practiced by everyone. In other words, it does not depend on having unusual psychic gifts or on joining a small group of

KEY TERMS

Aka—In Huna, the shadow body of the low self. The aka forms threads or cords between the low self and other persons, objects, or the High Self. These aka threads serve as energy channels.

High Self—The Huna term for the level of the personality that functions as a guardian spirit and forms the person's connection with God.

Kahuna—A native Hawaiian priest or healer.

Low self—The Huna term for the subconscious mind. The word "low" does not mean inferior in value, but refers only to what is below the level of consciousness.

Mana—The Hawaiian word for life energy. According to Huna, mana can be transferred from the conscious mind into parts of the body needing healing or into talismans or crystals to charge them with energy.

Middle self—The Huna term for the conscious mind, including the ability to reason. The middle self is what others recognize as an individual's personality.

"chosen" initiates. All humans have the basic capacity to practice and benefit from Huna.

Precautions

As of 2008, Huna is considered an unproved therapy for major physical disorders and should not be used to the exclusion of proven medical treatments. Huna is said to promote general wellness, and should therefore be used only in conjunction with other healing methods in cases of potentially serious illness.

Side effects

Huna healing has no known physical side effects. The system's emphasis on speaking only positive things, being of service to others, and not hurting others might well have beneficial side effects in a person's life. In addition, the Huna Fellowship maintains that Huna does not require anyone to give up other religious affiliations or belief systems. This understanding minimizes the possibility of emotional **stress** caused by conflicting loyalties.

Research and general acceptance

The healing methods of Huna are unproved by medical research, although medical practitioners acknowledge that benefits may be achieved through a **placebo effect**.

Training and certification

Training consists of brief courses (usually less than one week) offered in Hawaii and elsewhere. Individuals can also self-teach the method through the use of books, videos, and other teaching materials that are available from Huna Research. Huna healers and teachers can be found in many countries of the world.

Hydrotherapy

Definition

Hydrotherapy, or water therapy, is the use of water (hot, cold, steam, or ice) to relieve discomfort and promote physical well-being.

Origins

The therapeutic use of water has a long history. Ruins of an ancient bath were unearthed in Pakistan and date as far back as 4500 B.C. Bathhouses were an essential part of ancient Roman culture. The use of steam, baths, and aromatic massage to promote well being is documented since the first century. Roman physicians Galen and Celsus wrote of treating patients with warm and cold baths in order to prevent disease.

By the seventeenth and eighteenth centuries, bathhouses were extremely popular with the public throughout Europe. Public bathhouses made their first American appearance in the mid 1700s.

In the early nineteenth century, Sebastien Kneipp, a Bavarian priest and proponent of water healing,

VINZENZ PRIESSNITZ (1799–1851)

(Betmann/CORBIS. Reproduced by permission.)

Hydrotherapy inventor Vinzenz Priessnitz was the son of a Silesian farmer from a remote Austrian territory in the Jeseniky Mountains. From the age of 12, Priessnitz dutifully provided for his blind father, his elderly mother, and his sister. His formal education was sporadic at best. However, Priessnitz possessed a level head and a high degree of intelligence along with a keen and active mind. As he matured he became extremely aware of his sur roundings in nature.

At age 16, Priessnitz fell from a horse and was seriously hoofed by the animal. He received the morbid prognosis that he might be crippled at best, or might die at worst. He set to treating his own chest wound with cold packs, in emulation of a doe that he had once observed bathing a wound in a cool mountain stream. The hydrotherapy regi men proved highly effective and drew considerable atten tion to his small hometown of Gräfenberg. In 1822 he rebuilt the family home, renovating its wooden frame into a solid brick spa structure. The spa, known as the castle, housed as many as 1,500 guests each year by 1939. Among the guests were medical professionals who were intent upon exposing the therapy as a sham.

Detractors notwithstanding, word of the simple and effective treatment spread to Vienna, where Priessnitz trav eled on occasion to provide counsel at the emperor's court. Priessnitz, for his remarkable discovery, received the Austrian Gold Civil Merit Medal First Class, the highest civilian honor of the Austrian government.

Priessnitz died on November 28, 1851. He was sur vived by a wife, Zofie Priessnitz, and a young son, Vinzenz Pavel. Joseph Schindler took over the operation of the spa at Gräfenberg following the death its founder.

began treating his parishioners with cold water applications after he himself was cured of **tuberculosis** through the same methods. Kneipp wrote extensively on the subject, and opened a series of hydrotherapy clinics known as the Kneipp clinics, which are still in operation today. Around the same time in Austria, Vincenz Priessnitz was treating patients with baths, packs, and showers of cold spring water. Priessnitz also opened a spa that treated more than 1,500 patients in its first year of operation, and became a model for physicians and other specialists to learn the techniques of hydrotherapy.

Benefits

Hydrotherapy can soothe sore or inflamed muscles and joints, rehabilitate injured limbs, lower fevers, soothe headaches, promote **relaxation**, treat **burns** and **frostbite**, ease labor pains, and clear up skin problems. The temperature of water used affects the therapeutic properties of the treatment. Hot water is chosen for its relaxing properties. It is also thought to stimulate the immune system. Tepid water can also be used for **stress** reduction, and may be particularly relaxing in hot weather. Cold water is selected to reduce inflammation. Alternating hot and cold water can stimulate the circulatory system and improve the immune system. Adding herbs and **essential oils** to water can enhance its therapeutic value. Steam is frequently used as a carrier for essential oils that are inhaled to treat respiratory problems.

Since the late 1990s, hydrotherapy has been used in critical care units to treat a variety of serious conditions, including such disorders of the nervous system as Guillain-Barré syndrome.

Description

Water can be used therapeutically in a number of ways. Common forms of hydrotherapy include:

- Whirlpools, Jacuzzis, and hot tubs. These soaking tubs use jet streams to massage the body. They are frequently used by physical therapists to help injured

KEY TERMS

Contact dermatitis—Skin irritation as a result of contact with a foreign substance.

Episiotomy—An incision made in the perineum during labor to assist in delivery and to avoid abnormal tearing of the perineum.

Essential oil—A volatile oil extracted from the leaves, fruit, flowers, roots, or other components of a plant and used in aromatherapy, perfumes, foods, and beverages.

Hubbard tank—A large water tank or tub used for underwater exercises.

Jacuzzi—A trademark name for a whirlpool bath.

Sitz bath—A bathtub shaped like a chair, which allows a person to bathe in a sitting position so that only the hips and buttocks are immersed. The name comes from the German word for "sit."

patients regain muscle strength and to soothe joint and muscle pain. Some midwives and obstetricians also approve of the use of hot tubs to soothe the pain of labor.

- Pools and Hubbard tanks. Physical therapists and rehabilitation specialists may prescribe underwater pool exercises as a low-impact method of rebuilding muscle strength in injured patients. The buoyancy experienced during pool immersion also helps ease pain in such conditions as arthritis. The Arthritis Foundation has put together a set of Aquatic Program exercises that have been shown to improve isometric strength and range of motion in osteoarthritis patients.
- Baths. Tepid baths are prescribed to reduce a fever. Baths are also one of the oldest forms of relaxation therapy. Aromatherapists often recommend adding essential oils of lavender (*Lavandula angustifolia*) to a warm to hot bath to promote relaxation and stress reduction. Adding Epsom salts (magnesium sulfate) or Dead Sea salts to a bath can also promote relaxation and soothe rheumatism and arthritis.
- Showers. Showers are often prescribed to stimulate the circulation. Water jets from a shower head are also used to massage sore muscles. In addition, showering hydrotherapy has been shown to be preferable to immersion hydrotherapy for treating burn patients.
- Moist compresses. Cold, moist compresses can reduce swelling and inflammation of an injury. They can also be used to cool a fever and treat a headache. Hot or warm compresses are useful for soothing muscle aches and treating abscesses.
- Steam treatments and saunas. Steam rooms and saunas are recommended to open the skin pores and cleanse the body of toxins. Steam inhalation is prescribed to treat respiratory infections. Adding botanicals to the steam bath can increase its therapeutic value.
- Internal hydrotherapy. Colonic irrigation is an enema that is designed to cleanse the entire bowel. Proponents of the therapy say it can cure a number of digestive problems. Douching, another form of internal hydrotherapy, directs a stream of water into the vagina for cleansing purposes. The water may or may not contain medications or other substances. Douches can be self-administered with kits available at most drug stores.

Preparations

Because of the expense of the equipment and the expertise required to administer effective treatment, hydrotherapy with pools, whirlpools, Hubbard tanks, and saunas is best taken in a professional healthcare facility, and/or under the supervision of a healthcare professional. However, baths, steam inhalation treatments, and compresses can be easily administered at home.

Bath preparations

Warm to hot bath water should be used for relaxation purposes, and a tepid bath is recommended for reducing fevers. Herbs can greatly enhance the therapeutic value of the bath for a variety of illnesses and minor discomforts.

Herbs for the bath can be added to the bath in two ways—as essential oils or whole herbs and flowers. Whole herbs and flowers can be placed in a muslin or cheesecloth bag that is tied at the top to make an herbal bath bag. The herbal bath bag is then soaked in the warm tub, and can remain there throughout the bath. When using essential oils, add five to 10 drops of oil to a full tub. Oils can be combined to enhance their therapeutic value. Marjoram (*Origanum marjorana*) is good for relieving sore muscles; **juniper** (*Juniperus communis*) is recommended as a detoxifying agent for the treatment of arthritis; **lavender**, ylang ylang (*Conanga odorata*), and **chamomile** (*Chamaemelum nobilis*) are recommended for stress relief; cypress (*Cupressus sempervirens*), **yarrow** (*Achillea millefolium*), geranium (*Pelargonium graveolens*), clary **sage** (*Savlia sclaria*), and myrtle (*Myrtus communis*) can promote

healing of **hemorrhoids**; and spike lavender and juniper (*Juniperus communis*) are recommended for rheumatism.

To prepare salts for the bath, add one or two handfuls of Epsom salts or Dead Sea salts to boiling water until they are dissolved, and then add them to the tub.

A sitz bath, or hip bath, can also be taken at home to treat hemorrhoids and promote healing of an episiotomy. There is special apparatus available for taking a seated sitz bath, but it can also be taken in a regular tub partially filled with warm water.

Steam inhalation

Steam inhalation treatments can be easily administered with a bowl of steaming water and a large towel. For colds and other conditions with nasal congestion, aromatherapists recommend adding five drops of an essential oil that has decongestant properties, such as **peppermint** (*Mentha piperita*) and **eucalyptus** blue gum (*Eucalyptus globulus*). Oils that act as expectorants, such as myrtle (*Myrtus communis*) or **rosemary** (*Rosmarinus officinalis*), can also be used. After the oil is added, the individual should lean over the bowl of water and place the towel over head to trap the steam. After approximately three minutes of inhaling the steam, with eyes closed, the towel can be removed.

Other herbs and essential oils that can be beneficial in steam inhalation include:

- Tea tree oil (*Melaleuca alternaifolia*) for bronchitis and sinus infections.
- Sandalwood (*Santalum album*), virginian cedarwood (*Juniperus virginiana*), and frankincense (*Boswellia carteri*) for sore throat.
- Lavender (*Lavandula angustifolia*) and thyme (*Thymus vulgaris*) for cough.

Compresses

A cold compress is prepared by soaking a cloth or cotton pad in cold water and then applying it to the area of injury or distress. When the cloth reaches room temperature, it should be resoaked and reapplied. Applying gentle pressure to the compress with the hand may be useful. Cold compresses are generally used to reduce swelling, minimize bruising, and to treat headaches and **sprains**.

Warm or hot compresses are used to treat abscesses and muscle aches. A warm compress is prepared in the same manner as a cold compress, except steaming water is used to wet the cloth instead of cold water. Warm compresses should be refreshed and reapplied after they cool to room temperature.

Essential oils may be added to moist compresses to increase the therapeutic value of the treatment. Peppermint, a cooling oil, is especially effective when added to cold compresses. To add oils to compresses, place five drops of the oil into the bowl of water the compress is to be soaked in. Never apply essential oils directly to a cloth, as they may irritate the skin in undiluted form.

Precautions

Individuals with paralysis, frostbite, or other conditions that impair the nerve endings and cause reduced sensation should take hydrotherapy treatments only under the guidance of a trained hydrotherapist, physical therapist, or other appropriate healthcare professional. Because these individuals cannot accurately sense temperature changes in the water, they run the risk of being seriously burned without proper supervision. Diabetics and people with **hypertension** should also consult their healthcare professional before using hot tubs or other heat hydrotherapies.

Hot tubs, Jacuzzis, and pools can become breeding grounds for bacteria and other infectious organisms if they are not cleaned regularly, maintained properly, kept at the appropriate temperatures, and treated with the proper chemicals. Individuals should check with their healthcare provider to ensure that the hydrotherapy equipment they are using is sanitary. Those who are using hot tubs and other hydrotherapy equipment in their homes should follow the directions for use and maintenance provided by the original equipment manufacturer.

Certain essential oils should not be used by pregnant or nursing women or by people with specific illnesses or physical conditions. Individuals suffering from any chronic or acute health condition should inform their healthcare provider before starting treatment with any essential oil.

Such essential oils as cinnamon leaf, juniper, lemon, eucalyptus blue gum, peppermint, and **thyme** can be extremely irritating to the skin if applied in full concentration. Oils used in hydrotherapy should always be diluted in water before they are applied to the skin. Individuals should never apply essential oils directly to the skin unless directed to do so by a trained healthcare professional and/or aromatherapist.

Colonic irrigation should be performed only by a healthcare professional. Pregnant women should never douche, as the practice can introduce bacteria

into the vagina and uterus. They should also avoid using hot tubs without the consent of their healthcare provider.

The vagina is self-cleansing, and douches have been known to upset the balance of vaginal pH and flora, promoting **vaginitis** and other **infections**. Some studies have linked excessive vaginal douching to increased incidence of **pelvic inflammatory disease** (PID).

Side effects

Most forms of hydrotherapy are well tolerated. There is a risk of allergic reaction (also known as **contact dermatitis**) for some patients using essential oils and herbs in their bath water. These individuals may want to test for allergic sensitization to herbs by performing a skin patch test (i.e., rubbing a small amount of diluted herb on the inside of their elbow and observing the spot for redness and irritation). People who experience an allergic reaction to an essential oil should discontinue its use and contact their healthcare professional for further guidance.

The most serious possible side effect of hydrotherapy is overheating, which may occur when an individual spends too much time in a hot tub or Jacuzzi. However, when properly supervised, this is a minimal risk.

Research and general acceptance

Hydrotherapy treatments are used by both allopathic and complementary medicine to treat a wide variety of discomforts and disorders. Not as well accepted are invasive hydrotherapy techniques, such as colonic irrigation, enemas, and douching. These internal cleansing techniques can actually harm an individual by upsetting the natural balance of the digestive tract and the vagina. Most conventional medical professionals agree that vaginal douches are not necessary to promote hygiene in most women, and can actually do more harm than good.

Training and certification

Hydrotherapy is practiced by a number of physical therapists, medical doctors (especially those specializing in rehabilitation), nurses, and naturopathic physicians. Medical doctors, physical therapists, and nurses are licensed throughout the United States. Naturopaths are licensed in a number of states. Aromatherapists, who frequently recommend water-based treatments with herbs and essential oils, are not licensed, although there are certification programs available for practitioners.

Hyperactivity *see* **Attention-deficit hyperactivity disorder**

Hypercortisolemia

Definition

Cortisol is an essential glucocorticoid hormone, a sub-group of steroid hormones, the major hormone secreted by the adrenal glands. Hormones are messenger substances, substances produced in one gland or area of the body that move through the blood and stimulate activity in other glands or areas. Glucocorticoid hormones affect carbohydrate and protein metabolism. Steroid hormones are hormones related to **cholesterol**. Hypercortisolemia is high amounts of circulating cortisol and may be a pathological or non-pathological condition.

Description

Pathological hypercortisolemia, or Cushing's Syndrome, named after the United States surgeon, Harvey Cushing (1869–1939), may result from a **lung cancer**, tumor of the pituitary or adrenal glands, or from kidney failure. Non-pathological hypercortisolemia is a normal response of **pregnancy**, and to traumas, such as accidents or surgery (including circumcision, studies show), some forms of **depression** and **stress**. Over time, continued exposure to trauma and stress may produce chronic hypercortisolemia, and result in serious, long term, debilitating illness.

Causes and symptoms

The natural regulation of cortisol is governed by a circular feedback response system. Output is initiated when pituitary gland secretions of adrenocorticotropin hormone (ACTH) travel to and stimulate the adrenal glands, located atop the kidneys near the middle of the upper back. From the adrenals, cortisol travels to its target tissues, initiating a series of reactions known as the "flight-or-fight" response. Information from these target tissues is monitored by the brain. If the messages received tell the brain that more help is needed, the pituitary gland is stimulated to secrete more ACTH, which stimulates increased secretion of cortisol. The most significant feedback factor is stress. When stress levels are reported to the brain as high, high levels of cortisol are released in response. When stress remains high indefinitely, cortisol may also remain high indefinitely, producing a series of biochemical, physiological and even anatomical reactions.

Normally, cortisol output has a diurnal and circadian rhythm, rising in the morning, falling at night, and changing with the seasons. Changes are work-sleep cycles affect this rhythm, and changes in the rhythm affect night time sleep patterns. Changes in the length of daylight hours, blindness and loss of consciousness also affects the rhythm.

Cortisol target tissues include:

- liver
- bone
- blood vessels
- kidney
- muscle
- brain
- immune system

Long term exposure to cortisol, whether natural or synthetic—from steroid drugs such as Prednisone, Dexamethasone (Decadron), and Methylprednisone (Medrol)—may eventually result in changes such as **osteoporosis**, muscle weakening and wasting, high blood pressure, increased abdominal fat deposition, immune dysfunction, steroid-induced diabetes, and cardiovascular disease. Another serious consequence may be the eventual **fatigue** and failure of the adrenal glands. Cushing's syndrome classic symptoms include,

KEY TERMS

Circadian—Events that occur on a 24 hour rhythmic cycle; a biological clock.

Diurnal—Events that happen in the daytime, daily; associated with circadian rhythms.

Feedback response—A response to information carried back to the brain, or to other areas or glands from target tissues that generates a follow up response.

Ketoconazole—An antifungal medication.

Osteoporosis—A condition referring to bone which is thinned and weakened; loss of bone mass. It results from the process of osteopenia, or bone loss.

Pathological, or, non-pathological—Terms indicating whether a condition is considered a disease state.

Prognosis—Referring to the expected outcome of a disease and its treatment.

Target tissues—Tissues specifically receptive to a given hormone.

Tricyclics—A type of antidepressant; Elavil, for example.

in addition to "normal" longterm symptoms, a "moon face" (rounded), thinning of the skin accompanied by purple or pink stretch marks and easy bruising, **acne**, increased facial and body hair and decreased scalp hair in women, and fatigue.

Diagnosis

Initial diagnosis may be made through the office of a family practice physician or internist on the basis of signs and symptoms, physical examination, and lab work including testing levels of circulating cortisol. Three types of testing are available to check cortisol levels: 24-hour urine collection; blood testing; and, saliva sampling. The 24-hour urine collection test is done at home, beginning after the first urination of the morning and finishing after the first urination of the following day. This test can be done on infants. No special preparation is necessary. The test is described as not uncomfortable. Special considerations were reported to include emotional or physical stress, and medications: lithium, diuretics, estrogen, tricyclic antidepressants, ketoconazole, and glucocorticoids. Blood testing requires a visit to a lab, where blood is drawn and then analyzed. This test can be performed on infants, children and adults. Preparation for the test may include discontinuation of medications, similar to those medications listed above, as advised by one's healthcare provider. Some people experience **pain** or trauma with a blood draw, which may effect test results. Results may also be affected by the timing of the blood draw, since cortisol normally varies rhythmically. Risks of a blood draw include bruising, pain, excessive bleeding, infection, fainting or the need for multiple punctures. Saliva sampling is done at home by collecting four samples at specific times of day. Unlike the urine collection method that produces a daily average, or the blood test that produces a single spot sampling, saliva sampling produces a time-wave pattern for a more amplified diagnosis. Preparation includes discontinuation of medications listed with the other two methods, as well as a short list of foods and drinks, antacids, tooth brushing, and **smoking** prior to sampling. Cost comparisons were not reported. Test results may suggest follow up care with an endocrinologist, a specialist in glandular and hormonally related disease, for further testing and diagnosis.

Treatment

Preventive alternative care may focus on stress reduction, primarily. Since stress may be induced by emotional demands, dietary and nutritional imbalances, sub-clinical illness (illness which may not have fully shown itself), and physical inactivity, an alternative minded medical doctor, a licensed naturopathic physician, or other professional alternative healthcare provider may first work to re-establish balance through lifestyle changes specific to individual need. Treatment may include counseling; dietary and nutritional therapies; energy therapies, such as **Reiki**, Tai-chi, Qi Gong, **chakra balancing** or Healing Touch; **Traditional chinese medicine**, including chinese herbals and **acupuncture**; **chiropractic**; **Ayurvedic medicine**; environmental medicine; **homeopathy**; **relaxation** therapy; **biofeedback**; craniosacral work; massage; **exercise** therapies; **shamanism**; and, faith based therapies, including **prayer**, **meditation**, **yoga** and other spiritual exercises. Dietary supplement products to block cortisol or correct underlying dietary and nutritional insufficiencies are also being advertised. Assistance from a professional healthcare provider is recommended.

Allopathic treatment

Initial allopathic care may focus on antidepressants, hypoglycemics (blood sugar lowering), sedatives, or anti-hypertensives (blood pressure lowering), medications to correct underlying or related imbalances. Discontinuance of steroidal medications such as Prednisone, Dexamethasone (Decadron), and Methylprednisone (Medrol) may be warranted or advised. Treatment may also include higher protein recommendations to combat muscle wasting, or therapies that support kidney function.

Prognosis

In hypercortisolemia that has not progressed to serious disease, prognosis may be very good when committed changes in lifestyle are made. Prognosis may be further improved when medications are avoided that either add further imbalance, or overlook or disguise an underlying cause, thereby adding further stress. In Cushing's syndrome, or where hypercortisolemia has progressed to chronic disease, prognosis may be complicated by a need for difficult surgery, chemotherapy, or radiation. Follow up supplemental administration of cortisol may be required. Where surgery or other direct control of adrenal output is not an option, administration of cortisol output suppressing medications may be necessary.

Prevention

Given that stress is the single most influential feedback signal to the brain, a reasonable conclusion is that stress reduction is the single most influential prevention. Lifestyle changes, strategies, and therapies

that reduce or eliminate stress, directly by reducing burden, or indirectly by improving underlying health, are key. One theory in medicine is that if preventive intervention can be made before an organ or gland is exhausted, especially if supportive, strengthening or tonifying remedies and therapies are also employed, good health can be restored, and a higher quality of life preserved.

Hyperopia

Definition

Hyperopia (farsightedness) is an eye condition in which incoming rays of light reach the retina before they converge into a focused image.

Description

When light passes through the lens and cornea of the eye, its velocity decreases. The surfaces of the lens and cornea are not perpendicular to the incoming light, so the direction of the light changes. The greater the curvature of the lens system, the greater the change in the direction of the light.

When parallel light rays pass through the lens system of the eye, they are bent so they converge at a point some distance behind the lens. With perfect vision, this point of convergence where the light rays are focused is on the retina. Hyperopia is the condition in which the point of focus of parallel light rays from an object is behind the retina. This condition exists when the eyeball depth is too short for the curvature of its lens system.

There is a connection between the focusing of the lens of the eye (accommodation) and convergence of the eyes (the two eyes turning in to look at a close object). A good example is during reading, when the lens accommodates to make the close-up material clear and the eyes turn in to look at the print and keep it from doubling. Because of this connection between accommodation and convergence, if the lens needs to accommodate and focus for distance (to bring the image back onto the retina), the eyes may appear to turn in.

Causes and symptoms

Babies are generally born slightly hyperopic, but this tends to decrease with age. There is normal variation in eyeball length and curvature of the lens and cornea, and some combinations of these variables give rise to eyes in which the cornea is too flat for the distance between the cornea and the retina. If the hyperopia is not too severe, the lens may be able to accommodate and bring the image back onto the retina. This results in clear distance vision, but the constant focusing could cause headaches or eyestrain. If the lens cannot accommodate for the full extent of the hyperopia, the distant image is blurry. If the eyes are focused for distance and the person is looking at a nearby object, the lens needs to accommodate further. This may result in blurry nearby objects or headaches during close work.

Symptoms depend on the degree of hyperopia. Some individuals may have no symptoms, while others have blurry near vision and clear distance vision, and those with the most severe cases have blurry near and distance vision. Headaches and eyestrain may also occur, particularly when doing close work. An eye turned in (esotropia) may be a result of hyperopia, particularly in children. A turned eye could also signal a more serious problem, so a physician should be consulted.

KEY TERMS

Close work—Tasks that cause the eyes to focus on something close at hand, such as reading, writing, computer work, and sewing.

Cornea—The clear, dome-shaped outer covering of the front of the eye.

Iris—The colored ring of muscle that controls the amount of light allowed to reach the retina.

Pupil—The black hole in the center of the iris through which light enters on the way to the lens and retina.

Refraction—Method of determining the optical status of the eyes. Lenses are placed before the patient's eyes while the patient reads from an eye chart.

Retina—The inner, light-sensitive layer of the eye that transforms images into electrical messages which are sent to the brain.

Diagnosis

Because it is possible to have good visual acuity with some degree of hyperopia, it is important to relax accommodation before an eye exam. This is done with the use of eye drops and is called a cycloplegic exam, or cycloplegic refraction. The patient's visual status can be determined with a hand-held instrument called a retinoscope and/or by having the patient read from an eye chart while placing different lenses in front of the patient's eyes. The patient should be driven home after such an exam because the drops cause blurred vision.

Treatment

Herbals

Bilberry (*Vaccinium myrtillus*) increases the flow of blood through the vessels of the eye. Eye drops of **eyebright** (*Euphrasia officinalis*) tea can relieve eyestrain and, taken orally with rosemary (*Rosemarinus officinalis*) in white wine, can improve vision. **Schisandra** (*Schisandra chinensis*) improves visual clarity.

Homeopathy

Rue (*Ruta graveolens*) can be prescribed for eyestrain. A homeopathic practitioner should be consulted for a proper recommendation.

Supplements

Vitamins A and C, **magnesium**, zinc, and **selenium** can help strengthen the retina and improve vision. Flavonoids—present in bilberry and eyebright—improve visual clarity.

Deconditioning

Persons whose vision changes according to their emotional state may have vision problems because of negative conditioning. Exploration and deconditioning may improve their vision.

Ayurveda

Head massage and nasya (placing drops in the nose) using warm Jivantal taila oil (which contains *Asparagus racemosus*, *Glycyrrhiza glabra*, *Leptadenia reticulata*, *Sida cordifolia*, *Sida retusa*, and **sesame oil**) may improve vision in persons who are hyperopic.

Chinese medicine

Performing qiqong eye exercises significantly reduced hyperopia in children. In another study, children with hyperopia were cured following treatment with plum-blossom needle tapping plus external application of Huoxue Zengshi Ye (Infusion for Promoting Blood Circulation and Improving Eyesight) and Huoxue Zengshi Dan (Pellets for Promoting Blood Circulation and Improving Eyesight).

Bates method

The **Bates method** involves the use of therapeutic eye exercises to help strengthen and train the eye muscles. Some patients have found the eye exercises to help, although the method has not been tested in a clinical setting.

Other

Other movement exercises or disciplines can be useful including massage, **Feldenkrais movement therapy**, **yoga** and t'ai chi. A practitioner should be consulted to determine what would be most helpful for particular individuals.

Allopathic treatment

The usual treatment for hyperopia is corrective lenses (spectacles or contact lenses). Special contact lenses (vision orthotics) that are worn overnight temporarily reshape the cornea for ideal vision on the following day.

There are now several different surgical methods used to correct hyperopia. One approach is to implant corrective contact lenses behind the patient's iris. Another approach, called laser in situ keratomileusis (LASIK), is to surgically increase the curvature of the eye's existing cornea or lens using a laser. Many surgeries are successful, but complications, including worsening of vision, may occur.

In mid-2002, the Food and Drug Administration (FDA) approved a new surgical technique to correct hyperopia. Called conductive keratoplasty, it involves no cutting or removal of tissue. An ophthalmologist uses a small probe about the size of a human hair to pass radiofrequency waves that produce heat into the corneal tissue. They shrink the tissue and reshape the cornea.

Expected results

The prognosis for fully corrected vision is excellent for patients with low to moderate degrees of hyperopia. Patients with very high hyperopia may not achieve full correction.

Hyperopia increases the chances of chronic glaucoma, but vision loss from **glaucoma** is preventable.

Prevention

Hyperopia is usually present at birth and cannot be prevented. Eye strain may be prevented by resting the eyes when they become overworked, blinking often, and periodically changing the eyes' focus while driving or doing close work for extended periods of time.

Hyperparathyroidism

Definition

Hyperparathyroidism is the overproduction by the parathyroid glands of a hormone called parathyroid hormone (parathormone). Parathyroid glands are four pea-sized glands located just behind the thyroid gland in the front of the neck. Parathyroid hormone (parathormone) helps regulate **calcium** and phosphorous in the body.

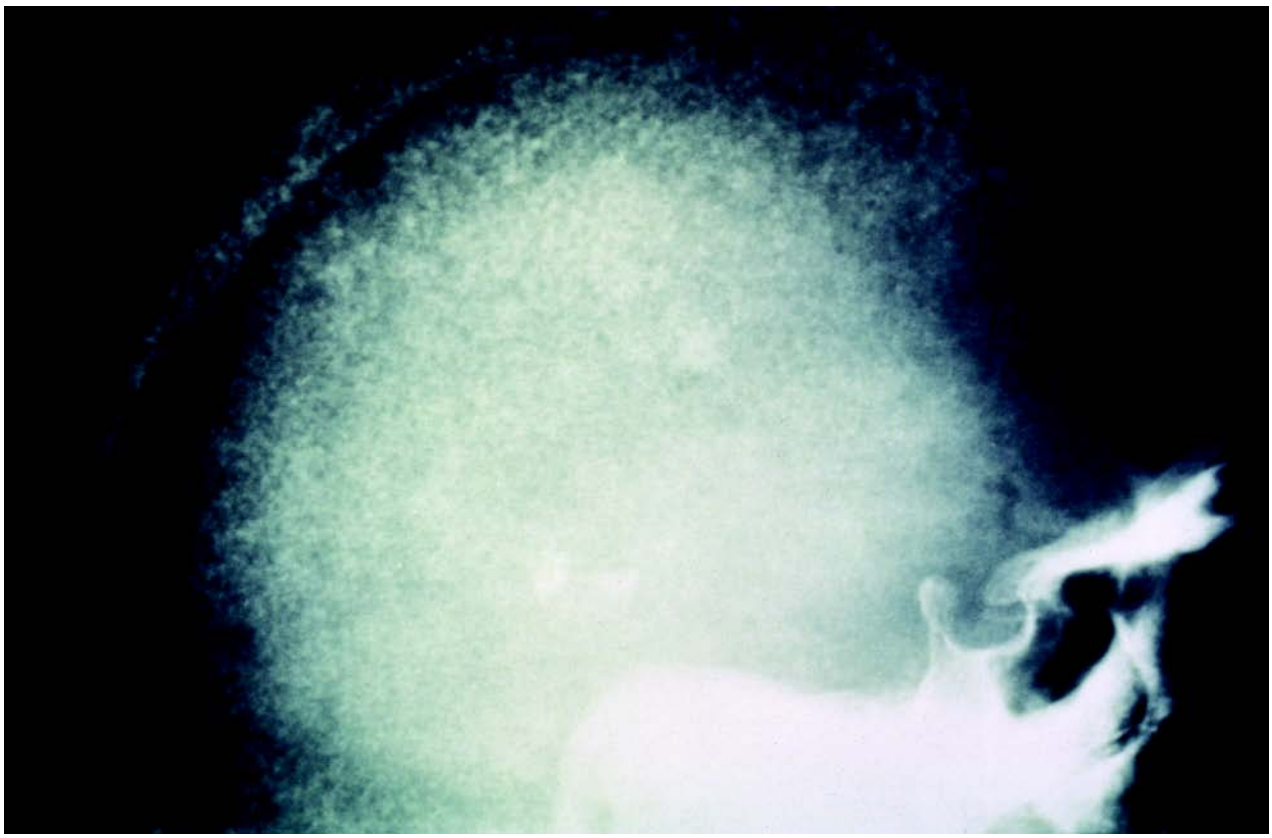
Description

Thyroid glands and parathyroid glands, despite their similar names and proximity, are entirely separate, and each produces hormones with different functions.

Hyperparathyroidism may be primary or secondary. It most often occurs in patients over age 30, and most commonly in patients 50 to 60 years old. It rarely occurs in children or the elderly. Women are affected by the disease up to three times more often than men. It is estimated that 28 of every 100,000 people in the United States will develop hyperparathyroidism each year.

Normally, parathyroid glands produce the parathormone as calcium levels drop and lower to meet the demands of a growing skeleton, pregnancy, or lactation. However, when one or more parathyroid glands malfunction, it can lead to overproduction of the hormone and elevated calcium level in the blood. Therefore, a common result of hyperparathyroidism is hypercalcemia, or an abnormally high level of calcium in the blood.

Primary hyperparathyroidism occurs as a malfunction of one of the glands, usually as a result of a benign tumor called an adenoma. Secondary hyperparathyroidism occurs as the result of an abnormality outside the parathyroid glands related to the body's metabolism, or chemical changes in living cells that help provide the body's energy. This causes a



X ray of skull showing lighter areas of bone demineralization. *(Custom Medical Stock Photo. Reproduced by permission.)*

resistance to the function of the parathyroid hormones. Primary hyperparathyroidism is one of the most common endocrine disorders, led only by diabetes and **hyperthyroidism**.

Causes and symptoms

Often, there are no obvious symptoms to give rise to suspicion of hyperparathyroidism, and it is first diagnosed when a patient is discovered to be hypercalcemic during a routine blood chemistry profile. Patients may believe they have been feeling fine, but realize improvements in sleep, irritability, and memory following treatment. When symptoms are present, they may include development of gastric ulcers or **pancreatitis** because high calcium levels can cause inflammation and **pain** in the linings of the stomach and pancreas.

Most of the symptoms of hyperparathyroidism are those present as a result of hypercalcemia, such as **kidney stones**, **osteoporosis**, or bone degradation resulting from the bones giving up calcium. Muscle weakness, central nervous system disturbances such as **depression**, psychomotor and personality disturbances, and rarely, even coma, can occur. Patients also may experience heartburn, **nausea**, constipation, or abdominal pain. In secondary hyperparathyroidism, patients may show signs of calcium imbalance, such as deformities of the long bones. Symptoms of the underlying disease also may be present.

Most commonly, hyperparathyroidism occurs as the result of a single adenoma, or benign tumor, in one of the parathyroid glands. About 90 percent of all cases of hyperparathyroidism are caused by an adenoma. The tumors seldom are cancerous. They will grow to a much larger size than the parathyroid glands, often to the size of a walnut. Genetic disorders or multiple endocrine tumors also can cause a parathyroid gland to enlarge and oversecrete hormone. In 10 percent or fewer of patients with primary hyperparathyroidism, there is enlargement of all four parathyroid glands. This condition is called parathyroid hyperplasia.

Diagnosis

Diagnosis of hyperparathyroidism most often is made when a blood test (radioimmunoassay) reveals

KEY TERMS

Demineralization—A loss or decrease of minerals in the bones.

Endocrine—Glands and hormone secretions in the body circulation.

Phosphorous—Referring to a chemical element occurring in all living cells.

high levels of parathyroid hormone and calcium. A blood test that specifically measures the amount of parathyroid hormone has made diagnosis simpler. Hypercalcemia is mild or intermittent in some patients, but persistent hypercalcemia is an excellent indicator of primary hyperparathyroidism. Dual energy x-ray absorptiometry (DEXA or DXA), a tool used to diagnose and measure osteoporosis, may be used once the diagnosis is made to show reduction in bone mass for primary hyperparathryroidism patients. Once a diagnosis of hyperparathyroidism is reached, the physician will probably order further tests to evaluate complications. For example, abdominal radiographs might reveal kidney stones.

For secondary hyperparathyroidism, normal or slightly decreased calcium levels in the blood and variable phosphorous levels may be visible. Patient history of familial kidney disease or convulsive disorders may suggest a diagnosis of secondary hyperparathyroidism. Other tests may reveal a disease or disorder that is causing the secondary hyperparathyroidism.

Treatment

Nutritional therapy

Limiting intake of soft drinks can prevent hyperparathyroidism. Soda drinks contain high levels of phosphorus. High **phosphorus** intake can cause hypocalcemia that leads to secondary hyperparathyroidism. In patients with hyperparathyroidism, forcing fluids and reducing intake of calcium-rich foods can help decrease calcium levels prior to surgery or if surgery is not necessary. These patients should not take any supplements that contain calcium without a doctor's approval.

Allopathic treatment

Hyperparathyroidism cases will usually be referred to an endocrinologist, a physician specializing in hormonal problems, or a nephrologist, who specializes in kidney and mineral disorders.

Patients with mild cases of hyperparathyroidism may not need immediate treatment if they have only slight elevations in blood calcium level and normal kidneys and bones. These patients should be regularly checked, probably as often as every six months, by physical examination and measurement of kidney function and calcium levels. A bone densitometry—a test to diagnose and monitor osteoporosis or thinning of bones—measurement should be performed every one or two years. After several years with no worsened symptoms, the length of time between exams may be increased.

Patients with more advanced hyperparathyroidism usually will have all or half of the affected parathyroid gland or glands surgically removed. This surgery is relatively safe and effective. The primary risks are those associated with general anesthesia. There are some instances when the surgery can be performed with the patient under regional, or cervical (neck) block, anesthesia. Often studies such as ultrasonography—a test with high-frequency sound waves (ultrasound) that are bounced off tissues and echoes are converted to pictures called sonograms— prior to surgery help pinpoint the affected areas.

Treatment of secondary hyperparathyroidism involves removing or treating the underlying cause. In 2004, a new drug therapy was shown to lower parathyroid levels and improve calcium and phosphorous function in patients receiving dialysis (a blood-purifying activity often performed on people with kidney diseases) who had uncontrolled secondary hyperparathyroidism. The drug, called Cinacalcet, was approved by the U.S. Food and Drug Administration for people who have chronic kidney disease with secondary hyperparathyroidism.

Expected results

Removal of the enlarged parathyroid gland or glands (parathyroidectomy) cures the disease 95 percent of the time, and relief of bone pain may occur in as few as three days. In 2004, a study showed that parathyroidectomy improved depression in patients with hyperparathyroidism. As many as 54 percent of patients who had the procedure no longer needed antidepressant medications after having the surgery. In up to five percent of patients undergoing surgery, chronically low calcium levels may result, and these patients will require calcium supplements or **vitamin D** treatment.

Damage to the kidneys as a result of hyperparathyroidism often is irreversible. Prognosis is generally good; however, complications of hyperparathyroidism such as osteoporosis, bone **fractures**, kidney stones,

peptic ulcers, pancreatitis, and nervous system difficulties may worsen prognosis.

Prevention

Secondary hyperparathyroidism may be prevented by early treatment of the disease causing it. Early recognition and treatment of hyperparathyroidism may prevent hypercalcemia. Since the cause of primary hyperparathyroidism, the adenoma which causes parathyroid enlargement, is largely unknown, there are no prescribed prevention methods.

Hypertension

Definition

Hypertension is high blood pressure. Blood pressure is the force of blood pushing against the walls of arteries as it flows through them. Arteries are the blood vessels that carry oxygenated blood from the heart to the body's tissues.

Description

As blood flows through arteries, it pushes against the inside of the artery walls. The more pressure the blood exerts on the artery walls, the higher the blood pressure. The size of small arteries also affects the blood pressure. When the muscular walls of arteries are relaxed, or dilated, the pressure of the blood flowing through them is lower than when the artery walls are narrow, or constricted.

Blood pressure is highest when the heart beats to pump blood out into the arteries. When the heart relaxes to fill with blood again, the pressure is at its lowest point. Blood pressure when the heart beats is called systolic pressure. Blood pressure when the heart is at rest is called diastolic pressure. When blood pressure is measured, the systolic pressure is stated first and the diastolic pressure second. Blood pressure is measured in millimeters of mercury (mm Hg). For example, if a person's systolic pressure is 120 and diastolic pressure is 80, it is written as 120/80 mm Hg. The label "mm Hg" is usually omitted when expressing blood pressure. The American Heart Association considers blood pressure above 140 over 90 as high for adults.

Hypertension is a major health problem, especially because it often has no symptoms. Many people have hypertension without knowing it. In the United States, about 50 million people age six and older have high blood pressure. Hypertension is more common in men than women and in people over the age of 65 than in younger persons. More than half of all Americans over the age of 65 have hypertension. It is also more common among African Americans than among white Americans.

Hypertension is a serious medical problem because people with the condition are at higher risk for **heart disease** and other medical problems than people with normal blood pressure. Serious complications can be avoided by getting regular blood pressure checks and treating hypertension as soon as it is diagnosed.

If left untreated, hypertension can lead to the following medical conditions:

- arteriosclerosis, also called atherosclerosis
- blindness
- heart attack
- stroke
- enlarged heart
- kidney damage

Arteriosclerosis is hardening of the arteries. The walls of arteries have a layer of muscle and elastic tissue that make them flexible and able to dilate and constrict as blood flows through them. High blood pressure can make the artery walls thicken and harden. When artery walls thicken, the inside of the blood vessel narrows. **Cholesterol** and fats are more likely to build up on the walls of damaged arteries, making them even narrower. **Blood clots** can also get trapped in narrowed arteries, blocking the flow of blood.

Arteries narrowed by arteriosclerosis may not deliver enough blood to organs and other tissues. Reduced or blocked blood flow to the heart can cause a **heart attack**. If an artery to the brain is blocked, a **stroke** can result.

Hypertension makes the heart work harder to pump blood through the body. The extra workload can make the heart muscle thicken and stretch. When the heart becomes too enlarged it cannot pump enough blood. If hypertension is not treated, the heart may fail.

The kidneys remove the body's wastes from the blood. If hypertension thickens the arteries to the kidneys, less waste can be filtered from the blood. As the condition worsens, the kidneys fail and wastes build up in the blood. Dialysis or a kidney transplant are needed when the kidneys fail. About 25% of people who receive kidney dialysis have kidney failure caused by hypertension.

Causes and symptoms

Many different actions or situations can cause an increase in blood pressure. Physical activity can temporarily raise blood pressure. Stressful situations can make blood pressure go up. When the **stress** goes away, blood pressure usually returns to normal. These temporary increases in blood pressure are not considered hypertension. A diagnosis of hypertension is made only when a person has multiple high blood pressure readings over a period of time.

The cause of hypertension is not known in 90–95% of the people who have it. Hypertension without a known cause is called primary or essential hypertension. When a person has hypertension caused by another medical condition, it is called secondary hypertension. Secondary hypertension can be caused by a number of different illnesses. Many people with kidney disorders have secondary hypertension. The kidneys regulate the balance of salt and water in the body. If the kidneys cannot rid the body of excess salt and water, blood pressure goes up. **Kidney infections**, a narrowing of the arteries that carry blood to the kidneys, called renal artery stenosis, and other kidney disorders can disturb the salt and water balance.

Cushing's syndrome and tumors of the pituitary and adrenal glands often increase levels of the adrenal gland hormones cortisol, adrenalin, and aldosterone, which can cause hypertension. Other conditions that can cause hypertension are blood vessel diseases, thyroid gland disorders, some prescribed drugs, **alcoholism**, and **pregnancy**.

Even though the cause of most hypertension is not known, some people have risk factors that give them a greater chance of getting hypertension. Many of these risk factors can be changed to lower the chance of developing hypertension or as part of a treatment program to lower blood pressure.

Risk factors for hypertension include:

- age over 60
- male sex
- race (African Americans have a higher incidence of hypertension.)
- heredity
- salt sensitivity
- obesity
- inactive lifestyle
- heavy alcohol consumption
- use of oral contraceptives

Some risk factors for getting hypertension can be changed, whereas others cannot. Age, male sex, and race are risk factors that a person cannot alter. Some people inherit a tendency to get hypertension. People with family members who have hypertension are more likely to develop it than those whose relatives are not hypertensive. People with these risk factors can avoid or eliminate the other risk factors to lower their chance of developing hypertension.

Diagnosis

Because people with hypertension are often asymptomatic, it is important to have blood pressure checked regularly. Blood pressure is measured with an instrument called a sphygmomanometer. A cloth-covered rubber cuff is wrapped around the upper arm and inflated. When the cuff is inflated, an artery in the arm is squeezed to stop the flow of blood momentarily. Then, the air is let out of the cuff while a stethoscope placed over the artery is used to detect the sound of the blood spurting back through the artery. This first sound is the systolic pressure, the pressure when the heart beats. The last sound heard as the rest of the air

is released is the diastolic pressure, the pressure between heart beats. Both sounds are recorded on the mercury gauge on the sphygmomanometer.

A number of factors such as **pain**, stress, or **anxiety** can cause a temporary increase in blood pressure. For this reason, hypertension is not diagnosed on the basis of one high blood pressure reading. If a blood pressure reading is 140/90 or higher for the first time, the physician will have the person return for another blood pressure check. Diagnosis of hypertension is usually made based on two or more readings after the first visit. Sometimes, patients have high blood pressure only while in the doctor's office. This phenomenon, called "white-coat hypertension" has usually been dismissed as mere anxiety over visiting the doctor. Some studies have raised questions about the dismissal of these patients as not being hypertensive, suggesting that further study is necessary to resolve the issue.

Systolic hypertension of the elderly is common and is diagnosed when the diastolic pressure is normal or low, but the systolic is elevated (e.g., 170/70 mm Hg). This condition usually co-exists with hardening of the arteries (**atherosclerosis**).

Blood pressure measurements are classified in stages, according to severity:

- normal blood pressure: less than 130/85 mm Hg
- high normal: 130–139/85–89 mm Hg
- mild hypertension: 140–159/90–99 mm Hg
- moderate hypertension: 160–179/100–109 mm Hg
- severe hypertension: 180–209/110–119
- very severe hypertension: 210/120 or higher

A typical physical examination to evaluate hypertension includes:

- medical and family history
- physical examination
- ophthalmoscopy (examination of the blood vessels in the eye)
- chest x ray
- electrocardiograph (ECG)
- blood and urine tests

Medical and family history help a physician determine if a patient has conditions or disorders that might contribute to or cause hypertension. A family history of hypertension might suggest a genetic predisposition for the disorder.

The physical examination may include several blood pressure readings at different times and in different positions. The physician uses a stethoscope to listen to sounds made by the heart and blood flowing through the arteries. The individual's pulse, reflexes, height, and weight are checked and recorded. Internal organs are palpated, or felt, to determine if they are enlarged.

Because hypertension can cause damage to the blood vessels in the eyes, the eyes may be checked with an instrument called an ophthalmoscope. The physician looks for thickening, narrowing, or hemorrhages in the blood vessels.

A chest x ray can detect an enlarged heart, other heart abnormalities, or lung disease.

An electrocardiogram (ECG) measures the electrical activity of the heart. It can detect enlargement of the heart muscle and damage to the heart muscle from blocked arteries.

Urine and blood tests may be done to evaluate health and to detect the presence of disorders that might cause hypertension.

Treatment

There is no cure for primary hypertension, but blood pressure can almost always be lowered with the correct treatment. The goal of treatment is to lower blood pressure to levels that will prevent heart disease and other complications of hypertension. In secondary hypertension, the disease that is responsible for the hypertension is treated in addition to the hypertension itself. Successful treatment of the underlying disorder may cure the secondary hypertension.

Treatment to lower blood pressure usually includes changes in diet and getting regular **exercise**. Patients with mild or moderate hypertension who do not have damage to the heart or kidneys may first be treated primarily with lifestyle changes.

Lifestyle changes that may reduce blood pressure by about 5–10 mm Hg include:

- reducing salt intake
- reducing fat intake
- losing weight
- getting regular exercise
- quitting smoking
- reducing alcohol consumption
- managing stress

Natural remedies approved by a physician may also lower or even prevent hypertension. **Aromatherapy** as a treatment option uses **essential oils** either inhaled from a bottle in times of anxiety or massaged daily into the skin at bedtime in the area beneath the collarbone. Blue **chamomile** and **lavender** are known for their stress relief and **relaxation** effects. Research

has suggested that one of the most potent supplements for treatment of hypertension may be the amino acid **arginine** (also known as L-arginine).

Food therapy has also been shown to affect blood pressure. Muscles that regulate blood pressure have been noted to dilate with the intake of celery; celery juice has also been found to have a mild diuretic effect. Eating fresh fruits and vegetables, high in **potassium** and **magnesium**, lowers systemic **sodium** and fluid levels in the circulatory system. A 2001 study showed that reducing intake of sodium decreases blood pressure in participants with or without hypertension. **Garlic** intake has also been linked with lowering blood pressures. Taken either via enteric coated capsules or fresh garlic cloves, allicin is thought to bring down blood pressure.

Relaxation and **meditation** can help lower blood pressure. Focusing on relaxing music can also slow the heart rate and lower blood pressure, as can imagery (e.g., envisioning coolness seeping into the pores and throughout the body, sensing that blood pressure is within normal range). **Yoga** experts cite two specific poses, the corpse and the knee squeeze, when used in combination with breathing exercises, as being particularly helpful in relieving tension and improving blood flow.

Allopathic treatment

Patients whose blood pressure remains higher than 139/90 will most likely be advised to take antihypertensive medication. Numerous drugs have been developed to treat hypertension. The choice of medication depends on the stage of hypertension, side effects, other medical conditions the patient may have, and other medicines the patient is taking.

Patients with mild or moderate hypertension are initially treated with monotherapy, a single antihypertensive medicine. If treatment with a single medicine fails to lower blood pressure enough, a different medicine may be tried or another medicine may be added to the first. Patients with more severe hypertension may initially be given a combination of medicines to control their hypertension. Combining antihypertensive medicines with different types of lifestyle changes often controls blood pressure with smaller doses of each drug than would be needed for monotherapy.

Antihypertensive medicines fall into several classes of drugs:

- diuretics
- beta-blockers
- calcium channel blockers
- angiotensin converting enzyme inhibitors (ACE inhibitors)
- alpha-blockers
- alpha-beta blockers
- vasodilators
- peripheral acting adrenergic antagonists
- centrally acting agonists

Diuretics help the kidneys eliminate excess salt and water from the body's tissues and the blood, which helps reduce the swelling caused by fluid buildup in the tissues. The reduction of fluid dilates the walls of arteries and lowers blood pressure.

Beta-blockers lower blood pressure by acting on the nervous system to slow the heart rate and reduce the force of the heart's contraction. They are used with caution in patients with heart failure, **asthma**, diabetes, or circulation problems in the hands and feet.

Calcium channel blockers block the entry of calcium into muscle cells in artery walls. Muscle cells need calcium to constrict, so reducing their calcium keeps them more relaxed and lowers blood pressure.

ACE inhibitors block the production of substances that constrict blood vessels. They also help reduce the build-up of water and salt in the tissues. They are often given to patients with heart failure, kidney disease, or diabetes. ACE inhibitors may be used together with diuretics.

Alpha-blockers act on the nervous system to dilate arteries and reduce the force of the heart's contractions.

Alpha-beta blockers combine the actions of alpha and beta blockers.

Vasodilators act directly on arteries to relax their walls so blood can move more easily through them. They lower blood pressure rapidly and are injected in hypertensive emergencies when patients have dangerously high blood pressure.

Peripheral acting adrenergic antagonists act on the nervous system to relax arteries and reduce the force of the heart's contractions. They usually are prescribed together with a diuretic. Peripheral acting adrenergic antagonists can cause slowed mental function and lethargy.

Centrally acting agonists also act on the nervous system to relax arteries and slow the heart rate. They are typically used with other antihypertensive medicines.

In 2001, the U.S. Food and Drug Administration (FDA) approved the use of a medical device called RESPeRATE, developed by the health services

KEY TERMS

Arteries—Blood vessels that carry oxygenated blood to organs and other tissues of the body.

Arteriosclerosis—Hardening and thickening of artery walls.

Cushing's syndrome—A disorder in which too much of the adrenal hormone, cortisol, is produced; caused perhaps by a pituitary or adrenal gland tumor.

Diastolic blood pressure—Blood pressure when the heart is resting between beats.

Hypertension—High blood pressure.

Renal artery stenosis—Disorder in which the arteries that supply blood to the kidneys constrict.

Sphygmomanometer—An instrument used to measure blood pressure.

Systolic blood pressure—Blood pressure when the heart contracts (beats).

Vasodilator—Any drug that relaxes blood vessel walls.

Ventricle—One of the two lower chambers of the heart.

company InterCure, that adjusts a patient's breathing patterns as a way of dealing with hypertension. By helping patients alter breathing patterns to lengthen the phase in which they exhale, the device slows breathing and produces beneficial effects on blood pressure. InterCure recommends the use of RESPeRATE in conjunction with antihypertensive medications.

Expected results

There is no cure for hypertension. However, it can be well controlled with proper treatment. The key to avoiding serious complications of hypertension is to detect and treat the disorder before damage occurs to the cardiovascular system. Because antihypertensive medicines control blood pressure but do not cure it, patients must continue taking the medications to maintain reduced blood pressure levels and avoid complications.

Prevention

Prevention of hypertension centers on avoiding or eliminating known risk factors. Even persons at risk because of age, race, or sex or those who have an inherited risk can lower their chance of developing hypertension.

The risk of developing hypertension can be reduced by making the same lifestyle changes recommended for treating hypertension.

Hyperthermia

Definition

Hyperthermia involves raising the body's core temperature as a means of eradicating tumors. The treatment simulates **fever**. Some therapies actually bring on fever through the introduction of fever-causing organisms, while others raise body temperature by directly heating the blood. The term hyperthermia also refers, in general, to any condition in which the body's temperature is significantly higher than normal.

Origins

The concept of hyperthermia dates back to investigations begun in 1883 by William B. Coley, a general surgeon at New York City's Memorial Hospital. Coley was intrigued by a paper published in 1868 by an American family physician named Peter Busch. Busch's paper described a patient with an untreatable sarcoma of the face. Though Busch had been unable to help the patient overcome her **cancer**, the patient went into remission spontaneously after suffering a bout of the skin infection erysipelas. The erysipelas resulted in a high fever ranging from 104°F to 105.8°F (40°C to 41°C). Over the next 20 years, Coley performed a series of experiments to study the effects of elevated temperature on various forms of cancer. After experimenting on animals, Coley moved to treating human cancer patients, injecting them with bacteria to induce high fevers. The bacteria he used are known as Coley's toxins. He reported much success with his method, especially against soft tissue sarcomas and sarcomas of the bone. Yet his treatment also had serious side effects due to the **infections** he introduced.

In spite of its drawbacks, Coley's work intrigued a few other researchers. A study published in *Cancer Research* in 1957 showed that in a review of 450 cases of supposed spontaneous remissions of cancer, 150 of the patients had suffered acute infections that raised their body temperatures. In the 1960s, a Cleveland surgeon and **breast cancer** specialist, George Crile Jr., published several studies of his experiments in eliminating tumors in mice using heat. Another doctor, Harry Leveen, of South Carolina, began building machines that used radio frequencies to heat either the whole body or affected parts. But Leveen's machines were not approved by the Food and Drug Administration (FDA), and Leveen took his inventory to the University of Bangor in Wales. Hyperthermia did not receive much attention in the United States after this point, but practitioners in other countries, particularly Germany, Italy, and Mexico, reported good results with it. An international congress on hyperthermia was held each year from 1977 to 2000.

Benefits

Hyperthermia has been shown in several studies to reduce malignant tumors either alone or in combination with chemotherapy. A 1998 study of patients with breast and **ovarian cancer** found that hyperthermia therapy increased the effectiveness of chemotherapy. This study suggested that patients undergoing hyperthermia might be successfully treated with lower doses of chemotherapy. A 2003 study demonstrated that women with breast cancer were less likely to experience spread of the cancer to distant lymph nodes or the lungs if they received a combination of whole-body hyperthermia and chemotherapy. A form of localized hyperthermia used to treat benign enlarged prostates can be performed in a doctor's office in as little as an hour, and this method does not have the side effects, such as **impotence** and incontinence, that often accompany traditional prostate surgery. In 2007, researchers reported at the annual meeting of the American Society of Clinical Oncology that patients with certain types of soft tissue sarcomas who had hyperthermia experienced significantly better progress with chemotherapy treatments than those who had no such ancillary treatment.

Newer methods of hyperthermia involving noninvasive (no penetration of skin) microwave technology have been introduced in other countries and made their way to the United States in early 2002. This technology offered excellent results for some cancer patients in improving five-year survival rates for some aggressive forms of cancer when combined with other cancer therapy procedures. In 2007, BSD Medical Corporation announced the development of specialized capsules used to deliver chemicals for the treatment of breast cancer through the bloodstream. The capsules not only release chemicals to tumors, but also become heated at the point of infection, increasing the efficiency of the chemicals attack on the tumor.

Description

Hyperthermia therapy involves raising the body's internal temperature, a process that can be achieved by several methods. Hyperthermia can be used to heat the whole body or an affected local region. For reducing an enlarged prostate, doctors use a device approved by the FDA in 1996 that delivers microwaves to the prostate, while water cools the surrounding tissue to prevent **burns**. For whole body hyperthermia, a method used in Europe employs a

KEY TERMS

Sarcoma—A malignant growth in the connective tissue, bone, cartilage or muscle; usually the most lethal form of cancer.

tent-like device that delivers infrared light to the body. The patient is injected with toxins to provoke a mild fever and then monitored under lights. The lights produce a slow rise in temperature, optimally to 107.6°F (42°C). A prominent practitioner of hyperthermia in Mexico heats the patient's blood directly. Under sedation, the doctor inserts a catheter into each leg near the groin. The two catheter tubes are connected to a heat exchanger. The heat exchanger heats the patient's blood, raising the entire body temperature. The patient is monitored by thermometers in the esophagus and rectum. Body temperature is raised to 107.6°F (42°C) for about one hour.

Side effects

The side effects of hyperthermia depend on the method by which it is delivered. Cardiac problems are possible. The patient should be closely monitored during the procedure and after. For treatment of the prostate, localized hyperthermia seems to be without the side effects of traditional prostate surgery.

Research and general acceptance

Although research into hyperthermia as a cancer treatment began in the United States, many practitioners in the late 2000s were working in Europe or Mexico. Localized hyperthermia has been studied for treatment of a variety of conditions, including menorrhagia (heavy menstrual periods) and malignant tumors of the liver and rectum. As of 2008, whole body hyperthermia continued to be studied and tested for its impact on cancers.

Training and certification

Practitioners performing hyperthermia are certified medical doctors and trained assistants such as nurses and anesthesiologists.

Hyperthyroidism

Definition

Hyperthyroidism is the overproduction of thyroid hormones by an overactive thyroid gland.

Description

Located in the front of the neck, the thyroid gland produces the hormones thyroxine (T_4) and triiodothyronine (T_3) that regulate the body's metabolic rate by regulating the production of protein and increasing oxygen absorption in every cell. In turn, the production of these hormones is controlled by thyroid-stimulating hormone (TSH) that is produced by the pituitary gland. When production of the thyroid hormones increases despite the level of TSH being produced, hyperthyroidism occurs. The excessive amount of thyroid hormones in the blood increases the body's metabolism, creating both mental and physical symptoms.

The term hyperthyroidism covers any disease that results in an overabundance of thyroid hormone. Other names for hyperthyroidism, or specific diseases within the category, include Graves' disease, diffuse toxic goiter, Basedow's disease, Parry's disease, and thyrotoxicosis. Hyperthyroidism affects 2.5 million people in the United States but could affect up to 4.5 million people because more than half of the people with thyroid

Symptoms of hyperthyroidism

- Goiter
- Weight loss with increased appetite/food intake
- Trembling hands
- Heightened blood pressure
- Excessive nervousness, anxiety or anxiety attacks
- Increased bowel movements
- Accelerated heart rate
- Sweating
- Fatigue, muscle weakness
- Increased sensitivity to heat
- Changes in menstrual patterns

(Illustration by Corey Light. Cengage Learning, Gale)

disease do not know they have it. Although it occurs at all ages, hyperthyroidism is most likely to occur after the age of 15. There is a form of hyperthyroidism called neonatal Graves' disease, which occurs in infants born of mothers with Graves' disease. Occult hyperthyroidism may occur in patients over age 65 and is characterized by a distinct lack of typical symptoms. Diffuse toxic goiter occurs in as many as 80% of patients with hyperthyroidism.

Causes and symptoms

Hyperthyroidism is often associated with the body's production of auto-antibodies in the blood that cause the thyroid to grow and secrete excess thyroid hormone. This condition, as well as other forms of hyperthyroidism, may be inherited. Regardless of the cause, hyperthyroidism produces the same symptoms, including weight loss with increased appetite, shortness of breath and **fatigue**, intolerance to heat, heart palpitations (strong, very fast heartbeats), increased frequency of bowel movements, weak muscles, tremors, **anxiety**, and difficulty sleeping. Women also may notice decreased menstrual flow and irregular menstrual cycles.

Patients with Graves' disease often have a goiter (visible enlargement of the thyroid gland), although as many as 10% do not. These patients also may have bulging eyes. Thyroid storm, a serious form of hyperthyroidism, may show up as sudden and acute symptoms, some of which mimic typical hyperthyroidism but with the addition of **fever**, substantial weakness, extreme restlessness, confusion, emotional swings or psychosis, and perhaps even coma.

Diagnosis

Physicians look for physical signs and symptoms indicated by patient history. On inspection, the physician may note symptoms such as a goiter or eye-bulging. Other symptoms or family history may be clues to a diagnosis of hyperthyroidism. An elevated basal (lowest range of normal) body temperature above 98.6 degrees Fahrenheit (37 degrees Centigrade) may be an indication of a heightened basal metabolic rate (which measures the energy used to maintain vitality) and hyperthyroidism. A simple blood test can be performed to determine the amount of thyroid hormone in the patient's blood. The diagnosis usually is straightforward with this combination of clinical history, physical examination, and routine blood hormone tests. Radioimmunoassay, or a test to show concentrations of thyroid hormones with the use of a radioisotope (a chemical element that emits particles or energy) mixed with fluid samples, helps confirm the diagnosis. A thyroid scan is a nuclear medicine procedure involving injection of a radioisotope dye that tags the thyroid and helps produce a clear image of inflammation or involvement of the entire thyroid.

Other tests can determine thyroid function and thyroid-stimulating hormone levels. Ultrasonography (a test whereby high-frequency sound waves [ultrasound] are bounced off tissues and echoes are converted to pictures [sonograms]), computed tomography (CT) scan (an x-ray computer procedure that produces a detailed picture of a cross-section of the body), and magnetic resonance imaging (MRI; an x-ray technique that produces a detailed image of the inner body using a powerful magnet, radio waves, and a computer) may provide visual confirmation of a diagnosis or help to determine the extent of involvement.

Treatment

Alternative treatments for hyperthyroidism include nutritional therapy, herbal therapy, and **homeopathy**, the use of tiny doses of diluted and harmless remedies to catalyze healing.

Nutritional therapy

Consumption of foods such as broccoli, brussels sprouts, cabbage, cauliflower, kale, rutabagas, spinach, turnips, peaches, and pears can help naturally suppress thyroid hormone production. Dairy products and any stimulants such as tea, coffee, soda, and other caffeinated drinks should be avoided. Under the supervision of a trained physician, high dosages of certain vitamin/mineral combinations can help alleviate hyperthyroidism.

Homeopathy

An experienced homeopath may give patients specific remedies tailored to their overall personality profile as well as their specific symptoms. Symptomatic treatments may include Iodium or Natrum muriaticum.

Other therapies

Alternative treatments that may help relieve hyperthyroidism symptoms include **traditional Chinese medicine** and Western herbal medicine. **Stress** reduction techniques such as **meditation** also may prove beneficial. Patients should contact experienced herbalists for specific preparations and treatment.

Allopathic treatment

Allopathy is the theory or system of medical practice that combats disease by use of remedies that produce effects different from those produced by the disease. Treatment depends on the specific disease and individual circumstances such as age, severity of disease, and other conditions affecting a patient's health.

Anti-thyroid drugs

Anti-thyroid drugs often are administered to help the patient's body cease overproduction of thyroid hormones. Some drugs used to interfere with the thyroid gland's uptake of **iodine** are propylthiouracil (PTU) and methimazole (Tapazole). Medication may work for young adults, pregnant women, and others. Women who are pregnant should be treated with the lowest dose required to maintain thyroid function in order to minimize the risk of **hypothyroidism** (underactive thyroid gland function) in the infant.

Radioactive iodine

Radioactive iodine is often prescribed to damage cells that make thyroid hormone. The cells need iodine to make the hormone, so they absorb any iodine found in the body. The patient may take an iodine capsule daily for several weeks, resulting in the eventual shrinkage of the thyroid in size, reduced hormone production, and a return to normal blood levels. A single large oral dose of radioactive iodine simplifies treatment but should be given only to patients who are not of reproductive age or are not planning to have children, since a large amount can concentrate in the reproductive organs (gonads).

KEY TERMS

Goiter—Chronic enlargement of the thyroid gland.

Gonads—Organs that produce sex cells the ovaries and testes.

Metabolic—Pertaining to metabolism, or the chemical processes that take place in the body, which result in growth, energy, elimination of waste, and other body functions.

Palpitations—Rapid and forceful heartbeat.

Radioisotope—A form of a chemical element that emits radiation in the form of energy or small particles.

Thyroidectomy—Removal of the thyroid gland.

Surgery

Patients treated with thyroidectomy, in the form of partial or total removal of the thyroid, most often suffer from large goiter and have suffered relapses, even after repeated attempts to address the disease through drug therapy with iodine. Following thyroidectomy or iodine therapy, patients must be carefully monitored for years to watch for signs of hypothyroidism, or insufficient production of thyroid hormones, which can occur as a complication of thyroid production suppression.

Expected results

Hyperthyroidism generally is treatable and carries a good prognosis. Most patients lead normal lives with proper treatment. The majority of patients who receive radioactive iodine report feeling better within about three to six weeks of treatment. Thyroid storm, however, can be life-threatening and can lead to heart, liver, or kidney failure. Some patients who undergo radioactive iodine treatment or surgery become hypothyroid.

Prevention

As of 2008, there were no known prevention methods for hyperthyroidism, since its causes are

either inherited or not completely understood. The best prevention tactic is knowledge of family history and close attention to symptoms and signs of the disease. Careful attention to prescribed therapy can prevent complications of the disease.

Hypnotherapy

Definition

Hypnotherapy is the treatment of a variety of health conditions by hypnotism or by inducing prolonged sleep.

Origins

Hypnotherapy is thought to date back to the healing practices of ancient Greece and Egypt. Many religions such as Judaism, Christianity, Islam, and others have attributed trance-like behavior to spiritual or divine possession.

Franz Mesmer *(Corbis-Bettmann. Reproduced by permission.)*

Austrian physician, Franz Mesmer (1734–1815), is credited with being the first person to scientifically investigate the idea of hypnotherapy, in 1779, to treat a variety of health conditions. Mesmer studied medicine at the University of Vienna and received his medical degree in 1766. Mesmer is believed to have been the first doctor to understand the relationship of psychological trauma to illness. He induced a trance-like state, which became known as mesmerism, in his patients to successfully treat nervous disorders. These techniques became the foundation for modern-day hypnotherapy.

Mesmer's original interest was in the effect of celestial bodies on human lives. He later became interested in the effects of magnetism, and found that magnets could have tremendous healing effects on the human body. Mesmer believed that the human body contained a magnetic fluid that promoted health and well being. It was thought that any blockage to the normal flow of this magnetic fluid would result in illness, and that the use of the Mesmerism technique could restore the normal flow.

Mesmer performed his technique by passing his hands up and down the patient's body. The technique was supposed to transmit magnetic fluid from his hands to the bodies of his patients. During this time period, there was no clear delineation between health conditions that were physical or psychological in

nature. Although Mesmer did not realize it at that time, his treatments were most effective for those conditions that were primarily psychosomatic.

Mesmer's technique appeared to be quite successful in the treatment of his patients, but he was the subject of scorn and ridicule from the medical profession. Because of all the controversy surrounding mesmerism, and because Mesmer's personality was quite eccentric, a commission was convened to investigate his techniques and procedures. A very distinguished panel of investigators included Benjamin Franklin, the French chemist Antoine-Laurent Lavoisier, and physician Jacques Guillotin. The commission acknowledged that patients did seem to obtain noticeable relief from their conditions, but the whole idea was dismissed as being medical quackery.

Other pioneers in this field, such as James Braid and James Esdaile discovered that hypnosis could be used to successfully anesthetize patients for surgeries. James Braid accidentally discovered that one of his patients began to enter a hypnotic state while staring at a fixed light as he waited for his eye examination to begin. Since mesmerism had fallen out of favor, Braid coined the term hypnotism, which is derived from the Greek word for sleep. Braid also used the techniques of monotony, rhythm, and imitation to assist in inducing a hypnotic state. These techniques are generally still in use.

Around 1900, there were very few preoperative anesthetic drugs available. Patients were naturally apprehensive when facing surgery. One out of 400 patients would die, not from the surgical procedure, but from the anesthesia. Dr. Henry Munro was one of the first physicians to use hypnotherapy to alleviate patient fears about having surgery. He would get his patients into a hypnotic state and discuss their fears with them, telling them they would feel a lot better following surgery. Ether was the most common anesthetic at that time, and Dr. Munro found that he was able to perform surgery using only about 10% of the usual amount of ether.

It took more than 200 years for hypnotherapy to become incorporated into medical treatment. In 1955, the British Medical Association approved the use of hypnotherapy as a valid medical treatment, with the American Medical Association (AMA) giving its approval in 1958.

Benefits

Hypnotherapy is used in a number of fields including **psychotherapy**, surgery, dentistry, research, and medicine. Hypnotherapy is commonly used as an alternative treatment for a wide range of health conditions, including weight control, **pain** management, and **smoking** cessation. It is also used to control pain in a variety of conditions such as **headache**, facial **neuralgia**, arthritis, **burns**, musculoskeletal disorders, **childbirth**, and many more. Hypnotherapy is being used in place of anesthesia, particularly in patients who prove to be allergic to anesthetic drugs, for surgeries such as hysterectomies, cesarean sections, certain cardiovascular procedures, thyroidectomy, and others. Dentistry is using hypnotherapy with success on patients who are allergic to all types of novocaine drugs. Hypnotherapy is also useful in helping patients overcome **phobias**.

Hypnotherapy is used for nonmedical patients as well as those who wish to overcome bad habits. Hypnotherapy has been shown to help those who suffer from performance **anxiety**, such as in sports, and speaking in public. In academic applications, it has also been shown to help with learning, participating in the classroom, concentrating, studying, focusing attention span, improving memory, and helping remove mental blocks about particular subjects.

In more general areas, hypnotherapy has been found to be beneficial for problems such as motivation, procrastination, decision making, personal achievement and development, job performance, buried or repressed memories, **relaxation**, and **stress** management.

Description

Hypnotherapy involves achieving a psychological state of awareness that is different from the ordinary state of consciousness. While in a hypnotic state, a variety of phenomena can occur. These phenomena include alterations in memory, heightened susceptibility to suggestion, paralysis, sweating, and blushing. All of these changes can be produced or removed in the hypnotic state. Many studies have shown that roughly 90% of the population is capable of being hypnotized.

This state of awareness can be achieved by relaxing the body, focusing on breathing, and shifting attention away from the external environment. In this state, the patient has a heightened receptivity to suggestion. The usual procedure for inducing a hypnotic trance in another person is by direct command repeated in a soothing, monotonous tone of voice.

Preparations

Ideally, the following conditions should be present to successfully achieve a state of hypnosis:

- willingness to be hypnotized
- rapport between the patient or client and the hypnotherapist
- a comfortable environment that is conducive to relaxation

Precautions

Hypnotherapy can have negative outcomes. When used as entertainment, people have been hypnotized to say or do things that would normally embarrass them. There have been instances where people already dangerously close to psychological breakdown have been pushed into an emotional crisis during what was supposed to be a harmless demonstration of hypnosis. A statement from the World Hypnosis Organization (WHO) warns against performing hypnosis on patients suffering from psychosis, organic psychiatric conditions, or antisocial personality disorders. Because there are no standard licensing requirements, in the wrong hands, there is a risk that the hypnotist will have difficulty in controlling or ending a hypnotic state that has been induced in the patient.

There is a commonly held belief that a person cannot be coerced into doing things that he or she would not normally do while under hypnosis. The hynotherapist should take care however, not to give suggestions during hypnosis that are contrary to the patient's moral code.

Many religions do not condone the practice of hypnotherapy. Leaders of the Jehovah's Witnesses and Christian Science religions oppose the use of hypnotherapy and advise their members to avoid it completely, whether for entertainment or therapy. The Church of Jesus Christ of Latter-Day Saints approves it for medical purposes, but cautions members against allowing themselves to be hypnotized for entertainment or demonstration purposes.

In 1985, The AMA convened a commission that warned against using hypnotherapy to aid in recollection of events. The commission cited studies that showed the possibility of hypnotic recall resulting in confabulation or an artificial sense of certainty about the course of events. As a result, many states limit or prohibit testimony of hypnotized witnesses or victims.

Side effects

Experiments have been conducted to determine any side effects of hypnotherapy. Some subjects have reported side effects such as headache, stiff neck, drowsiness, cognitive distortion or confusion, **dizziness**, and anxiety. However, most of these effects cleared up within several hours of the hypnotherapy session.

Research and general acceptance

Research on the effectiveness of hypnotherapy on a variety of medical conditions is extensive. In one study, the use of hypnotherapy did not seem to alter the core symptoms in the treatment of **attention-deficit hyperactivity disorder** (ADHD); however, it did seem useful in managing the associated symptoms including sleep disturbances and tics.

Hypnotherapy is being studied in children who have common, chronic problems and to aid in relieving pain. Children are particularly good candidates for hypnotherapy because their lack of worldly experience enables them to move easily between the rational world and their imagination. Studies with children have shown responses to hypnotherapy ranging from diminished pain and anxiety during a number of medical procedures, a 50% range in reduction of symptoms or a complete resolution of a medical condition, and a reduction in use of anti-nausea medication and **vomiting** during chemotherapy for childhood cancers.

In 2002, a report compiled several study results on hypnosis. One recent study evaluated how self&hypnosis relieved pain and anxiety in patients undergoing angioplasty with local anesthesia. Those patients needed less sedation and less procedure time. Another study found that pregnant adolescents counseled in hypnosis needed less anesthesia during delivery and less pain medication afterward. They also left the hospital sooner.

The use of hypnotherapy with **cancer** patients is another area being investigated. A meta-analysis of 116 studies showed positive results of using hypnotherapy with cancer patients. Ninety-two percent showed a positive effect on **depression**; 93% showed a positive effect on physical well-being; 81% showed a positive effect on vomiting; and 92% showed a positive effect on pain. In 2002, the National Hospice and Palliative Care Association reported that it recognizes hypnosis therapy as one effective tool to help terminally ill patients deal with their fears, feelings, emotions, and promote relaxation.

Training and certification

As of 2000, anyone could be a hypnotherapist. It is very easy to learn how to hypnotize someone, and the fact that hypnotism dates back to ancient times proves the ease with which a trance can be induced. There are no licensing procedures in place that limit the practice of hypnotherapy to medical professionals. Hypnotherapists are not regulated in any way; there are no uniform education or certification requirements to perform hypnotherapy.

The National Board for Hypnotherapy and Hypnotic Anaesthesiology (NBHA) has specific membership requirements, and also offers varying levels of professional recognition. Certification as a Clinical Hypnotherapist (C.Ht.) requires a minimum of 200 hours of classroom instruction, independent study and life learning experience in the medical, dental, psychological, or peer counseling professions. Certification as a Medical Hypnotherapist (C.M.H.) requires meeting the standards for the Clinical Hypnotherapist level plus attending a residential training course or home study training course that requires a clinical practicum/internship approved by the NBHA. Certification as a Hypno-Anesthesia Therapist (Ct.H.A.) requires the successful completion of an NBHA-approved course in Visualization and **Guided Imagery** for Pain Management, and a passing score on the examination. Certification as a Registered Hypnotic Anaesthesiologist (R.H.A.) requires two years of continuous membership in the NBHA at the Ct.H.A. level, and completion of advanced training seminars. The highest level of certification that can be obtained in this organization is Fellow (F.B.H.A.). Requirements for achieving this level of certification include membership at the R.H.A. level and a graduate degree from an accredited university, plus submitting a comprehensive thesis paper.

There is an ongoing debate regarding the issue of clinically trained versus lay hypnotists. The position of the American Society of Clinical Hypnotists (ASCH) is that the training of lay hypnotists is unethical. This organization supports only the training of those persons who are pursuing an advanced degree in the health sciences. ASCH further believes that hypnotherapy is a treatment modality to be used in conjunction with other forms of treatment, not a treatment that stands alone. Medical professionals believe that lay hypnotists keep the view of hypnotherapy in low esteem by the general public. They also believe that their practices are impacted economically by the lay hypnotists.

ASCH and the Society for Clinical and Experimental Hypnosis (SCEH) are two organizations that are trying to set up formal screening, training, and accrediting standards. Both of these organizations offer formal training to medical professionals at their annual meetings.

Hypoglycemia

Definition

Hypoglycemia is a condition in which one's blood sugar falls to abnormally low levels.

Description

Carbohydrates are the main dietary source of the glucose that is absorbed into the bloodstream and used to fuel the body's cells and organs. Glucose concentration is controlled by hormones, primarily insulin and glucagon. Glucose concentration is also controlled by epinephrine (adrenalin) and norepinephrine, as well as growth hormone. If these regulators are not working properly, levels of blood sugar can become either excessive (as in hyperglycemia) or inadequate (as in hypoglycemia). If individuals have a blood sugar level of 70 mg/dL or less, they are considered hypoglycemic, although glucose levels vary widely from one person to another.

Hypoglycemia can occur in several ways.

Drug-induced hypoglycemia

Drug-induced hypoglycemia, a complication of diabetes, is the most commonly seen and most dangerous form of hypoglycemia.

Hypoglycemia occurs most often in diabetics who must inject insulin periodically to lower their blood sugar. While other diabetics are also vulnerable to low blood sugar episodes, they have a lower risk of a serious outcome than do insulin-dependent diabetics. Unless recognized and treated immediately, severe hypoglycemia in the insulin-dependent diabetic can lead to generalized convulsions followed by amnesia and unconsciousness. Death, though rare, is a possible outcome.

In insulin-dependent diabetics, hypoglycemia known as an insulin reaction or insulin shock can be caused by several factors. These include overmedicating with manufactured insulin, missing or delaying a meal, eating too little food for the amount of insulin taken, exercising too strenuously, drinking too much alcohol, or any combination of these factors.

Reactive hypoglycemia

Reactive hypoglycemia (also called idiopathic postprandial hypoglycemia) occurs two to four hours after consumption of a high-carbohydrate meal. A number of kinds of reactive hypoglycemia have been identified. They occur as the result of a deficiency of certain essential hormones or enzymes or problems with the digestive system, especially as the result of stomach surgery. In some cases, this form of hypoglycemia appears to be associated with malfunctions or diseases of the liver, pituitary, adrenals, liver, or pancreas. Children intolerant of a natural sugar (fructose) or who have inherited defects that affect digestion may also experience hypoglycemic attacks. Some children with a negative reaction to aspirin also experience reactive hypoglycemia. It sometimes occurs among people with an intolerance to the sugar found in milk (galactose), and it also often begins before the onset of diabetes.

Fasting hypoglycemia

Fasting hypoglycemia sometimes occurs after long periods without food, but it also happens occasionally following strenuous **exercise**, such as running in a marathon.

Other factors sometimes associated with hypoglycemia are:

- pregnancy
- a weakened immune system
- a poor diet high in simple carbohydrates
- prolonged use of drugs, including antibiotics
- chronic physical or mental stress
- heartbeat irregularities (arrhythmias)
- allergies
- breast cancer
- high blood pressure treated with beta-blocker medications (after strenuous exercise)
- upper gastrointestinal tract surgery

Causes and symptoms

When carbohydrates are eaten, they are converted to glucose that goes into the bloodstream and is distributed throughout the body. Simultaneously, a combination of chemicals that regulate how the body's cells absorb that sugar is released from the liver, pancreas, and adrenal glands. These chemical regulators include insulin, glucagon, epinephrine (adrenalin),

and norepinephrine. The mixture of these regulators released following digestion of carbohydrates is never the same, since the amount of carbohydrates that are eaten is never the same.

Interactions among the regulators are complicated. Any abnormalities in the effectiveness of any one of the regulators can reduce or increase the body's absorption of glucose. Gastrointestinal enzymes such as amylase and lactase that break down carbohydrates may not be functioning properly. These abnormalities may produce hyperglycemia or hypoglycemia and can be detected when the level of glucose in the blood is measured.

Cell sensitivity to these regulators can be changed in many ways. Over time, a person's **stress** level, exercise patterns, advancing age, and dietary habits influence cellular sensitivity. For example, a diet consistently overly rich in carbohydrates increases insulin requirements over time. Eventually, cells can become less receptive to the effects of the regulating chemicals, which can lead to glucose intolerance.

Diet is both a major factor in producing hypoglycemia as well as the primary method for controlling it. **Diets** typical of western cultures contain excess refined carbohydrates, especially in the form of simple carbohydrates such as sweeteners, which are more easily converted to sugar. In poorer parts of the world, the typical diet contains even higher levels of carbohydrates. Fewer dairy products and meat are eaten, and grains, vegetables, and fruits are consumed. This dietary trend is balanced, however, since people in these cultures eat more complex carbohydrates, eat smaller meals, and usually use carbohydrates more efficiently through physical labor.

Early symptoms of severe hypoglycemia, particularly in the drug-induced type of hypoglycemia, resemble an extreme shock reaction. Symptoms include:

- cold and pale skin
- numbness around the mouth
- apprehension
- heart palpitations
- emotional outbursts
- hand tremors
- mental cloudiness
- dilated pupils
- sweating
- fainting

Mild attacks, however, are more common in reactive hypoglycemia and are characterized by extreme tiredness. Patients first lose their alertness, then their muscle strength and coordination. Thinking grows fuzzy, and finally patients become so tired that they become "zombie-like," awake but not functioning. Sometimes they actually fall asleep. Unplanned naps are typical of the chronic hypoglycemic patient, particularly following meals.

Additional symptoms of reactive hypoglycemia include headaches, double vision, staggering or an inability to walk, a craving for salt and/or sweets, abdominal distress, premenstrual tension, chronic **colitis**, **allergies**, ringing in the ears, unusual patterns in the frequency of urination, skin eruptions and inflammations, **pain** in the neck and shoulder muscles, memory problems, and sudden and excessive sweating.

Unfortunately, a number of these symptoms mimic those of other conditions. For example, the **depression**, **insomnia**, irritability, lack of concentration, crying spells, **phobias**, forgetfulness, confusion, unsocial behavior, and suicidal tendencies commonly seen in nervous system and psychiatric disorders may also be hypoglycemic symptoms. It is very important that anyone with symptoms that may suggest reactive hypoglycemia see a doctor.

Because all of its possible symptoms are not likely to be seen in any one person at a specific time, diagnosing hypoglycemia can be difficult. One or more of its many symptoms may be due to another illness. Symptoms may persist in a variety of forms for long periods of time. Symptoms can also change over time within the same person. Factors that can influence symptoms include physical or mental activities, physical or mental state, the amount of time passed since the last meal, the amount and quality of sleep, and exercise patterns.

Diagnosis

Drug-induced hypoglycemia

Once diabetes is diagnosed, patients then monitor their blood sugar level with a portable machine called a glucometer. The diabetic places a small blood sample on a test strip that the machine can read. If the test reveals that the blood sugar level is too low, the diabetic can make a correction by eating or drinking additional carbohydrates.

Reactive hypoglycemia

Reactive hypoglycemia can be diagnosed only by a doctor. Symptoms usually improve after the patient has gone on an appropriate diet. Reactive hypoglycemia was diagnosed more frequently in the 1980s and 1990s than it is in the late 2000s. Studies have shown

that most people suffering from its symptoms test normal for blood sugar, leading many doctors to suggest that actual cases of reactive hypoglycemia are quite rare. Some doctors think that people with hypoglycemic symptoms may be particularly sensitive to the body's normal postmeal release of the hormone epinephrine or are actually suffering from some other physical or mental problem. Other doctors believe reactive hypoglycemia is actually the early onset of diabetes that occurs after a number of years. In the late 2000s there continues to be disagreement about the cause or causes of reactive hypoglycemia.

A common test to diagnose hypoglycemia is the extended oral glucose tolerance test. Following an overnight fast, a concentrated solution of glucose is drunk and blood samples are taken hourly for five to six hours. Though this test remains helpful in early identification of diabetes, its use in diagnosing chronic reactive hypoglycemia has lost favor because it can trigger hypoglycemic symptoms in people with otherwise normal glucose readings. As of 2008 some doctors recommend that blood sugar be tested at the actual time a person experiences hypoglycemic symptoms.

Treatment

Treatment of the immediate symptoms of hypoglycemia can include eating sugar. For example, a patient can eat a piece of candy, drink milk, or drink fruit juice. Glucose tablets can be used by patients, especially those who are diabetic. Effective treatment of hypoglycemia over time requires the patient to follow a modified diet. Patients are usually encouraged to eat small, but frequent, meals throughout the day, avoiding excess simple sugars (including alcohol), fats, and fruit drinks.

One of the herbal remedies commonly suggested for hypoglycemia is a decoction (an extract made by boiling) of gentian (*Gentiana lutea*). It should be drunk warm 15–30 minutes before a meal. Gentian is believed to help stimulate the endocrine (hormone-producing) glands.

In addition to the dietary modifications recommended above, people with hypoglycemia may benefit from supplementing their diet with **chromium**, which is believed to help improve blood sugar levels. Chromium is found in whole grain breads and cereals, cheese, molasses, lean meats, and **brewer's yeast**. Eating oats can help stabilize blood sugar levels. Daily supplements of **vitamin E** are also recommended. Hypoglycemics should avoid alcohol, **caffeine**, and cigarette smoke, since these substances can cause significant swings in blood sugar levels.

Allopathic treatment

Those patients with severe hypoglycemia may require fast-acting glucagon injections that can stabilize their blood sugar within approximately 15 minutes.

Prevention

Drug-induced hypoglycemia

Preventing hypoglycemic insulin reactions in diabetics requires taking glucose readings through frequent blood sampling. Insulin can then be regulated based on those readings. Maintaining proper diet is also a factor. Programmable insulin pumps implanted under the skin have proven useful in reducing the incidence of hypoglycemic episodes for insulin-dependent diabetics. Drug manufacturers have also developed a number of insulin analogs, forms of insulin produced by recombinant DNA (genetic engineering) technology that can be used in place of natural insulin. Some examples of these analogs are lispro (Humalog), aspart (NovoLog), insulin glulisine (Apidra), insulin glargine (Lantus), and insulin detemir (Levemir).

Reactive hypoglycemia

The onset of reactive hypoglycemia can be avoided or at least delayed by following the same kind of diet used to control it. While not as restrictive as the diet diabetics must follow to keep tight control over their disease, it is quite similar.

There are a variety of diet recommendations for the reactive hypoglycemic. Patients should:

- Avoid overeating.
- Never skip breakfast.
- Include protein in all meals and snacks, preferably from sources low in fat, such as the white meat of chicken or turkey, most fish, soy products, or skim milk.
- Restrict intake of fats (particularly saturated fats, such as animal fats), and avoid refined sugars and processed foods.
- Keep a "food diary." Until the diet is stabilized, patients should note what and how much they eat and drink at every meal. If symptoms appear following a meal or snack, patients should note them and look for patterns.

KEY TERMS

Adrenal glands—Two organs that sit atop the kidneys, which make and release hormones such as epinephrine.

Epinephrine—Also called adrenalin, a secretion of the adrenal glands (along with norepinephrine) that helps the liver release glucose and limits the release of insulin. Norepinephrine is both a hormone and a neurotransmitter, a substance that transmits nerve signals.

Fructose—A type of natural sugar found in many fruits, vegetables, and in honey.

Glucagon—A hormone produced in the pancreas that raises the level of glucose in the blood. An injectable form of glucagon, which can be bought in a drug store, is sometimes used to treat insulin shock.

Postprandial—After eating or after a meal.

- Eat fresh fruits, but restrict the amount eaten at one time. Patients should remember to eat a source of protein whenever they eat high sources of carbohydrate such as fruit. Apples make particularly good snacks because, of all fruits, the carbohydrate in apples is digested most slowly.
- Follow a diet that is high in fiber. Fruit is a good source of fiber, as is oatmeal and oat bran, which slows the buildup of sugar in the blood during digestion.

A doctor can recommend a proper diet, and there are many cookbooks available for diabetics. Recipes found in such books are equally effective in helping to control hypoglycemia.

Expected results

Like diabetes, there is no cure for reactive hypoglycemia, only ways to control it. While some chronic cases continue through life (rarely is there complete remission of the condition), others develop into type II (age onset) diabetes. Hypoglycemia appears to have a higher-than-average incidence in families in which there has been a history of hypoglycemia or diabetes among their members, but whether hypoglycemia is a controllable warning of oncoming diabetes had not been determined by clinical research as of 2008.

Hypothyroidism

Definition

Hypothyroidism occurs when there are abnormally low amounts of thyroid hormones in the bloodstream. The condition develops when the thyroid gland fails to produce or secrete as much thyroxine (T_4) and/or triiodothyronine (T_3) as the body needs. Because T_3 and T_4 regulate such essential functions as heart rate, digestion, physical growth, and mental development, an insufficiency of these hormones can slow life-sustaining processes, damage organs and tissues in every part of the body, and lead to life-threatening complications.

Symptoms of hypothyroidism

Goiter

Unexplained weight gain

Tingling or numbness in the hands

Heightened sensitivity to cold

Lethargy

Decreased heart rate

Hoarse voice

Pain, stiffness or swelling in your joints

Elevated blood cholesterol level

Muscle ache, weakness, or stiffness

Heavier than normal menstrual periods

(Illustration by Corey Light. Cengage Learning, Gale)

Description

Hypothyroidism is one of the most common chronic diseases in the United States. Symptoms may not appear until years after the thyroid has stopped functioning, and they are often mistaken for signs of other illnesses, **menopause**, or **aging**. Although this condition is believed to affect as many as 11 million adults and children, as many as two of every three people with hypothyroidism may not know they have the disease.

The thyroid gland influences almost every organ, tissue, and cell in the body. It is shaped like a butterfly and located just below the Adam's apple. The thyroid stores **iodine** the body gets from food and uses this mineral to synthesize T_4 and T_3. T_3 is also produced outside the thyroid gland by the deiodination (removal of iodine) from T_4. This process actually accounts for more than half of the T_3 that circulates in the bloodstream. Low thyroid hormone levels can alter weight, appetite, sleep patterns, body temperature, sex drive, and a variety of other physical, mental, and emotional characteristics.

Scientists know of three types of hypothyroidism. The most common is primary hypothyroidism, in which the thyroid does not produce an adequate amount of T_4. Secondary hypothyroidism develops when the pituitary gland does not release enough of the thyroid-stimulating hormone (TSH) that prompts the thyroid to manufacture T_4. Tertiary hypothyroidism results from a malfunction of the hypothalamus, the part of the brain that controls the endocrine system. Drug-induced hypothyroidism, an adverse reaction to medication, occurs in two of every 10,000 people, but rarely causes severe hypothyroidism.

Hypothyroidism is at least twice as common in women as it is in men. Although hypothyroidism is most common in women who are middle-aged or older, the disease can occur at any age. Newborn infants are tested for congenital (acquired in uterus) thyroid deficiency (cretinism) using a test that measures the levels of thyroxine and TSH in the infant's blood. Treatment within the first few months of life can prevent mental retardation and physical abnormalities. Older children who develop hypothyroidism suddenly stop growing.

Factors that increase a person's risk of developing hypothyroidism include age, weight, and medical history. Women are more likely to develop the disease after age 50; men, after age 60. **Obesity** (excessively fat condition) also increases the risk. A family history of thyroid problems or a personal history of high **cholesterol** levels or such autoimmune diseases as lupus, **rheumatoid arthritis**, or diabetes can make an individual more susceptible to hypothyroidism.

Causes and symptoms

Hypothyroidism is most often the result of Hashimoto's disease, also known as chronic thyroiditis (inflammation of the thyroid gland). In this disease, the immune system fails to recognize that the thyroid gland is part of the body's own tissue and attacks it as if it were a foreign body. The attack by the immune system impairs thyroid function and sometimes destroys the gland. Other causes of hypothyroidism include:

- Radiation (the process whereby an element such as radium emits rays). Radioactive (the quality some atoms have of producing energy) iodine used to treat hyperthyroidism (overactive thyroid) or radiation treatments for head or neck cancers can destroy the thyroid gland
- Surgery. Removal of the thyroid gland because of cancer or other thyroid disorders can result in hypothyroidism
- Viruses (very small organisms that cause disease) and bacteria (one-cell organisms that divide and can cause disease). Infections that depress thyroid hormone production usually cause permanent hypothyroidism.

- Human immunodeficiency virus (HIV). Among viruses, HIV, the virus that causes acquired immunodeficiency syndrome (AIDS), may cause overt hypothyroidism.
- Medication. Nitroprusside, lithium, or iodides can induce hypothyroidism. Because patients who use these medications are closely monitored by their doctors, this side effect is very rare.
- Pituitary gland malfunction. In this rare condition the pituitary gland fails to produce enough TSH to activate the thyroid's production of T_4.
- Congenital defect. One of every 4,000 babies is born without a properly functioning thyroid gland.
- Diet. Because the thyroid makes T_4 from iodine contained in food, an iodine-deficient diet can cause hypothyroidism. Adding iodine to table salt and other common foods has all but eliminated iodine deficiency in the United States. Certain foods (cabbage, rutabagas, peanuts, peaches, soybeans, spinach) can interfere with thyroid hormone production.
- Environmental contaminants. Certain industrial chemicals, such as PCBs, found in the local environment at high levels also may cause hypothyroidism.

Hypothyroidism sometimes is referred to as a silent disease because early symptoms may be so mild that no one realizes anything is wrong. Untreated symptoms become more noticeable and severe and can lead to confusion and mental disorders, breathing difficulties, heart problems, fluctuations in body temperature, and death.

Someone who has hypothyroidism will probably have more than one of the following symptoms:

- fatigue
- decreased heart rate
- progressive hearing loss
- weight gain
- problems with memory and concentration
- depression
- goiter (enlarged thyroid gland)
- muscle pain or weakness
- loss of interest in sex; decreased libido
- numb, tingling hands
- dry skin
- swollen eyelids
- dryness, loss, or premature graying of hair
- extreme sensitivity to cold
- constipation
- irregular menstrual periods
- hoarse voice

Hypothyroidism usually develops gradually. When the disease results from surgery or other treatment for **hyperthyroidism**, symptoms may appear suddenly and include severe **muscle cramps** in the arms, legs, neck, shoulders, and back. It is important to see a doctor if any of these symptoms appear unexpectedly. When hypothyroidism remains undiagnosed and untreated, a person may eventually develop myxedema. Symptoms of this rare but potentially deadly complication include enlarged tongue, swollen facial features, hoarseness, and physical and mental sluggishness.

Myxedema coma can cause unresponsiveness, irregular and shallow breathing, and a drop in blood pressure and body temperature. The onset of this medical emergency can be sudden in people who are elderly or have been ill, injured, or exposed to very cold temperatures; who have recently had surgery; or who use sedatives or antidepressants. Without immediate medical attention, myxedema coma can be fatal.

Diagnosis

The diagnosis of hypothyroidism is based on the patient's observations, medical history, physical examination, and thyroid function tests. Doctors who specialize in treating thyroid disorders (endocrinologists) are most apt to recognize subtle symptoms and physical indications of hypothyroidism. A blood test known as a thyroid-stimulating hormone (TSH) assay tests of T_4 and T_3 levels; a thyroid nuclear medicine scan and thyroid ultrasound are used to confirm the diagnosis. A woman being tested for hypothyroidism should let her doctor know if she is pregnant or breastfeeding. All patients should be sure their doctors are aware of any recent procedures involving radioactive materials or contrast media.

The TSH assay is extremely accurate, but some doctors doubt the test's ability to detect mild hypothyroidism. They advise patients to monitor their basal (resting) body temperature for below-normal readings that could indicate the presence of hypothyroidism. These readings should be taken for five consecutive days, starting on the second day of the menstrual cycle for female patients.

Treatment

Alternative treatments are aimed primarily at strengthening the thyroid gland and will not eliminate the need for thyroid hormone medications. They include nutritional therapy, herbal therapy, and **exercise**.

Nutritional therapy

If a person is experiencing symptoms resembling those of hypothyroidism, it is best to talk to a family physician immediately for appropriate diagnosis and treatments. Nutritional therapy should only be complementary and not be used to replace conventional treatment for this disorder. In 2004, a study found that feeding soy formula to infants with congenital hypothyroidism led to prolonged increases in TSH levels. The study authors recommended close follow-up and frequent TSH measures if infants are put on soy-based formulas.

A naturopath or a nutritionist may recommend the following dietary changes to improve mild hypothyroidism:

- Avoiding eating the following raw foods: cabbage, mustard, spinach, cassava roots, peanuts, soybeans, and peaches. They may interfere with thyroid hormone production if not cooked.
- Eating foods with high iodine content such as fish, shellfish, and seaweed.
- Taking multivitamin and mineral supplements daily. Vitamins A, B_2, B_3, B_6, E, and zinc are needed for normal thyroid hormone production.
- Strengthening thyroid function with thyroid preparations sold at local food stores. They are used to treat mild hypothyroidism only. Available products include thyroid extracts, iodine, zinc, or tyrosine. Most Americans may not need iodine supplements as the daily requirement can easily be met by eating iodine-rich foods or using iodized salt. Consuming more than 600 mcg of iodine per day may result in harmful or toxic effects

Herbal therapies

Herbal remedies to improve thyroid function and relieve thyroid symptoms include **Siberian ginseng** (for treatment of **fatigue**), *Panax ginseng,* and **bladderwrack** (*Fucus vesiculosus,*) which can be taken in capsule form or as a tea.

Homeopathic remedies

Homeopathic treatments (tiny doses of diluted, safe remedies to promote healing) may gradually reduce the need for supplemental thyroid hormone in some patients. Homeopathic remedies for hypothyroidism include homeopathic thyroid as well as others based on the patient's individualized symptoms.

Exercise

Exercise improves thyroid function by stimulating more production of thyroid hormone and making body tissues more responsive to the effects of thyroid hormone. It also increases the metabolic (chemical changes in cells providing energy to the body) rate and helps hypothyroid patients lose weight.

KEY TERMS

Cretinism—Severe hypothyroidism that is present at birth.

Endocrine system—The network of glands that produces hormones and releases them into the bloodstream. The thyroid gland is part of the endocrine system.

Hypothalamus—The part of the brain that controls the endocrine system.

Myxedema—A condition that can result from a thyroid gland that produces too little of its hormone. In addition to a decreased metabolic rate, symptoms may include anemia, slow speech, an enlarged tongue, puffiness of the face and hands, hair loss, coarse and thickened skin, and sensitivity to cold.

Pituitary gland—A small oval endocrine gland attached to the hypothalamus. The pituitary gland releases TSH, the hormone that activates the thyroid gland.

Thyroid-stimulating hormone (TSH)—A hormone secreted by the pituitary gland that controls the release of T_4 by the thyroid gland.

Thyroxine (T_4)—A thyroid hormone that regulates many essential body processes.

Triiodothyronine (T_3)—A thyroid hormone similar to thyroxine but more powerful. Preparations of triiodothyronine are used in treating hypothyroidism.

Allopathic treatment

In allopathic treatment—medical practice that combats disease with remedies that produce effects different from those produced by the disease—natural or synthetic thyroid hormones are used to restore normal (euthyroid) thyroid hormone levels. Synthroid, or synthetic T_4, is easy to take and works for about 80% of patients. In addition, some patients need additional T_3. However, physicians typically disagree about adding this therapy. Synthetic hormones are at least as effective as natural substances, but it may take several months to determine the correct dosage. Patients start to feel better within 48 hours, but symptoms return if they stop taking the medication.

Many doctors prescribe levothyroxine **sodium** tablets, and many people with hypothyroidism take the medication for the rest of their lives. Aging, other medications, and changes in weight and general health can affect how much replacement hormone a patient needs, and regular TSH tests are used to monitor hormone levels. Patients should not switch from one brand of thyroid hormone to another without a doctor's permission.

Possible side effects of too much T_4 or T_3 include **osteoporosis** (after long-term use), occasional **anxiety**, heart palpitations (very fast, strong heartbeat), **insomnia**, and occasional episodes of mania (acting crazed).

Regular exercise and a **high-fiber diet** can help maintain thyroid function and prevent **constipation**.

Expected results

Thyroid hormone replacement therapy generally maintains normal thyroid hormone levels unless treatment is interrupted or discontinued.

Prevention

Primary hypothyroidism cannot be prevented, but routine screening of adults can detect the disease in its early stages and prevent complications.

Hyssop

Description

Hyssop (*Hyssopus officinalis*) is a member of the Lamiaceae or mint family. This aromatic evergreen, classified by botanists as a sub-shrub, should not be confused with several distinct species of plants also called hyssop, including giant hyssop, hedge hyssop, prairie hyssop, or wild hyssop. Hyssop is native to southern Europe and Asia. The London surgeon and apothecary John Gerard, author of the *Herball or Generall Historie of Plantes* brought hyssop to England in 1597. The attractive herb soon became a component in many ornamental knot gardens. The sun-loving hyssop has naturalized throughout North America, and grows wild in chalky soil and on dry and rocky slopes in the Mediterranean.

Hyssop has a short and fibrous rhizome. The stalk emerges from a woody base and divides into numerous erect, square, and branching stems that may reach a height of 2 ft (61 cm). The small leaves are opposite, without stems, and lance-shaped, with fine hairs and smooth margins. They have a somewhat bitter taste. Flowers have a tubular, two-lipped corolla, and four stamens. They bloom in successive whorls in the leaf axils at the top of the stems, only growing along one side. The blooms may be in shades of rose, purple, mauve, blue, and sometimes white, depending on the variety. Hyssop comes into flower from June through October, and the blossoms are well loved by bees. The

perennial hyssop is a sweet and warming aromatic with a camphor-like scent. This garden favorite is especially useful in companion planting. Hyssop attracts the white butterfly, a pest to cabbage and broccoli, thus sparing the food crops from the infestation. The herb also has been used to increase the yield of grapevines and the flavor of the fruit when it is planted nearby.

The Hebrew people called this herb *azob*, meaning "holy herb." Hyssop was used in ancient times as a cleansing herb for temples and other sacred places. It was also used to repel insects. The Romans used hyssop to bring protection from the plague, and prepared an herbal wine containing hyssop. In ancient Greece, the physicians Galen and Hippocrates valued hyssop for inflammations of the throat and chest, pleurisy, and other bronchial complaints. In the early seventeenth and eighteenth centuries, hyssop tea and tincture were used to treat **jaundice** and dropsy.

General use

The flowers and leaves of hyssop are considered medicinally valuable by some herbalists; however, the German Commission E has not approved hyssop for any medicinal purposes. The herb has some antimicrobial and antiviral properties. It is especially useful in helping the immune system to combat respiratory infections and colds. Hyssop, taken in a warm infusion, acts as an expectorant and will help to expel phlegm and break up congestion in the lungs. It is frequently recommended for the treatment of congested sinuses and catarrh. It is also a beneficial herb for treatment of the **cold sore** virus, *Herpes simplex*. An infusion has also been used to relieve the distress of **asthma**. Hyssop is a diaphoretic, and acts to promote perspiration. It will help to reduce fever and eliminate toxins through the skin. Hyssop also acts as a carminative and digestive aid, relieving flatulence and relaxing the digestive system. This versatile herb is also a nervine, which calms anxiety. It is useful in children's digestive and respiratory herbal formulas, as well.

Used externally as a skin wash, a decoction of the flowering tops can help the healing of **burns** and relieve skin inflammations. The fresh, crushed leaves promote healing of bruises, and relieve the discomfort of insect **bites** and stings. When applied as a hair rinse, hyssop may help eliminate head lice. Hyssop preparations have also been used to relieve muscular pain and rheumatism when taken as a tea or as a bath additive. The hot vapors of a steaming decoction of hyssop may bring relief for **earache** and inflammation.

KEY TERMS

Carminative—Any medication or preparation given to expel gas from the digestive tract.

Catarrh—Inflammation of the mucous membranes in the respiratory tract accompanied by heavy secretions.

Diaphoretic—A medication or herbal preparation given to induce or increase perspiration.

Essential oil—A concentrated oil that has been distilled from a plant, usually by the steam method.

Expectorant—A drug given to help bring up mucus or phlegm from the respiratory tract.

Infusion—A method for releasing the herbal essence of herbal leaves and flowers by pouring boiling water over the plant matter and allowing it to steep.

Nervine—A type of medication or herbal preparation given to calm the nerves.

Rhizome—A horizontal underground stem that sends up shoots from its upper surface.

Tincture—The concentrated solution of an herbal extract, usually made with alcohol.

A research study published in 2002 confirmed the results of studies done in the early 1990s, which found that hyssop leaf extract demonstrates strong anti-HIV activity. The specific compounds responsible for this antiviral action, however, were not identified in these studies. Moreover, none of these studies tested the efficacy of hyssop in human subjects. The volatile oil of hyssop contains camphene, pinenes, terpinene, the glycoside hyssopin, flavonoids (including diosmin and **hesperidin**), tannins, acids, resin, gum, and the bitter substance known as marrubiin. Marrubiin is also found in white horehound (*Marrubium vulgare*).

More recently, researchers have discovered that essential oil of hyssop is an effective muscle relaxant. The component that has been identified as most likely responsible for this effect is isopinocamphone.

Preparations

Harvest hyssop when the herb reaches a height of about 1.5 ft (46 cm). Frequent cuttings from the tops of mature plants will keep the foliage tender for use in salads, soups, or teas. Used sparingly in culinary preparations, hyssop's tender shoots are a digestive aid, especially with greasy meats. When harvesting the

herb for medicinal uses, the flowering tops are used. Gather the herb on a sunny August day after the dew has dried. Hang the branches to dry in a warm, airy room out of direct sunlight. Remove leaves and flowers from the stems and store in clearly labeled, tightly sealed, dark-glass containers.

Infusion: Place 3 Tbsp dried, or twice as much fresh, hyssop leaf and blossom in a warm glass container. Bring 2.5 cups of fresh, nonchlorinated water to the boiling point, and add it to the herbs. Cover and infuse the tea for 10–15 minutes. Strain and drink warm. The prepared tea will store for about two days if kept in a sealed container in the refrigerator. Hyssop tea may be enjoyed by the cupful up to three times a day. Hyssop may be combined with white **horehound** for additional expectorant action to relieve coughs. For sore throats, a warm infusion of hyssop combined with sage (*Salvia officinalis*) is a home remedy recommended by some herbalists.

Tincture: Combine four ounces of finely-cut fresh or powdered dry herb with one pint of brandy, gin, or vodka, in a glass container. The alcohol should be enough to cover the plant parts. Place the mixture away from light for about two weeks, shaking several times each day. Strain and store in a tightly-capped, dark glass bottle. A standard dose is 1–2 ml of the tincture three times a day.

Essential oil: The commercially available essential oil of hyssop is obtained by steam distillation of the flowering tops. The oil is highly aromatic and is used in perfumes, **aromatherapy**, and to flavor liqueurs, especially Chartreuse and Benedictine. The oil has a warm and pungent aroma with a slight camphor-like smell. It may be used in dilute form as an external nonirritating application on **bruises**, **cuts**, eczema, and **dermatitis**, as a chest rub for bronchitis and the congestion of colds, and as an additive to bath water to relieve nervous exhaustion and melancholy.

Precautions

Only moderate amounts of hyssop essential oil should be used. Do not use the herb continuously in any form for long periods of time. Pregnant women, children, and persons with **epilepsy** should avoid any use of this potent essential oil. High doses (10–30 drops for adults) may cause convulsions due to the ketone known as pinocamphone. Pregnant or lactating women should not use any form of hyssop.

Side effects

Hyssop can cause **nausea**, upset stomach, and **diarrhea** in susceptible persons. Symptoms of overdose include **dizziness**, tightness in the chest, and disturbances of the central nervous system.

Interactions

No interactions between hyssop and standard pharmaceuticals have been reported as of early 2003.

Iceland moss

Description

Iceland moss (*Cetraria islandica*) is a lichen (a moss-like plant) that grows on the ground in mountains, forests, and arctic areas. In addition to Iceland, the lichen is found in Scandinavia, Great Britain, North America, Russia, and other areas in the Northern Hemisphere. Iceland moss also grows in Antarctica.

The plant's thallus (shoot) curls from 1–4 in (2.5–10 cm) tall. The dried thallus is used as an herbal remedy. Iceland moss is also known as Iceland lichen, cetraria, fucus, muscus, and eryrngo-leaved (spiny-leaf) liverwort.

General use

Iceland moss is rich in **calcium**, **iodine**, **potassium**, phosphorous, and vitamins. The lichen is a bitter-tasting plant that is said to smell like seaweed when it is wet. Despite these unappetizing characteristics, Iceland moss has long been used in Scandinavia and Europe as a food source and a remedy for numerous conditions.

Historic uses of Iceland moss

People in countries including Iceland, Sweden, Norway, Finland, and Russia have used Iceland moss for food and medicine. When used for nourishment, the Iceland moss plant was ground into flour, which was used to bake bread. Boiling the plant was said to remove the bitter taste, so the plant was boiled and made into a jelly. The lichen became part of a gelled dessert with ingredients that could include chocolate, almonds, or lemon.

In addition, Iceland moss was boiled in milk, a beverage served as a remedy for conditions such as malnutrition. The milk-and-lichen beverage was served to sick people, frail children, and the aged. It was also used for serious conditions when the person was vomiting.

Iceland moss also had numerous folk medicine uses. The lichen was a folk remedy for **tuberculosis**, lung disease, chest ailments, and problems with the kidney and bladder. Iceland moss was also used to treat **wounds** that did not heal, **diarrhea**, problems with lactation, fevers, and **gastritis**.

Furthermore, people in Norway ate Iceland moss during a seven-year famine that started in 1807. The Russians found another use for the lichen during World War II, when they prepared a version of molasses with Iceland moss.

Contemporary uses of Iceland moss

The acids in Iceland moss have an antibiotic effect. It is a mild antimicrobial and a demulcent—a remedy that soothes irritated or inflamed mucous membranes. The lichen is used for inflammation of the mouth and pharynx, and for treatment of the **common cold**, fever, dry **cough**, and bronchitis. It is also used for people who have a tendency toward infection. Furthermore, the bitter herb is a remedy for digestive complaints, loss of appetite, and **gastroenteritis**. Iceland moss boiled in milk is still used as a tonic beverage for people recovering from illnesses. In addition, the lichen has been used to treat diabetes.

Preparations

In Europe, Iceland moss cough drops are sold in pharmacies. The lichen is also sold in other forms for a range of conditions. In the United States, Iceland moss is generally found in powdered form and is usually

Iceland moss (Cetraria islandica). *(© Arco Images / Alamy)*

consumed as a tea. It can be used as a gargle to soothe a sore throat .

Iceland moss is made by pouring 1 cup of boiling water over 1–2 tsp of powdered Iceland moss. The mixture is covered and steeped for 10–15 minutes. Sweetener can be added to the tea, or the herb can be mixed with cocoa or chocolate. The average daily dosage of Iceland moss is 1–3 tsp.

An Iceland moss decoction can be made by putting 2 tsp of shredded lichen in 2 cups of cold water. The mixture is simmered for 10 minutes. It is then strained to squeeze out the juice. One cup of the decoction is consumed in the morning and another at night. Iceland moss can also be taken as a tincture.

In addition, Iceland moss can be used topically for skin rashes and fungus.

Precautions

Iceland moss is safe when taken in proper dosages. However, Iceland moss is not regulated by the FDA. Before beginning herbal treatment, people should consult a physician, health practitioner, or herbalist to discuss potential cautions.

Powdered Iceland moss must be soaked in lye for 24 hours or filtered through ash in order to properly extract the lichen acids. One study found that poorly prepared Iceland moss may contain toxic levels of lead. A person should talk to an experienced herbalist or other health practitioner to determine a proper source for Iceland moss, and should not attempt to prepare it oneself.

In rare cases, external use of Iceland moss has caused sensitivity reactions.

KEY TERMS

Decoction—A system for releasing the herbal essence of bark or roots that includes simmering in water.

Infusion—A system for releasing the herbal essence of leaves and flowers in which the herbs are steeped in boiled water.

Tincture—A method of preserving herbs with alcohol or water.

Side effects

Side effects include the rare sensitivity reaction, and the risk of **lead poisoning** in poorly prepared Iceland moss. In excessive doses or with prolonged use, Iceland moss may cause gastric irritation and liver problems.

Interactions

There are no known interactions associated with use of Iceland moss.

Ignatia

Description

Ignatia is a homeopathic remedy that is derived from the bean of a small tree that is native to the Philippine Islands and China. The tree belongs to the Loganiaceae family, and has long, twining, smooth branches. On the branches grows a fruit that is the size and shape of a pear. Inside the fruit are almond-shaped seeds, or beans, that have a fine, downy covering and are blackish gray or clear brown in color.

The Latin name is *Ignatius amara*, amara being the Latin word for bitter. The bean was named after St. Ignatius Loyola, a Spanish Jesuit who was responsible for bringing the beans to Europe from the Philippines in the seventeenth century. As a result, the beans are often called St. Ignatius beans. The missionaries were introduced to the beans by the locals, who wore the beans as amulets to prevent disease. The bean was then used as a treatment for **gout**, **epilepsy**, cholera, and **asthma**.

The beans contain a substantial amount of strychnine, a bitter substance that is often used in rat poison. Strychnine is fatal to humans if taken in large doses. Small doses cause headaches, loss of appetite, cramps, muscle twitching, trembling, frightening dreams, cold sweat, nervous laughter, and giddiness.

General use

Ignatia is one of the best remedies for conditions brought about by emotional upset such as grief, shock, jealousy, fear, anger, **depression**, embarrassment, fright, or ridicule. Homeopaths frequently recommend ignatia when the patient is suffering from romantic disappointment or the loss of a spouse, relative, friend, or pet. The remedy helps the patient bear the grief and suffering common to emotional upsets.

Suppression of the emotions is the general cause of ignatia complaints. Men and women of all ages may benefit from ignatia when they are grieving, but ignatia is particularly well suited for sensitive, delicate women and children. It is recommended for children who develop ailments after being punished, teenagers who are suffering from a lost love, women who have had a miscarriage, and elderly folk who grieve silently. Ignatia is a good remedy for children who suffer from extreme trembling after a fright. Ignatia is frequently prescribed in cases of physical or sexual abuse. Women who suffer from nervousness, confusion, or forgetfulness during their menstrual cycles may also benefit from ignatia.

KEY TERMS

Succussion—A process integral to the creation of a homeopathic remedy in which a homeopathic solution is struck against a firm surface. This is performed to thoroughly mix the substance and magnify its healing properties.

Persons who require the interaction of ignatia are idealistic, introspective, moody, quarrelsome, sensitive to **pain**, timid, easily startled, weepy, and depressed. As a result of their grief they become fearful, apprehensive, and antisocial. They dislike consolation and desire to be alone. When in the company of others they are secretive and try to hold in their emotions, although they sigh frequently and loudly. When alone, they are prone to frequent bouts of sobbing alternating with nervous laughter. They are conscientious about performing tasks correctly.

Ignatia is a remedy of contradictions. Symptoms are often paradoxical and erratic. For example, symptoms of **nausea** are relieved by eating, a **sore throat** is better from swallowing solids, and simple foods are harder to digest than heavier foods. Symptoms may be relieved after passing a hard stool. Lying on the painful side may make the symptoms better. Eating causes the patient to have more hunger. She may crave sour or hard to digest foods. She may also want to remain uncovered when cold. The patient dislikes fresh air and is sensitive to coffee and tobacco.

General symptoms are aggravated by cold air, emotional excitement, mental exertion, sweets, and consolation. They are worse in the morning, evening, night, and before and during **menstruation**. Symptoms may appear at regular intervals, such as headaches that occur every seven days. Symptoms are improved by warmth and eating.

Ignatia is also used as a remedy for headaches, sore throat, trembling, nervousness, **insomnia**, heart palpitations, **gas**, **indigestion**, weakness, and weeping. Other conditions include **irritable bowel syndrome**, painful **hemorrhoids**, or a dry, tickling **cough**.

The cough is a dry, irritating cough that is often accompanied by a stitching pain in the chest. Suppression of the cough is helpful. The patient is made worse by coughing or lying in bed, and the cough is worse in the evening. Ignatia is often used in the treatment of **whooping cough** or **croup**.

The **fever** is often accompanied by extreme thirst and **chills**. The patient feels better when uncovered, and is worse in the afternoon.

Headaches typical of ignatia start gradually and stop suddenly. The pain is gathered in the forehead. The patient may complain of a sensation as if a nail were being driven through her head. Headaches are often caused by emotional upset and are worse in a smoky room.

A sore throat accompanied by stitching pains and a sensation as if there were a lump in the throat is often present as a result of suppressed emotions. The throat is worse in the evening and is better from swallowing.

When indigestion is present, the patient may feel as though her stomach were empty. She may suffer from sour-tasting belches that ameliorate her symptoms.

Preparations

Ignatia is prepared by grinding the bean into a powder and steeping the powder in alcohol. The mixture is strained and diluted until it becomes a non-toxic substance. It is then succussed to create the final preparation.

During an emotional crisis, take a single dose of 30X or 30C. If the symptoms are unchanged after eight hours, try another remedy. If the dose helps, repeat the dose only when the symptoms worsen. Do not take more than two times a day for three days.

Precautions

If symptoms do not improve after the recommended time period, consult your homeopath or health-care practitioner.

Do not exceed the recommended dose.

Ignatia may cause insomnia and should be taken in the morning.

Side effects

The only side effects are individual aggravations that may occur.

Interactions

When taking any homeopathic remedy, do not use **peppermint** products, coffee, or alcohol. These products may cause the remedy to be ineffective.

Immuno-augmentation therapy

Definition

Immuno-augmentation therapy (IAT), also called immuno-augmentative or immuno-augmentive therapy, is a **cancer** treatment aimed at restoring the immune system with injections of a mixture of blood factors.

Origins

Dr. Lawrence Burton formulated the theory behind IAT in the 1950s. After earning his doctorate in experimental zoology in 1955 from New York University, Burton moved to the California Institute of Technology (Caltech) as a postdoctoral fellow in the laboratory of H. K. Mitchell. There, he and his coworkers discovered a tumor-inducing factor (TIF) in fruit flies. A few years later, Burton and his colleague, Dr. Frank Friedman, joined the cancer research staff of Dr. Antonio Rottino at St. Vincent's Hospital in New York City. Rottino was one of the first scientists to conclude that a connection existed between the body's immune system and cancer.

Burton and the development of IAT

Burton and his colleagues reported finding an inhibitor of fruit-fly TIF in mice and human tissue, but afterward, Mitchell published a retraction of the papers he had coauthored with Burton. Mitchell claimed that Burton's assay for TIF—on which Burton was basing his recent work—could not be repeated independently. Undeterred, Burton continued using fruit flies and mice to develop a mixture of blood proteins to slow or stop the proliferation of cancer cells.

By the mid-1960s, Burton was making sensational presentations. In 1966, at an American Cancer Society (ACS) seminar for science writers, Burton injected mice with his "unblocking factor," and their tumors shrunk in less than an hour. Although newspaper headlines read "15-Minute Cancer Cure," the medical community was unconvinced. Professional journals refused to publish Burton's papers and he eventually lost his research funding. The American Cancer Society (ACS) placed Burton's IAT on its list of unproven methods.

In 1973, Burton and Friedman left St. Vincent's and, with independent funding, founded the Immunology Researching Foundation in Great Neck, New York. They began treating cancer patients with IAT. The following year they submitted an investigational new drug application to the United States Food and Drug Administration (FDA) in order to begin clinical trials of IAT. When FDA officials asked for his experimental evidence, however, Burton withdrew his application.

Burton and Friedman eventually patented four substances that they claimed to have isolated from human blood:

- deblocking protein
- tumor antibody 1
- tumor antibody 2
- tumor complementBurton claimed that when used in the correct combination, these substances restored normal immune function in cancer patients.

During the 1970s and early 1980s, the National Cancer Institute (NCI) tried to evaluate IAT. Burton refused to disclose his methods for isolating his blood substances, and and the NCI and Burton could not reach an agreement regarding evaluation methods.

The Bahamian clinic

Hostility from the medical establishment drove Burton to close his New York clinic in 1977. With private funding, he founded the Immunology Researching Centre (IRC), Ltd. in Freeport on Grand Bahama Island. This not-for-profit organization was licensed to treat people who had been diagnosed with cancer. In 1978, representatives from the Bahamian Ministry of Health and the Pan American Health Organization found violations in admissions, treatment, and evaluation of the clinic's patients. They could not determine the blood components used in IAT, and found no records of patient survival rates. They concluded that there was no evidence that IAT was effective, and recommended that the facility be closed.

Nonetheless, the Bahamian health authority did not shut down the clinic until 1985. At that time, blood supplies across the United States had been found to be contaminated with the human immunodeficiency virus (HIV) and Burton's clinic was no exception. Indeed, the clinic had treated Kaposi's sarcoma in patients with acquired immune deficiency syndrome (**AIDS**). Although no HIV **infections** were ever traced to the clinic, and some scientists questioned the HIV screening used by the authorities, the sera used in IAT were found to carry **hepatitis** virus and infectious bacteria. At least two cases of hepatitis were traced to the sera. The Bahamian government, at the apparent insistence of the FDA and the NCI, closed the Burton's clinic for seven months, until screening and sterilization methods for serum production were improved.

Shortly thereafter, the FDA banned the import of IAT drugs. IAT had been legalized in Florida and Oklahoma in the early 1980s, although Florida rescinded its law when the clinic closed.

The closing of Burton's clinic and the ban on sera import enraged many patients and their families. They formed the Immuno-Augmentative Therapy Patient Association (IATPA), later renamed People Against Cancer, and began lobbying the United States Congress. In 1986, the Office of Technology Assessment (OTA), then a research branch of Congress, was told to investigate alternative cancer therapies. OTA worked with Burton to develop procedures for an IAT clinical trial on colon cancer patients, but the arrangement broke down, and the OTA concluded that no reliable data existed with which to evaluate IAT.

During the 1990s, the Burton's Immunology Researching Centre opened additional clinics in Germany and Mexico. Burton died in 1993 and his longtime associate, Dr. R. John Clement, took over IRC operations. In 2003, Clement founded the ITL Cancer Clinic, a new operating company for the IRC. This new, expanded clinic began offering cancer vaccines, and additional mainstream and alternative treatments combined with IAT.

Benefits

Proponents claim that the therapy can stop the spread of many cancers and may send the cancer into remission. They claim that by treating deficiencies or imbalances in the immune system, the body is able treat itself, resulting in an extended lifespan and enhanced quality of life. They note, however, that sometimes the disease has spread too far within the body to respond to IAT. Furthermore, if chemotherapy or radiation treatment has over-suppressed the immune system, response to IAT may be slow.

IAT has been claimed to have about a 19 percent effectiveness rate, but various cancers respond differently:

- Bladder cancer responds favorably.
- Brain cancer: astrocytomas (non-capsulated brain tumors arising in brain cells called astrocytes), grades I and II, respond favorably; grade III does not respond well; glioblastoma multiforme (the fastest-growing type of brain tumor) is not a candidate for IAT.
- Breast cancer: all types respond, although inflammatory cancers respond poorly.
- Cervical cancer: responds in early stages; mixed results in late stages.
- Colorectal cancer: good response in most stages; metastasis to the liver disqualifies it for IAT.
- Head and neck cancers respond favorably.
- Leukemias: adult chronic types respond to IAT.
- Lung cancers: adeno- and squamous-cell (large-cell) cancers and mesotheliomas respond well to IAT; small-cell, oat-cell, and undifferentiated cancers are not candidates for IAT.
- Lymphoma: responses vary.
- Melanomas: extremely variable responses.
- Myeloma responds well, even at late stages.
- Pancreatic cancer: good response in some cases, although IAT may be inappropriate because of disease complications.
- Prostate cancer responds at all stages.
- Skin metastasis does not respond to IAT.

Description

Both conventional cancer immunotherapy and IAT are based on enhancement of the immune system. Sometimes called immune enhancement or immune modulation, conventional immunotherapy is used at many U. S. clinics. Clinical trials have found conventional immunotherapy useful for treating various cancers, including melanoma, lymphoma, kidney, and bladder cancers.

IAT components and treatment

Three serum factors are used in IAT:

- Tumor antibody factor (TAF), more commonly called tumor necrosis factor (TNF), may induce antibodies that destroy tumors.
- Tumor complement factor (TCF) is said to induce antibody formation.
- De-blocking protein factor (DPF) is claimed to remove an endogenous blocking protein that prevents the immune system from detecting the cancer.TAF and DPF are isolated from the blood of healthy donors. TCF is isolated from the clotted blood of cancer patients.

IAT patients are screened for imbalances in immune system components. During the initial treatment, blood factors are measured once or twice per day, five days per week. In addition to measuring the serum factors used in treatment, the blood is analyzed for blocking protein factor (BPF). High levels of BPF and low levels of DPF and TCF are claimed to cause immunosuppression or immunodeficiency, enabling the cancer to grow and spread. This data determines the amount of each serum to be injected into the patient.

Treatment varies from one to 12 daily injections. Treatment is on an outpatient basis for an average of 10–12 weeks. Following outpatient treatment, patients are given supplies of sera and a computerized prescription for home injections. Home treatment may last weeks, months, or the rest of one's life. Patients typically return to the clinic for about two weeks, every four to six months. They undergo measurements of tumor activity and IAT responses, in conjunction with conventional methods for determining tumor regression, and symptom and disease remission.

Approximate costs

IAT is expensive:

- Four weeks of initial and intensive therapy—$7,500.
- Each week thereafter—$700.
- Home maintenance supplies—$50 per week.

These fees do not include:

- Special medications or nutrients not used in routine IAT.
- Laboratory or other tests performed outside of the clinic.
- Outside physician or hospital services.
- Medical aids or equipment not prescribed or supplied by the clinic.
- Transportation, lodging, and living expenses during outpatient treatment.IAT usually is not covered by insurance.

Preparations

Under Bahamian law, IAT patients must have been previously diagnosed with cancer. Patients are screened to determine if IAT is appropriate for their type of cancer. Typically, patients travel to an IAT clinic, where they receive a physical exam, and blood and urine tests to determine the status of their immune

KEY TERMS

Adenocarcinoma—A cancerous tumor derived from epithelial (surface) cells or a gland-like tumor.

Antibody—A protein that recognizes and destroys a specific foreign antigen, such as a cancer cell.

Best-case series—A preliminary study that relies on assumptions about patient outcomes without a specific treatment, compared with similar patients receiving the best available conventional treatments. There are no control cases.

Blocking protein factor (BPF)—A serum component that may prevent the immune system from recognizing cancer cells.

Complement—A large group of serum proteins that are involved in the immune response.

De-blocking protein factor (DPF)—A serum component used in IAT that is claimed to inactivate or remove BPF.

Immune system—The body system that fights infection and disease.

Mesothelioma—A tumor consisting of spindle cells or fibrous tissue, usually in the lining of the lung.

Metastasis, pl. metastases—A secondary tumor; the process by which cancerous cells form secondary tumors in distant parts of the body.

Serum, pl. sera—The clear liquid that remains after cellular components are removed from blood by clotting; a blood derivative containing an antitoxin for diagnostic or therapeutic use.

Tumor—An overgrowth of body tissue.

Tumor antibody factor (TAF)—A component of IAT sera, possibly tumor necrosis factor (TNF), that may induce antibodies that destroy tumors.

Tumor complement factor (TCF)—A component of IAT sera that stimulates antibody production.

Tumor-inducing factor (TIF)—A blood component that can initiate tumor growth.

system. IAT appears to be more effective among patients who have not had chemotherapy.

IAT patients are asked to abstain from tobacco and to limit alcohol consumption during treatment. **Lung cancer** patients must have stopped **smoking** prior to treatment at the IRC. In addition, patients should:

- Avoid dietary animal fats
- Avoid excess vitamin C
- Take antioxidant supplements that are recommended

Precautions

Proponents of IAT claim that it is nontoxic, safe, and effective. However, there have been no controlled clinical studies of IAT, and scientists have not been able to replicate Burton's original results with mice. In addition:

- IAT sera have not been tested for safety by accepted medical standards.
- Some medical practitioners caution that the unregulated IAT sera may contain infectious agents transmitted in human blood.
- Relying on IAT in place of conventional cancer treatments may have serious health consequences.

Side effects

Anecdotal reports from patients indicate that the side effects of IAT are minor and include:

- Fatigue
- Pain at the injection site
- Flu-like symptoms
- Pain and edema (fluid accumulation) during IAT given to bone cancer patients

Research and general acceptance

There is no scientific evidence that IAT is an effective cancer treatment. In addition, there is no scientific evidence that IAT sera contain specific components. In 1980, MetPath, a biomedical firm, terminated a contract with Burton after they could not identify or measure a substance that Burton claimed was present in IAT serum. Most anecdotal claims and testimonials for IAT's effectiveness against cancer are without supporting evidence.

In 1984, researchers at the University of Pennsylvania Cancer Center collected data from 79 patients who had received IAT at Burton's clinic. They concluded that reliable comparisons with those receiving conventional cancer treatment were not possible; however, their survey did find extended survival times among the IAT patients. They suggested that a well-controlled prospective study be performed.

In April 2003, the United States Agency for Healthcare Research and Quality (AHRQ) issued a report on IAT. Using criteria developed by the NCI, they conducted a "best-case series" to examine nine cancer patients treated with IAT. Their cancers included:

- Hodgkin's lymphoma
- Non-small cell carcinoma of the lung

- Poorly differentiated nodular lymphoma
- Peritoneal mesothelioma (two cases)
- Ovarian adenocarcinoma
- Squamous cell carcinoma of the vocal cords (two cases)
- Adenocarcinoma of the colonThe report concluded that IAT warranted further study. It recommended either a random controlled clinical trial or a prospective case series with treatment protocol and documentation established prior to treatment. Also in 2003, however, a research study from the Samueli Institute for Information Biology in Virginia tested 46 patients who were undergoing IAT treatment. The researchers found no indication of effectiveness, nor any improvement in the patients' quality of life.

Training and certification

IAT practitioners are usually medical doctors.

Impetigo

Definition

Impetigo is a contagious bacterial infection of the skin. It primarily afflicts children and the elderly. Ecthyma is a more severe form of impetigo with sores affecting a deeper layer of the skin. It often leaves scarring and discoloration of the skin.

Description

The first sign of impetigo is a clear, fluid-filled bump, called a vesicle, which appears on the skin. The vesicle soon dries out and develops a scab-like, honey-colored crust, which breaks open and leaks fluid. These vesicles usually appear grouped closely together, and they may spread out and cover a large area of the skin. Impetigo often affects the area around the nose and mouth; however, it can spread to anywhere on the skin, but especially the arms and legs, as well as the diaper areas of infants. The condition called ecthyma is a form of impetigo in which the sores that develop are larger, filled with pus, and covered with brownish-black scabs that may lead to scarring. Impetigo **infections** most commonly occur during warmer weather.

Impetigo on a patient's foot. *(ISM/Phototake, Reproduced by permission.)*

Causes and symptoms

Impetigo is most frequently caused by the bacteria *Staphylococcus aureus,* also known as staph, and less frequently, by group A beta-hemolytic streptococci, also known as strep. These bacteria are highly contagious. Impetigo can quickly spread from one part of the body to another through scratching. It can also be spread to other people if they touch the infected sores or if they have contact with the soiled clothing, diapers, bed sheets, or toys of an infected person. Factors such as heat, humidity, crowded conditions, and poor hygiene increase the chance that impetigo will spread rapidly among large groups.

Impetigo tends to develop in areas of the skin which have already been damaged through some other means such as injury, insect bite, **sunburn**, **diaper rash**, chicken pox, or herpes, especially oral herpes. The sores tend to be very itchy, and scratching may lead to the spread of the disease. Keeping the hands washed with antibacterial soap, and fingernails well trimmed are good precautions for limiting further infection.

Diagnosis

Observation of the appearance, location, and pattern of sores is the usual method of diagnosis. Fluid from the vesicles can be cultured and examined to identify the causative bacteria.

Treatment

Echinacea tincture can be applied directly to the skin. The homeopathic remedy *Antimonium tartaricum* can be used when impetigo affects the face.

Bag Balm, an anti-bacterial salve, can be applied to sores to relieve **pain** and heal the skin.

A tincture of the pansy flower, *Viola tricolor,* can be taken internally twice daily for a week to speed healing.

Burdock root oil can be directly applied to the skin to help it heal.

Topical washes with **goldenseal**, **grapefruit seed extract** (which may sting), or **tea tree oil** are also recommended.

Allopathic treatment

Uncomplicated impetigo is usually treated with a topical antibiotic cream such as mupirocin (Bactroban). Oral antibiotics are also commonly prescribed. Patients are advised to wash the affected areas with an antibacterial soap and water several times per day and to otherwise keep the skin dry. Scratching is discouraged, and the suggestion is that nails be cut or that mittens be worn—especially with young children. Ecthyma is treated in the same manner but at times may require surgical debridement, or removal of the affected area.

KEY TERMS

Sequela—Any abnormal condition that follows as the result of a disease or injury.

Systemic—Involving the whole body; the opposite of localized.

Expected results

The vast majority of those with impetigo recover quickly, completely, and uneventfully. However, there is a chance of developing a serious disease, or sequela, especially if the infection is left untreated. Local spread of the infection can cause osteomyelitis, septic arthritis, cellulitis, or lymphangitis. If large quantities of the bacteria begin to circulate in the bloodstream, there is also a danger of a systemic infection developing, such as glomerulonephritis or **pneumonia**.

Prevention

Prevention of impetigo involves good hygiene. In order to avoid spreading the infection from one person to another, those with impetigo should be isolated until all sores are healed, and their used linen, clothing, and toys should be kept out of contact with others.

Impotence

Definition

Impotence, also known as erectile dysfunction (ED), is the inability to achieve or maintain an erection long enough to engage in sexual intercourse.

Description

Under normal circumstances, when a man is sexually stimulated, his brain sends a message down the spinal cord and into the nerves of the penis. The nerve endings in the penis release chemical messengers, called neurotransmitters, that signal the arteries that supply blood to the corpora cavernosa (the two spongy rods of tissue that span the length of the penis) to relax and fill with blood. As they expand, the corpora cavernosa close off other veins that would normally drain blood from the penis. As the penis becomes engorged with blood, it enlarges and stiffens, causing an erection. Problems with blood vessels, nerves, or tissues of the penis can interfere with an erection.

Causes and symptoms

Estimates of the rate of impotence vary widely. A 2006 review of 13 studies on ED completed prior to 1998 reported on the Public Library of Science (PLoS) Web site found impotency rates ranging from 1% to more than 70%, depending on age, nationality, health status, and other factors. The figure most commonly quoted for the prevalence of ED among American males appears to be between 15 and 30 million, again depending on a number of personal factors. The PLoS article points out that estimates of the prevalence of ED are not a purely scientific issue. Drug manufacturers who make medications for the treatment of the disorder may wish to inflate the actual number of cases to broaden the appeal of their product.

In any case, medical views on impotence have changed significantly over the past few decades. For example, as of 2008, the disorder was being diagnosed much more commonly than it had been previously. A study conducted as part of the National Ambulatory Medical Care Survey in 1998 found that the rate of impotence cases reported at physician's offices had nearly tripled between 1985 and 1999, from 7.7 per 1,000 visits for 1985 to 22.3 visits per 1,000 in 1999. At one time, doctors thought that most cases of impotence were psychological in origin. They later recognized that, at least in older men, physical causes may play a primary role in 60% or more of all cases. In men over the age of 60, the leading cause is **atherosclerosis**, or narrowing of the arteries, which can restrict the flow of blood to the penis. Injury or disease of the connective tissue, such as Peyronie's disease, may prevent the corpora cavernosa from completely expanding. Damage to the nerves of the penis from certain types of surgery or neurological conditions, such as Parkinson's disease or **multiple sclerosis**, may also cause impotence. Men with diabetes are especially at risk for impotence because of their high risk of both atherosclerosis and a nerve disease called diabetic neuropathy.

Some drugs, including certain types of blood pressure medications, antihistamines, tranquilizers (especially before intercourse), and antidepressants known as selective serotonin reuptake inhibitors (SSRIs, including Prozac and Paxil) can interfere with erections. **Smoking**, excessive alcohol consumption, and illicit drug use may also contribute. In some cases, low levels of the male hormone testosterone may contribute to erectile failure. Finally, psychological factors, such as **stress**, guilt, or **anxiety**, may also play a role, even when the impotence is primarily due to organic causes.

Diagnosis

When diagnosing the underlying cause of impotence, the doctor begins by asking the man a number of questions about when the problem began, whether it happens only with specific sex partners, and whether he ever wakes up with an erection. (Men whose dysfunction occurs only with certain partners or who wake up with erections are more likely to have a psychological cause for their impotence.) Sometimes, the man's sex partner is also interviewed. In some cases, domestic discord may be a factor.

The doctor also obtains a thorough medical history to find out about past pelvic surgery, diabetes, cardiovascular disease, kidney disease, and any medications the man may be taking. The physical examination should include a genital examination, hormone tests, and a glucose test for diabetes. Sometimes a measurement of blood flow through the penis may be taken.

Alternative health practitioners often forgo such extensive testing and rely on information obtained from the patient. Usually the fact that the man cannot get or maintain an erection is reason enough to begin alternative or holistic therapy.

Treatment

A number of herbs have been promoted for treating impotence. The most widely touted is **yohimbe**

(*Corynanthe yohimbe*), derived from the bark of the yohimbe tree native to West Africa. It was used in Europe for for most of the twentieth century to treat erectile dysfunction. In the United States, yohimbe products are available in two formats. One is a prescription drug that contains yohimbine, the active ingredient in yohimbe bark. This drug has been approved by the U.S. Food and Drug Administration (FDA) for use with ED and some other medical problems. It is available under a number of trade names, including Yocon, Aphrodyne, Erex, Yohimex, Testomar, Yohimbe, and Yovital. The second form includes a variety of supplements that contain more or less of the natural product. As a dietary supplement, this form of yohimbe is not regulated by the FDA. In fact, the agency strongly recommends against use of the product because of its very serious side effects, which may include paralysis, **fatigue**, stomach disorders, and even death.

There is no clear medical research that indicates exactly how or why yohimbe works in treating impotence. It is generally believed that yohimbe dilates blood vessels and stimulates blood flow to the penis, causing an erection. It also prevents blood from flowing out of the penis during an erection. It may also act on the central nervous system, specifically the lower spinal cord area where sexual signals are transmitted. Studies show it is effective in 30–40% of men with impotence. It is primarily effective in men with impotence caused by vascular, psychogenic (originating in the mind), or diabetic problems. It usually does not work in men whose impotence is caused by organic nerve damage. In healthy men without impotence, yohimbe in some cases appears to increase sexual stamina and prolong erections.

The usual dosage of yohimbine (yohimbe extract) to treat erectile dysfunction is 5.4 mg three times a day. It may take three to six weeks for it to take effect. Most commercially available supplements do not contain enough yohimbe to be effective and doctors recommend obtaining a prescription for yohimbe to get enough active ingredient to meet with success.

Ginkgo (*Ginkgo biloba*) is also used to treat impotence, although it has not been shown to help the condition in controlled studies and probably has more of a psychological effect. In addition, ginkgo carries some risk of abnormal blood clotting and should be avoided by men taking blood thinners, such as coumadin. Other herbs promoted for treating impotence include true unicorn root (*Aletrius farinosa*), **saw palmetto** (*Serenoa repens*), ginseng (*Panax ginseng*), and **Siberian ginseng** (*Eleuthrococcus senticosus*). Nux vomica (*Strychnos nux-vomica*) has been recommended, especially when impotence is caused by excessive alcohol, cigarettes, or dietary indiscretions. Nux vomica can be very toxic if taken improperly, so it should be used only under the strict supervision of a physician trained in its use.

A number of Chinese herbal remedies are available for treatment of impotence, usually combinations of herbs and sometimes such animal parts as deer antler and sea horse.

Allopathic treatment

Years ago, the standard treatment for impotence was a penile implant or long-term **psychotherapy**. Although physical causes are in the late 2000s more readily diagnosed and treated, individual or marital counseling is still an effective treatment for impotence when emotional factors play a role. Fortunately, other approaches are available to treat the physical causes of impotence.

The first drug developed for the treatment of ED was sildenafil citrate, sold under the brand name Viagra. It quickly became one of the most dramatic commercial successes in drug history. In the two-year period following its approval by the FDA in March 1998, sales reached more than a billion dollars annually. In 2007, worldwide sales were still high, at $1.76 billion. Viagra is a very effective treatment for ED, with a success rate of more than 60%. The drug boosts levels of a substance called cyclic GMP, which is responsible for widening the blood vessels of the penis. In clinical studies, Viagra produced headaches in 16% of men who took it, and other side effects included flushing, **indigestion**, and stuffy nose.

The primary drawback to Viagra, which works about an hour after it is taken, is that the FDA cautions men with **heart disease** or low blood pressure to be thoroughly examined by a physician before obtaining a prescription. At least 130 men have died while taking Viagra. Shortly after use of the drug skyrocketed, concerns were expressed over cardiovascular effects from Viagra. However, studies reported in 2002 that sildenafil had no effect on cardiac symptoms in older men who used it. Instead, cardiac events reported with use of Viagra are more likely the result of the physical demands of sexual activity in patients using the drug who were already at higher risk for cardiovascular disease.

In 2003, the FDA approved two additional drugs for the treatment of ED, vardenafil (Levitra) and tadalafil (Cialis). The three drugs all work in essentially the same way and have about the same success rate. Manufacturers claim that one or the other works

KEY TERMS

Atherosclerosis—A disorder in which plaques of cholesterol, lipids, and other debris build up on the inner walls of arteries, narrowing them.

Cialis—Trade name for tadalafil, an oral medication for the treatment of impotence.

Corpus cavernosum (plural, corpora cavernosa)—One of two rods of spongy tissue in the penis that become engorged with blood in order to produce an erection.

Gene therapy—A method of treating a disorder by replacing damaged or abnormal genes with normal ones. Some researchers think that gene therapy may offer a new way to treat impotence.

Levitra—Trade name for vardenafil, an oral medication for the treatment of impotence.

Neurotransmitters—Chemicals that modify or help transmit impulses across nerve synapses.

Penile implant—An artificial device inserted by surgery in the penis to produce an erection. Implantation of rigid or semi-rigid bars produces a permanent erection; use of an inflatable device allows the man to produce an erection at will.

Peyronie's disease—A disease resulting from scarring of the corpus cavernosa, which causes painful erections.

Topical—A type of medication that is applied to a specific and limited area of skin and affects only the area to which it is applied.

Urethra—The small tube that drains urine from the bladder and in men serves as a conduit for semen during ejaculation.

Viagra—Trade name of an orally administered drug for erectile failure first cleared for marketing in the United States in March 1998. Its generic name is sildenafil citrate.

faster, has fewer side effects, and lasts longer, but such differences are relatively insignificant.

Other medications under investigation as treatments for impotence are topical agents, which means that they are applied externally to the skin rather than being injected or taken by mouth. If approved, these drugs would provide a noninvasive alternative for men who cannot take sildenafil, vardenafil, tadalafil, or other oral medications for impotence. In November 2007, the FDA accepted a new drug application filed by NexMed, Inc., for its topical ointment containing the compound alprostadil for treatment of impotence.

Other traditional therapies for impotence include vacuum pump therapy, injection therapy involving injecting a substance into the penis to enhance blood flow, and a penile implantation device. In rare cases, if narrowed or diseased veins are responsible for impotence, surgeons may reroute the blood flow into the corpus cavernosa or remove leaking vessels.

A later approach to the treatment of erectile dysfunction is gene therapy. As of early 2008, several preclinical studies had shown promise, but none of the gene-based strategies at the time had been tested for safety.

Expected results

With proper diagnosis, impotence can nearly always be treated or coped with successfully. Unfortunately, fewer than 10% of impotent men seek treatment.

Prevention

There is no specific treatment to prevent impotence. Perhaps the most important measure is to maintain general good health and avoid atherosclerosis by exercising regularly, controlling weight, controlling **hypertension** and high **cholesterol** levels, and not smoking. Avoiding excessive alcohol intake may also help.

Indigestion

Definition

Indigestion, which is sometimes called dyspepsia, is a general term covering a group of nonspecific symptoms in the digestive tract. It is often described as a feeling of fullness, bloating, **nausea**, **heartburn**, or gassy discomfort in the chest or abdomen. The symptoms develop during meals or shortly afterward. In approximately 44% of cases, indigestion is a minor problem that often clears up without professional treatment. Researchers believe, however, that chronic heartburn can lead to more serious disorders, such as esophageal **cancer**. It is also important for patients with indigestion to be evaluated for a possible cardiac disease.

Description

Indigestion, or dyspepsia, is a widespread condition, estimated to occur in 25% of the adult population of the United States. Most people with indigestion do not feel sick enough to see a doctor; nonetheless, it is a common reason for office visits. About 3% of visits to primary-care doctors are for indigestion.

Effective therapies for indigestion

Therapy	Description
Acupressure	Massage the soft flesh between the thumb and pointer finger (Large Intestine 4) and press two fingers width away from the navel on both sides of the stomach (Stomach 25)
Aromatherapy	Ingest one drop of tarragon, marjoram, or rosemary accompanied by honey or other edible oils (safflower, almond, etc.)
Herbal medicine	Lavender, chamomile, peppermint, goldenseal, or lemon balm tea
Hydrotherapy	Hot water bottle or hot compresses on abdomen
Massage	Abdominal massage
Traditional Chinese medicine (TCM)	Chinese herbal formulas such as Po Chai and Pill Curing

(Illustration by Corey Light. Cengage Learning, Gale)

Causes and symptoms

Physical causes

The symptoms associated with indigestion have a variety of possible physical causes, ranging from commonplace food items to serious systemic disorders:

- Diet. Milk, milk products, alcoholic beverages, tea, and coffee cause indigestion in some people because they stimulate the stomach's production of acid.
- Medications. Certain prescription drugs as well as over-the-counter medications can irritate the stomach lining. These medications include nonsteroidal anti-inflammatory drugs (NSAIDs, or over-the-counter pain killers such as aspirin), some antibiotics, digoxin, calcium antagonists, nitrates, theophylline, corticosteroids, iron (ferrous sulfate), oral contraceptives, and tricyclic antidepressants.
- Disorders of the pancreas and gallbladder. These include inflammation of the gallbladder or pancreas, cancer of the pancreas, and gallstones.
- Intestinal parasites. Parasitic infections that cause indigestion include amebiasis, fluke and tapeworm infections, giardiasis, and strongyloidiasis.
- Systemic disorders, including diabetes, thyroid disease, and collagen vascular disease.
- Cancers of the digestive tract.
- Conditions associated with women's reproductive organs. These conditions include menstrual cramps, pregnancy, and pelvic inflammatory disease.

Psychological & emotional causes

Indigestion often accompanies an emotional upset because the part of the nervous system involved in the so-called fight-or-flight response also affects the digestive tract. People diagnosed with **anxiety** or somatoform disorders frequently have problems with indigestion. Many people in the general population, however, also experience heartburn, what is commonly called butterflies in the stomach, or stomach cramps when they are in upsetting situations—such as school examinations, arguments with family members, crises in their workplace, and so on. Some people's digestive systems appear to react more intensely to emotional **stress** due to hypersensitive nerve endings in their intestinal tract.

Specific gastrointestinal disorders

In some cases, the patient's description of the symptoms suggests a specific digestive disorder as the cause of the indigestion. Some doctors classify these cases into three groups:

ESOPHAGITIS TYPE. Esophagitis is an inflammation of the tube that carries food from the throat to the stomach (the esophagus). The tissues of the esophagus can become irritated by the flow (reflux) of stomach acid backward into the lower part of the esophagus. If the patient describes the indigestion in terms of frequent or intense heartburn, the doctor considers gastroesophageal reflux disease (GERD) as a possible cause. GERD is a common disorder in the general population, affecting about 30% of adults. In 2001, a study showed that **obesity** impairs the antireflux action. Those who are overweight have more severe reflux than most patients. Nighttime GERD affects 79% of adults with heartburn and is potentially more destructive to the esophagus than daytime indigestion. Another study found that acid reflux leads to **cough** and **wheezing** problems, particularly in people with **asthma**.

GERD also affects some infants and children and is a common cause of babies' spitting up formula. In most cases, the condition resolves itself, but children older than one year with regularly occurring **pain** in the lower chest or upper abdomen should cause concern. If a child is bothered by these symptoms during sleep or activities, a physician should be consulted.

PEPTIC ULCER TYPE. Patients who smoke and are over 45 are more likely to have indigestion of the peptic ulcer type. This group also includes people who find that their indigestion is relieved by taking antacids or eating a small amount of food. Patients in this category are often found to have *Helicobacter pylori* **infections**. *H. pylori* is a rod-shaped bacterium that lives in the tissues of the stomach and causes irritation of the mucous lining of the stomach walls. Most people with *H. pylori* infections do not develop chronic indigestion, but the organism appears to cause peptic ulcer disease (PUD) in a vulnerable segment of the population.

NONULCER TYPE. Most cases of chronic indigestion—as many as 65%—fall into this third category. Nonulcer dyspepsia is sometimes called functional dyspepsia because it appears to be related to abnormalities in the way that the stomach empties its contents into the intestine. In some people, the stomach empties either too slowly or too rapidly. In others, the stomach's muscular contractions are irregular and uncoordinated. These disorders of stomach movement (motility) may be caused by hypersensitive nerve endings in the stomach tissues. Patients in this group are likely to be younger than 45 and have a history of taking medications for anxiety or **depression**.

Diagnosis

Patient history

Because indigestion is a nonspecific set of symptoms, patients who feel sick enough to seek medical

attention are likely to go to their primary-care doctor. The history does not always point to an obvious diagnosis. The doctor can, however, use the process of history-taking to evaluate the patient's mood or emotional state in order to assess the possibility of a psychiatric disturbance. In addition, asking about the location, intensity, timing, and recurrence of the indigestion can help the doctor weigh the different diagnostic possibilities.

An important part of the history-taking is asking about symptoms that may indicate a serious illness. These warning symptoms include:

- weight loss
- persistent vomiting
- difficulty or pain in swallowing
- vomiting blood or passing blood in the stools
- anemia.

Imaging studies

If the indigestion should be investigated further, the doctor orders an endoscopic examination of the stomach. An endoscope is a slender tube-shaped instrument that allows the doctor to look at the lining of the patient's stomach. If the patient has indigestion of the esophagitis type or nonulcer type, the stomach lining will appear normal. If the patient has PUD, the doctor will be able to see breaks or ulcerated areas in the tissue. The physician may also order ultrasound imaging of the abdomen, or a radionuclide scan, to evaluate the motility of the stomach.

Laboratory tests

BLOOD TESTS. If the patient is over 45 years old, the doctor will have the patient's blood analyzed for a complete blood cell count, measurements of liver enzyme levels, electrolyte and serum **calcium** levels, and thyroid function.

TESTS FOR *HELICOBACTER PYLORI*. Doctors can test patients for the presence of *H. pylori* without having to take a tissue sample from the stomach. One of these noninvasive tests is a blood test and the other is a breath test.

Treatment

Nutritional supplements

Nutritionists or naturopaths may recommend the following to improve digestion:

- Avoid foods that may cause an upset stomach. These include spicy, fried, cured, or junk foods, cucumbers, onions, peppers, tomatoes, beans, carbonated beverages, or beverages containing caffeine.
- Eat lighter but more frequent meals.
- Avoid smoking.
- Adopt a high-fiber diet to improve regularity and treat digestive problems such as constipation, hemorrhoids, irritable bowel disease, and colon cancer. A high-fiber diet provides such additional health benefits as boosting the immune system function and preventing heart disease, cancer, and other diseases.
- Increase water intake. Proper hydration helps the digestive system work better.
- Improve poor digestive enzyme function with hydrochloric acid and pancreatic enzyme supplements such as lipase, amylase, and protease.
- Thicken a baby's food to help with reflux (add one tablespoon of dry rice cereal to each ounce of formula or breast milk). Hold babies upright after feedings rather than laying them down right away.

Herbal medicine

Practitioners of Chinese traditional herbal medicine might recommend medicines derived from peony (*Paeonia lactiflora*), **hibiscus** (*Hibiscus sabdariffa*), or hare's ear (*Bupleurum chinense*) to treat indigestion. Western herbalists are likely to prescribe **fennel** (*Foeniculum vulgare*), **lemon balm** (*Melissa officinalis*), or **peppermint** (*Mentha piperita*) to relieve stomach cramps and heartburn.

Homeopathy

Homeopaths tailor their remedies to the patient's overall personality profile as well as the specific symptoms. Depending on the patient's reaction to the indigestion and some of its likely causes, the homeopath might choose *Lycopodium*, *Carbo vegetalis*, ***Nux vomica***, or *Pulsatilla*.

Diet and stress management

Many patients benefit from the doctor's reassurance that they do not have a serious or fatal disorder. Cutting out alcoholic beverages and drinks containing **caffeine** often helps. The patient may also be asked to keep a record of food intake, daily schedule, and symptom severity. Food diaries sometimes reveal psychological or dietary factors that influence indigestion. Eating small frequent meals may also offer relief.

Other treatments

Some alternative treatments are aimed at lowering the patient's stress level or changing attitudes and beliefs that contribute to indigestion. These therapies and practices include **Reiki**, **reflexology**, **hydrotherapy**, therapeutic massage, **yoga**, and **meditation**.

Allopathic treatment

Since most cases of indigestion are not caused by serious disorders, many doctors prefer to try medications and other treatment measures before ordering an endoscopy. However, in cases of individuals over 55 years of age, the physician may perform an endoscopy earlier in the course of treatment.

Many patients with acid reflux treat themselves with over-the-counter remedies. For nighttime GERD, a 2001 study recommended a dose of proton pump inhibitor before breakfast and another dose before dinner. Some medicines are also approved for use in infants and children with indigestion that does not resolve itself.

Medications

Patients with the esophagitis type of indigestion are often treated with H_2 antagonists, drugs that block the secretion of stomach acid. They include ranitidine (Zantac) and famotidine (Pepcid).

Patients with motility disorders may be given prokinetic drugs. Prokinetic medications such as metoclopramide (Reglan) and cisapride (Propulsid) speed up the emptying of the stomach and increase intestinal motility.

Removal of H. pylori

Antibiotic therapy may be given to wipe out *H. pylori* bacteria from the gastrointestinal tract.

Expected results

Most cases of mild indigestion do not need medical treatment. For patients who consult a doctor and are given an endoscopic examination, 5–15% are diagnosed with GERD and 15–25% with PUD. About 1% of patients who are endoscoped have stomach cancer. Most patients with functional dyspepsia do well on either H_2 antagonists or prokinetic drugs, depending on the cause of their indigestion.

Prevention

Indigestion can often be prevented by attention to one's diet, general stress level, and ways of managing stress. Specific preventive measures include:

- Stopping smoking.
- Cutting down on or eliminating alcohol, tea, or coffee.
- Avoiding foods that are highly spiced or loaded with fat.
- Eating slowly and keeping mealtimes relaxed.
- Practicing yoga or meditation.
- Not taking aspirin or other medications on an empty stomach.
- Keeping one's weight within normal limits.

KEY TERMS

Dyspepsia—Another name for indigestion.

Endoscope—A slender tubular instrument used to examine the inside of the stomach.

Gastroesophageal reflux disease (GERD)—A disorder of the lower end of the esophagus, caused by stomach acid flowing backward into the esophagus and irritating the tissues.

H_2 antagonist—A type of drug that relieves indigestion by reducing the production of stomach acid.

Heartburn—A popular term for an uncomfortable burning sensation in the stomach and lower esophagus, sometimes caused by the reflux of small amounts of stomach acid.

Helicobacter pylori—A gram-negative rod-shaped bacterium that lives in the tissues of the stomach and causes inflammation of the stomach lining.

Motility—The movement or capacity for movement of an organism or body organ. Indigestion is sometimes caused by abnormal patterns in the motility of the stomach.

Peptic ulcer disease (PUD)—A stomach disorder marked by corrosion of the stomach lining due to the acid in the digestive juices.

Prokinetic—A drug that works to speed up the emptying of the stomach and the motility of the intestines.

Reflux—The backward flow of a body fluid or secretion. Indigestion is sometimes caused by the reflux of stomach acid into the esophagus.

Infant massage

Definition

Infant massage refers to massage therapy as specifically applied to infants. In most cases, oil or lotion is used as it would be on an adult subject by a trained and licensed massage therapist. Medical professionals caring for infants might also use massage techniques on infants born prematurely, on those with motor or gastrointestinal problems, or on those who have been exposed to cocaine in utero.

Origins

The practice of massaging infants dates back to ancient times, particularly in Asian and Pacific Island cultures; that is, massage was a component of the baby's regular bath routine among the Maoris and Hawaiians. Touch in these cultures is considered healthful both physically and spiritually. In the West, however, infant massage has received more attention in recent years in conjunction with the popularity of natural **childbirth** and midwife-assisted births. Dr. Frédéric Leboyer, a French physician who was one of the leaders of the natural childbirth movement, helped to popularize infant massage through his photojournalistic book on the Indian art of baby massage.

Infant massage. *(© Photo Researchers, Inc. Reproduced by permission.)*

Infant massage was introduced formally into the United States in 1978 when Vimala Schneider McClure, a **yoga** practitioner who served in an orphanage in Northern India, developed a training program for instructors at the request of childbirth educators. An early research study by R. Rice in 1976 had showed that premature babies who were massaged surged ahead in weight gain and neurological development over those who were not massaged. From McClure's training in India, her knowledge of **Swedish massage** and reflexology, along with her knowledge of yoga postures that she had already adapted for babies, she became the foremost authority on infant massage. In 1986 she founded the International Association of Infant Massage (IAIM), which has 27 chapters worldwide as of 2000.

Benefits

Research from experiments conducted at the Touch Research Institutes at the University of Miami School of Medicine and Nova Southeastern University has been cited for the clinical benefits massage has on infants and children. Tiffany Field, Ph. D., director, noted that the research "... suggests that touch is as important to infants and children as eating and sleeping. Touch therapy triggers many physiological changes that help infants and children grow and develop. For example, massage can stimulate nerves in the brain which facilitate food absorption, resulting in faster weight gain. It also lowers level of **stress** hormones, resulting in improved immune function."

The benefits of infant massage include:

- relaxation
- relief from stress
- interaction with adults
- stimulation of the nervous system

The results of several studies showed that infant massage alleviates the stress that newborns experience as a result of the enormous change that birth brings about in their lives after the 6–9 months they have spent in the womb. Both premature infants and full-term babies need the relaxation that comes from massaging and moving their limbs and muscles. In infants with **colic**, massage provides the relief necessary to disperse **gas**, ease **muscle spasms**, tone the digestive system and help it work efficiently. Some techniques even help bring relief from teething and emotional stress. The stimulation an infant receives from massage can aid circulation, strengthen muscles, help digestion, and relieve **constipation**. The bonding that occurs with massage between a parent and child enhances the entire process of bonding that comes with contact through all of the senses, including touch, voice, and sight. It affords a physical experience of quality time between the parents and the child as well as with any significant others in a baby's life.

Description

Various techniques are used in infant massage, with the different strokes specific to a particular therapy. Special handling is used for treating a baby with gas and colic. Some of the strokes are known as "Indian milking," which is a gentle stroking of the child's legs; and the "twist and squeeze" **stroke**, a gentle squeeze of the muscles in the thigh and calf. The light "feather" strokes often employed in regular Swedish massage are applied at the end of a massage. The procedure is not unlike certain forms of adult massage, but with extra care taken for the fragility of the infant.

There are also specific Chinese techniques of pediatric massage, including massage of children with special needs. In China, these forms of massage can be given by medical professionals, but parents are often taught how to do the simpler forms for home treatment of their children.

Preparations

If lotions or oils are used, care is taken to ensure their safety on a baby's delicate skin. The most important consideration is to use vegetable oils rather than mineral oils, which can clog the pores in the skin. The oil that is used should be warmed in the caregiver's hands before applying it to the baby's skin. The environment in which the massage is given to an infant should be comfortably warm, and as calm and non-threatening as possible.

Precautions

Extreme caution is necessary when performing infant massage. Strokes are made with the greatest delicacy in order not to harm the infant in any way. Proper techniques are taught by licensed massage therapists ensuring that the infant is treated with appropriate physical touch. Anyone who is unfamiliar with handling a baby should receive appropriate instruction before beginning infant massage.

Side effects

No adverse side effects have been reported when infant massage is done properly after careful instruction, or by a licensed massage therapist who specializes in infant care.

Research and general acceptance

In addition to the study already noted regarding touch therapy, a website devoted to infant massage lists research published as early as 1969, and cites hundreds of individual projects that have been conducted throughout the world focusing on infant massage. Many of the studies are related to the benefits of massage and touch for premature infants and others born with such risk factors as drug dependence. Conclusions regarding the benefits are overwhelmingly positive. The proliferation of therapists licensed in infant massage across the United States and worldwide indicates that infant massage is increasingly recognized as a legitimate health care treatment.

Training and certification

The International Association of Infant Massage (IAIM) has developed a basic course for licensing infant massage therapists. The pioneer in the field, Vimala McClure, began to prepare a course of instruction in the 1970s. The course is introduced in four-day sessions around the United States. Licensing is obtained by those who complete the course, pass a take-home examination, and complete a teaching practicum with five families over a three-month period. IAIM listed its course in 2000 as costing $550.00 if paid in full two weeks prior to training, and $595 after that. It includes a $100 nonrefundable deposit due one month before training. The cities where the basic course was offered in 2000 included Augusta, GA; Gaithersburg, MD; Chicago, IL; Boston, MA; Washington, DC; Charlottesville, VA; Minneapolis, MN; and Albuquerque, NM. In 2000, the International Institute of Infant Massage in Albuquerque also offered an Infant Massage Instructor Certification Course specifically geared to men, entitled "Men Teaching Fathers," and scheduled to last four days.

The licensing of massage therapists varies from state to state, as infant massage qualifies for consideration as medical treatment. Infant massage is becoming an increasingly popular discipline within the field. Numerous websites provide listings for infant massage specialists throughout the United States. The IAIM course is recognized as the official course for infant massage.

Infections

Definition

An infection is a condition in which viruses, bacteria, fungi, or parasites enter the body and cause a state of disease. These foreign invaders are called pathogens. They damage the body by adhering to or invading cells, altering the body's metabolism, releasing toxic substances, or causing allergic reactions. The body's immune system has a set series of responses to attempt to control infection; however, these reactions are not always successful. Chronic lower respiratory infection, **influenza** and **pneumonia** (combined), and sepsis (overwhelming systemic infection) were among the top ten causes of death in the United States in 2005.

Description

Pathogens are everywhere in the environment. They may enter the body through breathing, ingesting food or water, through sexual contact, open **wounds**, or contact

with contaminated materials. The body has many natural barriers to infection. For example, harmless bacteria normally found on the skin, known as commensal bacteria, inhibit the growth of some pathogens. Sweat and oil gland secretions also protect the skin, and the skin itself offers a significant physical barrier to the entry of many pathogens. Mucus in the mouth and throat help physically trap inhaled pathogens before they can reach the lungs.

In addition to physical barriers, many of the body's secretions contain compounds that help destroy pathogens. The mucous membranes that line the airways and digestive system contain enzymes and chemicals that kill or disable pathogens. Commensal bacteria also live in the intestines and slow multiplication of pathogens just as they do on the skin. The digestive tract contains stomach acid, pancreatic enzymes, and other secretions that can kill certain pathogens. Peristalsis and the shedding of the lining of the intestinal tract also help to remove pathogens. The acid pH of the vagina is protective, as is the long urethra in males. The flushing action of urine as it is excreted also protects against infection. Nevertheless, some pathogens are able to enter the body and survive.

Most pathogens that succeed in entering the body are quickly killed before they have a chance to multiply. If, however, the body is unable to keep the pathogens in check, serious disease or death may occur. Acute infections develop suddenly, and they disappear when a person receives treatment or the body's immune system responds and destroys the pathogen. Chronic infections develop if the body has only limited control over a pathogen. In chronic infections, the body is never completely rid of the pathogen, but symptoms may disappear temporarily. Symptoms will then flare up again in response to physical or emotional **stress** or when the body is weakened by another illness. Sepsis is a serious, often fatal, condition in which a pathogen spreads throughout the body by way of the bloodstream. This type of infection affects the entire body and can cause major organ failure and death.

The body's immune system (mainly the spleen, thymus, lymph nodes, and white blood cells [WBCs]) does not stand by helplessly when pathogens begin to multiply. In response to chemicals released by cells damaged by pathogens, WBCs circulating in the blood migrate to the site of the infection. Several types of WBCs engulf pathogens and render them harmless. At the same time, body temperature often increases (a **fever**) in response to the chemical interferon that is released by damaged body cells. Low to moderate fever is a helpful part of the body's response to an infection because many pathogens do not thrive at higher-than-normal body temperatures. However, if body temperature climbs above 102°F (38.9°C), the individual may need treatment to lower it in order to avoid seizures, dehydration, and tissue damage.

WBCs are involved in another immune system response. This response takes a week or more to become effective. Pathogens are antigens. Antigens are foreign materials that stimulate the immune system to respond by making special proteins called antibodies. When a pathogen successfully establishes itself in the body, specialized WBCs respond by making antibodies. Antibodies interfere with the surface structure of the pathogen so that it cannot attach to or enter cells. Making enough antibodies to control a pathogen takes time, so the individual gets sicker before beginning to recover. Sometimes the pathogen multiplies so fast that the immune system cannot suppress it, and recovery does not occur. Once a person has made antibodies to a specific pathogen, the person is highly unlikely to be made ill by that pathogen again and is said to have immunity against that particular pathogen. Vaccination against diseases such as **measles** and polio is a way to create artificial immunity without the person having symptoms of the disease.

Causes and symptoms

Infections are caused by pathogens invading the body and multiplying. Headaches, muscle aches, fever, **chills**, and **fatigue** are common systemic symptoms of infections. These symptoms most often are due to inflammation and the response of the body to the release of interferon and other chemicals by damaged cells rather than by the pathogen. At the infection site, release of the chemical histamine brings an increased blood supply to that site and causes the blood capillaries become "leaky" so that WBCs can escape the capillaries and attack the pathogen. The infection site then becomes reddened, warm, and swollen. When the WBCs die and decay they form a thick fluid known as pus.

More specific symptoms of infection vary according to the site and type of the infection. Some of these symptoms include the following:

- Gastrointestinal system: diarrhea, vomiting, nausea, stomachaches, cramps, gas pains, and dehydration.
- Respiratory system: coughing, sneezing, sore throat, congestion, fever, bronchitis, and runny nose.
- Urinary system: increased frequency and urgency of urination; pain on urination; blood, pus, or other discharge in the urine; bad-smelling urine or discharge; and vaginal itching.

- Skin: rashes, sores, itching, and blisters; redness, swelling, tenderness, and pain.
- Joints: local pain, stiffness, redness, and swelling.

Factors that increase the risk of acquiring an infection include chronic disease (e.g., **AIDS**), severe emotional stress, broken skin, changes in the pH of various body fluids, malnutrition, surgery, rupture of amniotic membranes in pregnant women, invasive medical or dental procedures, tissue injuries, decreased flow of body fluids (often a contributing factor in bladder infections) changes in peristalsis, decreased output of stomach acid, and suppressed immune function (e.g., in chemotherapy patients, people with AIDS, transplant patients). Many infections are contagious; that is, they can be passed from person to person. Contagion is especially typical in respiratory diseases, which can be transmitted through contact with the sputum and droplets produced by coughing or **sneezing**. Contact with infected waste products, open sores, skin eruptions, infected clothing and bedclothes, and sexual contact are other ways of spreading common pathogens.

In the first decade of the twenty-first century, people around the world are acutely aware of the threat of infection from bioterrorism. For example, Americans faced a scare from the deliberate distribution of anthrax spores through the United States postal system following the September 11, 2001 attacks. The U.S. Army Research Institute of Infections Diseases (USAMRIID) at Fort Detrick in Frederick, Maryland, researches ways to prevent and treat biological threats. As the threat of bioterrorism increased, USAMRIID provided training and diagnostic support to the FBI and state and local law enforcement, as well as researching medical methods for protecting military personnel from biological weapons.

The development of mutated (genetically changed as the result of natural selection) pathogens that are not killed by commonly used antibiotics is of increasing concern to healthcare workers. Methicillin-resistant *Staphylococcus aureus* (MRSA) is a strain of staphylococcal bacteria that is resistant to the antibiotic methicillin and other common antibiotics that normally control **staphylococcal infections**. Although this strain of staph has existed in hospitals for years, in the 1990s, MRSA began appearing in places other than hospitals. By 2007, two forms of MRSA were recognized, hospital-acquired MRSA (HA-MRSA) and community-acquired MRSA (CA-MRSA). Symptoms of a MRSA infection are similar to those of other staph infection symptoms, only MRSA is much more dangerous and has a much higher mortality rate because treatment with common antibiotics does not kill the bacterium. The incidence of drug-resistant **tuberculosis** was also rising as of 2008. Overuse of antibiotics accelerates the development of these drug-resistant pathogens.

Diagnosis

Many infections are minor and self-limiting. Superficial infections can generally be cured by keeping the area clean and antiseptic and applying warm, moist compresses to the affected area for 20 to 30 minutes three or four times a day. Some infections, however, are more serious and can lead to permanent impairment or death. For example, an untreated streptococcal infection (**strep throat**) can develop into **rheumatic fever**. Rheumatic fever damages the valves of the heart, although this damage may not show up for years. If an infection does not clear up within a few days, or if it gets worse, a healthcare provider should be consulted.

Infections usually are initially diagnosed by the patient's symptoms and a history of the illness or injury. A complete blood count (CBC) is a simple clinical test that can be used to diagnose or confirm an infection. Increases in the total WBC count usually indicate infection. Increases in specific types of white blood cells known as neutrophils, lymphocytes, and monocytes also point to an infection. An increase in eosinophils may be due to a parasitic infection. A blood chemistry panel may be done to determine whether significant chemical changes have been brought on by infection.

A serious illness may require further evaluation and diagnostic tests. Additional laboratory tests can be performed using blood, feces, or samples of the infected tissue. Laboratory tests, for example, can determine what type of bacterium is causing an infection and which antibiotics will kill it. Ultrasound, computed tomography (CT) scans, and magnetic resonance imaging (MRI) also may be used. In some cases, a tissue sample (biopsy) is taken from the affected site for microbial culture tests and microscopic examination.

Treatment

Herbal therapy

Herbs that may help the body overcome or withstand infection include the following:

- Garlic (*Allium sativum*). This herb is believed to have antibacterial properties. Herbalists recommend consuming three garlic cloves or three garlic oil capsules a day, starting when symptoms of infection first appear.

- Cleavers (*Galium aparine*). This anti-inflammatory herb is believed to support the lymphatic system. It may be taken internally to help heal staph abscesses and reduce swelling of the lymph nodes. A cleavers compress can also be applied directly to a skin infection.
- Goldenseal (*Hydrastis canadensis*). Another herb believed to fight infection and reduce inflammation, goldenseal may be taken internally when symptoms of infection first appear. Making a paste of water and powdered goldenseal root and applying it directly to the affected area can treat skin infections. The preparation should be covered with a clean bandage and left in place overnight.
- Echinacea (*Echinacea* spp.). Taken internally, this herb is believed to have antibiotic properties and is also thought to strengthen the immune system.
- Thyme (*Thymus vulgaris*), lavender (*Lavandula officinalis*), or bergamot (*Citrus bergamot*) oils. These oils are believed to have antibacterial properties and may help to prevent the scarring that may result from skin infections. A few drops of these oils are added to water and then a compress soaked in the water is applied to the affected area.
- Tea tree oil (*Melaleuca* spp., or ylang ylang). Another infection-fighting herb, this oil can be applied directly to a boil or other skin infection.
- Reishi (*Ganoderma lucidum*), shiitake (*Lentinus edodes*), and maitake (*Grifola frondosa*) mushrooms are known for their ability to strengthen the immune system and their antimicrobial properties.

Dietary modifications

A healthful balanced diet and lifestyle are important supports of the immune function. Regular supplementation with **vitamin C**, **vitamin A** or beta-carotene, **zinc**, and **bioflavonoids** is also thought to boost the immune response.

Sugary foods, including honey, may depress the immune system. Very high levels of fat in the diet may also interfere, as well as causing other negative health effects. Alcohol decreases the functioning of the immune system. All of these substances should be avoided during the course of an infection. People should increase their intake of fluids, including soups, teas, diluted fruit and vegetable juices, and pure water when fighting an infection, especially if they have a fever.

Aromatherapy

Aromatherapy may be a useful supportive measure in infectious conditions. An essential oil of cedarwood (*Cedrus atlantica*) is recommended in **fungal infections**. **Essential oils** of tea tree (*Melaleuca alternifolia*) and patchouli are also useful. Essential oils are very concentrated and toxic to the liver and kidneys; they should be used only in very small doses (drops) under the supervision of an aromatherapist.

Acupuncture and yoga

Acupuncture may be helpful in stimulating the immune system and drawing heat away from the infected area. It reduces the effects of stress, improves circulation, and increases the production of red blood cells (RBCs) and WBCs. **Yoga** stimulates the immune system and promotes **relaxation**.

Hydrotherapy

Constitutional **hydrotherapy** is the use of applications of hot water alternated with cold. It is effective in respiratory infections and may stimulate the immune system. For proper administration of hydrotherapy, a naturopath or other healthcare provider familiar with its techniques should be consulted.

Allopathic treatment

Symptoms arising from minor infections are often relieved by over-the-counter medications. A high fever or joint **pain** may be a sign of infection spreading throughout the body. A physician should be contacted promptly. Infections from **bites** and puncture wounds should also receive medical attention and they may require a **tetanus** shot.

Serious infections are treated with antibiotics. Some antibiotics are effective against certain parasitic and fungal infections as well as bacteria. Antibiotics are ineffective against viral infections, and there is a trend away from giving them unless a bacterial infection has been clinically documented. The elderly or seriously ill may receive antibiotics when infected with a virus to prevent a secondary bacterial infection, which often occurs because of the weakened state brought on by the virus. In the case of viral infections, antiviral drugs may reduce symptoms. These drugs tend to be expensive and their usefulness is somewhat limited by the timing with which they must be administered.

Antifungal drugs are often applied directly to surface fungal infections such as athlete's foot. They also may be taken orally or injected. Fungal infections tend to be stubborn and often require several weeks of treatment and repeated courses of the drug.

Expected results

Most minor infections resolve within a week. Chronic infections may last for years. Serious infections need to be attended by a physician, as tissue and organ damage and death may result from failure to treat. **Anemia** may result from severe infections, since RBCs or their production may be affected.

Prevention

Various vaccines are available to prevent some specific infections. Vaccines are made from deactivated parts of viruses or bacteria that stimulate the body to produce antibodies against the pathogen without producing symptoms of the disease. They produce future immunity to infection from those pathogens that last anywhere from a season (influenza) to a lifetime (smallpox). Vaccinations for **mumps**, measles, chicken pox, tetanus, **hepatitis**, diphtheria, **whooping cough**, pneumonia, and **meningitis** are widely available in the United States. They are routinely given to infants and children to provide immunity from these diseases. Most states require certain vaccinations before children may attend public school (although exceptions can be made on religious and other grounds), and many universities require certain re-vaccinations before matriculation. Individuals in the military are also vaccinated or re-vaccinated against many diseases. Individuals traveling to developing countries often require non-routine vaccination against diseases uncommon on nonexistent in the United States.

Good hygienic practices help slow the spread of infection. These include keeping the body clean, as well as keeping food, utensils, and areas of preparation clean and free from contamination. The mantra for preventing food-borne infection is: "Keep cold food cold. Keep hot food hot." Warm or room-temperature food is a breeding ground for food-borne pathogens. Meat, seafood, and dairy products should be properly refrigerated until used. Meat, seafood, and eggs should be completely cooked to an internal temperature that kills food-borne pathogens. Breaks in the skin should be cleaned, disinfected, and covered. Direct contact with people known or suspected to have infections should be limited, depending on the nature of the disease. Thorough hand washing is one of the simplest and most cost-effective ways to prevent the spread of infection.

A positive mental outlook also is important in maintaining a healthy immune system, as are getting adequate amounts of sleep, relaxation, **exercise**, and stress reduction. A diet high in fresh fruits, fresh vegetables, and whole grains and low in saturated (animal) fats promotes general good health. Good lifestyle habits, such as avoiding **smoking**, recreational drugs, and limiting alcohol intake should be cultivated.

KEY TERMS

Allergen—Any substance, usually a protein, that induces an allergic reaction in a particular individual.

Antibiotic—An agent able to kill or interfere with the development of bacteria and other micro-organisms.

Antibody—A protein produced by the immune system to fight infection or rid the body of foreign material. The foreign material that stimulates the production of antibodies is called an antigen. Specific antibodies are produced in response to each different antigen and can only inactivate that particular antigen.

Commensal bacteria—Bacteria that live in or on the human body and are in an often beneficial relationship with the human host. For example, some bacteria in the digestive tract produce needed B vitamins.

Inflammation—The body's response to tissue damage; includes hotness, swelling, redness, and pain in the affected part.

Lymph nodes—Small, bean-shaped masses of tissue scattered along the lymphatic system that act as filters and immune monitors, removing fluids, bacteria, or cancer cells that travel through the lymph system.

Pathogens—Micro-organisms capable of causing disease.

Peristalsis—The smooth muscle contractions that move food, bile, and urine through their respective passageways.

pH—A comparative measure of the acidity or alkalinity of a solution.

Vaccine—Any preparation introduced into the body to prevent a disease by stimulating antibodies against it.

Infertility

Definition

Infertility is the failure of a couple to conceive a **pregnancy** after trying to do so for at least one full year. In primary infertility, pregnancy has never occurred. In secondary infertility, one or both members of the couple have previously conceived but are unable to conceive again after a full year of trying.

Description

Approximately 20% of couples struggle with infertility at any given time. Infertility increased as a problem after 1975. Some studies blamed this increase on social phenomena, including the tendency for marriage and starting a family to occur at a later age. For women, fertility decreases with increasing age:

- Infertility in married women ages 16 to 20: 4.5%.
- Infertility in married women ages 35 to 40: 31.8%.
- Infertility in married women over the age of 40: 70%.

Individuals may have multiple sexual partners before they marry and try to have children. The increase in numbers of sexual partners has led to an increase in sexually transmitted diseases. Scarring from these **infections**, especially from **pelvic inflammatory disease** (PID, an infection of the female reproductive organs) seems to be partially responsible for the increase in infertility. Furthermore, use of some forms of the contraceptive called the intrauterine device (IUD) has contributed to an increased rate of pelvic inflammatory disease, with subsequent scarring. As of 2008 IUDs were not a common form of birth control in the United States, but they were widely used in Europe. In the late twentieth century, **copper** IUDs were linked to increased tubal infertility. Research subsequently strongly suggested that infection from the sexually transmitted disease **chlamydia** was likely the true cause.

To understand issues of infertility, it is first necessary to understand the basics of human reproduction. Fertilization occurs when a sperm from the male merges with an egg (ovum) from the female, creating a zygote that contains genetic material (DNA) from both the father and the mother. If pregnancy is then established, the zygote will develop into an embryo, then a fetus, and ultimately, if all goes well, a baby will be born in about nine months.

Sperm are small cells that carry the father's genetic material. The sperm are mixed into fluid called semen, which is discharged from the penis during sexual intercourse. The whip-like tail of the sperm allows the sperm to swim up the female reproductive tract, in search of an egg.

The ovum is the cell that carries the mother's genetic material. Once a month, a single mature ovum is produced and leaves the ovary in a process called ovulation. This ovum enters a tube leading to the uterus (the fallopian tube) where fertilization occurs.

When fertilization occurs, the resulting cell (which now contains genetic material from both the mother and the father) is called the zygote. This single cell will divide into multiple cells and the resulting cluster of cells (called a blastocyst) moves into the womb (uterus). The uterine lining (endometrium) has been stimulated by female hormones and grows thicker to prepare it to receive a blastocyst. If the blastocyst successfully attaches itself to the wall of the uterus, pregnancy has been achieved.

Causes and symptoms

Unlike most medical problems, infertility is an issue requiring the careful evaluation of two separate

individuals, as well as an evaluation of their interactions with each other. In about 3 to 4% of couples, no cause for infertility is discovered. About 40% of the time, infertility is due to a problem with the male; about 40% of the time, infertility is due to the female; and the remainder of the time, there are fertility problems with both the male and the female.

The main factors involved in causing infertility are:

- male sperm problems: 35%
- ovulation problems: 20%
- tubal problems: 20%
- endometriosis: 10%
- cervical factors: 5%

Male factors

Male infertility can be caused by a number of different characteristics of the sperm. To check for these characteristics, a sample of semen is obtained and examined under the microscope (semen analysis). Four basic characteristics are evaluated:

- Sperm count is the number of sperm present in a semen sample. The normal number of sperm present in just 1 ml of semen is over 20 million. A man with only 5 to 20 million sperm is considered subfertile and a man with less than 5 million sperm is considered infertile.
- Sperm are also examined to see how well they swim (sperm motility) and to be sure that most have normal structure.
- Not all sperm within a specimen of semen are perfectly normal. Some may be immature, and some may have abnormalities of the head or tail. A normal semen sample contains no more than 25% abnormal forms of sperm.
- Volume of the semen sample is important. An abnormal amount of semen could affect the ability of the sperm to successfully fertilize an ovum.

Any number of conditions result in abnormal findings in the semen analysis. Men can be born with testicles that have not descended properly from the abdominal cavity (where testicles develop originally) into the scrotal sac, or they may be born with only one instead of the normal two testicles. Testicle size can be smaller than normal. Past infection (including **mumps**) can affect testicular function, as can a past injury. The presence of abnormally large veins (varicocele) in the testicles can increase testicular temperature, which decreases sperm count. History of having been exposed to various toxins, drug use, excess alcohol use, use of anabolic steroids, certain medications, diabetes, thyroid problems, or other endocrine disturbances can have direct effects on the formation of sperm (spermatogenesis). Certain organic solvents that men encounter in the workplace are also a possible cause of low sperm count. These solvents are most likely encountered by professional printers, painters, and decorators. Problems with the male anatomy also can cause sperm to be ejaculated not out of the penis, but into the bladder, and scarring from past infections can interfere with ejaculation.

Researchers continue to try and determine reasons for male infertility. They have reported that a certain protein lacking in the sperm could prevent formation of the structure on the head of the sperm that contains enzymes that help penetrate the egg, allowing conception. The finding may lead to further study of the molecular/chemical basis of male fertility.

Ovulatory problems

Infertility in women can occur for a variety of reasons. The first step in diagnosing ovulatory problems is to make sure that an ovum is being produced each month. A woman's morning body temperature is slightly higher around the time of ovulation. A woman can measure and record her temperature daily, and a chart can be drawn to show whether ovulation has occurred. Luteinizing hormone (LH) is released just before ovulation. A simple urine test can be done to check if LH has been released around the time that ovulation is expected.

Pelvic adhesions and endometriosis

Pelvic adhesions cause infertility by blocking the fallopian tubes and preventing the sperm from reaching the egg. Pelvic adhesions are fibrous scars. These scars can be the result of past infections, such as PID, or infections following abortions or prior births. Previous abdominal surgeries can also cause scarring.

A hysterosalpingogram (HSG) can show if the fallopian tubes are blocked. This is an x-ray exam that tests whether dye material can travel through the patient's fallopian tubes. Scarring also can be diagnosed by examining the pelvic area through the use of a laparoscope that is inserted into the abdomen through a tiny incision made near the navel.

Endometriosis is the abnormal location of uterine tissue outside the uterus. When uterine tissue is planted elsewhere in the pelvis, it still bleeds on a monthly basis with the start of the normal menstrual period, which leads to irritation within the pelvis around the site of this abnormal tissue and bleeding

and may cause scarring. Endometriosis may lead to pelvic adhesions.

Cervical factors

The cervix is the opening between the vagina and the uterus through which the sperm must pass. Mucus produced by the cervix helps to transport the sperm into the uterus. Injury to the cervix or scarring of the cervix after surgery or infection can result in a smaller than normal cervical opening, making it difficult for the sperm to enter. Injury or infection can also decrease the number of glands in the cervix, leading to a smaller amount of cervical mucus. In other situations, the mucus produced is the wrong consistency (perhaps too thick) to allow sperm to travel through. In addition, some women produce antibodies (immune cells) that are specifically directed to identify sperm as foreign invaders and to kill them.

Cervical mucus can be examined under a microscope to diagnose whether cervical factors are contributing to infertility. The interaction of a live sperm sample from the male partner and a sample of cervical mucus from the female partner can also be examined. This procedure is called a post-coital test.

Treatment

Conventional treatment for infertility usually involves invasive, expensive procedures. There are many alternative treatments available that can increase the chance of conception. Some have been proven effective in clinical studies.

General measures to increase fertility include monitoring ovulation and timing intercourse (optimal chance for conception is in the days prior to and including the day of ovulation), and quitting **smoking**, excessive drinking, and drug taking. To improve sperm quality, men can wear boxer shorts instead of briefs.

Both men and women can increase fertility by eating a well-balanced diet. Good food choices include legumes (especially soy), dark-colored vegetables, fruits, seeds, nuts, and sufficient good quality protein, including meat, fish, and eggs. Some people believe that refined sugar, processed cheeses, foods made with white flour, and chemical preservatives should be avoided. Adequate sleep is also important.

Supplements

Dietary supplements that may enhance fertility include the following:

- Multivitamins can help treat infertility in women.
- Vitamin E has antioxidant activity that prevents reproductive damage in men and women. It can increase sperm count and motility in men and balance hormones in women.
- Vitamin C has antioxidant activity that prevents reproductive damage in men and women. Also, a study found that vitamin C supplementation led to improved sperm count and decreased sperm clumping in infertile men.
- Folic acid (with a multivitamin) improved fertility in a study of infertile women.
- Zinc deficiency is often associated with low sperm count. Studies have found that zinc supplementation can improve male fertility.
- Arginine supplementation led to major increases in sperm count and motility in a study of infertile men.
- Selenium has antioxidant activity. Selenium supplementation led to increased sperm count and motility and decreased number of abnormal sperm in a study of infertile men.
- Beta-carotene supplementation can increase sperm count and motility.
- B vitamins (B_2, B_6, and B_{12}) are important for optimal fertility.

Herbals and Chinese medicine

The following may be taken by women to treat infertility:

- Dong quai (*Angelica sinensis*) has been used to regulate menstrual cycles and for infertility.
- Licorice helps to balance levels of estrogen and testosterone and is used for infertility.
- Red clover (*Trifolium pratense*) has a beneficial effect on the uterus, can calm the nervous system, and can balance hormone levels.
- Nettle (*Urtica dioica*) supports the uterus and hormonal system.
- Raspberry leaf strengthens the mucous lining of the uterus.
- Chasteberry (*Vitex agnus-castus*) balances hormone production.
- Ladies mantle (*Alchemilla vulgaris*) balances hormone production.
- Shatavari (*Asparagus racemosus*) is an Ayurvedic remedy for infertility and works by balancing hormones.
- *Rehmannia* is an Ayurvedic remedy for infertility.
- Myrrh (*Commiphora myrrha*) is an Ayurvedic remedy for infertility.

- False unicorn (*Chamaelirium luteum*) balances hormone levels.
- Pomegranate essence balances the reproductive system.

The following may be taken by men to treat infertility:

- Ginseng may increase the formation of sperm, testosterone levels, and sexual activity.
- Pygeum may help infertile men who have a reduced secretion of semen.
- Pine bark extract improves sperm shape.
- Chasteberry (*Vitex agnus-castus*) balances hormone production.
- Shatavari (*Asparagus racemosus*) is an Ayurvedic remedy for infertility and works by balancing hormones; may increase sperm production.
- Saw palmetto (*Serenoa serrulata*) increases the production of testosterone and strengthens the reproductive system.
- Ashwaganda (*Withania omnifera*) is an Ayurvedic remedy that improves the quality of semen and sperm count.
- Chinese herbals must be specifically designed and used to treat infertility in males.

Other treatments

A variety of other alternative treatments may be used for infertility:

- stress reduction
- cognitive behavior therapy
- visualization
- homeopathy
- reflexology
- essential oils
- acupuncture

Allopathic treatment

The first step in the treatment of infertility is performing thorough physical exams and testing of both partners in the hope of finding the source of infertility. For the woman this involves blood testing and ultrasound examinations at specific days during the menstrual cycle. This may include an endometrial biopsy in which a sample of the lining of the uterus is taken and examined. Hysteroscopy, in which a special camera examines the inside of the uterus, may be performed.

Pelvic adhesions can be treated during laparoscopy. The adhesions are cut using special instruments. Endometriosis can be treated with certain medications but may also require surgery to repair any obstruction caused by adhesions.

Treatment of cervical factors includes antibiotics in the case of an infection, steroids to decrease production of anti-sperm antibodies, and artificial insemination techniques to completely bypass the cervical mucus.

Treatment of ovulatory problems depends on the cause. If a thyroid or pituitary gland problem is responsible, simply treating that problem can restore fertility. Medications that stimulate ovulation are clomiphene citrate (Clomid) that is taken by mouth and follicle stimulating hormone (Pergonal, Fertinex, and Follistim) that is given by injection. These drugs increase the risk of multiple births (e.g., twins, triplets) and may cause side effects.

Treatment of male infertility includes addressing known reversible factors first; for example, discontinuing any medication known to have an effect on spermatogenesis or ejaculation, as well as decreasing alcohol intake, and treating thyroid or other endocrine disease. Varicoceles can be treated surgically. Testosterone in low doses can improve sperm motility.

Other treatments of male infertility include collecting semen samples from multiple ejaculations, pooling them, and depositing them into the female's uterus during ovulation. When the male partner's sperm is proven to be absolutely unable to produce pregnancy, donor sperm may be used. Depositing the male partner's sperm or donor sperm by mechanical means into the female is called artificial insemination.

Assisted reproductive techniques include in vitro fertilization (IVF), gamete intrafallopian transfer (GIFT), and zygote intrafallopian tube transfer (ZIFT). These are usually used after other techniques to treat infertility (surgery, medications, and/or insemination) have failed.

IVF involves the use of drugs to induce the simultaneous production of many eggs from the ovaries, which are retrieved surgically or via ultrasound-guided needle aspiration through the vaginal wall. The ova and sperm are combined in a laboratory, where several of the ova may be fertilized. Cell division is allowed to take place up to the pre-embryo stage. While this takes place, the female may be given progesterone to ensure that her uterus is ready for implantation. Two or more pre-embryos are transferred to the female's uterus.

Success rates of IVF were rather low as of 2008. The national average success rate of IVF is approximately

KEY TERMS

Blastocyst—A cluster of cells representing multiple cell divisions that have occurred in the fallopian tube after successful fertilization of an ovum by a sperm. This is the developmental form that must enter the uterus and implant to achieve pregnancy.

Cervix—The opening from the vagina leading into the uterus.

Embryo—The stage of development of a baby between the second and eighth weeks after conception.

Endometrium—The lining of the uterus.

Fallopian tube—The tube leading from the ovary into the uterus.

Ovary—The female organ in which eggs (ova) are stored and mature.

Ovum—The reproductive cell of the female that contains genetic information and participates in the act of fertilization; also popularly called the egg.

Semen—The fluid that contains sperm, which is ejaculated by the male.

Sperm—The reproductive cell of the male that contains genetic information and participates in the act of fertilization of an ovum.

Spermatogenesis—The process by which sperm develop to become mature sperm, capable of fertilizing an ovum.

Zygote—The result of the sperm successfully fertilizing the ovum. The zygote is a single cell that contains the genetic material of both the mother and the father.

27%, but some centers have higher pregnancy rates. Because most IVF procedures put more than one embryo into the uterus, the chance for a multiple birth (twins or more) is greatly increased.

GIFT involves retrieval of both multiple ova and semen, and the mechanical placement of both within the female's fallopian tubes, where fertilization may occur. ZIFT involves the same retrieval of ova and semen, and fertilization and growth in the laboratory up to the zygote stage, at which point the zygotes are placed in the fallopian tubes. Both GIFT and ZIFT have higher success rates than IVF. These procedures can be expensive. Insurance coverage for all assisted reproductive techniques varies widely.

Expected results

In general, about half of the couples who undergo a complete evaluation of infertility followed by treatment will ultimately have a successful pregnancy. About 5% of those couples who choose to not undergo evaluation or treatment will go on to conceive after a year or more.

Inflammatory bowel disease

Definition

Inflammatory bowel disease (IBD) is an inflammation of the intestines, especially the colon and rectum. It occurs primarily in two forms, ulcerative **colitis** and Crohn's disease. The disease is characterized by swelling, ulcerations, and loss of function of the intestines.

Description

The primary problem in IBD is inflammation, as the name suggests. Inflammation is a process that often occurs to fight off foreign invaders in the body, including viruses, bacteria, and fungi. In response to such organisms, the body's immune system begins to produce a variety of cells and chemicals intended to stop the invasion. These immune cells and chemicals, however, also have direct effects on the body's tissues, resulting in heat, redness, swelling, and loss of function. No one knows what starts the cycle of inflammation in IBD, but the result is a swollen, boggy intestine.

In ulcerative colitis, the inflammation affects the lining of the rectum and large intestine. It is thought that the inflammation typically begins in the last segment of large intestine, which empties into the rectum (sigmoid colon). This inflammation may spread through the entire large intestine, but only rarely does it affect the very last section of the small intestine (ileum). The rest of the small intestine remains normal.

Crohn's disease is a form of IBD that affects both the small and large intestines. The inflammation of ulcerative colitis occurs only in the lining of the intestine, unlike Crohn's disease which affects all of the layers of the intestinal wall. As the inflammation continues, the tissue of the intestine begins to slough off, leaving pits (ulcerations) that often become infected.

IBD can occur in all age groups, with the most common age of diagnosis being between 15 and 35 years of age. Men and women are affected equally. Whites are more frequently affected than other racial groups, and people of Jewish origin have three to six times greater likelihood of suffering from IBD. IBD is familial; an IBD patient has a 20% chance of having other relatives who also have the disease.

Causes and symptoms

No specific cause of IBD has been identified. Although no organism (virus, bacteria, or fungi) has been found to set off the cycle of inflammation, some researchers continue to suspect that an organism is responsible. Other researchers have concentrated on identifying some change in the cells of the colon that cause the body's immune system to accidentally begin treating those cells as foreign. Additional evidence for a disorder of the immune system includes the high number of other immune disorders that frequently accompany IBD. The condition has also been linked to physical, mental, and emotional **stress**.

The first symptoms of IBD are abdominal cramping and **pain**, a sensation of urgent need to have a bowel movement (defecate), and blood and pus in the stools. Some patients experience **diarrhea**, **fever**, and weight loss. If the diarrhea continues, signs of severe fluid loss (dehydration) begin to appear, including low blood pressure, fast heart rate, and **dizziness**.

Severe complications of IBD include perforation of the intestine, toxic dilation (enlargement) of the colon, and the development of colon **cancer**. Intestinal perforation occurs when long-standing inflammation and ulceration of the intestine weakens the wall to such an extent that a hole occurs. This complication is life-threatening because the contents of the intestine (which contain a large number of bacteria) spill into the abdomen. The presence of bacteria in the abdomen can result in a massive infection called peritonitis.

Toxic dilation of the colon is thought to occur because the intestinal inflammation interferes with the normal function of the muscles of the intestine. This condition allows the intestine to become lax, and its diameter begins to increase. The enlarged diameter thins the walls further, increasing the risk of perforation and peritonitis. When the diameter of the intestine is quite large, and infection is present, the condition is referred to as toxic megacolon.

Patients with IBD have a significant risk of developing colon cancer. This risk seems to begin around 10 years after diagnosis. The overall risk of developing cancer seems to be greatest for those patients with the largest extent of intestine involved. The risk becomes statistically greater every year:

- At 10 years, the risk of cancer is about 0.5–1%.
- At 15 years, the risk of cancer is about 12%.
- At 20 years, the risk of cancer is about 23%.
- At 24 years, the risk of cancer is about 42%.

Patients with IBD also have a high chance of experiencing other disorders, including inflammation of the joints (arthritis); inflammation of the vertebrae (spondylitis); ulcers in the mouth and on the skin; the development of painful, red bumps on the skin;

inflammation of several areas of the eye; and various disorders of the liver and gallbladder.

Diagnosis

IBD is first suspected based on the symptoms that a patient is experiencing. Examination of the stool usually reveals the presence of blood and pus (white blood cells). Blood tests may show an increase in the number of white blood cells, which is an indication of inflammation occurring somewhere in the body. The blood test may also reveal **anemia**, particularly when a great deal of blood has been lost in the stool.

The most important allopathic method of diagnosis is endoscopy, during which a doctor passes a flexible tube with a tiny, fiber-optic camera device through the rectum and into the colon. The doctor can then examine the lining of the intestine for signs of inflammation and ulceration. A tiny sample (biopsy) of the intestine is removed through the endoscope, which is examined under a microscope for evidence of IBD. X-ray examination is helpful to determine the amount of affected intestine. However, x-ray examinations requiring the use of barium compound should be delayed until treatment has begun. The barium compound used is a chalky solution that the patient drinks or is administered through the rectum and into the intestine (enema). The presence of barium in the intestine makes possible a more distinct picture on x-ray films.

Treatment

Treatment for IBD targets the underlying inflammation, as well as the problems occurring due to continued diarrhea and blood loss. The use of alternative medicines in the treatment of IBD is common. IBD sufferers have used a variety of treatments; however, few controlled studies of their effectiveness have been performed.

Chamomile tea is used to treat IBD. Chamomile is known to have anti-inflammatory, antispasmodic, and antibacterial properties. The patient should steep dried flowers for 10 to 15 minutes and drink three to four cups daily. Chamomile can cause allergic reactions to those who are allergic to other daisies. Other antispasmodics include **valerian**, wild yam, and **cramp bark**.

There is some preliminary evidence that alteration of the kinds of bacteria in the intestine prevents or controls colitis. Intestinal bacteria can be manipulated through use of **probiotics** or prebiotics. Probiotics refers to treatment with beneficial microbes either by ingestion or through a suppository. Prebiotics refers to dietary changes which favor the overgrowth of beneficial microbes. Preliminary animal and human studies have shown that *Lactobacilli* and related bacteria can control colitis and prolong remission. Ingestion of the nondigestable carbohydrates inulin or lactulose as prebiotics stimulates growth of these beneficial bacteria.

In a related treatment, preliminary evidence suggests that ingestion of parasitic worm eggs eases the symptoms of IBD. Within two to three weeks, five out of the six IBD patients who ingested the eggs went into complete remission which lasted one month. The tiny, harmless **worms** cannot reproduce in humans and are excreted within a few months.

Ingestion of enteric coated **fish oil** capsules may reduce the IBD relapse rate. A small study found that patients taking fish oil supplements had a lower relapse rate (59%) than those on placebo (90%).

A number of studies have attempted to assess the efficacy of various complementary and alternative approaches to the treatment of IBD. In many cases, these studies have not been repeated or confirmed, although they may suggest future lines of research. In one study, 72 percent of ulcerative colitis patients taking a Kui Jie Qing enema (alum, Halloysite, Calamine, *Indigo naturalis*) and plum-blossom tongue-pointing pills daily were considered cured as compared to 5% of those who were taking anti-inflammatory drugs. Fifty-three percent of ulcerative colitis patients taking Jian Pi Ling tablet and root of *Sophorae flavescentis* plus the flower of *sophora* enema were considered cured as compared to 28% of those taking sulfasalazine and dexamethasone and 19% of those taking a placebo tablet and the enema. There are many other Chinese herbs that are useful in treating diarrhea and mucus in the bowel. Sometimes these are effective when drugs are not.

Forty-five percent of ulcerative colitis patients on an enzyme potentiated hyposensitization protocol (B-glucuronidase enzyme and 1,3-cyclohexanediol with egg, milk, wheat, potato, and yeast) improved as compared to 6% of those on placebo.

Nutritionists often recommend changes in the diet for patients with inflammatory bowel disease. Food **allergies** and certain kinds of food are linked with the increased incidence of the disease. Eliminating diary and wheat products, common allergens, often alleviates symptoms. The incidence of Crohn's disease has increased in areas in which people consume a diet high in refined sugars and carbohydrates and saturated fats and low in dietary fiber. Elimination **diets** or those restricted in refined foods have sometimes proved successful in the alleviation of inflammatory bowel disease.

Dietary supplements are generally beneficial in the treatment of digestive disorders. Some typical recommendations are:

- vitamin C: 4000 mg daily
- vitamin B_6: 250 mg daily
- Magnesium (aspartate): 400 mg daily
- vitamin E: 800 IU daily
- glutamine: 3000 mg daily, taken between meals
- garlic, deodorized: 2000 mg daily
- deglycyrrhizinated licorice: chew as needed.

Other treatments for IBD include **acupuncture**, macrobiotics, **cat's claw** (*Uncaria tomentosa*), **slippery elm**, **acupressure**, **biofeedback**, **relaxation** techniques, and **hypnotherapy**. A 2006 review of complementary and alternative methods for treating IBD by researchers at University College London Hospitals found suggestive evidence for the efficacy of some methods, but it concluded that further clinical trials were necessary to confirm their value. The reviewers also pointed out a number of safety problems involved in the use of herbal and other treatments and called for enhanced legislation that would further protect consumers from the risks posed by some remedies.

Allopathic treatment

Inflammation is often treated with an immune-suppressive drug called sulfasalazine. Because of poor absorption, sulfasalazine stays primarily within the intestine, where it is broken down into its two components: an antibiotic and an anti-inflammatory. It is believed to be primarily the anti-inflammatory component, salicylic acid, that is active in treating IBD. For patients who do not respond to sulfasalazine, steroid medications (such as prednisone) are the next choice.

Depending on the degree of blood loss, a patient with IBD may require blood transfusions and fluid replacement through a needle in the vein (intravenous or IV). Medications that can slow diarrhea must be used with great care because they may actually cause the development of toxic megacolon.

Patients with toxic megacolon require close monitoring and care in the hospital. They usually are given steroid medications through an IV and may be put on antibiotics. If these measures do not improve the situation, they may have to undergo surgery to remove the colon. This procedure reduces the risk of death after perforation of toxic megacolon, which is greater than 50%.

A patient with proven cancer of the colon, or even a patient who shows certain precancerous signs, may need a colectomy (colon removal). When a colectomy is performed, a piece of the small intestine (ileum) is pulled through an opening in the abdomen and fashioned surgically to allow attachment of a special bag to catch the body's waste (feces). This opening, which remains for the duration of the patient's life, is called an ileostomy.

KEY TERMS

Endoscopy—A medical examination in which an instrument called an endoscope is passed into an area of the body (the bladder or intestine, for example). The endoscope usually has a fiber-optic camera, which allows the operator to see a greatly magnified image on a video screen.

Immune system—The system of the body that is responsible for producing various cells and chemicals that fight off infection by viruses, bacteria, fungi, and other foreign bodies. In autoimmune disease, these cells and chemicals are turned against the body itself.

Inflammation—The result of the body's attempts to fight off and wall off an area that is infected. Inflammation results in redness, heat, swelling, and loss of function.

Expected results

Remission refers to a disease's becoming inactive for a period of time. The rate of remission of IBD (after a first attack) is nearly 90%. Those individuals whose colitis is confined primarily to the left side of the large intestine have the best prognosis. Those individuals with extensive colitis, involving most or all of the large intestine, have a much poorer prognosis. Some studies show that about 10% of these patients have died within 10 years after diagnosis. About 20–25% of all IBD patients require colectomy. Unlike the case for patients with Crohn's disease, however, such radical surgery results in a cure of the disease.

Influenza

Definition

Usually referred to as the flu or grippe, influenza is a highly infectious respiratory disease. Its name comes from the Italian word for "influence," because people in eighteenth-century Europe thought that the disease was caused by the influence of bad weather. Later people learned that flu is caused by a virus. When the influenza virus is inhaled, it attacks cells in the upper respiratory tract, causing such typical flu symptoms as **fatigue**, **fever** and **chills**, a hacking **cough**, and body aches. Although the stomach or intestinal flu is commonly blamed for stomach upsets and **diarrhea**, the influenza virus affects humans less often than is commonly believed. According to the Centers for Disease Control, approximately 5% to 20% of the U.S. population contracts the flu each year.

Description

Influenza is considerably more debilitating than the **common cold**. Influenza outbreaks occur suddenly, and infection spreads rapidly. The annual death toll attributable to influenza and its complications averages 20,000 in the United States alone. In the 1918–1919 Spanish flu pandemic, the death toll reached a staggering 20–40 million worldwide. Approximately 500,000 of these fatalities occurred in North America.

Influenza outbreaks occur on a regular basis. The most serious outbreaks are pandemics, which affect millions of people worldwide and last for several months. The 1918–1919 influenza outbreak serves as the primary example of an influenza pandemic. Pandemics also occurred in 1957 and 1968 with the Asian flu and Hong Kong flu, respectively.

Epidemics are widespread regional outbreaks that occur every two to three years and affect 5–10% of the population. A regional epidemic is shorter lived than a pandemic, lasting only several weeks. Finally, there are smaller outbreaks each winter that are confined to specific locales.

There are three types of influenza viruses, identified as A, B, and C. Influenza A can infect a range of animal species, including humans, pigs, horses, and birds, but only humans are infected by types B and C. Influenza A is responsible for most flu cases, while infection with types B and C virus are less common and cause a milder illness.

In the United States, 90% of all deaths from influenza occur among persons older than 65. Flu-related deaths have increased substantially in the United States since the 1970s, largely because of the **aging** of the American population. In addition, elderly persons are vulnerable because they are often reluctant to be vaccinated against flu.

A new concern regarding influenza is the possibility that hostile groups or governments could use the virus as an agent of bioterrorism. A report published in early 2003 noted that Type A influenza virus has a high potential for use as such an agent because of the virulence of the Type A strain that broke out in Hong Kong in 1997 and the development of laboratory methods for generating large quantities of the virus. The report recommended the stockpiling of present antiviral drugs and speeding up the development of new ones.

In 2008, the Centers for Disease Control and Prevention (CDC) issued a health alert stating that the number of children's deaths from influenza in the

2006–2007 flu season was five times greater than in past years. The agency investigated whether bacteria such as staphylococcus can cause illnesses such as influenza. During the 2006–2007 flu season, the CDC learned of 73 children whose deaths were related to influenza, compared to 47 and 46 children's deaths in the two previous years.

Causes and symptoms

Approximately one to four days after infection with the influenza virus, the victim is hit with an array of symptoms. Symptoms are usually sudden, although the sequence can be quite variable. They include the onset of **headache**, **sore throat**, dry cough, and chills, nasal congestion, fatigue, malaise, overall soreness, and a fever that may run as high as 104°F (40°C). Some patients may experience **pain** when they inhale, known as pleuritic chest pain. Flu victims feel extremely tired and weak and may not return to their normal energy levels for several days or weeks.

Influenza complications usually arise from bacterial **infections** of the lower respiratory tract. Signs of a secondary respiratory infection often appear just as the patient seems to be recovering. These signs include high fever, intense chills, chest pains associated with breathing, and a productive cough or sinus discharge with thick yellowish green sputum. If these symptoms appear, medical treatment is often necessary. Other secondary infections, such as sinus or ear infections, may also require medical intervention. Heart and lung problems, and other chronic diseases, can be aggravated by influenza, which is a particular concern with elderly patients.

With children and teenagers, it is advisable to be alert for symptoms of Reye's syndrome, a rare, but serious complication that occurs when children are given aspirin. Symptoms of Reye's syndrome are **nausea** and **vomiting**, and more seriously, neurological problems such as confusion or delirium. The syndrome is primarily associated with the use of aspirin to relieve flu symptoms in children.

Diagnosis

Although there are specific laboratory tests to identify the flu virus strain from respiratory samples, doctors typically rely on a set of symptoms and the presence of influenza in the community for diagnosis. Specific tests are useful to determine the type of flu in the community, but they do little for individual treatment. Doctors may administer such tests as throat or sinus cultures or blood tests to identify secondary infections.

After 1999, however, seven rapid diagnostic tests for flu became commercially available. These tests appear to be especially useful in diagnosing flu in children, allowing doctors to make more accurate treatment decisions in less time.

Treatment

The patient should drink plenty of fluids and eat nutritious foods. Chicken soup with **ginger**, scallions, and rice noodles is nutritious and has healing powers. Rest, to allow the body to fight infection, is very important. Gargling with salt water (half teaspoon salt in one cup of water) helps to soothe a sore throat. A vaporizer with **eucalyptus** or Vicks makes the patient feel more comfortable by easing breathing and aiding sleep. Applying Vicks ointment over chest and back assists and speeds recovery. Returning to normal activities too quickly invites a possible relapse or complications.

Herbals

Herbal teas and other preparations can be taken to stimulate the immune system, for antiviral activity, and to relieve symptoms. The following herbs are used to treat influenza:

- Ginger (*Zingiber officinalis*) reduces fever and pain, has a sedative effect, settles the stomach, and suppresses cough.
- Forsythia (*Forsythia suspensa*) fruit can be taken as a tea for its anti-inflammatory, fever reducing, and antimicrobial properties.
- Honeysuckle (*Lonicera japonica*) flower can be taken as a tea for its anti-inflammatory, fever reducing, and antimicrobial properties.
- Anise seed (*Pimpinella anisum*) can be added to tea to expel phlegm, induce sweating, ease nausea, and ease stomach gas.
- Slippery elm (*Ulmus rubra*) can be taken as a tea or slurry to soothe sore throat and ease cough.
- Echinacea (*Echinacea purpurea* or *angustifolia*), in clinical studies, reduced flu symptoms, including sore throat, chills, sweating, fatigue, weakness, body aches, and headaches. The usual dosage is 500 mg thrice on the first day, then 250 mg four times daily thereafter.
- Goldenseal (*Hydrastis canadensis*) has fever reducing, antibacterial, anti-inflammatory, and antitussive properties. The usual dose is 125 mg three to four times daily. Goldenseal should not be taken for more than one week.

- Astragalus (*Astragalus membranaceus*) boosts the immune system and improves the body's response to stress. The common dose is 250 mg of extract four times daily.
- Cordyceps (*Cordyceps sinensis*) modulates and boosts the immune system and improves respiration. The usual dose is 500 mg two to three times daily.
- Elder (*Sambucus nigra*) has antiviral activity, increases sweating, decreases inflammation, and decreases nasal discharge. In a study, elderberry extract reduced flu symptoms within two days whereas placebo took six days. The usual dose is 500 mg of extract thrice daily. Also use 2 tsp of dried flowers in 1 cup of water as a tea.
- Schisandra (*Schisandra chinensis*) helps the body fight disease and increases endurance.
- Grape (*Vitis vinifera*) seed extract has antihistamine and anti-inflammatory properties. The usual dose is 50 mg three times daily.
- Eucalyptus (*Eucalyptus globulus*) or peppermint (*Mentha piperita*) essential oils added to a steam vaporizer may help clear chest and nasal congestion.
- Boneset infusion (*Eupatorium perfoliatum*) relieves aches and fever.
- Yarrow (*Achillea millefolium*) relieves chills.

Other remedies

Acupuncture and **acupressure** are said to stimulate natural resistance, relieve nasal congestion and headaches, fight fever, and calm coughs, depending on the points used.

A homeopathic remedy called *Oscillococcinum* may be taken at the first sign of flu symptoms and repeated for a day or two. This remedy is said to shorten the duration of flu by one or two days. Although oscillococcinum is a popular flu remedy in Europe; however, a research study published in 2003 found it to be ineffective.

Other homeopathic remedies recommended vary according to the specific flu symptoms present. *Gelsemium* (*Gelsemium sempervirens*) is recommended to combat weakness accompanied by chills, a headache, and nasal congestion. *Bryonia* (*Bryonia alba*) may be used to treat muscle aches, headaches, and a dry cough. For restlessness, chills, hoarseness, and achy joints, poison ivy (*Rhus toxicodendron*) is recommended. Finally, for soreness and a dry cough or chills, *Eupatorium perfoliatum* is suggested.

Hydrotherapy can be used. A bath to induce a fever will speed recovery from the flu. While supervised, patients should take a bath as hot as they can tolerate and remain in the bath for 20–30 minutes. While in the bath, the patients drink a cup of **yarrow** or elderflower tea to induce sweating. During the bath, a cold cloth is held on the forehead or at the nape of the neck to keep the temperature down in the brain. Patients are assisted when getting out of the bath (they may feel weak or dizzy) and then get into bed and cover up with layers of blankets to induce more sweating.

Supplemental vitamins are recommended for treating influenza and include 500–2000 mg **vitamin C**, 400 IU to 500 IU of **vitamin E**, 200 micrograms to 300 micrograms **selenium**, and 25,000 IU beta-carotene. **Zinc** lozenges are helpful, as is supplemental zinc at 25 mg per day for two weeks or more.

Traditional Chinese medicine (TCM) uses mixtures of herbs to prevent flu as well as to relieve symptoms once a person has fallen ill. There are several different recipes for these remedies, but most contain ginger and Japanese **honeysuckle** in addition to other ingredients.

Allopathic treatment

Because influenza is a viral infection, antibiotics are useless in treating it. However, antibiotics are frequently used to treat secondary infections.

Over-the-counter medications are used to treat flu symptoms. Any medication that is designed to relieve such symptoms as pain and coughing will provide some relief. The best medicine for symptoms is an analgesic, such as aspirin, acetaminophen, or naproxen. Without a doctor's approval, aspirin is generally not recommended for people under 18 owing to its association with Reye's syndrome, a rare aspirin-associated complication seen in children recovering from viral infections. Children should receive acetaminophen or ibuprofen to treat their symptoms.

There are several antiviral drugs marketed for treating influenza. To be effective, treatment should begin no later than two days after symptoms appear. Antivirals may be useful in treating patients who have weakened immune systems or who are at risk for developing serious complications. They include oseltamavir phosphate (Tamiflu) and zanamavir (Relenza), which have few side effects but can cause **dizziness**, jitters, and **insomnia**. Other antiviral medications are amantadine (Symmetrel, Symadine) and rimantadine (Flumandine), which work against Type A influenza. Amantadine and rimantadine can cause side effects such as nervousness, **anxiety**, lightheadedness, and nausea. Severe side effects, including seizures, delirium, and hallucination, are rare and are nearly always limited to people who have kidney

problems, seizure disorders, or psychiatric disorders. Zanamavir and oseltamavir phosphate work against both Types A and B influenza.

At the 2006 Interscience Conference on Antimicrobial Agents and Chemotherapy, the first research was presented showing that patients admitted to the hospital with either influenza or **pneumonia** as a complication of the former experienced a reduction in complications and mortality if they were given oseltamavir phosphate. In the study, patients were given the medication longer than 48 hours after symptoms began, a timeframe usually considered outside the drug's limits of maximum effectiveness. In 2007, officials in Japan ordered the manufacturer of oseltamivir phosphate to include a warning that the drug may have the potential to cause severe neuropsychiatric effects in adolescents ages 10 to 19 years.

Expected results

Following proper treatment guidelines, healthy people under the age of 65 usually suffer no long-term consequences associated with flu infection. The elderly and the chronically ill are at greater risk for secondary infection and other complications, but they can also enjoy a complete recovery.

Most people recover fully from an influenza infection, but it should not be viewed complacently. Influenza is a serious disease, and approximately 1 in 1,000 cases proves fatal.

Prevention

The Centers for Disease Control and Prevention recommend that people get an influenza vaccine injection each year before flu season starts. In the United States, flu season typically runs from late December to early March. Vaccines should be received two to six weeks prior to the onset of flu season to allow the body enough time to establish immunity.

Each season's flu vaccine contains three virus **strains** that are the most likely to be encountered in the coming flu season. The virus strains used to make the vaccine are inactivated and will not cause illness. When there is a good match between the anticipated flu strains and the strains used in the vaccine, the vaccine is 70–90% effective in people under 65. Because immune response diminishes somewhat with age, people over 65 may not receive the same level of protection from the vaccine, but even if they do contract the flu, the vaccine diminishes the severity and helps prevent complications.

KEY TERMS

Bioterrorism—The intentional use of disease-causing microbes or other biologic agents to intimidate or terrorize a civilian population for political or military reasons. Type A influenza virus could be used as an agent of bioterrorism.

Common cold—An illness caused by an upper respiratory viruses. Usual symptoms include nasal congestion, coughing, sneezing, throat irritation, and a low-grade fever.

Epidemic—A widespread regional disease outbreak.

Guillain-Barré syndrome—Also called acute idiopathic polyneuritis, a neurologic syndrome that can cause numbness in the limbs and muscle weakness following certain viral infections.

Pandemic—Worldwide outbreak of an infection, afflicting millions of people.

Secondary infection—An infection by a microbe that occurs during an infection by a different kind of microbe.

It should be noted that certain people should not receive an influenza vaccine. Infants younger than six months have immature immune systems and will not benefit from the vaccine. Because the vaccines are prepared using hen eggs, people who have severe **allergies** to eggs or other vaccine components should not receive the influenza vaccine. Some persons may receive a course of amantadine or rimantadine, which are 70–90% effective in preventing influenza.

Certain groups are strongly advised to be vaccinated because they are at greater risk for influenza-related complications:

- All people 50 years and older
- Residents of nursing homes and chronic-care facilities
- Children ages 6 months to 5 years
- Pregnant women
- People of any age with certain chronic medical conditions
- Anyone in contact with the above groups, such as teachers, care givers, health-care personnel, and family members

In addition to an injectable flu vaccine, an intranasal spray vaccine (made from a live virus) may be given to healthy persons ages 2 years 49 years of age who are not pregnant.

The following dietary supplements may be taken to help prevent influenza:

- Elderberry to prevent influenza virus from infecting cells
- Astragalus, 250–500 mg daily
- Multivitamin with zinc
- Vitamin C, 500 mg
- Echinacea, at the first sign of malaise or infection, take 3–5 ml of tincture or 2 tablets three or four times daily for three to 10 days.

Ingrown nail

Definition

Ingrown nail refers to the condition in which the edge of a nail cuts into the adjacent skin fold, causing **pain**, redness, and swelling.

Ingrown toenails. *(Custom Medical Stock Photo. Reproduced by permission.)*

Description

Ingrown nail (onychocryptosis) occurs when the nail plate (the horny covering) grows into and cuts the skin alongside the nail (lateral nail fold). Ingrown toenails make up 3–5% of all foot problems. Most cases of ingrown nail occur in men between the ages of 10–30 years. In this age group, males are affected twice as often as females. In older adults, the incidence is equal. There are three major types of ingrown nail: subcutaneous ingrown nail in which the nail grows under the skin; overcurvature of the nail plate; and hypertrophy (overgrowth) of the lateral nail fold.

Ingrown nails occur most often on the big toe. Penetration of the nail into the skin causes inflammation (swelling and redness). Infection by bacteria or fungi may follow. Severe infection may lead to **abscess** formation, characterized by an oozing, pus-filled blister. Small, translucent, red bumps called granulation tissue may develop along the lateral nail fold.

Causes and symptoms

Ingrown nails are most commonly caused by incorrect cutting of the nails and wearing poorly-fitting shoes. Other causes of ingrown nail include:

- abnormally long toes
- overcurvature of the nail
- excessive sweating
- shoes that put pressure on the toes (pointed-toe, high-heeled)
- poor foot hygiene
- high lateral nail folds
- discrepancy between the widths of the nail and nail bed

KEY TERMS

Granulation tissue—Small, red, bumpy, velvety-looking tissue produced during the healing of wounds.

Lateral nail fold—The fold of skin along the side of the nail.

Nail plate—The horny plate covering the tips of the fingers and toes. Commonly called the nail.

Onychocryptosis—The medical term for ingrown nail.

- improper alignment of the large toenail
- repeated trauma to the large toe

Persons who are at increased risk of developing ingrown nails include people with arthritis, immune system deficiencies, neoplasms (tumors), **obesity**, and circulatory disorders.

The symptoms of ingrown nail include swelling, redness, and pain in the lateral nail fold. Increased swelling, pus drainage, and ulceration (tissue destruction) can occur as the condition progresses. Advanced onychocryptosis is characterized by long-term swelling, the formation of granulation tissue, and lateral fold overgrowth.

Diagnosis

Ingrown nail is easily diagnosed in a physical examination done by a family physician, a podiatrist (foot specialist), or a dermatologist (skin specialist).

Treatment

Because of the possibility of serious complications, a physician should be consulted for treatment of severe and/or infected ingrown nails. Alternative treatments for treating ingrown nail include:

- Ayurveda. Ayurvedic principles state that persons whose constitutions are dominated by vata and kapha have stronger nails and are prone to ingrown nails. Ingrown nails are treated with warm water soaks followed by application of a solution of equal parts tea tree and neem oils under the nails.
- Herbal therapy. When an ingrown nail is forming, the toe should be soaked for 15–30 minutes in five drops each of hypericum and calendula tinctures diluted in 1/2 pint of warm water. Afterward, the toe should be wrapped in linen, placing it between the fold and the nail.
- Homeopathy. Preparations of *Hepar sulph* or *Silica* in 6c potency may be taken every 12 hours for two weeks, to reduce the inflammation around the nail.
- Hydrotherapy. To treat ingrown nail, the patient should soak the foot in hot, soapy water for 20 minutes, trim the nail square, wrap the toe in a hot compress, and cover it with a dry cloth overnight. In the morning, the patient should trim the nail into a U shape and place a bit of cotton between the nail and the fold. The cotton should be kept in place until the nail grows out.
- Massage. If an ingrown nail is developing the patient should push the skin away from the nail. Repeated massage of the overgrown lateral nail folds can reduce pain and separate the fold away from the nail.

Allopathic treatment

Nonsurgical

Nonsurgical methods of treating ingrown nails focus on eliminating infection with medications and separating the ingrown nail from the lateral nail fold. Whenever possible, the offending nail is clipped, and the patient is instructed to soak the foot in water containing Epsom salts and povidone-iodine thrice daily. Procedures used to separate the nail from the fold include inserting a piece of fabric (moistened with antiseptics), plastic, or metal between the nail and the fold until the nail grows out. Cryotherapy, in which the affected nail fold is frozen with liquid nitrogen, is also used. Cauterization (destruction of tissue using heat) may be performed to eliminate granulation tissue. A metal brace may be worn on the toe for several months to flatten overcurvature.

Surgical

In cases of severe ingrown nail or ineffective nonsurgical treatment, part or all of the nail is surgically removed. Most commonly, only a portion of the nail is removed. Ingrown nail recurs in 60%–80% of the patients. If nail regrowth is expected to cause a recurrence of ingrown nail, then the nail matrix (where nail growth occurs) is destroyed, which prevents nail regrowth. In most cases, only local anesthesia is needed for surgical treatment.

Expected results

Although natural remedies can be effective in healing minor ingrown nails, prevention is the best solution. Many cases of ingrown nail require surgical treatment.

Complications of ingrown toenail include infection, osteomyelitis (infection of the bone), and **gangrene** (tissue death). The elderly are at increased risk of complications because of decreased sensation resulting from such conditions as diabetes, **heart disease**, or arteriosclerosis (hardening of the arteries).

Prevention

Ingrown nails may be prevented by:

- clipping nails straight across
- leaving the nail edge slightly longer than the end of the toe
- not trimming the sides of nails
- wearing shoes with ample toe space
- not pulling or tearing at the toenails

Inositol

Description

Inositol is a natural glucose isomer that is normally found in animal cells, with its highest concentration in the brain and heart. It is also referred to as myoinositol, IP6, phytic acid, and vitamin B8 (although it is not officially a vitamin as the body can make it). It aids the liver in processing fats and also plays a role in nerve transmission and muscle functions. Inositol is also available in supplement form.

Inositol is not considered an essential nutrient. Foods such as beans, cantaloupe, citrus fruits, nuts, whole grains, and seeds provide a substance known as phytic acid. When phytic acid comes into contact with the bacteria normally found in the stomach, inositol is released.

General Use

Inositol is used to treat **depression** and panic disorders. It has been found to be at low levels in the spinal fluid of persons suffering from depression. Furthermore, inositol plays a role in the processing of serotonin, a neurotransmitter in the brain. Low levels of serotonin have been associated with clinical depression. Because of these associations, inositol is believed to provide benefits for persons with clinical depression.

The use of inositol in treating the following disorders continues in the 2000s to be investigated:

- Panic disorders
- Polycystic ovary syndrome
- Obsessive-compulsive disorders
- Alzheimer's disease
- Autism
- Post-traumatic stress disorders

More investigation is needed to determine conclusive evidence of benefit for these conditions.

In 2001, data were released from a study comparing inositol with fluvoxamine in the treatment of **obsessive-compulsive disorder**. Inositol showed fewer side effects, an attractive benefit for a drug designed to treat a **panic disorder**. But further investigation was suggested.

In 1999, a study conducted in Israel recommended that manic patients on lithium therapy eat an inositol-free diet because of the role inositol plays in blocking the body's ability to use lithium. A study released in 2004 found that persons with **psoriasis** who were taking lithium benefited from inositol supplementation. Psoriasis patients who were not undergoing lithium treatment did not realize this benefit.

Some researchers believe that inositol hexaphosphate (IP6) is capable of launching **cancer** cells on a path to destruction. The cancer-related studies have used animal subjects. In these tests, IP6 supplementation resulted in prevention of cancerous tumors in the colon, prostate, lung, skin, and other areas. It also showed a possible ability to improve the effectiveness of hormone or chemotherapy treatments. A preliminary study performed on humans indicated that IP6 supplementation may cause shrinkage of a malignant lung tumor. As of 2008, IP6 had not been studied as a treatment for humans with cancer. The anti-cancer properties of IP6 were first studied in the 1980s at the University of Maryland. Pathologist Abulkalam Shamsuddin first began studying the compound's anti-cancer capabilities at that time.

Inositol is sometimes taken in supplement form by bodybuilders and athletes, who desire its potential role in fat distribution and promoting a calm mind.

KEY TERMS

Isomer—Two compounds that have the same molecular formulas but different chemical structures.

Neurotransmitter—A substance involved in the transmission of nerve impulses.

Preparations

There is no recommended dietary intake for inositol. However, the typical diet in the United States provides approximately 1.0 gram of inositol per day. In research settings, doses up to 18 grams per day have been used.

Inositol supplements are available in capsule, tablet, and powder forms.

Precautions

Inositol supplementation may inhibit the body's ability to absorb minerals, including **calcium**, **iron**, and **zinc**, prompting concern particularly in regards to use in infants. As of 2008, long-term safety studies had not been performed. Its safety had not been established for pregnant or breastfeeding women, young children, and persons with liver or kidney ailments. A number of experts advise consumers to obtain inositol through dietary sources before taking the supplemental form.

Side Effects

The most common side effects are **gas** and **diarrhea**. Consumers should stop taking inositol and report to a healthcare provider immediately any sign of an allergic reaction such as **hives**, rash, **itching**, tightness in the throat or chest, or difficulty breathing. Like any supplement, inositol should be taken under the guidance of a healthcare professional.

Interactions

Inositol should not be taken with lithium, except under the guidance of a physician. Inositol is said to block the absorption of the minerals calcium, iron, and zinc.

Insomnia

Definition

Insomnia is the inability to obtain an adequate amount or quality of sleep. The difficulty may be in falling asleep, remaining asleep, or waking up too early. A person may experience one or all of these symptoms. People with insomnia do not feel refreshed when they wake up. Insomnia affects more than 70 million people, according to the National Institutes of Health. The sleeplessness is a symptom that may be caused by physical or mental conditions or circumstances. Furthermore, research indicated that insomnia may also be a medical condition, according to the National Sleep Foundation (NSF).

Description

Adults need approximately seven to eight hours of sleep each night. Teenagers should get about nine hours of sleep, and infants need to sleep from 16 to 18 hours of sleep each day. Sleep is essential for mental and physical restoration. It is a cycle with two separate states: rapid eye movement (REM), the stage in which most dreaming occurs; and non-REM (NREM). Four stages of sleep take place during NREM: stage I, when the person passes from relaxed wakefulness; stage II, an early stage of light sleep; stages III and IV, which are increasing degrees of deep sleep. Most stage IV sleep (also called delta sleep) occurs in the first several hours of sleep. A period of REM sleep normally follows a period of NREM sleep.

Disrupted sleep

Sleeplessness or insomnia may be caused by a physical condition such as **obesity**, a mental condition such as **depression**, shift work with irregular hours, or a traumatic event. In the days immediately after the terrorist attacks on September 11, 2001, 47% of Americans rated their sleep as "poor," or "fair," according to NSF's "2002 Sleep in America" poll. In comparison, 27% of poll participants rated sleep as poor or fair for most nights of that year.

The foundation's 2005 poll indicated that women were more likely to experience insomnia than men. NSF explored that demographic in the "2007 Sleep in America" poll of women between the ages of 18 and 64. That study showed that sleep problems such as insomnia were experienced by 72% of working mothers and 68% of single working women. Furthermore, 74% of stay-at-home mothers displayed symptoms of insomnia during a couple nights each week.

That poll paralleled other research that showed that women are 1.3 more likely to report insomnia than men. They may experience sleeplessness before and at the onset of their menstrual cycle, during **pregnancy**, and **menopause**. In addition, the foundation reported that people over the age of 65 are more likely to be bothered by insomnia than younger individuals.

Furthermore, people who are divorced, widowed, or separated are more likely to have the problem than those who are married. In addition, insomnia is more frequently reported by those with lower socioeconomic status.

Insomnia is classified both by its nightly symptoms and its duration. Sleep-onset insomnia refers to difficulty falling asleep. Maintenance insomnia refers to waking frequently during the night or waking early. Insomnia is also classified in relation to the number of sleepless nights. Short-term, or transient, insomnia is a common occurrence and usually lasts only a few days. Long-term, or chronic, insomnia lasts more than three weeks. This condition increases the risk for injuries in the home, at the workplace, and while driving because of the person experiences daytime sleepiness and decreased concentration ability. Chronic insomnia could also lead to mood disorders such as depression.

Causes and symptoms

Transient insomnia is often caused by a temporary situation in a person's life such as an argument with a loved one, a brief medical illness, or **jet lag**. When the situation is resolved or the precipitating factor disappears, the condition goes away, usually without medical treatment.

Prescription drugs such as **asthma** medicine, steroids, and anti-depressants may cause insomnia. Sleeplessness may also be a side effect of over-the-counter products such as nasal decongestants and appetite suppressants.

Chronic insomnia usually has different causes, and there may be more than one factor contributing to sleeplessness. Causes of insomnia include:

- A medical condition or its treatment, including sleep apnea, diabetes, arthritis, a heart condition, and asthma
- Use of substances such as caffeine, alcohol, and nicotine
- Psychiatric conditions such as mood or anxiety disorders
- Stress or depression, such as sadness caused by the loss of a loved one or a job.
- A change in work shift
- A work schedule with nontraditional hours. Shift workers who may experience insomnia include medical professionals, truck drivers, the military, and people working at businesses open 24 hours a day.
- Sleep-disordered breathing, such as snoring
- Periodic jerky leg movements, *nocturnal myoclonus*, which occur just as the individual is falling asleep.
- Restless legs syndrome, which involves the urge to move the legs. The person may also experience feelings such as tingling or cramping.
- Repeated nightmares or panic attacks during sleep

Excessive worrying about whether the person will be able to fall asleep may also cause insomnia. The concern creates so much **anxiety** that the individual's bedtime rituals and behavior actually trigger insomnia, a condition called psychophysiological insomnia.

Symptoms of insomnia

People who have insomnia do not start the day refreshed from a good night's sleep. They may have difficulty falling asleep and commonly lie in bed tossing and turning for hours. Or the individual may go to sleep without a problem but wakes in the early hours of the morning. The person is either unable to go back to sleep or drifts into a restless, unsatisfying sleep. This is a common symptom in the elderly and those suffering from depression. Sometimes sleep patterns are reversed and the individual has difficulty staying awake during the day and takes frequent naps. The sleep at night is fitful and frequently interrupted.

Diagnosis

Insomnia, unlike some medical conditions, is easily recognizable, as people know when they are not getting enough sleep. The key to treating insomnia is determining its causes. Some people can identify sleep-inhibiting factors such as a death in the family or a hectic work schedule with too much caffeine consumption and not enough **exercise**. A doctor will take factors such as these into account when making a diagnosis.

The physician's diagnosis is based on the patient's reported signs and symptoms. The doctor may review a patient's health history or order tests to determine if a medical condition is causing the insomnia. The physician may ask if the patient is depressed, in **pain**, under **stress**, or taking medications, according to the National Sleep Foundation. The doctor may ask about disruptions in a patient's life such as working nontraditional shifts or traveling across different time zones.

It may be useful for the patient to keep a daily record for two weeks of sleep patterns, food intake, use of alcohol, **caffeine**, nicotine, medications, exercise, and any other information recommended by the physician. If the patient has a bed partner, information can be obtained about whether the patient snores or is restless during sleep. This information, together with a medical history and physical examination, can help confirm the doctor's assessment.

A wide variety of healthcare professionals can recognize and treat insomnia. When a patient with chronic insomnia does not respond to treatment, or the condition is not adequately explained by the patient's physical, emotional, or mental circumstances, then more extensive testing by a specialist in sleep disorders may be warranted.

Treatment

In both alternative and conventional medicine, treatment of insomnia includes alleviating or coping with any physical and emotional problems that contribute to the condition. Also effective is exploring changes in lifestyle that will improve the situation.

Changes in behavior

Patients can make changes in their daily routine that are simple and effective in treating insomnia. Eating a healthy diet rich in calcium, **magnesium**, and the B vitamins is also beneficial.

Patients should go to bed only when sleepy and use the bedroom only for sleep or sex. Activities such as reading, watching television, or snacking should take place elsewhere. If people are unable to go to sleep, they should go into another room and do some quiet activity such as reading. People should return to bed only when sleepy. Patients should set the alarm and get up every morning at the same time, no matter how much they have slept, to establish a regular sleep-wake pattern. Naps during the day should be avoided, but if absolutely necessary, then a 30-minute nap early in the afternoon may not interfere with sleep at night.

Another successful technique is called sleep-restriction therapy, restricting the time in bed to the actual time spent sleeping. This approach allows a slight sleep debt to build up, which increases the individual's ability to fall asleep and stay asleep. If a patient sleeps five hours a night, the time in bed is limited to 5–5.5 hours. The time in bed is gradually increased in small segments, with the individual rising at the same time each morning; at least 85% of the time in bed must be spent sleeping.

Mind and body relaxation

Incorporating **relaxation** techniques into bedtime rituals helps a person go to sleep faster and improves the quality of sleep. These, alone or in combination with other relaxation techniques, can safely promote sleepiness. Also effective are massage techniques such as **shiatsu**, the traditional Japanese form of body work. Gentle pressure is applied to points of the body to bring on sleep.

Learning to substitute pleasant thoughts for unpleasant ones (imagery training) helps reduce worrying. Another technique is using recordings that combine the sounds of nature with soft relaxing music. **Meditation**, **prayer**, and breathing exercises could also be effective.

Insomnia may be treated professionally through techniques such as cognitive therapy. The therapist works with the patient to discover attitudes and feelings that disrupt sleep.

Herbal remedies

Many alternative treatments are effective in treating both the symptom of insomnia and its underlying causes. Much treatment is centered on herbal remedies, but the United States Food and Drug Administration does not regulate these treatments, which means that the remedies have not proven to be safe or effective. Furthermore, ingredients are not standardized to comply with regulations. People should consult with their healthcare provider or complementary medicine practitioner before taking herbal remedies. This is especially important because some remedies such as **melatonin** interact with herbals like **valerian** and prescription medicines.

Valerian

Research up to the spring of 2008 indicated that valerian may help with insomnia. People who took valerian fell asleep more quickly and experienced improved slumber. Because of the herb's sedative properties, valerian is used to treat insomnia and anxiety. It is an approved remedy in the German Commission E Monographs, a guide to herbal remedies. Approved uses include sleeping disorders caused by nervousness.

Valerian's sedative properties have been studied in animals and people. As of the spring of 2008, valerian was regarded as probably safe when taken at the recommended dosage. The remedy did not appear to disrupt sleep cycles or REM sleep.

Furthermore, a combination of valerian and **hops** could help with sleeplessness. Other herbs most recommended for treating insomnia include **skullcap** and ginseng. Herbal products are available in capsule, tincture, and powdered form. Some people treat insomnia by sipping a warm cup of tea made with an herb mixture such as valerian, **chamomile**, hops, **lemon balm**, **passionflower**, or **St. John's wort**.

Aromatherapy and hydrotherapy

Aromatherapy involves healing through **essential oils**, the aromatic extracts of plants. Essential oils may be used for a soothing bath; applied to the face, neck, shoulders, and pillow; or diffused in air.

Hydrotherapy consists of a warm bath, scented with an essence such as rose, **lavender**, or marjoram. Valerian may also be added to bath water.

Dream pillows

Another form of aromatherapy involves sleeping on a dream pillow. Also known as a sleep pillow, it can be made by sewing together two 8-inch pieces of fabric. There should be an opening to insert a tablespoon. Herbs such as hops, chamomile, and lavender are spooned into the dream pillow, which is placed under the bed pillow.

Melatonin

Melatonin is a natural hormone that is secreted from the brain's pineal gland. The gland regulates a person's biological clock, particularly day and night cycles. Melatonin is generally used as a jet lag remedy. It may also help establish sleep patterns for shift workers. While melatonin may help people fall asleep more quickly, studies indicated limited success when it was used for treating insomnia. Melatonin is not regulated by the FDA, so the long-term effects of taking it are not known.

Traditional Chinese medicine

Traditional Chinese medicine (TCM) treatments for insomnia include **acupuncture** and herbal remedies. Acupuncture involves the insertion of needles to manipulate energy flows around the body. Acupuncture is also applied to the treatment of conditions, including anxiety.

In TCM, herbs are used as remedies in teas and other preparations. Treatments for insomnia include reishi, a medicinal mushroom available in extract form. However, the side effects of reishi could include **dizziness** and nose bleeds, so it is important to consult with a healthcare professional before taking this remedy.

Light therapy

In **light therapy**, natural or artificial light is used to boost serotonin, a neurotransmitter in the brain related to reducing anxiety. This therapy is used to treat **seasonal affective disorder**, a condition that some people experience when there is less sunlight or fewer daylight hours. Some people with this disorder feel depressed during the winter, and their spirits pick up during the summer. Light therapy is used to combat the depression experienced during the winter. There were no known risks as of the spring of 2008.

A study on the use of bright light therapy to treat insomnia was described in the July 2005 edition of the professional journal *Sleep*. The research involved 24 men diagnosed with early-morning waking insomnia. During the two nights of the study, the men were exposed to light while watching television. Some received bright light (2,500-lux white light) from 8 p.m. to midnight the first night and from 9 p.m. to 1 a.m. the following night. The other subjects were in the dim-light control group. The subjects in the bright light group said they tended to sleep longer than they did before the treatment. They woke up later. When they did waken, they went back to sleep more quickly.

Allopathic treatment

A physician may determine that drug therapy is necessary to treat insomnia. Drugs may be prescribed if the patient is undergoing a crisis or insomnia persists after a patient has made lifestyle changes. However, drug therapy is regarded as a short-term remedy, not a solution.

Conventional medications given for insomnia include sedatives, tranquilizers, and anti-anxiety drugs. All require a doctor's prescription and may be habit-forming. They could lose effectiveness over time and can reduce alertness during the day. The medications should be taken up to four times daily or as directed for approximately three to four weeks. The dose will vary with the physician, patient, and medication. If insomnia is related to depression, then an antidepressant medication may be helpful.

Drugs prescribed for improving sleep are called hypnotics. This category includes benzodiazepines, which are prescribed for anxiety and insomnia. Benzodiazepines commonly prescribed for insomnia include triazolam (Halcion), tempazepam (Restoril), lorazepam (Ativan), alprazolam (Xanax), fluazepam (Dalmane), and oxazepam (Serax). Other medications prescribed for insomnia include zolpidem tartrate (Ambien), eszopiclone (Lunesta), and ramelteon (Rozerem).

Over-the-counter sleep products include Nytol, Sominex, Unisom Nightime Tablets, and Tylenol PM. While these products are usually not addictive, some experts believe they are not very effective in sustaining stage IV sleep and could affect the quality of sleep.

Expected results

Insomnia has numerous causes and treatments, so the amount of time may vary before results are seen. A prescription drug may bring immediate results to someone coping with a spouse's death. An herbal remedy may not work immediately for a person who consumed excessive amounts of caffeine to stay awake at work after a sleepless night. A procedure such as cognitive therapy may take some time as therapist and patient work to resolve issues that hinder sleep.

Research has provided information about when some treatments take effect:

- Valerian is sold commercially in the form of capsules, extracts, and teas. The capsule or extract dosage ranges from 300 to 600 mg. As a sleep aid, it should be taken shortly before bedtime. People who have trouble falling asleep may see results quickly. It could take from two weeks to a month before a person with chronic insomnia experiences improved sleep.
- A combination of hops and valerian at bedtime could provide a good night's sleep.
- Melatonin is taken in a dose of from 0.3 to 3 mg an hour of retiring. When taken as a 3-mg dose one to two hours before bed for a maximum of four to five days per week, the dietary supplement melatonin was said to be effective in shortening the time before a person fell asleep. Side effects could include nightmares and sleepwalking.
- St. John's wort can take two weeks to take effect.
- A combination of alternative therapies should bring a difference in disturbed sleep within two to four days.
- Combinations of treatments could more quickly bring about an uninterrupted night of sleep. The person who reduces caffeine intake, walks for 15 minutes, and enjoys an herbal bath may discover that that combination brings restful sleep.
- Acupuncture is said to bring some people immediate relief. In small studies, people said that after treatment that it was easier to fall asleep and they remained asleep. This treatment is safe when it is done correctly.
- Light therapy proved to be effective in the treatment of men whose insomnia caused them to wake early. In that study, the men said they experienced an immediate benefit. However, no women were studied, and the research did not include people with other types of insomnia.

KEY TERMS

Biofeedback—A training technique that enables an individual to gain some element of control over involuntary body functions.

Mood disorder—A group of mental disorders involving a disturbance of mood, along with either a full or partial excessively happy (manic) or extremely sad (depressive) syndrome not caused by any other physical or mental disorder. Mood refers to a prolonged emotion.

Sleep apnea—A condition in which a person stops breathing while asleep. These periods can last up to a minute or more and can occur many times each hour. In order to start breathing again, the person must become semi-awake. The episodes are not remembered, but the following day the person feels tired and sleepy. If severe, sleep apnea can cause other medical problems.

Sleep disorder—Any condition that interferes with sleep. As of 2008, at least 84 have been identified, according to the American Sleep Disorders Association.

Prevention

Prevention of insomnia centers around the promotion of a healthy lifestyle. A balance of rest, recreation, and exercise in combination with stress management, regular physical examinations, and a healthy diet can do much to reduce the risk. Walking is also recommended. However, exercise should be done no more than three hours before bedtime.

Also to be avoided in the evening are drinks that contain caffeine such as coffee, tea, and colas. Chocolate contains a stimulant and may keep people awake. In addition, alcohol may initially make a person sleepy. However, it could have the opposite effect a few hours later.

Maintaining a comfortable bedroom temperature, reducing noise, and eliminating light are also helpful. The bedroom should be used only for sleeping, not watching television or reading.

Exercise, relaxation, and **nutrition** should be considered ongoing preventive measures. While life brings unexpected stresses and pressures, the person who is familiar with relaxation techniques is more prepared to cope with insomnia.

Insulin resistance

Definition

Insulin resistance is a condition in which cells, particularly those of muscle, fat, and liver tissue, display "resistance" to insulin by failing to take up and utilize glucose for energy and metabolism (insulin normally promotes take up and utilization of blood glucose from the blood stream). In its early stages, the condition is asymptomatic, but may develop into Type II Diabetes. Although there are several established risk factors, the underlying cause is unknown.

It has been estimated that 30 to 33 million Americans are insulin resistant, and the number appears to be increasing.

Description

Insulin resistance is initially asymptomatic, and in its early stages can be detected only by laboratory tests. These tests will show an abnormally high blood sugar (glucose) level, but not high enough to be considered pre-diabetic or diabetic. While the condition does not always lead to further problems, the majority of people who reach the pre-diabetic level go on to develop Type II Diabetes (formerly called Maturity Onset Diabetes.

Causes and symptoms

The cause of insulin resistance is unknown, although the condition has been seen to run in families, indicating that there is a genetic association. Being overweight, and lack of **exercise** are also associated with insulin resistance, although the nature of the relationship is not clear. Risk factors for insulin resistance are:

- having a family history of diabetes
- having a low HDL (good) cholesterol—and high serum lipids
- having high blood pressure
- having a history of diabetes during pregnancy, or having given birth to a baby weighing more than 9 pounds
- being a member of one of the racial groups that appear to have a high incidence of insulin resistance (African American, Native American, Hispanic American/Latino, or Asian American/Pacific Islander)
- having syndrome X
- being obese

In its mildest form, insulin resistance causes no symptoms, and is only recognizable on laboratory tests. In more severe cases, there may be dark patches on the back of the neck, or even a dark ring around the neck. The dark patches are called *Acanthosis nigricans* and may also cause darkening of skin color in the elbows, knees, knuckles, and armpits.

There is a constellation of symptoms now called metabolic syndrome or insulin resistance syndrome that is linked to insulin resistance. This syndrome was formerly called syndrome X. Metabolic syndrome is defined by the National **Cholesterol** Education Program as the presence of any three of the following conditions:

- excess weight around the waistline (waist measurement of more than 40 inches for men and more than 35 inches for women)
- high levels of serum triglycerides (150 mg/dL or higher)
- low levels of HDL, or "good," cholesterol (below 40 mg/dL for men and below 50 mg/dL for women)
- high blood pressure (130/85 mm Hg or higher)
- high fasting blood glucose levels (110 mg/dL or higher)

KEY TERMS

Acanthosis nigricans—A localized darkening of the skin that is associated with insulin resistance. This is not seen in all cases, and is considered a rare disorder.

Diabetes—Any of several metabolic diseases affecting the body's use of blood sugars or the intake and excretion of fluids. In Type 2 diabetes, formerly called maturity onset diabetes, there is sufficient insulin, but the insulin is unable to penetrate the cell membrane.

Insulin—A hormone, secreted by the pancreas, which is essential for the body's ability to use glucose to provide energy. Inadequate insulin supplies result in Type 1 diabetes.

Metformin—An anti-diabetic drug of the biguanide class. This drug increases the sensitivity of cells to insulin, but is capable of causing very severe adverse reactions, including lactic acidosis and anemia.

Pioglitazone—An anti-diabetic drug of the thiazolidinedione class. This drug increases the sensitivity of the cells to insulin, but is capable of causing severe adverse reactions, including congestive heart failure.

Note that the numbers are those from an expert panel convened by the National Institutes of Health in 2001. Other panels of similarly qualified experts have given slightly different definitions.

Diagnosis

The only means of diagnosis for insulin resistance is laboratory test. While there are several tests that may be performed, the two most common screening tests are the **Fasting** Blood Sugar Test and Glucose Tolerance Test.

Fasting blood sugar measures the blood glucose level after a 12 hour fast (no food). A normal level, according to the United Sates National Institute of Diabetes and Digestive and Kidney Disease (NIDDK), should be below 100 mg/dL (milligrams of glucose in every deciliter of blood. A value in the n the 100 to 125 mg/dL range is considered evidence of insulin resistance, and is considered pre-diabetic. A value of 126 mg/dL is considered diabetic. (Blood sugar levels after a 12 hr fast are typically lower than this, and are controlled by pancreatic insulin secretion that transports blood glucose out of the blood and into the muscles, brain, organs, and other tissues.)

The glucose tolerance test is performed after the patient has had nothing but water for 10 to 16 hours. The patient has his blood drawn for a a baseline blood glucose level. Next, the patient drinks a special sweetened test drink that contains exactly 75 grams of glucose (pregnant women are normally given 100 grams of glucose.) Blood is drawn again at one half hour and each of the next six hours to compare blood glucose levels and watch their pattern in response to the sweet drink. Normally the blood sugar level is lower before the drink, rises quickly during the first few hours, and slowly drops again. In insulin resistance, the blood sugar rises but stays abnormally high, because it is resistant to being removed from blood into tissues by insulin. High blood sugar from food or the test glucose drink stimulates the pancreas to secrete insulin into the blood. However in insulin resistance, the insulin is secreted but only partially absorbed by the tissues. According to the National Diabetes Information Clearinghouse (NDIC) a normal level would be below 140 mg/dL 2 hours after the drink. If it is in the 140 to 199 mg/dL range 2 hours after drinking the solution, the diagnosis is impaired glucose tolerance (IGT) or prediabetes. A level of 200 or higher, if confirmed, represents a diagnosis of diabetes.

Treatment

Among the most important treatment modalities are diet and exercise, weight loss if obese, endocrine hormone correction- if unbalanced. In 2001, the National Institutes of Health completed the Diabetes Prevention Program (DPP), a clinical trial designed to find the most effective ways of preventing type 2 diabetes in overweight people with prediabetes. The researchers found that lifestyle changes reduced the risk of diabetes by 58 percent. Also, many people with prediabetes showed a return to normal blood glucose levels.

According to the DDP results, a mere half hour of brisk walking or bicycling five days a week can significantly reduce the risk of developing type 2 diabetes. Patients should use diet and exercise to reduce their body mass index (BMI) to 25 or below.

Smoking has been associated with insulin resistance, as well as with some of the more severe problems associated with diabetes. Discontinuing smoking should be a top priority.

A healthful diet, in addition to assisting in weight loss, may reduce serum lipids and reduce some of the risk factors for diabetes. One study recommended the

Mediterranean diet as being the most beneficial for people with insulin resistance. Diet improvements include reducing sweets, desserts and high glycemic meals; eating balanced meals that contain protein, complex carbohydrates, fiber, greens and healthy oils, eating at regular times, and avoiding excess junk food and sugar.

No complimentary or alternative therapies have been proven to cure insulin resistance. Although several herbal remedies have been traditionally used for treatment of diabetes, none have been adequately documented as effective. Among medicinal plants shown to help lower elevated blood sugar are the Asian **bitter melon** and the Navaho Optunia cactus. Such herbal **bitters** as **dandelion** root and **yellow dock** can improve digestive strength and sometimes help; though no herbal remedy alone "cures" insulin resistance or diabetes. Guar gum, glucomannan, and **psyllium** seed all have demonstrated some ability to lower blood sugar in insulin resistance or diabetes, but none have been shown to be reliably effective for use in treatment of humans.

Allopathic treatment

Insulin resistance does not normally require drug therapy; however, some studies have shown that the drugs used to treat type 2 diabetes may delay development of diabetes. Two classes of dugs now used to treat diabetes act by increasing insulin sensitivity, the biguanides and the thiazolidinediones; the other drugs used to treat diabetes act in different ways.

Although drugs from both classes have been effective in treatment of insulin resistance, neither drug has been as effective as a regimen of diet and exercise. Both classes of drugs have the potential for very severe adverse effects.They are also not approved by the FDA for control of insulin resistance, although physicians may prescribe them for this use if the condition appears to be progressing without drug therapy. In one study, oral hypoglycemic drugs of various mechanisms that help reduce elevated blood blood glucose reduced the rate of disease progression from insulin resistance to diabetes by about one-third over a three year period.

Expected results

In mild, asymptomatic insulin resistance, proper treatment may lead to a complete reversal, with normalization of blood sugar.

Even if complete normalization is impossible, treatment will lead to control of the condition, and a significant reduction in its rate of progression to diabetes.

Prevention

In insulin resistance, prevention is even better than treatment. Maintaining a normal weight, a balanced diet, and a regular program of aerobic exercise is the best preventive measure.

Interstitial cystitis

Definition

Interstitial Cystitis is a chronic bladder disorder involving symptoms such as pelvic **pain**, urinary frequency and urgency, which occurs in the absence of infection.

Description

Interstitial Cystitis (IC) is a condition affecting the bladder, often presenting with urinary symptoms and pelvic pain. Although many of the symptoms are similar to urinary tract **infections** (UTIs), IC is distinct in that a criterion for diagnosis is that no infectious organisms are present. The cause of IC is not fully known, and it is probable that multiple factors contribute to its development.

IC is characterized by chronic or remitting and recurring urinary symptoms. There is typically chronic urinary frequency and urgency which may significantly interfere with activities of daily living. Frequent nighttime urination causes sleep disruption that can lead to **fatigue** and **depression**.

Demographics

In the late 1990s between 500,000 and 1,000,000 cases of IC were reported in the United States. It is likely that prevalence of IC may be substantially greater than this due to the strict diagnostic criteria and many cases have gone undiagnosed.

Interstitial cystitis affects predominantly women, who comprise about 90% of cases. This may be in part because estrogen appears to play a role in the disorder. Women also have increased incidence of autoimmune conditions in general, and IC may have an autoimmune component.

Causes and Symptoms

The etiology of interstitial cystitis is largely theoretical and not well understood. It is likely a multifactorial condition with multiple causes. Research has confirmed several contributing aspects to the pathology of IC, including neurological, immunological, hormonal and structural origins.

The nervous system is involved in the pathology of interstitial cystitis as the site of neurogenic inflammation. Sensory nerves in the pelvis secrete immunological agents, causing inflammation and pain. One such agent is known as Substance P, a neuropeptide that acts to communicate a pain signal to the central nervous system, resulting in sensation of pain. Elevated levels of Substance P are found in patients with IC, contributing to the sensation of pelvic and bladder pain.

The immune system promotes neurogenic inflammation through chemical mediators such as substance P, inflammatory cytokines, and mast cells. Mast cells release histamine, an immune agent that promotes a local inflammatory response. In 30-65% of cases of IC, elevated mast cell levels were found in the bladder wall, contributing to chronic inflammation. It is suspected that there is autoimmune activity in IC, but studies have been inconclusive.

Estrogen plays a role in the etiology of IC, which may partially explain the higher incidence in women. Studies have shown that estrogen plays a role in determining the intensity of nerve inflammation. Symptoms are typically more severe in premenopausal women, especially at ovulation when estrogen levels peak.

As a result of chronic inflammation of the bladder wall, the mucosal lining of the bladder is compromised in IC. The surface layer of the bladder is comprised of glycosaminoglycans (GAGs) which protect the bladder from microorganisms, toxins and the acidity of the urine. In IC, the GAG layer is broken down, leading to increased permeability, inflammation and stimulation of pain receptors. IC is sometimes referred to as "leaky bladder syndrome," as the urine leaks through the protective membrane and irritates the deeper layers of the bladder.

Diagnosis

In 1987-88, the National Institutes of Health established a task force to define the diagnostic criteria of IC, which were revised in 1999 by the National Institute of Diabetes and Digestive and Kidney Diseases (NIDDK). These criteria have also been critiqued as being too restrictive, resulting in underdiagnosis of interstitial cystitis by as much as 60%. In 2007, a Consensus Group on Interstitial Cystitis/Painful Bladder Syndrome met to discuss and further refine the definition of IC, also referred to as Painful Bladder Syndrome (PBS), to the following: "Pelvic pain, pressure, or discomfort related to the bladder, typically associated with persistent urge to void or urinary frequency, in the absence of infection or other pathology."

IC is a diagnosis of exclusion, meaning that other conditions must first be ruled out before a diagnosis of interstitial cystitis can be made. The conditions that must be ruled out include **pelvic inflammatory**

disease, sexually transmitted disease, **bladder infection**, kidney or bladder stones and **bladder cancer**.

Interstitial cystitis is diagnosed based on history of symptoms for greater than nine months and absence of other diagnoses upon urological evaluation. The "gold standard" of diagnosis is cystoscopy with hydrodistention. This outpatient surgical procedure involves filling the bladder with fluid and viewing the bladder wall with a scope, under local anesthesia. This procedure will reproduce the sensation of intense urgency for urination, as well a diminished filling capacity. Cystoscopy often reveals pinpoint hemorrhages on the bladder wall called glomerulations, and more rarely reveals ulceration of the bladder lining known as Hunner's ulcers.

At this writing in 2008, additional testing had been developed to use potassium-chloride (KCl) to diagnose IC. Due to increased permeability of the bladder wall, **potassium** in the urine can pass through the bladder, provoking the inflammatory and pain reactions. The KCl sensitivity test utilizes an infusion of KCl through a catheter into the bladder to reproduce the symptoms. This test has been found to be about 60-75% accurate and is not yet approved for diagnosis.

Treatment

Conventional treatment includes the oral heparinoid compound pentosan polysulfate (PPS) and heparin injected to the bladder intravesically. PPS and heparin are similar in structure to the GAGs that regulate the permeability of the bladder surface. This form of treatment has found to be successful in clinical studies when used for at least one to two years. One study of long-term use of PPS oral therapy found that 65% of study participants found relief.

PPS and similar drugs may be used in conjunction with other medications that address the immunological and neurological components of IC, such as antihistamines and anti-depressants. Additional pharmacologic agents used for adjunct treatment are gabapentin, an antiepileptic drug, and in extreme cases, opioids for pain management.

Hydrodistention, the procedure for diagnosing IC, has been found to bring short-term relief for 3-6 months and is often used therapeutically. Other agents applied directly to the bladder include dimethyl sulfoxide (DMSO), which has been found to reduce inflammation and mastocytosis of the bladder. One study found 53% of participants reported improvement after treatment with DMSO.

Natural therapies are similarly selected to address the underlying mechanisms of interstitial cystitis. Oral supplementation of glycosaminoglycans such as **glucosamine** sulfate and **chondroitin** sulfate may help repair the GAG layer of the bladder and reduce leakage of potassium-containing urine through the protective surface. Glucosamine sulfate, chondroitin sulfate and other sulfate donors may act as sulfate donors for glycosaminoglycan repair. Sulfate is required for GAG synthesis and glucosamine increases serum sulfate concentrations.

The nutrients L-arginine and quercitin have been studied for their use in treating IC. L-arginine is an amino acid found to increase nitric oxide (NO) and its precursor nitric oxide synthase (NOS), which may be deficient in patients with IC, causing increased bladder irritability. Randomized clinical trials of L-arginine are conflicting, although it may decrease pain intensity, frequency and nighttime urination. Quercitin, a bioflavinoid, stabilizes mast cells and reduces histamine secretion. It has shown some promise in small studies for significantly decreasing pain, although further study is needed.

Botanical medicine can offer much relief to sufferers of interstitial cystitis. Botanicals that may be useful are demulcent herbs such as marshmallow (Althea officinalis) and couch grass (Agropyren repens). **Licorice** root (Glycerrhiza glabra) has both anti-inflammatory and demulcent properties, soothing irritated mucosa. Kava (Piper methysticum) is a well-known nervine botanical that alleviates inflammation and irritation of the urinary system as well as relieving neuralgic pain. Its use should be supervised by a practitioner knowledgeable about botanical medicine because although it is generally safe, long-term use has been associated with adverse liver effects.

Therapeutic **nutrition** is another consideration for IC treatment, particularly the identification and elimination of food sensitivities. Keeping a diet diary can help identify foods that aggravate IC symptoms, usually within 2-4 hours of ingestion. Inflammation may be reduced by following an anti-inflammatory diet, eliminating foods that promote inflammation such as wheat, dairy, soy, peanuts and nightshade vegetables such as peppers and tomatoes. Avoidance of **caffeine**, sugar and artificial sweeteners, alcohol, spicy and acidic foods, and food additives may reduce irritation to the bladder.

Hydrotherapy treatments such as sitz baths may help reduce inflammation and relieve pelvic pain, using alternating hot and cold water. This home treatment is done by using two large basins or tubs, one with hot water and one with cold (approximately 105° and 45°, respectively). The water should be deep enough to submerge the pelvis up to the navel when

KEY TERMS

Cystoscopy—A procedure for examination of the interior of the bladder using an instrument introduced through the urethra into the bladder.

Cytokines—Produced by white blood cells, cytokines are chemical signalers that commune immunologic messages and direct specific immune responses.

Glycosaminoglycans—Any of a group of polysaccharides with high molecular weight that contain amino sugars and often form complexes with proteins.

Histamine— An amine acting as an immunologic agent or neurotransmitter, producing a range of responses including redness, flushing, inflammation and edema.

Hydrodistention—Filling the bladder with fluid for the purpose of examining the internal bladder with a cystoscope.

seated in the tub. Taking care not to get chilled, the bather first sits in the hot tub for 3-5 minutes, then moving to the cold tub for 30-60 seconds. This cycle can be repeated three times, always ending with the cold water bath.

Lastly, homeopathic remedies that are individually selected for the patient may improve the symptoms when used acutely for pain and discomfort. **Homeopathy** may also be used to improve the overall constitutional health, and is best used with the supervision of a skilled homeopath.

Prognosis

Many clinical trials of conventional treatments indicate at least marginal improvement with pharmacologic therapy. Fewer studies exist on the efficacy of nutritional or botanical therapeutics, although empirical evidence and some small clinical trials of various natural remedies brought about symptom relief and improved quality of life.

Prevention

As the etiology of IC is poorly understood, it is difficult to determine means of preventing its onset. One theory is that food **allergies** and sensitivities contribute the generalized inflammation and local irritation to the gut lining and may similarly affect the bladder. For this reason, identifying and removing food sensitivities may prevent the occurrence of IC or its worsening in individuals with mild pelvic and urinary symptoms.

proper functioning of nerves and muscles, differentiation of the fetus, growth and repair of tissues, and the condition of skin, hair, teeth, and nails. Iodine is also needed for the production of thyroid hormones. The thyroid (a small gland in the front of the neck), which contains 80% of the body's iodine pool, converts iodine into the thyroid hormones thyroxine (T_4) and triiodothyronine (T_3). These hormones are released into the bloodstream, controlling the body's metabolic rate.

General use

The recommended dietary allowance (RDA) for iodine was revised in 2001 by the Food and **Nutrition** Board of the Institute of Medicine, and the data is provided in the table in this entry. That standard differs for various ages and each sex and for pregnant and lactating women.

Estimates of the average daily intake of iodine for citizens of the United States and other countries around the world vary widely depending on a number of factors, one of which is geographical location. The most recent estimates for iodine intake in the United States range from about 200 mcg/day to 500 mcg/day, with the upper level reaching nearly 750 mcg/day in some parts of the country. According to the *Merck Manual of Diagnosis and Therapy*, less than 20 mcg per day of iodide results in iodine deficiency; iodide intake 20 times greater than the daily requirement (1.5 mg) results in chronic iodine toxicity.

Iodine is available from a variety of food sources, drugs, and most commercial vitamin preparations. Some seafood and sea vegetables provide good sources of dietary iodine: canned sardines, canned tuna, clams, cod, haddock, halibut, herring, lobster, oyster, perch, salmon, sea bass, and shrimp. Dulse, **kelp**, and seaweed are also sources of dietary iodine. If grown in iodine-rich soil, foods including asparagus, green peppers, lettuce, lima beans, mushrooms, pineapple, raisins, spinach, summer squash, Swiss chard, turnip greens, and whole-grain wheat may provide good sources of dietary iodine. Animal products can also provide a source of iodine, especially if the animals are fed iodine-enriched foods or salt: beef, beef liver, butter, cheddar cheese, cottage cheese, cream, eggs, lamb, milk, and pork. Some foods such as breads may contain iodine additives.

Another source of dietary iodine is iodized salt. Iodized table salt was introduced in the United States in 1924 and significantly reduced the incidence of iodine deficiency. Providing iodized salt licks for livestock adds iodine to animal products. In some parts of the world, iodized oil supplements and water iodination provide other means of iodine supplementation. In 2007, the Network for Sustained Elimination of Iodine Deficiency reported that 70% of the world's population had access to supplemental iodine in one form or another. Many countries, however, still have insufficient iodine supplementation programs.

Iodine has several medical applications. Typically, in conjunction with drug therapy, iodine may be used to treat goiter (an enlargement of the thyroid gland), symptoms of **hypothyroidism** (diminished production of thyroid hormone), and **hyperthyroidism** (increased production of the thyroid gland). It may also be used as an expectorant in **cough** medications. Applications of iodine to conditions such as arteriosclerosis, arthritis, and **angina** pectoris have also been noted. Iodine tinctures (dilute mixtures of alcohol and iodine) or a combination of Bacitracin **zinc** and Polymyxin B sulfate (Betadine) are used as antiseptics to kill bacteria in skin **cuts**. Atomidine, a product

containing iodine trichloride and other unlisted ingredients, is also sold as an antiseptic. Atomidine taken orally in minute, cyclic doses is also recommended as a glandular stimulant and purifier.

Some research has shown that oral iodine supplements have antifibrotic and anti-inflammatory effects. Commonly reported studies have also suggested that iodine deficiency may be a factor in **fibrocystic breast disease** (FBD), a catch-all term that describes general, often normal, lumpiness of the breast. Clinical trials on women diagnosed with FBD found that, even in women showing normal thyroid function, thyroid hormone supplementation resulted in decreased breast **pain** and decreased breast nodules. Some early research also correlated higher incidence of breast, endometrial, and ovarian cancers with hypothyroidism and/or iodine deficiency. However, others have noted that low levels of **selenium**, which is more typically associated with **cancer**, were also present in these studies.

Iodine is used in several compounds for a variety of medical testing procedures. For example, it may be used in x-raying the gallbladder or kidneys or in cardiac imaging. It is used as a diagnostic tool to examine the thyroid gland's output. A common test measures thyroid radioactive iodine uptake (RAIU). Trace amounts of radioactive iodine (^{123}I or ^{131}I) are used to test thyroid function. Together with blood tests, examining how much iodine is taken up by the thyroid gland helps physicians diagnose hypothyroid conditions (when the thyroid takes up too little iodine) and hyperthyroid conditions (when it takes up too much). Radioactive iodine therapy is also used for treating thyroid disease and cancer. But radioactive iodine can cross the placenta, causing severe dysfunction and damage to the fetus's thyroid gland, so experts recommend that nursing mothers should discontinue nursing for a period of time after receiving test or treatment doses of radioactive iodine. Medical professionals may also prescribe low iodine **diets** in combination with radioactive iodine tests or treatments.

Precautions

Too much or too little iodine intake results in a wide spectrum of disorders that are addressed by adjusting iodine intake. Too much iodine can result in toxicity.

Iodine deficiency disorders (IDDs) are preventable, but not curable, by ensuring adequate iodine intake. Only a small amount of iodine is required over the human lifespan. The body, however, does not store iodine for long periods so the intake must be regular. Too little iodine intake can result in cold feet; **fatigue**; **insomnia**; problems with skin, nails, and hair; and weight gain. Goiter can result from iodine deficiency. Certain substances called goitrogens can also induce goiter by interfering with thyroid functioning. Some foods have goitrogenic tendencies, as do certain drugs, for example, thiourea, sulfonamides, and antipyrine. Foods containing substances that can prevent the utilization of iodine when eaten in large quantities include brussels sprouts, cabbage, cauliflower, kale, millet, mustard, peaches, peanuts, pears, pine nuts, soybeans, and turnips. Limiting consumption of these foods may be recommended for persons with an underactive thyroid.

Iodine deficiency can also result in serious, irreversible disorders, widely recognized as a serious global health problem by organizations such as the World Health Organization (WHO) and the United Nations Children's Fund (UNICEF). According to the International Council on Control of Iodine Deficiency Disorders (ICCIDD), IDDs are the most common cause of preventable brain damage and mental retardation worldwide. IDD results in cretinism (a form of stunted growth) and problems in movement, speech, and hearing. A pregnant woman with an iodine deficiency risks miscarriage, stillbirth, and mental retardation of her baby. In 2006, WHO estimated that at least 800 million people worldwide live in environments that are deficient in iodine, placing them at serious risk for IDDs. In 2002, the United Nations Children's Fund announced a pledge to eliminate iodine deficiency in the world by 2005, citing the problem as a major cause of mental and learning disabilities. The 2005 goal turned out to be overly optimistic, although the effort to reduce iodine deficiency problems around the world, later called the Iodine Network, continued in operation in the late 2000s.

Side effects

Excess iodine is typically excreted, and output can be measured in the urine. Regular excessive iodine intake is needed for toxicity. Excess iodine, when used as a supplement or in drug therapy, may reduce thyroid function. Although more commonly associated with iodine deficiency, goiter can also result from too much iodine due to thyroid hyperactivity. Additionally, high amounts of iodine from sources such as overuse of iodized salt, vitamins, cough medications, kelp tablets, or from medical testing can cause effects, including rapid pulse, nervousness, headaches, fatigue, a brassy taste in the mouth, excessive salivation, gastric irritation, and hypothyroidism. **Acne** can appear or become worse. Some iodine-sensitive individuals may have an allergic reaction to iodine, often a skin rash. A physician may recommend

that high iodine foods be removed from the diet of those who are iodine-sensitive. Similar side effects have also been observed in some women participating in studies on iodine and diagnosed FBD. Radioactive iodine has been implicated in producing thyroid dysfunction and thyroid cancer.

Ipecac

Description

There are two categories of ipecac preparations—a syrup used in standard medical practice and a homeopathic remedy. They are given for different purposes. The medicinal effects of ipecac were recognized centuries ago by the Portuguese who settled in South America. They found a plant that can make people vomit and appropriately named it *Caephalis ipecacuanha*, meaning sick-making plant. Nowadays, ipecac is used to treat a variety of conditions. Its most widely accepted use is to induce **vomiting** in cases of accidental poisoning. When ipecac is swallowed, a substance in it called cephaeline irritates the stomach and causes vomiting. Syrup of ipecac is now considered the safest drug to treat poisoning and is often the most effective. There are different types of ipecac preparations that vary greatly in strength. Syrup of ipecac is best for use at home to treat accidental poisoning. Ipecac fluid extract and ipecac tincture should be avoided as they are much stronger compounds and can be toxic.

Ipecacuanha is a homeopathic remedy made from ipecac by a process of dilution and succussion (shaking). In contrast to syrup of ipecac, it is given to relieve vomiting.

General use

Treatment of poisoning

Standard medical practice uses ipecac to cause vomiting in cases of poisoning in order to remove the toxic substance from the stomach before absorption occurs. It can be used on animals as well as humans. Ipecac is safer and more effective than many other methods for inducing vomiting, such as sticking a finger down a child's throat or using salt water. There are times, however, when ipecac should not be used because it can make certain kinds of poisoning worse. Syrup of ipecac should not be used if the poison is one of the following.

- strychnine
- alkalis (lye)
- strong acids
- kerosene
- fuel oil
- gasoline
- coal oil
- paint thinner
- cleaning fluid

Poisoning is a potentially serious condition. It is best to contact a local poison control center, local hospital emergency room, or the family doctor for instructions before using syrup of ipecac.

Ipecac's reputation for inducing vomiting has encouraged some bulimics to take it on a regular basis

KEY TERMS

Bulimia nervosa—An eating disorder characterized by episodic binge eating followed by self-induced vomiting or laxative abuse.

Cephaeline—A chemical compound found in ipecac that irritates the stomach lining and triggers the vomiting reflex.

Fluid extract—A concentrated preparation of a drug.

Law of similars—A principle of homeopathic treatment according to which substances that cause specific symptoms in healthy people are given to sick people with similar symptoms.

Modality—A factor or circumstance that makes a patient's symptoms better or worse. Modalities include such factors as time of day, room temperature, the patient's level of activity, sleep patterns, etc.

Tincture—An alcoholic solution of a chemical or drug.

in order to purge the contents of the stomach after an eating binge. This misuse of ipecac is extremely dangerous; it can cause heart problems, tears in the esophagus or stomach lining, vomiting blood, seizures, or even death.

Homeopathy

The homeopathic remedy made from ipecac is called *Ipecacuanha*. Homeopathic preparations are given for a reason completely opposite from that of standard allopathic treatment. In **homeopathy**, ipecac is given to stop vomiting rather than to induce it. According to Hahnemann's law of similars, a substance that would cause vomiting in large doses when given to a healthy person will stimulate a sick person's natural defenses when given in extremely diluted and carefully prepared doses. *Ipecacuanha* is a favorite homeopathic remedy for **morning sickness** associated with **pregnancy**. It is also given to stop **nausea** that is not relieved by vomiting; when the vomitus is slimy and white; when there is gagging and heavy salivation; when the tongue is clean despite the patient's feelings of nausea; and when the patient is not thirsty. The nausea may be accompanied by a **headache**, **cough**, or heavy menstrual bleeding. The modalities (circumstances) that suggest *Ipecacuanha* as the appropriate homeopathic remedy is that the patient feels worse lying down; in dry weather; in winter; and when exercising or moving about.

A homeopathic practitioner would not necessarily prescribe ipecac for all cases of nausea. *Arsenicum* would be given when the nausea is caused by **food poisoning** and accompanied by strong thirst, ***Nux vomica*** when the nausea is the result of overindulgence in food or alcohol and accompanied by **gas** or **heartburn**. A sick child might be given *Pulsatilla*, particularly if rich foods have been eaten.

On the other hand, a homeopathic practitioner may prescribe ipecac for any of the following conditions that are not related to nausea and vomiting.

- Nosebleeds producing bright red blood.
- Dental bleeding.
- Diarrhea with cramping abdominal pain. The stools are green with froth or foam.
- Asthma of sudden onset. The patient has to sit up in order to breathe, but cannot bring up any mucus in spite of violent coughing.
- Hoarseness or loss of voice following a cold.
- Physical or mental exhaustion.

Preparations

Syrup of ipecac

Syrup of ipecac is made from the dried roots and rhizomes (underground stems) of *Cephaelis ipecacuanha*. It is available over the counter in 0.5–1 oz bottles. Larger bottles require a doctor's prescription. The dosage for infants under 6 months old should be prescribed by the family doctor or poison control center. For children six months to one year, the usual dose is 5–10 ml or 1–2 tsp. One-half or one full glass (4–8 oz) of water should be taken immediately before or after the dose. The dose may be repeated once after 20–30 minutes if vomiting does not occur. For children one to 12 years of age, the usual dose is 15 ml (1 tbsp) to be taken with one full glass (8 oz) of water. Adults and teenagers should take 15–30 ml of ipecac with at least 1 full glass of water. Syrup of ipecac should not be taken with milk or soda drinks as these foods may prevent it from working properly. If vomiting does not occur within 20–30 minutes after the first dose, a second dose may be needed. If the second dose fails to induce vomiting, the patient should be taken to a hospital emergency room.

If both **activated charcoal** and syrup of ipecac are recommended to treat poison, ipecac must be used first. Activated charcoal should not be taken until 30

minutes after taking syrup of ipecac, or until the vomiting caused by ipecac stops.

Homeopathic preparations

Ipecacuanha is available as an over-the-counter remedy in 30x potency. This is a decimal potency, which means that one part of ipecac has been mixed with nine parts of alcohol or water; 30x means that this decimal dilution has been repeated 30 times. The dilute solution of ipecac is then added to sugar tablets so that the remedy can be taken in tablet form.

Precautions

Syrup of ipecac

For inducing vomiting in cases of accidental poisoning, only the syrup form of ipecac should be used. Syrup of ipecac should not be mixed with milk or carbonated drinks as they may prevent vomiting. If syrup of ipecac is not immediately available in the home, it generally cannot be used. A 2002 report studied parents' attempts to administer the syrup upon calling a poison center when they felt they could obtain it within 15 minutes. However, actual time to administration was generally closer to 30 minutes and the report recommended that parents not be referred to purchase ipecac when their children have ingested a significant amount of a poisonous substance and the syrup is not already available in the home.

Syrup of ipecac should not be used in the following situations (contact poison control center or family doctor for alternative treatments).

- Poisoning caused by strychnine; sustained-release theophylline; such corrosive substances as strong alkalis (lye); strong acids (such as toilet bowl cleaner); and such petroleum products as kerosene, gasoline, coal oil, fuel oil, paint thinner, or cleaning fluids.
- Overdoses of medications given for depression.
- Excessive vomiting.
- A serious heart condition.
- Timing. Do not give ipecac more than 4–6 hours after the poison was ingested.
- Pregnancy.
- Very young children (less than six months old). Infants and very young children may choke on their own vomit or get vomit into their lungs.
- Drowsy or unconscious patients.
- Seizures.

Homeopathic preparations

Ipecacuanha should not be given after *Arsenicum* or *Tabac* because these remedies will counteract it.

Side effects

The following side effects have been associated with the use of syrup of ipecac.

- Loose bowel movements.
- Diarrhea.
- Fast irregular heartbeat.
- Inhaling or choking on vomit.
- Stomach cramps or pains.
- Coughing.
- Weakness.
- Aching.
- Muscle stiffness.
- Severe heart problems often occur in cases of ipecac abuse. Because ipecac stays in the body for a long time, damage to the heart frequently occurs in persons who repeatedly take ipecac to induce vomiting.
- Seizures. These are most likely to occur in patients who accidentally swallow ipecac or in ipecac abusers.
- Death. Deaths have been reported due to ipecac abuse in bulimic persons.

Homeopathic *Ipecacuanha* has been highly diluted and is relatively nontoxic.

Interactions

Ipecac should not be given with other drugs because it can decrease their effectiveness and increase their toxicity. If both syrup of ipecac and activated charcoal are needed to treat suspected poisons, ipecac should be given first. Activated charcoal should not be given until vomiting induced by ipecac has stopped. Soda should also be avoided because it can cause the stomach to swell. The person should lie on the stomach or side in case vomiting occurs.

Homeopathic *Ipecacuanha* is considered complementary to *Arnica* and *Cuprum*. It is counteracted by *Arsenicum* and *Tabac*.

Ipraflavone *see* **Ipriflavone**

KEY TERMS

Calcitonin—A hormone that inhibits bone resorption in response to high blood levels of calcium.

Daidzein—A soy isoflavone used to produce ipriflavone.

Genistein—A plant isoflavone, found as genistin in soy, that is used to produce ipriflavone.

Isoflavones—Compounds, including plant estrogens, with two phenolic rings, that are found in significant quantities in soybeans and soy foods. Isoflavones belong to the larger category of flavonoids, plant compounds that are often a source of the plant fruit or flower color, and possess anticancer, anti-inflammatory, anti-allergy, and antioxidant qualities.

Menopause—The cessation of menstruation.

Osteoporosis—A progressive disease characterized by loss of bone density and increased bone fragility.

Resorption—The dissolution of bone tissue.

Ipriflavone

Description

Ipriflavone (IP), also called ipraflavone, is a mass-produced synthetic derivative of genistein (genistin) or daidzein. Genistein and daidzein are unique plant compounds called isoflavones, which are primarily found in soy products. Isoflavones belong to a larger category known as flavonoids, which are natural plant components that have antioxidant, anti-inflammatory, anti-allergy, and anticancer properties. Although most soy isoflavones are classified as plant estrogens (phytoestrogens), ipriflavone does not have estrogenic activity, and does not activate any estrogen receptors in the body. However, it may prevent or treat bone loss—osteoporosis—associated with **menopause** (the cessation of **menstruation**) and **aging**.

Ipriflavone contains three carbon rings. Its chemical names are:

- 7-isopropoxyisoflavone
- 7-isopropoxy-3-phenyl-4H-1-benzopyran-4-one
- 7-(1-methylethoxy)-3-phenyl-4H-1-benzopyran-4-one
- 7-isopropoxy-3-phenylchromone

One source notes that ipriflavone is found in foods, but only in trace amounts. In addition to soy products (including some soy sauces), trace amounts are found in **alfalfa** and other foods. It also is found in propolis, a resin that bees collect from tree buds for use as a hive cement. Ipriflavone is a solid that dissolves only slightly in water.

The liver metabolizes ipriflavone into 7-hydroxy-ipriflavone and 7-(1-carboxy-ethoxy)-isoflavone. IP and its derivatives are bound to albumin, a blood protein, and distributed to tissues throughout the body.

Ipriflavone may be one of the best-studied compounds in the natural health industry. However, the results of these studies are not clear with regard to efficacy in increasing bone density, its primary claim. Ipriflavone was first isolated at a Hungarian pharmaceutical company in 1969. Since the 1980s, it has been a registered prescription drug for the prevention and treatment of **osteoporosis** in Japan, Argentina, and Europe.

General use

Like other cells in the human body, bone cells are constantly being replaced. Furthermore, bones serve as a **calcium** bank because they are a source of calcium used for other functions, such as buffering the blood. Osteoporosis is a net loss of bone mass, caused either by excessive bone-resorping (dissolving) or low bone-forming activities. These activities are often related to the increased bone turnover rate that accompanies menopause.

Women have a lifetime risk of 40% for developing osteoporosis. One-half of all women over the age of 50 will develop the disease. One in eight men experience bone **fractures** as a result of osteoporosis. Hip fractures caused by osteoporosis are a direct or indirect cause of death in one-quarter of elderly Americans. Bone building and breakdown are influenced by the following:

- hormones, including estrogen and calcitonin (from the parathyroid gland)
- minerals such as magnesium, phosphorus, boron, zinc, silica, and vanadium
- vitamins, including vitamin D.
- other factors such as corticosteroid use, sunlight, dietary acidity, physiologic pH, and overall bodily health

Numerous studies have indicated that ipriflavone maintains or increases bone mineral density in osteoporosis, particularly in conjunction with calcium supplementation. Clinical studies have demonstrated that ipriflavone supplementation may:

- prevent rapid bone loss immediately following menopause
- increase bone density in postmenopausal women by as much as 3%
- increase bone mineral density in women with osteoporosis by up to 6%
- decrease the incidence of bone fractures among postmenopausal women
- reduce bone pain caused by osteoporosis
- increase mobility in women with osteoporosis
- stimulate the synthesis and secretion of calcitonin, a hormone that controls calcium metabolism
- lower the high cholesterol levels associated with menopausal estrogen deficiency
- have some activity against cancer

Ipriflavone also slows bone loss in women whose ovaries have been removed, although it does not appear to prevent acute bone loss immediately following ovariectomy. Further studies in this area have not obtained the same conclusions, except under very specific conditions including younger age and active bone loss. Therefore, the presence of osteoporosis alone does not appear to be sufficient for obtaining good results, even with calcium supplementation.

The mechanisms of ipriflavone activity are not understood. *In vitro* and animal studies have indicated that:

- Genistein inhibits the breakdown of bone.
- Ipriflavone inhibits bone resorption (the breakdown and recycling of bone tissue).
- Ipriflavone may stimulate bone formation.

In contrast, one large study of postmenopausal women with slight osteoporosis found no significant bone density changes between the group taking calcium supplements alone and those taking calcium plus ipriflavone.

Since ipriflavone does not have estrogenic activity, it may be appropriate for treating bone loss in men, particularly in those with **prostate cancer** who are receiving therapies that reduce androgen (masculinizing hormone) levels.

Preparations

Ipriflavone is available over-the-counter (OTC) in many generic and brand name forms (e.g. Ostivone, Natrol, and Bone Support Ipriflavone Blend). It is supplied in capsules, each containg 100, 200, or 300 mg. A typical IP dose for the management of osteoporosis is 200 mg, two to three times daily. Almost all studies consistently used 600 mg daily. A two-month supply costs about $20.

Food items, particularly those containing lipids, increase the small intestine's absorption of ipriflavone. IP supplements are more effective if combined with calcium and other supplements that help to diminish bone loss during menopause and aging. Ipriflavone sometimes is combined with low-dose estrogen preparations.

Natural isoflavone supplements isolated from soy do not appear to have the same benefits or phytoestrogen neutral qualities as ipriflavone.

Precautions

Ipriflavone has not been subjected to long-term safety studies. In one study, a consistent precaution resulting from research that spanned as much as three years, is that ipriflavone appears to decrease lymphocyte (disease-fighting white-blood-cell) levels in a significant number of postmenopausal women with minor osteoporosis. Additionally, since ipriflavone is metabolized by the liver, those with liver disease are advised to avoid it unless directed otherwise by a healthcare professional. Other contraindications include **pregnancy** and breast-feeding, gastric or duodenal ulcers, and kidney disease. Ipriflavone is not recommended for small children.

Side effects

No significant side effects have been observed with ipriflavone, although there are reports of **heartburn**, **nausea**, **diarrhea**, or other mild gastrointestinal disturbances. These side effects may be avoided by

taking the supplement with food. One source noted that the percentage of perceived side effects was actually less among the IP users than in the placebo group. Generally, ipriflavone is considered to be well tolerated, to have no effect on fertility, and to not promote precancerous cellular changes (mutagenicity). Approximately 13% of women studied had a decrease in white blood cell count, usually within the first six months. However, this group did not become more susceptible to disease or illness. Their normal white blood cell counts returned within one to two years of discontinuing the IP. There were occasional reports of hypersensitivity reactions, and increases in liver function test scores.

Interactions

Similar to grapefruit juice, IP has an inhibiting effect on a liver **detoxification** pathway involving an enzyme known as cytochrome P450. This effect increases both the blood levels and the effects of these drugs:

- theophylline: IP and 7-hydroxy-ipriflavone may inhibit the metabolism and elimination of this asthma drug, leading to elevated—and potentially toxic—blood levels
- zafirlukast (Accolate), an asthma medication
- antipsychotic medications
- caffeine
- celecoxib (Celebrex), a pain reliever for arthritis
- cyclobenzaprine (Flexeril), a muscle relaxant
- nifedipine
- nonsteroidal anti-inflammatory medications and pain relievers
- tacrine (Cognex), a medication for Alzheimer's disease
- tamoxifen (Nolvadex), for cancer prevention and treatment
- tolbutamide, levels are increased by both ipriflavone and 7-hydroxy isoflavone
- warfarin (Coumadin), a blood-thinner

The effects of ipriflavone may be additive with the effects of these drugs:

- bisphosphonates, for the treatment of osteoporosis
- calcitonin
- estrogen
- selective estrogen receptor modulators (SERMs)

During the management of osteoporosis, ipriflavone effects may be additive with the effects of the following nutritional supplements:

- boron
- calcium
- fluoride
- vitamin D
- vitamin K

Iridology

Definition

Iridology, also called iris analysis or iris diagnosis, is the study of the iris (the colored part of the eye). Iris "readings" are made by iridologists to assess a person's health picture (physical, emotional, mental, and spiritual) and guide them to take measures to improve their health.

Origins

The basic concept of iridology has existed for centuries. The medical school of the University of Salerno in Italy offered training in iris diagnosis. A book published by Philippus Meyers in 1670, called *Chiromatica medica*, noted that signs in the iris indicate diseases. Dr. Ignatz von Peczely, however, is generally considered the father of iridology, with the date of his discovery given as 1861. Von Peczely was a Hungarian physician. As a child, he accidentally broke an owl's leg. He observed that a black line formed in the owl's lower iris at the time of the injury. After the owl's leg healed, the young von Peczely noted that the black streak had changed appearance. As a physician, he treated a patient with a broken leg in whose eye he observed a black streak in the same location as on the injured owl's iris. Von Peczely became intrigued by the possibility of a connection between diseases and eye markings. Through observing his patients' eyes, he became convinced of this connection and developed a chart that mapped iris-body correlations. After several decades of comparative study, von Peczely mapped organs across zones identified by hours and minutes on a clock face superimposed over drawings of the eyes. In 1881, he published his theories in a book called *Discoveries in the Field of Natural Science and Medicine: Instruction in the Study of Diagnosis from the Eye*.

A Swedish pastor and homeopath named Nils Liljequist also developed the concept of iris-body correlations at roughly the same time but independently of von Peczely's work. He was the first iridologist to identify the effects of such drugs as **iodine** and quinine on the iris. Liljequist based his initial observations on changes in his own irises after illnesses and injuries, publishing writings and eye drawings during the late nineteenth century. One of his students, Dr. Henry Lahn, brought the practice of iridology to the United States. A variety of practitioners, primarily European, have sought to popularize iridology since these early works. Dr. Bernard Jensen, a chiropractor, is the best-known contemporary American advocate of iridology.

Benefits

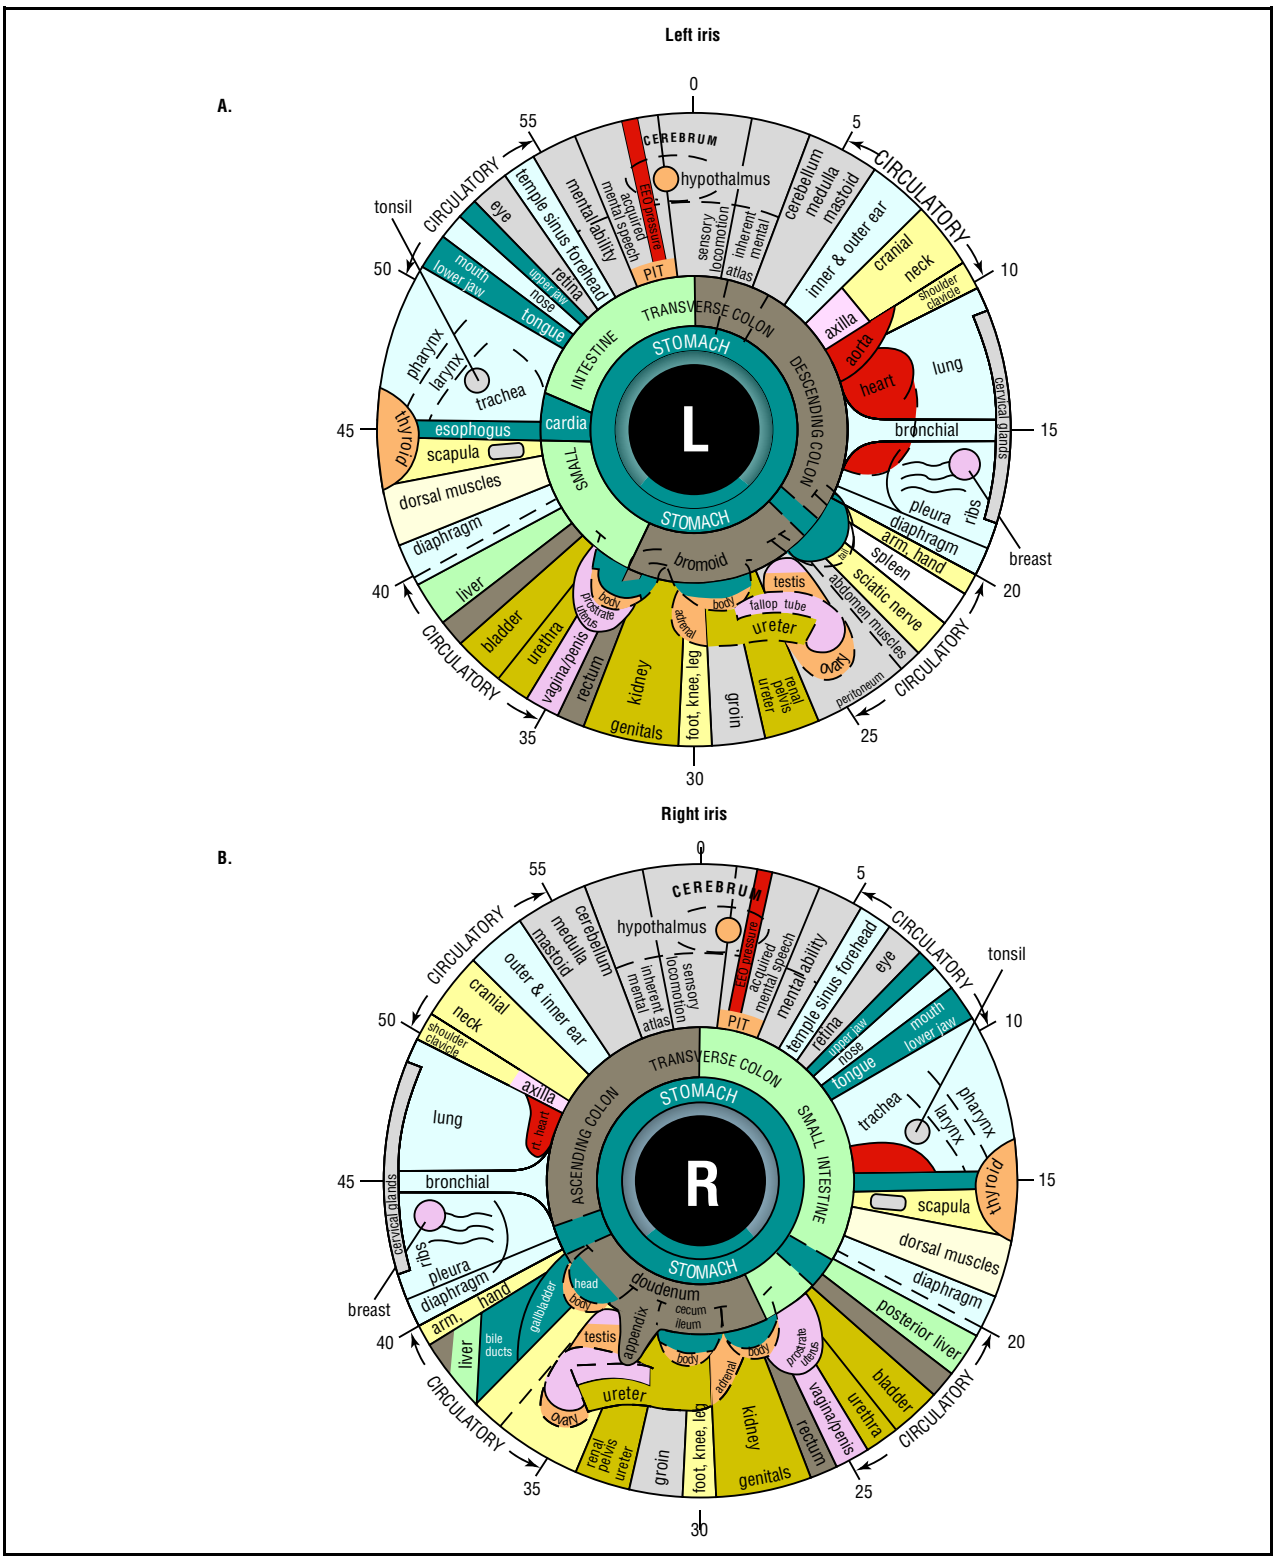
Iridologists claim that by studying the patterns of a person's iris, they can provide helpful and accurate health and wellness information. Iridology is a holistic endeavor in that it addresses the person's whole being in the reading. The range of information gleaned encompasses physical, emotional, mental, and spiritual aspects of the person's health picture. In addition to assessing the person's general level of health, readings can reveal other data, including energy quotients; internal areas of irritation, degeneration, injury, or inflammation; nutritional and chemical imbalances; accumulation of toxins; life transitions; and subconscious tensions. Iridologists maintain that the eyes reveal information about the person's physical and emotional constitution, such as inherited weaknesses and risks to which the person may be prone. Strengths may also be revealed, including inherited emotional tendencies from which the person derives particular talents. Cleansing and healing can be verified by changes in the iris. By looking for certain signs such as healing lines, iridologists obtain information about previous health problems and injuries and discover what may have gone wrong in the person's past.

An iridology reading reflects the causes of problems, not symptoms. It may, iridologists claim, reveal that organs or systems are overstressed or predisposed to disease before clinical symptoms even develop. By predicting future problems, iridology can be used as a preventive tool. People can use the information from iridology readings to improve their health and make better behavioral choices in the future, thereby heading off problems before they occur.

In North America, iridology is generally considered to be an assessment tool to be used in cooperation with other health specialties. Iridology is not a diagnostic tool (although it is more likely to be considered so by European iridologists) and should not be used to diagnose or name specific diseases. Not only would diagnosis represent an improper application of iridology according to many iridologists, as noted by the International Iridology Research Association (IIRA), it could also be construed in many countries as practicing medicine without a license.

Description

Iridology is generally based on the concept of neural pathways between the body and the iris. Although iridologists may differ on the exact mechanism, most maintain that the iris reflects what is happening throughout the body via nerve conduction from all parts of the body to the eye. The client's health



Iridology charts for left and right irises. *(Illustration by GGS Information Services, Inc. Cengage Learning, Gale)*

KEY TERMS

Iris—The colored portion of the eye.

Sclera—A dense white fibrous membrane that, together with the cornea, forms the outer covering of the eyeball.

is assessed by the iridologist, who interprets patterns, shapes, rings, colors and pigmentation markings, fibers, structures, and changes in the pupil and iris. Many iridologists also use sclerology (reading the lines in the white part of the eyes) in their health evaluation.

Iridology readings are typically performed by such holistically oriented practitioners as naturopaths, chiropractors, or nutritionists. The reading may be done using a bright light, a magnifying glass, and a notepad. The iridologist may also use various tools to better view the eye, a special camera to take pictures of the iris, and/or a computer.

Iridologists conduct their readings using charts on which each area of the iris is mapped to a specific body system or organ. Iridology charts vary, with at least 20 different ones in existence. Some charts are more widely used than others; however, many iridologists believe that there is more than one correct map and that each practitioner should become familiar with several charts. Some iridologists even develop their own charts. Differences also exist among practitioner techniques; among American, European, and other approaches; and in the interpretation of specific iris signs.

Iridology charts divide the iris into numerous zones corresponding to different parts of the body. Although the specifics may differ on each chart, all share a general pattern. The left eye is mapped to the left side of the body and the right eye to the right side. The top of the eye is mapped to the upper body (e.g., brain, face, neck, chest and heart). The center of the eye is mapped to the stomach and digestive organs, with other organs being represented by concentric circular zones moving outward toward the edge of the iris. The bottom of the eye is mapped to the legs and lower half of body. Paired organs (e.g., the kidneys) are mapped to both irises.

Using a holistic approach that considers each client as an individual with unique health patterns and concerns, behaviors, and experiences, the iridologist will examine the eyes and make a health assessment. Based on the results of that reading, the iridologist generally recommends a wellness program tailored to the individual's physical, emotional, and life situation. This program may incorporate various health improvement, maintenance, and prevention regimes. Recommendations may include vitamins, minerals, herbs, supplements, and/or diet and **nutrition**, among other suggestions.

Preparation

No special preparations are necessary before an iridology reading.

Precautions

An iridology reading is unlikely to cause any physical harm by itself, as it does not involve direct contact with the eye or applying eye drops of any kind. Critics of iridology, however, argue that iridology can be detrimental to health if a sick person delays treatment for a condition not suggested by the iridology reading; or that it can can cause anguish and unnecessary expense if a reading suggests a problem when there actually is none.

Research and general acceptance

Rita M. Holl, RN, PhD, states that "Within Western medicine, iridology is considered a controversial science at best and medical fraud at worst." Proponents of iridology argue that the practice is time-tested with proven results. Although critics acknowledge that certain symptoms of non-ocular disease do appear in the eyes (e.g., brain injury), there is, they argue, a lack of rigorous scientific testing and no evidence that iridology has any merit. Studies published in the *Australian Journal of Optometry*, the *British Medical Journal*, and the *Journal of the American Medical Association (JAMA)* have found iridologists' assessment of patients with diagnosed serious diseases including kidney and gall bladder disease to be inaccurate. Iridologists counter that the research itself was faulty, citing problems including poor-quality photos; the absence of important additional information including the ability to see/interview the client; and inappropriate expectations of diagnosing specific diseases, a task outside the parameters of iridology. A more recent study conducted to reevaluate *JAMA's* findings in regard to renal failure was published in the *Alternative Health Practitioner*. Acknowledging that the "study leaves several questions unanswered," the author reported both similarities and variations in the iridologists' readings and concluded that the iridologist's level of expertise is extremely important as well.

Training and certification

Iridologists receive training from various sources. They may learn their trade through books, tapes,

correspondence courses, online classes, or live classes. According to the IIRA, "Iridology operates in a gray area in North America. In general, there are no laws defining or regulating the practice. In Europe, especially in Germany, Iridology is well recognized and routinely used by natural medicine practitioners." Also according to the IIRA, "Because Iridology has no official standards of practice, anyone can call themselves an Iridologist, often with little training or experience. There are also great differences in the Iridology information being taught, especially in North America."

Iron

Description

Iron is a mineral that the human body uses to produce the red blood cells (hemoglobin) that carry oxygen throughout the body. It is also stored in myoglobin, an oxygen-carrying protein in the muscles that fuels cell growth.

General use

Iron is abundant in red meats, vegetables, and other foods. A well-balanced diet can usually provide an adequate supply of the mineral, but when there is insufficient iron from dietary sources or as a result of blood loss in the body, the amount of hemoglobin in the bloodstream is reduced and oxygen cannot be efficiently transported to tissues and organs throughout

the body. The resulting condition, iron-deficiency **anemia**, is characterized by **fatigue**, shortness of breath, pale skin, concentration problems, **dizziness**, a weakened immune system, and energy loss.

Iron-deficiency anemia can be caused by a number of factors, including poor diet, heavy menstrual cycles, **pregnancy**, kidney disease, **burns**, and gastrointestinal disorders. Individuals with iron-deficiency anemia should always undergo a thorough evaluation by a physician to determine the cause.

Children two years old and younger also need adequate iron in their **diets** to promote proper mental and physical development. Children under two who are not breastfeeding should eat iron-fortified formulas and cereals. Women who breastfeed their babies need at least 15 mg of dietary or supplementary iron a day in order to pass along adequate amounts of the mineral in their breast milk. Parents should consult a pediatrician or other healthcare professional for guidance on iron supplementation in children.

Some authorities have theorized that excess stored iron can lead to **atherosclerosis** and ischemic **heart disease**. Phlebotomy, or blood removal, has been used with some success to reduce stored iron in patients with iron overload. Iron chelation with drugs such as desferrioxamine (Desferal) that help patients excrete excess stores of iron can be used in treating iron overload caused by multiple blood transfusions.

Iron levels in the body are measured by both hemoglobin and serum ferritin blood tests.

Normal total hemoglobin levels are:

- neonates: 17–22 g/dL
- one week: 15–20 g/dL
- one month: 11–15 g/dL
- children: 11–13 g/dL
- adult males: 14–18 g/dL (12.4–14.9 g/dL after age 50)
- adult females: 12–16 g/dL (11.7–13.8 g/dL after menopause)

Normal serum ferritin levels are:

- neonates: 25–200 ng/mL
- one month: 200–600 ng/mL
- two to five months: 50–200 ng/mL
- six months to 15 years: 7–140 ng/mL
- adult males: 20–300 ng/mL
- adult females: 20–120 ng/mL

Preparations

Iron can be found in a number of dietary sources:

- pumpkin seeds
- dried fruits (apricots)
- lean meats (beef and liver)
- fortified cereals
- turkey (dark meat)
- green vegetables (spinach, kale, and broccoli)
- beans, peas, and lentils
- enriched and whole grain breads
- molasses
- sea vegetables (blue-green algae and kelp)

Eating iron-rich foods in conjunction with foods rich in **vitamin C** (such as citrus fruits) and lactic acid (sauerkraut and yogurt) can increase absorption of dietary iron. Cooking food in cast-iron pots can also add to their iron content.

The recommended dietary allowances (RDA) of iron as outlined by the United States Department of Agriculture (USDA) are as follows:

- children 7–12 months: 11 mg/day
- children 1–3 years: 7 mg/day
- children 4–8 years: 10 mg/day
- adolescent males, 9–13 years: 8 mg/day
- adolescent females, 9–13 years: 8 mg/day
- males, 14–18 years: 11 mg/day
- females, 14–18 years: 15 mg/day
- males, 19–50 years: 8 mg/day
- females, 19–50 years: 18 mg/day
- adults, over 50 years: 8 mg/day
- pregnant females: 27 mg/day
- breastfeeding females: 9–10 mg/day

A number of herbal remedies contain iron and can be useful as a natural supplement. The juice of the herb stinging **nettle** (*Urtica dioica*) is rich in both iron and vitamin C (which is thought to promote the absorption of iron). It can be taken daily as a dietary supplement. **Dandelion** (*Taraxacum officinale*), curled dock (*Rumex crispus*), and **parsley** (*Petroselinum crispum*) also have high iron content and can be prepared in tea or syrup form.

In Chinese medicine, dang gui (**dong quai**), or *Angelica sinensis*, the root of the **angelica** plant, is said to both stimulate the circulatory system and aid the digestive system. It can be administered as a decoction or tincture and should be taken in conjunction with an iron-rich diet. Other Chinese remedies include **foxglove**

root (*Rehmannia glutinosa*), **Korean ginseng** (*Panax ginseng*), and **astragalus** (*Astragalus membranaceus*).

Ferrum phosphoricum (iron phosphate) is used in homeopathic medicine to treat anemia. The remedy is produced by mixing iron sulfate, phosphate, and **sodium** acetate, which is administered in a highly diluted form to the patient. Other homeopathic remedies for anemia include ***natrum muriaticum***, *Chinchona officinalis*, *cyclamen europaeum*, *ferrum metallicum*, and *manganum aceticum*. As with all homeopathic remedies, the type of remedy prescribed for iron deficiency depends on the individual's overall symptom picture, mood, and temperament. Patients should speak with their homeopathic professional or physician, or healthcare professional before taking any of these remedies.

Iron is also available in a number of over-the-counter supplements (i.e., ferrous fumerate, ferrous sulfate, ferrous gluconate, iron dextran). Both heme iron and non-heme iron supplements are available. Heme iron is more efficiently absorbed by the body, but non-heme iron can also be effective if used in conjunction with vitamin C and other dietary sources of heme iron. Some multivitamins also contain supplementary iron. Ingesting excessive iron can be toxic and may have long-term negative effects. For this reason, iron supplements should be taken only under the recommendation and supervision of a doctor.

Precautions

Iron deficiency can be a sign of a more serious problem, such as internal bleeding. Anyone suffering from iron-deficiency anemia should always undergo a thorough evaluation by a healthcare professional to determine the cause of the problem.

Iron overdose in children can be fatal and is a leading cause of poisoning in children. Children should never take supplements intended for adults, and they should receive iron supplementation only under the guidance of a physician.

Individuals with chronic or acute health conditions, including kidney infection, **alcoholism**, liver disease, **rheumatoid arthritis**, **asthma**, heart disease, **colitis**, and stomach ulcer, should consult a physician before taking herbal or pharmaceutical iron supplements.

If individuals taking homeopathic dilutions of *ferum phosphoricum* experience worsening of their symptoms (known as a homeopathic aggravation), they should stop taking the remedy and contact their healthcare professional. A homeopathic aggravation can be an early indication that a remedy is working properly, but it can also be a sign that a different remedy is needed.

Patients diagnosed with hemochromatosis, a genetic condition in which the body absorbs too much iron and stores the excess in organs and tissues, should never take iron supplements.

Side effects

Taking herbal or pharmaceutical iron supplements on an empty stomach may cause **nausea**. Iron supplementation may cause hard, dark stools, and individuals who take iron frequently experience **constipation**. Patients who experience dark bowel movements accompanied by stomach pains should check with their doctor, as this symptom can also indicate bleeding in the digestive tract.

Other reported side effects include stomach cramps and chest **pain**. These symptoms should be evaluated by a physician if they occur.

Some iron supplements, particularly those taken in liquid form, may stain the teeth. Taking these through a straw or with a dropper placed towards the back of the throat may be helpful in preventing staining. Toothpaste containing baking soda and/or hydrogen peroxide can be useful in removing iron stains from teeth.

Signs of iron overdose include severe **vomiting**, racing heart, bloody **diarrhea**, stomach cramps, bluish lips and fingernails, pale skin, and weakness. If overdose is suspected, the patient should contact poison control and/or seek emergency medical attention immediately.

Interactions

Iron supplements may react with certain medications, including antacids, acetohydroxamic (Lithostat), dimercaprol, etidronate, and fluoroquinolones. In addition, they can decrease the effectiveness of certain tetracyclines (antibiotics). Individuals taking these or any other medications should consult their healthcare professional before starting iron supplements.

Certain foods decrease the absorption of iron, including some soy-based foods, foods with large concentrations of **calcium**, and beverages containing **caffeine** and tannin (a substance found in black tea). These should not be taken within two hours of using an iron supplement. Some herbs also contain tannic acid and should be avoided during treatment with iron supplements. These include allspice (*Pimenta dioica*) and **bayberry** (*Myrica cerifera*, also called wax myrtle).

Individuals considering treatment with homeopathic remedies should also consult their healthcare

KEY TERMS

Chelation—The use of a medication or herbal substances to inactivate toxic substances in the body. Chelation is used to treat iron overload in some patients.

Decoction—An herbal extract produced by mixing an herb in cold water, bringing the mixture to a boil, and letting it simmer to evaporate the excess water. The decoction is then strained and consumed hot or cold. Decoctions are usually chosen over infusion when the botanical being used is a root or berry.

Ferritin—An iron storage protein found in the blood. High levels of serum ferritin may indicate iron overload.

Hemochromatosis—Also known as iron overload; a genetic condition in which excess iron is stored in the tissues and organs by the body where it can build up to toxic amounts.

Homeopathic remedy—Used to treat illnesses that manifest symptoms similar to those that the remedy itself causes, but administered in extremely diluted doses to prevent any toxic effects.

Infusion—An herbal preparation made by mixing boiling water with an herb, letting the brew steep for 10 minutes, and then straining the herb out of the mixture. Tea is made through infusion.

Thalassemia—A group of several genetic blood diseases characterized by absent or decreased production of normal hemoglobin. Individuals who have thalassemia have to undergo frequent blood transfusions, and are at risk for iron overload.

Tincture—A liquid extract of an herb prepared by steeping the herb in an alcohol and water mixture.

professional about possible interactions with certain foods, beverages, prescription medications, aromatic compounds, and other environmental elements—factors known in **homeopathy** as *remedy antidotes*—that could counteract the efficacy of treatment for iron deficiency.

Irritable bowel syndrome

Definition

Irritable bowel syndrome (IBS) is a common intestinal condition characterized by abdominal **pain** and cramps; changes in bowel movements (**diarrhea**, **constipation**, or both); gassiness; bloating; **nausea**; and other symptoms. There is no recognized cure for IBS. Much about the condition remains unknown or poorly understood; however, dietary changes, drugs, and psychological treatment are often able to eliminate or substantially reduce its symptoms.

Description

IBS is a condition that was once called **colitis**, spastic colon, nervous colon, spastic bowel, and functional bowel disorder. Some of these names reflected the now outdated belief that IBS is a purely psychological disorder and a product of the patient's imagination. Although modern medicine recognizes that **stress** can trigger IBS attacks, medical specialists agree that IBS is a genuine physical disorder, or group of disorders, with specific identifiable characteristics.

No one knows for sure how many Americans suffer from IBS. Surveys indicate a range of 10–20%, with perhaps as many as 30% of Americans experiencing IBS at some point in their lives. IBS normally makes its first appearance during young adulthood, and in half of all cases, symptoms begin before age 35. Women with IBS outnumber men by two to one, for

reasons not understood as of 2008. IBS is responsible for more time lost from work and school than any medical problem other than the **common cold**. It accounts for a substantial proportion of the patients seen by gastroenterologists, who are specialists in diseases of the digestive system. Yet only half—possibly as few as 15%—of IBS sufferers ever consult a doctor.

Symptoms and Causes

The symptoms of IBS tend to rise and fall in intensity rather than grow steadily worse over time. They always include intestinal (abdominal) pain, which may be relieved by defecation; diarrhea or constipation; or diarrhea alternating with constipation. Other symptoms, which vary from person to person, include: cramps, gassiness, bloating, nausea, a powerful and uncontrollable urge to defecate (urgency), passage of a sticky fluid (mucus) during bowel movements, or the feeling after finishing a bowel movement that the bowels are still not completely empty. The accepted diagnostic criteria, known as the Rome criteria, require at least three months of continuous or recurrent symptoms before IBS is diagnosed. An estimated 70% of IBS cases can be described as "mild;" 25% as "moderate;" and 5% as "severe." In mild cases the symptoms are slight. As a general rule, they are not present all the time and do not interfere with work and other normal activities. Moderate IBS disrupts normal activities and may cause some psychological problems. People with severe IBS may constantly fear the unpredictable need for a bathroom. They often find living a normal life impossible and experience crippling psychological problems as a result. For some, the physical pain is constant and intense.

Causes

Researchers remain unsure about the cause or causes of IBS. It is called a functional disorder because it is thought to result from changes in the activity of the major part of the large intestine (the colon). After food is digested by the stomach and small intestine, the undigested material passes in liquid form into the colon, which absorbs water and salts. This process may take several days. In a healthy person the colon is quiet during most of that period except after meals, when its muscles contract in a series of wavelike movements called peristalsis. Peristalsis helps absorption by bringing the undigested material into contact with the colon wall. It also pushes undigested material that has been converted into solid or semisolid feces toward the rectum, where it remains until defecation.

In IBS, however, the normal rhythm and intensity of peristalsis is disrupted. Sometimes there is too little peristalsis, which can slow the passage of undigested material through the colon and cause constipation. Sometimes there is too much, which has the opposite effect and causes diarrhea. A Johns Hopkins University study found that healthy volunteers experienced six to eight contractions of the colon each day, compared with up to 25 contractions a day for volunteers suffering from IBS with diarrhea, and an almost complete absence of contractions among constipated IBS volunteers. In addition to differences in the number of contractions, many of the IBS volunteers experienced powerful spasmodic contractions affecting a larger-than-normal area of the colon—"like having a Charlie horse in the gut," according to one of the investigators.

DIET. Some kinds of food and drink appear to play a key role in triggering IBS attacks. Food and drink that healthy people can ingest without any trouble may disrupt peristalsis in IBS patients, which probably explains why IBS attacks often occur shortly after meals. Chocolate, milk products, **caffeine** (in coffee, tea, colas, and other drinks), and large quantities of alcohol are some of the chief culprits. Other kinds of food have also been identified as problems, however, and the pattern of what can and cannot be tolerated is different for each person. Characteristically, IBS symptoms rarely occur at night and disrupt the patient's sleep.

In 2002, a research study reported that some children had trouble absorbing certain sugars from some fruit juices, particularly apple and pear juices. When children with IBS went off these juices for one month, 46% saw improvement in their IBS symptoms. Apple and pear juice contain more fructose than glucose sugar, which may be the cause of the poor absorption in IBS sufferers' intestines. Yet white grape juice, which contains almost equal portions of fructose and glucose, is more easily absorbed.

STRESS. Stress is an important factor in IBS because of the close nervous system connections between the brain and the intestines. Although researchers do not yet understand all of the links between changes in the nervous system and IBS, they point out the similarities between mild digestive upsets and IBS. Just as healthy people can feel nauseated or have an upset stomach when under stress, people with IBS react the same way, but to a greater degree. Finally, IBS symptoms sometimes intensify during **menstruation**, which suggests that female reproductive hormones are another trigger. In fact, a study published in 2002 confirmed that IBS symptoms worsened in women and that rectal sensitivity changed with the menstrual cycle in women with IBS. It also was the first study to contrast these changes with those of healthy women.

Diagnosis

Diagnosing IBS is a fairly complex task because the disorder does not produce changes that can be identified during a physical examination or by laboratory tests. When IBS is suspected, the doctor (a family doctor or a specialist) needs to determine whether the patient's symptoms satisfy the Rome criteria. The doctor rules out other conditions that resemble IBS, such as Crohn's disease and ulcerative colitis. These disorders are ruled out by taking a standard medical history, performing a physical examination, and ordering laboratory tests. The patient may be asked to provide a stool sample that can be tested for blood and intestinal parasites. In some cases x rays, bowel studies, or an internal examination of the colon using a flexible instrument inserted through the anus (a sigmoidoscope or colonoscope) is necessary.

Patients may also be asked to keep a diary of symptoms for two or three weeks, covering daily activities, including meals and emotional responses to events. The doctor can then review the diary with the patient to identify possible problem areas.

Treatment

Dietary adjustments are critical to controlling IBS. For some patients, a **high-fiber diet**, including whole grain breads and cereals, dried and fresh fruits, spinach, and oat bran, can reduce digestive system irritation. For others, a high-fiber diet aggravates the symptoms. Many patients with IBS also find that avoiding alcohol, caffeine, sugar, and fatty, **gas** producing, or spicy foods can prevent symptoms.

To control IBS symptoms that are triggered or made worse by stress, several stress management therapies may be helpful. These include **yoga**, **meditation**, hypnosis, **biofeedback**, **exercise**, muscle **relaxation** training, **aromatherapy**, **hydrotherapy**, and **reflexology**. Reflexology is a foot massage technique that focuses on manipulating different regions of the foot in order to bring harmony to specific organs and body systems. Hydrotherapy is the therapeutic use of water, as in a whirlpool bath.

Biofeedback, which teaches an individual to control muscle tension and any associated pain through thought and visualization techniques, is also a treatment option for IBS. In biofeedback treatments, sensors placed on the forehead of the patient are connected to a special machine that allows the patient and healthcare professional to monitor a visual and/or audible readout of the level of muscle tension and stress in the patient. Through relaxation and visualization exercises, the patient learns to relieve tension and can actually see or hear the results of his or her efforts instantly through a sensor readout on the biofeedback equipment. Once the technique is learned and the patient is able to recognize and differentiate between the feelings of muscle tension and muscle relaxation, the biofeedback equipment itself is no longer needed and the patient has a powerful, portable, and self-administered treatment tool for dealing with pain and tension.

To soothe an irritated or inflamed digestive tract, an herbalist or holistic healthcare practitioner may recommend one or more herbs, including **comfrey** root (*Symphytum officinale*), **hops** (*Humulus lupulus*), **Iceland moss** (*Cetraria islandica*), Irish moss (*Chondrus crispus*), **marsh mallow** root (*Althaea officinalis*), oats (*Avena sativa*), quince seed (*Cydonia oblonga*), and **slippery elm** (*Ulmus rubra*).

Herbs that relieve gas associated with IBS (known as carminatives) include **angelica** (*Angelica archangelica*), aniseed (*Pimpinella anisum*), caraway (*Carum carvi*), **cayenne** (*Capsicum annuum*), German **chamomile** (*Matricaria recutita*), **ginger** (*Zingiber officinale*), **thyme** (*Thymus vulgaris*), and **peppermint** (*Mentha* x *piperata*).

An infusion of meadowsweet (*Filipendula ulmaria*) may be helpful in treating diarrhea related to IBS, and herbs such as **barberry** (*Berberis vulgaris*), **Psyllium** ovata seed, **dandelion** root (*Taraxacum officinale*), **licorice** (*Glycyrrhiza glabra*), and **yellow dock** (*Rumex crispus*) have laxative properties that can help to relieve constipation. More powerful laxative herbs, such as **rhubarb root** (*Rheum palmatum*), **buckthorn** (*Rhamnus catharticus*), and cascara (*Rhamnus purshiana*) should only be taken under the direction of a healthcare professional.

Individuals with cramp-like pains, or **colic**, can benefit from antispasmodic herbs such as German chamomile (*Matricaria recutita*), **Valerian** (*Valeriana officinalis*), **lemon balm** (*Melissa officinalis*), ginger (*Zingiber officinale*), and wild yam (*Dioscorea villosa*).

Homeopathy uses highly diluted remedies that cause similar effects to the symptoms they are intended to treat in an effort to stimulate the body's natural immune response. A homeopathic physician might recommend a remedy of **belladonna**, colocynthis (bitter cucumber), phosphate of magnesia (Magnesia phosphorica), or wild hops (*Bryonia alba*) to relieve abdominal pain and cramping associated with IBS. As with all homeopathic remedies, the prescription depends on the individual's overall symptoms, mood, and temperament.

Acupuncture and **guided imagery** may be useful tools in treating IBS symptoms. Acupuncture involves the placement of thin needles into the skin at targeted locations on the body known as acupoints in order to harmonize the energy flow within the human body. An acupuncturist may also use **moxibustion**, which involves applying a heat source such as warm herbs to the acupoint, to treat IBS symptoms. Guided imagery techniques teach the patient to visualize a peaceful, soothing scene or situation to relax the body and better cope with the discomfort caused by IBS.

Several studies have indicated **probiotics** may be beneficial in treating IBS. Researchers believe this may be due to the antiviral, antibacterial, and anti-inflammatory effects of probiotics, such as *Lactobacillus acidophilus*, commonly referred to simply as **acidophilus**, a friendly inhabitant of the gastrointestinal (GI) tract. It, as well as some related **strains** of bacteria, is known as a probiotic. Probiotic organisms secrete enzymes that support healthy digestion. They keep the flora of the intestines balanced and compete with some pathogenic organisms. One small study of the use of acidophilus to treat IBS showed more improvement in the treated group than in those who took a placebo. This is not conclusive evidence, but in view of the safety of the treatment and the scarcity of effective alternatives, many health practitioners believe acidophilus may be worth trying.

KEY TERMS

Anus—The opening at the lower end of the rectum.

Crohn's disease—A disease characterized by inflammation of the intestines. Its early symptoms may resemble those of IBS.

Defecation—Passage of feces through the anus.

Feces—Undigested food and other waste that is eliminated through the anus. Feces are also called fecal matter or stools.

Homeopathy—A system of medical practice that treats a disease by administering diluted doses of a remedy that would, in a healthy person, cause symptoms like the illness being treated. Homeopaths believe that this treatment stimulates the body's natural healing processes.

Lactose—A sugar found in milk and milk products. Some people are lactose intolerant, meaning they have trouble digesting lactose. Lactose intolerance can produce symptoms resembling those of IBS.

Peristalsis—The periodic waves of muscular contractions that move food through the intestines during the process of digestion.

Ulcerative colitis—A disease that inflames and causes breaks (ulcers) in the colon and rectum, which are parts of the large intestine.

Allopathic treatment

Dietary changes, sometimes supplemented by drugs or **psychotherapy**, are considered the key to successful treatment. A drug called alosetron was approved by the Food and Drug Administration (FDA) in 2002 for limited marketing for treating women with diarrhea-prominent IBS after some controversy in 2000 because of serious side effects from the drug. Its use should be limited to only those patients suffering from severe, chronic diarrhea-predominant IBS who have failed to respond to conventional therapy.

An individualized diet, low in saturated fats and foods that trigger the patient's reaction, can reduce symptoms for many IBS sufferers. Caffeine sources, sugar, and alcohol usually worsen symptoms. Bran or 15–25 grams a day of an over-the-counter psyllium laxative may also help both constipation and diarrhea. The patient can have milk or milk products if lactose intolerance is not a problem. Establishing set times for meals and bathroom visits may help people with irregular bowel habits, especially for constipated patients.

Although a high-fiber diet remains the standard treatment for constipated patients, such laxatives as lactulose or sorbitol may be prescribed. Loperamide and cholestyramine are suggested for diarrhea. Abdominal pain after meals can be reduced by taking antispasmodic drugs such as hyoscyamine or dicyclomine before eating.

Psychological counseling or **behavioral therapy** may be useful for some patients in reducing **anxiety** and learning to cope with the pain and other symptoms of IBS. Relaxation therapy, hypnosis, biofeedback, and cognitive-behavioral therapy are examples of behavioral therapy.

When IBS produces constant pain that interferes with everyday life, antidepressant drugs can help by blocking pain transmission from the nervous system.

Expected results

IBS is not a life-threatening condition. It does not cause intestinal bleeding or inflammation, nor does it cause other bowel diseases or **cancer**. Although IBS

can last a lifetime, in up to 30% of cases the symptoms eventually disappear. Even if the symptoms cannot be eliminated, with appropriate treatment they can usually be decreased so that IBS becomes merely an occasional inconvenience. Treatment requires a long-term commitment, however; six months or more may be needed before the patient notices substantial improvement.

Ischemia

Definition

Ischemia is an insufficient supply of oxygenated blood to an organ, usually due to a blocked artery.

Description

Myocardial ischemia is an intermediate condition in coronary artery disease during which the heart tissue is slowly or suddenly starved of oxygen and other nutrients. Eventually, the affected heart tissue dies. When blood flow is completely blocked to the heart, ischemia can lead to a **heart attack**. Ischemia can be silent or symptomatic. According to the American Heart Association, up to four million Americans may have silent ischemia and be at high risk of having a heart attack with no warning.

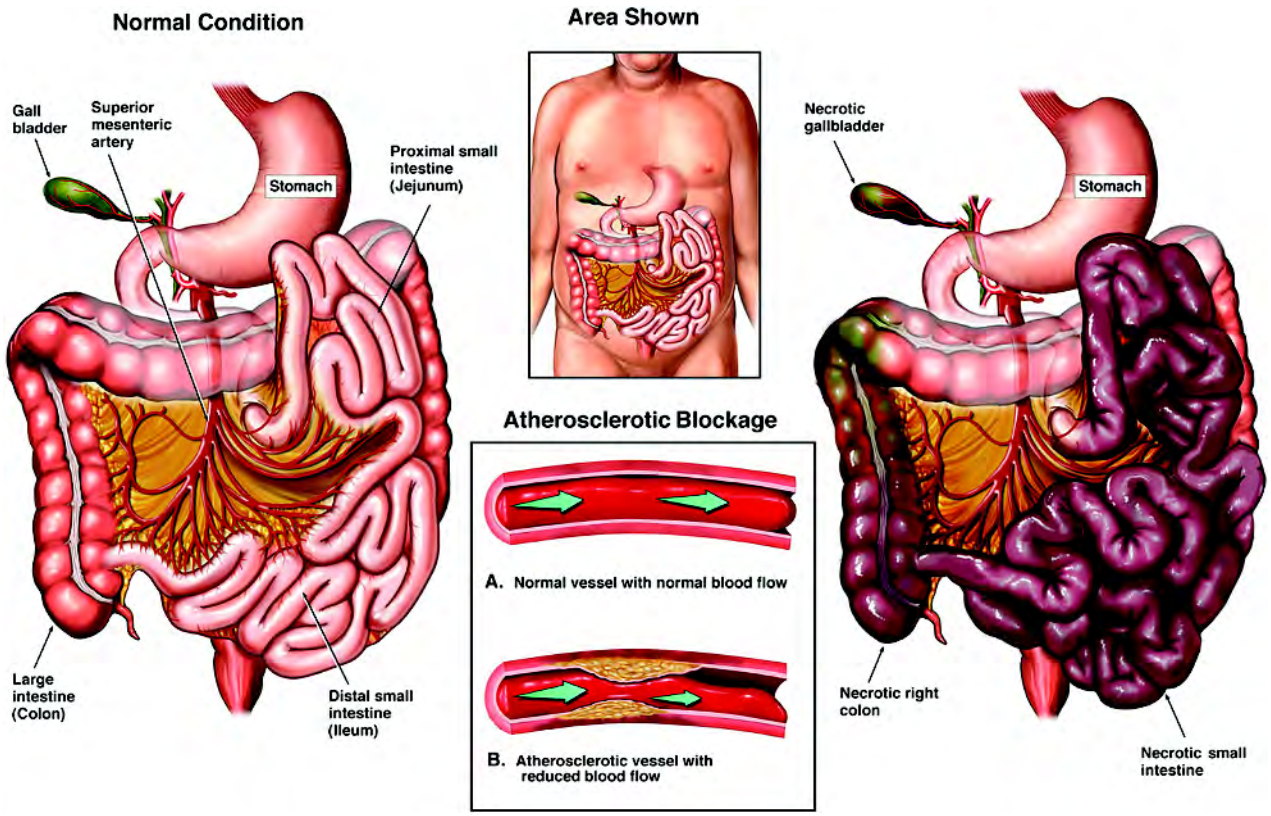
Symptomatic ischemia is characterized by chest **pain** called **angina** pectoris. The American Heart Association estimates that nearly seven million Americans have angina pectoris, usually called angina. Angina occurs more frequently in women than in men and more often in African Americans and Hispanics than in Caucasians. It also occurs more frequently as people age—25% of women over the age of 85 and 27% of men between 80 and 84 years of age have angina.

People with angina are at risk of having a heart attack. Stable angina occurs during exertion, can be quickly relieved by resting or taking nitroglycerine, and lasts from three to 20 minutes. Unstable angina, which increases the risk of a heart attack, occurs more frequently, lasts longer, is more severe, and may cause discomfort during rest or light exertion.

Ischemia also can occur in the arteries of the brain, where blockages can lead to a **stroke**. About 80 to 85% of all strokes are ischemic. Most blockages in the cerebral arteries are due to a blood clot, often in an artery narrowed by plaque. Sometimes, a blood clot in the heart or aorta travels to a cerebral artery. A transient ischemic attack (TIA) is a mini-stroke caused by a temporary deficiency of blood supply to the brain or by a blood clot briefly blocking a cerebral artery. It occurs suddenly, lasts a few minutes to a few hours, and is a strong warning sign of an impending stroke. Ischemia can also affect intestines, legs, feet, and kidneys. Pain, malfunctions, and damage in those areas may result.

Causes and symptoms

Ischemia almost always is caused by blockage of an artery, usually due to atherosclerotic plaque.



Mesenteric Ischemia. *(© Nucleus Medical Art, Inc. / Alamy)*

Myocardial ischemia also is caused by **blood clots** (which tend to form on plaque), artery spasms or contractions, or any of these factors combined. Silent ischemia usually is caused by emotional or mental **stress** or by exertion, but there are no symptoms. Angina usually is caused by increased oxygen demand when the heart is working harder than usual, for example, during **exercise** or during mental or physical stress. Researchers point out that physical stress is harder on the heart than mental stress.

Risk factors

The risk factors for myocardial ischemia are the same as those for coronary artery disease, TIA, and stroke:

- Heredity. People whose parents have coronary artery disease are more likely to develop the condition. African Americans also are at higher risk.
- Sex. Men are more likely to have heart attacks than women and to have them at a younger age. Angina is more likely to occur in women.
- Age. Men who are 45 years of age and older and women who are 55 years of age and older are considered to be at risk. Risk also increases with age.
- Smoking. Smoking increases both the chance of developing coronary artery disease and the chance of dying from it. Second-hand smoke also may increase risk.
- High cholesterol. Risk of developing coronary artery disease increases as blood cholesterol levels increase. When combined with other factors, the risk is even greater.
- High blood pressure. High blood pressure makes the heart work harder, and with time, weakens it. When combined with obesity, smoking, high cholesterol, or diabetes, the risk of heart attack or stroke increases several times.
- High fibrinogen levels. Fibrinogens are proteins involved in blood clotting and plaque formation.
- High homeocysteine levels. Homeocysteine is also involved in plaque formation.
- Oxidant damage, as indicated by high lipid peroxide levels. High lipid peroxide levels represent a high level of free radical damage and antioxidant deficiency.
- Lack of physical activity. Lack of exercise increases the risk of coronary artery disease.

- Diabetes mellitus. The risk of developing coronary artery disease is seriously increased for diabetics.
- Obesity. Excess weight increases the strain on the heart and increases the risk of developing coronary artery disease, even if no other risk factors are present. Obesity increases blood pressure and blood cholesterol, and can lead to diabetes.
- Stress and anger. Some scientists believe that stress and anger can contribute to the development of coronary artery disease. Stress increases the heart rate and blood pressure and can injure the lining of the arteries. Angina attacks often occur after anger, as do many heart attacks and strokes.

Angina symptoms include:

- a tight, squeezing, heavy, burning, or choking pain that is usually beneath the breastbone—the pain may spread to the throat, jaw, or one arm
- a feeling of heaviness or tightness that is not painful
- a feeling similar to gas or indigestion
- attacks brought on by exertion and relieved by rest

If the pain or discomfort continues or intensifies, immediate medical help should be sought, ideally within 30 minutes.

TIA symptoms include:

- sudden weakness, tingling, or numbness, usually in one arm or leg or both the arm and leg on the same side of the body, as well as sometimes in the face
- sudden loss of coordination
- loss of vision or double vision
- difficulty speaking
- vertigo and loss of balance

Diagnosis

Diagnostic tests for myocardial ischemia include: resting, exercise, or ambulatory electrocardiograms; scintigraphic studies (radioactive heart scans); echocardiography; coronary angiography; and, rarely, positron emission tomography (PET) studies. Diagnostic tests for TIA include physician review of symptoms, computed tomography (CT) scans, carotid artery ultrasound (Doppler ultrasonography), and magnetic resonance imaging (MRI). Angiography is the best test for ischemia of any organ.

An electrocardiogram (ECG) shows the heart's activity and may reveal a lack of oxygen. Electrodes covered with conducting jelly are placed on the patient's chest, arms, and legs. Impulses of the heart's activity are recorded on paper. The test takes about 10 minutes and is performed in a physician's office. About 25% of patients with angina have normal electrocardiograms. Another type of electrocardiogram, the exercise stress test, measures response to exertion when the patient is exercising on a treadmill or a stationary bike. It is performed in a physician's office or an exercise laboratory and takes 15–30 minutes. This test is more accurate than a resting ECG in diagnosing ischemia. Sometimes an ambulatory ECG is ordered. For this test, the patient wears a portable ECG machine called a Holter monitor for 12, 24, or 48 hours.

Myocardial perfusion scintigraphy and radionuclide angiography are nuclear studies involving the injection of a radioactive material (e.g., thallium), that is absorbed by healthy tissue. A gamma scintillation camera displays and records a series of images of the radioactive material's movement through the heart. Both tests usually are performed in a hospital's nuclear medicine department and take about 30 minutes to an hour. A perfusion scan sometimes is performed at the end of a stress test.

An echocardiogram uses sound waves to create an image of the heart's chambers and valves. The technologist applies gel to a handheld transducer then presses it against the patient's chest. The heart's sound waves are converted into an image on a monitor. Performed in a cardiology outpatient diagnostic laboratory, the test takes 30 minutes to an hour. It can reveal abnormalities in the heart wall that indicate ischemia, but it does not evaluate the coronary arteries directly.

Coronary angiography is the most accurate diagnostic technique, but it also is the most invasive. It shows the heart's chambers, great vessels, and coronary arteries by using a contrast solution and x-ray technology. A moving picture is recorded of the blood flow through the coronary arteries. The patient is awake but sedated, and connected to ECG electrodes and an intravenous line. A local anesthetic is injected. The cardiologist then inserts a catheter into a blood vessel and guides it into the heart. Coronary angiography is performed in a cardiac catheterization laboratory and takes from 30 minutes to two hours.

Positron emission tomography (PET) is a noninvasive nuclear test used to evaluate the heart tissue. A PET scanner traces high-energy gamma rays released from radioactive particles to provide three-dimensional images of the heart tissue. Performed at a hospital, it usually takes from one hour to one hour and 45 minutes.

CT and MRI are computerized scanning methods. CT scanning uses a thin x-ray beam to show three-dimensional views of soft tissues. It is performed

at a hospital or clinic and takes only minutes. MRI uses a magnetic field to produce clear, cross-sectional images of soft tissues. The patient lies on a table that slides into a tunnel-like scanner for about 30 minutes.

Treatment

Ischemia can be life-threatening. Although there are alternative treatments for angina, traditional medical care may be necessary. Prevention of the cause of ischemia, primarily **atherosclerosis**, is primary. This becomes even more important for people with a family history of **heart disease**.

Nutritional therapy

Dietary modifications are essential in the treatment and prevention of ischemic heart disease. The following dietary changes are recommended:

- Limiting intake of red meat and animal fats that contain high amounts of cholesterol and saturated fats.
- Eating a heart-wise diet with emphasis on fresh fruits and vegetables, grains, beans, and nuts. Increased fiber (found in fresh fruits and vegetables, grains, and beans) can help the body eliminate excessive cholesterol through the stools.
- Avoiding coffee (caffeinated and decaffeinated) and smoking. Not smoking will prevent damage from smoke and the harmful substances (oxidants) it contains.
- Taking high-potency multivitamin/mineral supplement (one tablet daily). Heart patients may require higher amounts of antioxidants, such as vitamins C and E. They should aim for total daily intake of 500–1000 mg of vitamin C and 400–800 IU of (natural) vitamin E. They also should take 1 tbsp of flaxseed oil or fish oil per day. Flaxseed oil is a good source of omega-3 oils. Numerous studies have demonstrated the cardio-protective effects of omega-3 fatty acids.
- Considering supplements for specific health problems. Individuals with diabetes might benefit from chromium, garlic, and pantethine supplements. Niacin, flaxseed oil, and garlic help treat elevated fibrinogen levels. For those with high homocysteine levels, vitamin B_6, B_{12}, and folic acid may be needed. Patients with high lipid peroxide levels require more antioxidants to prevent free radical damage. Antioxidants, such as vitamins C and E, selenium, *Ginkgo biloba*, bilberry (*Vaccinium myrtillus*), and hawthorn, can help prevent initial arterial injury that can lead to the formation of plaque deposits. In 2008, the U.S. Office of Complementary and Alternative Medicine reported that hawthorne was safe and effective for the treatment of mild kinds of heart failure but that there is not enough scientific evidence to support its use for other types of heart problems.

Herbal therapy

Western herbal medicine recommends **hawthorn** (*Crataegus laevigata* or *C. oxyacantha*) to help prevent long-term angina, since they strengthen heart muscles' ability to contract.

Homeopathy

Cactus (*Cactus grandiflorus*) is a homeopathic remedy used for pain relief during an attack.

Ayurvedic medicine

Abana, a mixture of herbs and minerals used in **Ayurvedic medicine**, may reduce the frequency and severity of angina attacks.

Exercises

Exercise, particularly aerobic exercise, is essential for circulation health. It is recommended that the patient exercise for 20 minutes, at least three times a week.

Mind/body medicine

Mind/body **relaxation** techniques such as **yoga**, **meditation**, stress reduction, and **biofeedback** can help ease strong emotions and stress.

Chelation therapy

The use of **chelation therapy**, a long-term injection by a physician of a mix containing synthetic amino acid, ethylenediaminetetracetic acid (EDTA), and anticoagulant drugs and nutrients, remained controversial as of 2008.

Allopathic treatment

Angina is treated with drug therapy and surgery. Drugs such as nitrates, beta-blockers, and **calcium** channel blockers relieve chest pain, but they cannot clear blocked arteries. There is some evidence that administering testosterone to men with myocardial ischemia may help reduce the risk of ischemia. Aspirin helps prevent the formation of blood clots. Many authorities recommend that people at risk for ischemia take one child's aspirin (81 mg) at night before bed. Surgical procedures include percutaneous transluminal coronary angioplasty and coronary artery bypass graft surgery.

Nitroglycerin is the classic treatment for angina. It quickly relieves pain and discomfort by opening the

coronary arteries and allowing more blood to flow to the heart. Beta-blockers reduce the amount of oxygen required by the heart during stress. Calcium channel blockers help keep the arteries open and reduce blood pressure. Statins help reduce **cholesterol** levels, which can lessen the risk of ischemic events.

Percutaneous transluminal coronary angioplasty and coronary artery bypass graft surgery are invasive procedures that improve blood flow in the coronary arteries. Percutaneous transluminal coronary angioplasty is a procedure in which a catheter tipped with a balloon is threaded from a blood vessel in the thigh into the blocked artery. The balloon is inflated, compressing the plaque to enlarge the blood vessel and open the blocked artery. The balloon is deflated and the catheter is removed. Sometimes a metal stent is placed in the artery to prevent closing.

In coronary artery bypass graft, called bypass surgery, a detour is built around the coronary artery blockage with a healthy leg vein or chest wall artery. The healthy vein or artery then supplies oxygen-rich blood to the heart. Bypass surgery is major surgery appropriate for patients with blockages in two or three major coronary arteries or severely narrowed left main coronary arteries, as well as those who have not responded to other treatments.

As of 2008, there were several experimental surgical procedures. Two of these were atherectomy, in which a surgeon shaves off and removes strips of plaque from the blocked artery, and laser angioplasty, in which a catheter with a laser tip is inserted to burn or break down the plaque. A stenting procedure was widely used in the treatment of coronary blockages as of the late 2000s; in this procedure a metal coil, called a stent, is implanted permanently to keep a blocked artery open.

TIAs are treated by drugs that control high blood pressure and reduce the likelihood of blood clots and surgery. Aspirin is commonly used and anticoagulants are sometimes used to prevent blood clots. In some cases, carotid endarterectomy surgery is performed to help prevent further TIAs. The procedure involves removing arterial plaque from inside blood vessels.

Expected results

In many cases, ischemia can be successfully treated, but the underlying disease process of atherosclerosis is usually not cured. Certain diagnostic techniques have been developed to enable doctors to identify ischemia earlier. These technologies and surgical procedures can prevent angina from leading to a heart attack or TIA from resulting in a stroke. The outcome for patients with silent ischemia had not been well established as of 2008.

Prevention

A healthy lifestyle, including eating right, getting regular exercise, maintaining a healthy weight, not **smoking**, drinking in moderation, not using illegal drugs, controlling **hypertension**, and managing stress, can reduce the risk of ischemia progressing to a heart attack or stroke.

A healthy diet includes a variety of foods that are low in fat (especially saturated fat), low in cholesterol, and high in fiber. Plenty of fruits and vegetables should be eaten and **sodium** should be limited. Fat should comprise no more than 30% of total daily calories. Cholesterol should be limited to about 300 mg and sodium to about 2,400 mg per day.

The Centers for Disease Control and Prevention and the American College of Sports Medicine recommend moderate aerobic exercise lasting about 30 minutes four or more times per week for maximum heart health. Three 10-minute exercise periods also are beneficial. If any risk factors are present, a physician's clearance should be obtained before starting exercise.

Maintaining a desirable body weight also is important. People who are 20% or more over their ideal body weight have an increased risk of developing coronary artery disease or stroke.

Smoking has many adverse effects on the heart and arteries and should be avoided. Heart damage caused by smoking can be improved by quitting. Several studies have shown that ex-smokers face the same risk of heart disease as nonsmokers within five to ten years after quitting.

Excessive drinking can increase risk factors for heart disease. Modest consumption of alcohol, however, can actually protect against coronary artery disease. The American Heart Association defines moderate consumption as one ounce of alcohol per day—roughly one cocktail, one 8 oz glass of wine, or two 12 oz glasses of beer.

Commonly used illegal drugs can seriously harm the heart and should never be used. Even stimulants such as **ephedra** and decongestants like pseudoephedrine can be harmful to patients with hypertension or heart disease.

Treatment should be sought for hypertension. High blood pressure can be completely controlled through lifestyle changes and medication. Stress, which can increase the risk of a heart attack or stroke, should also be managed. While it cannot always be avoided, it can be controlled.

KEY TERMS

Atherosclerosis—A process in which the walls of the arteries thicken due to the accumulation of plaque in the blood vessels. Atherosclerosis is the cause of most coronary artery disease.

Coronary artery disease—A narrowing or blockage, due to atherosclerosis, of the arteries that provide oxygen and nutrients to the heart. When blood flow is cut off, the result is a heart attack.

Plaque—A deposit of fatty and other substances that accumulate in the lining of the artery wall.

Stroke—A sudden decrease or loss of consciousness caused by rupture or blockage of a blood vessel by a blood clot or hemorrhage in the brain. Ischemic strokes are caused by blood clots in a cerebral artery.

Itching

Definition

Itching is an intense, distracting irritation or tickling sensation that may be felt all over the skin's surface or confined to just one area. The medical term for itching is pruritus.

Description

Itching leads most people instinctively to scratch the affected area. Different people can tolerate different amounts of itching, and anyone's threshold of tolerance can be changed due to **stress**, emotions, and other factors. In general, itching is more severe if the skin is warm, and if there are few distractions. This is why people tend to notice itching more at night.

Causes and symptoms

As of 2002, the recent discovery of itch-specific neurons (nerve cells) has given doctors a better understanding of the causes of the sensation of itching. Another factor that contributes to itching is the release of endogenous opioids in the body. While these chemicals function primarily to relieve **pain**, they also appear to enhance the sensation of itching. Although itching is the most noticeable symptom of many skin diseases, however, it doesn't necessarily mean that a person who feels itchy has a disease.

Stress and emotional upset can make itching worse, no matter what the underlying cause. If emotional problems are the primary reason for feeling itchy, the condition is known as psychogenic itching. Some people become convinced that their itch is caused by a parasite or some medical disorder. This conviction is often linked to burning sensations in the tongue, and may be caused by a major psychiatric disorder.

Generalized itching

Itching that occurs all over the body may indicate a medical condition such as **diabetes mellitus**, liver disease, kidney failure, **jaundice**, thyroid disorders, and rarely, **cancer**. Blood disorders such as **leukemia**, and lymphatic conditions such as **Hodgkin's disease** may sometimes cause itching as well.

Some people may develop an itch without a rash when they take certain drugs (such as aspirin, codeine, cocaine). Others may develop an itchy, red "drug rash" or **hives** because of an allergy to a specific drug.

A team of researchers in Texas has discovered that some people infected by *Helicobacter pylori*, a bacterium that causes **gastritis**, also develop itching that

KEY TERMS

Atopic dermatitis—An intensely itchy inflammation often found on the face of people prone to allergies. In infants and early childhood, it's called infantile eczema.

Creeping eruption—Itchy irregular, wandering red lines on the skin made by burrowing larvae of the hookworm family and some roundworms. Also called cutaneous larva migrans.

Dermatitis herpetiformis—A chronic, very itchy skin disease with groups of red lesions that leave spots behind when they heal. It is sometimes associated with cancer of an internal organ.

Eczema—A superficial type of inflammation of the skin that may be very itchy and weeping in the early stages; later, the affected skin becomes crusted, scaly, and thick. There is no known cause.

Endogenous opioids—Natural pain relievers produced by the body that are also associated with the sensation of itching.

Hodgkin's disease—A type of cancer characterized by slowly enlarging lymph tissue; symptoms include generalized itching.

Lichen planus—A noncancerous, chronic, itchy skin disease that causes small, flat purple plaques on wrists, forearm, and ankles.

Neurodermatitis —An itchy skin disease (also called lichen simplex chronicus) found in nervous, anxious people.

Psoriasis—A common, chronic skin disorder that causes red patches anywhere on the body.

Scabies—A contagious parasitic skin disease characterized by intense itching.

Swimmer's itch—An allergic skin inflammation caused by a sensitivity to flatworms that die under the skin, causing an itchy rash.

does not respond to usual treatments. When the bacterium is eradicated from the patient's digestive tract, the itching is relieved.

Itching also may be caused when hookworm larvae penetrate the skin. This includes swimmer's itch, creeping eruption caused by cat or dog hookworm, and ground itch caused by the "true" hookworm.

Skin conditions that cause an itchy rash include:

- atopic dermatitis
- chickenpox
- contact dermatitis
- dermatitis herpetiformis (occasionally)
- eczema
- fungal infections (such as athlete's foot)
- hives (urticaria)
- insect bites
- lice
- lichen planus
- neurodermatitis (lichen simplex chronicus)
- psoriasis (occasionally)
- Scabies

Itching all over the body can be caused by something as simple as bathing too often, which removes the skin's natural oils and may make the skin too dry and scaly.

Localized itching

Specific itchy areas may occur if a person comes in contact with soaps, detergents, and wool or other rough-textured, scratchy material. Adults who have **hemorrhoids**, anal fissure, or persistent **diarrhea** may notice pruritus ani (itching around the anus). In children, itching in this area is most likely due to **worms**.

Intense itching called pruritus vulvae (itching of the external genitalia in women) may be due to a **yeast infection**, hormonal changes, **contact dermatitis**, or the use of certain spermicides, vaginal suppositories, ointments, or deodorants.

It's also common for older people to suffer from dry, itchy skin (especially on the back) for no obvious reason. Moreover, older people are more likely to develop itching as a side effect of prescription medications. Younger people may notice dry, itchy skin in cold weather. Itching is also a common complaint during **pregnancy**.

Diagnosis

Itching is a symptom that is quite obvious to its victim. Someone who itches all over should seek medical care. Because itching can be caused by such a wide variety of triggers, a complete physical exam and medical history will help diagnose the underlying problem. A variety of blood and stool tests may help determine the underlying cause.

Treatment

In general, itchy skin should be treated very gently. While scratching may temporarily ease the itch, in the long run scratching just makes it worse. In

addition, scratching can lead to an endless cycle of more itching and scratching.

To avoid the urge to scratch, a person can apply a cooling or soothing lotion or cold compress to the area. Itching may be relieved by applying a warm compress of diluted vinegar, preferably herbal vinegars such as **plantain**, violet, lavender, or rose.

The itching associated with mosquito **bites** can be reduced by applying meat tenderizer paste, table salt (to wet skin), or toothpaste. Any alkaline preparation (like a paste of baking soda and water) will help ease the itch.

Probably the most common cause of itching is dry skin. **Flaxseed** oil and **vitamin E** taken orally can help to rehydrate dry skin and can reduce itching. There are a number of simple things a person can do to relieve itching.

- Don't wear tight clothes.
- Avoid synthetic fabrics.
- Don't take long baths.
- Wash the area in lukewarm water with a little baking soda.
- Take a lukewarm shower for generalized itching.
- Try a lukewarm oatmeal (or Aveeno) bath for generalized itching.
- Apply bath oil or lotion (without added colors or scents) right after bathing.

Practitioners of Chinese medicine utilize a wide variety of herbs as well as **acupuncture** and ear acupuncture to treat itching based upon the cause. The medicine Xiao Feng Zhi Yang Chong Ji (Eliminate Wind and Relieve Itching Infusion) can be taken three times daily to relieve itching. For external treatment of itching, the patient may bathe in Zhi Yang Xi Ji (Relieve Itching Washing Preparation) and apply She Chuang Zi Ding (Cnidium Tincture) and Zhi Yang Po Fen (Relieve Itching Powder).

Emotional stress can trigger many different dermatoses including certain itching **rashes**. Hypnosis has been helpful in treating atopic **dermatitis**, itching, **psoriasis**, hives, and other dermatoses.

In several small studies, transcutaneous electrical nerve stimulation (TENS) has been effective in temporarily relieving chronic itch associated with varying dermatoses. TENS is a treatment where mild electrical current is passed through electrodes on the skin to stimulate nerves and block pain signals. Portable TENS units are available for home use.

Cutaneous field stimulation (CFS) was found to safely relieve experimentally induced itching for a longer time period than TENS. CFS electrically stimulates nerves in the skin to harmlessly mimic scratching and inhibit the itch sensation.

Herbal itch remedies

The following herbal remedies for itching are used externally:

- aloe vera
- bracken juice
- bird-of-paradise (*Strelitzia reginae*) flowers
- cabbage leaf poultice
- cattail (*Typha latifolia*) juice
- chickweed (*Stellaria media*) salve
- comfrey (*Symphytum officinale*) juice
- evening primrose (*Oenothera biennis*) oil
- heal-all (*Prunella vulgaris*) juice
- honeysuckle vine flowers and leaves
- marigold (*Caledula officinalis*)
- marsh mallow (*Althaea officinalis*) leaf poultice
- myrrh (*Commiphora* species) oil
- oats (*Avena sativa*) bath or poultice
- onion juice
- papaya fruit
- plantain (*Plantago major*) juice or poultice
- red pepper juice
- Sage (*salvia officinalis*) leaves
- St. John's wort (*Hypericum perforatum*)
- tea tree (*Melaleuca alternifolia*) oil
- yellow dock (*Rumex crispus*) tea bath

Allopathic treatment

Specific treatment of itching depends on the underlying cause. Such antihistamines as diphenhydramine (Benadryl) can help relieve itching caused by hives, but won't affect itching from other causes. Most antihistamines also make people sleepy, which can help patients sleep who would otherwise be awake from the itch. Newer antihistamines that do not make people drowsy as a side effect are also available to treat itching.

Creams or ointments containing cortisone may help control the itch from insect bites, contact dermatitis, or **eczema**. Cortisone cream should not be applied to the face unless a doctor prescribes it, and should not be used over the body for prolonged periods without a doctor's approval.

A newer medication that relieves the itching associated with **burns** as well as speeding the healing

process is called dexpanthenol. Dexpanthenol helps to relieve the itching by preventing the affected skin from drying out.

Expected results

Most cases of itching go away when the underlying cause is treated successfully.

Prevention

Soaps are often irritating and drying to the skin and can make an itch worse. They should be avoided or used only when necessary. People who tend to have itchy skin should:

- Avoid bathing daily.
- Use lukewarm water when bathing.
- Use mild soap.
- Pat (not rub) the skin dry after bathing, leaving some water on the skin.
- Apply a moisturizer immediately after the bath, but avoid lanolin products.
- Use a humidifier, particularly during heating season in colder climates.

Eating **garlic** and onion and taking vitamin B supplements may help to repel mosquitoes. Application of cedar, **sage**, **pennyroyal**, **rosemary**, artemisia, or marigold to the skin may also repel mosquitoes

Jamaica dogwood

Description

Jamaica dogwood, *Piscidia erythrina* or *Piscidia piscipula,* is an herb that is used to treat **insomnia**, **muscle spasms**, and severe nerve **pain** called **neuralgia**. The plant is native to Central America, the West Indies, and Florida. It is also called *Fish Poison Tree*. As of 2008, it could also be found growing in parts of Texas, Mexico, and the northern region of South America. The plant is covered with a yellowish or grayish brown bark, which emits an offensive odor. Inside, the surface is light colored or white. The herb tastes acrid and bitter and causes a burning sensation in the mouth. The bark is the portion of the plant containing its medicinal properties. Jamaica dogwood is a potent herb, with the potential for toxicity. As of 2008 it had not undergone safety testing or much research.

Jamaica dogwood was discovered by scientists in the mid-1800s, when its pain-relieving properties and ability to promote sweat gained acclaim. In Central America and South America, it has been a widely used fish poison. In the early part of the twentieth century, Jamaica dogwood made its way into the medical literature when a Harvard researcher named Vedux-Tyrode wrote about it. His 1902 article, published in the *Journal of Medical Research,* explained that a solution containing Jamaica dogwood was toxic to frogs, eventually causing death, yet death did not occur in warm-blooded creatures such as rabbits. The researcher concluded that more investigation was needed to determine the pharmacological properties inherent in Jamaica dogwood.

Jamaica dogwood contains a substance known as rotenone, an insect-killing agent used to destroy fleas, lice, and larvae. At recommended doses, rotenone is not known to be harmful to humans or other warm-blooded animals.

General uses

In general, Jamaica dogwood is used to control nerve pain, promote sleep, and reduce spasms. In studies, Jamaica dogwood has been shown to possess a variety of other potential benefits, although further research in these areas is needed:

- Cough reliever
- Fever reducer
- Anti-inflammatory agent

In alternative health treatments, it may be used to treat the following:

- Anxiety
- Coughing
- Menstrual pain
- Headache, particularly migraine
- Nerve Pain
- Toothache
- Insomnia

Preparations

Jamaica dogwood has been available as dried root bark, powder, tincture, or liquid extract. But as of 2008 the liquid extract was no longer available in the marketplace. However, Jamaica dogwood can be found in some medicinal preparations.

Precautions

Jamaica dogwood is a powerful herb that can be toxic at higher dosages. Its safety had not been tested as of 2008. It should be used only under the advice of a healthcare professional. Jamaica dogwood should not be taken by women who are pregnant or breastfeeding, nor should older individuals or children take it.

KEY TERMS

Anti-inflammatory agent—A medication or treatment that reduces inflammation, redness, and swelling.

Trembling—A shaking of a body part.

Side effects

Jamaica dogwood should be stopped immediately and the physician should be promptly notified if signs of an allergy occur, such as **itching**, rash, swelling, tightness in the chest or throat, or difficulty breathing. Side effects include increased drooling and sweating, **fatigue**, **nausea**, gastric disorders, and nerve symptoms such as numbness, twitching, or trembling.

Interactions

Jamaica dogwood may increase the effects of drugs used for **anxiety** or sleeplessness, such as Ambien, Seconal, and Valium. Consumers should check with their physician before taking Jamaica dogwood.

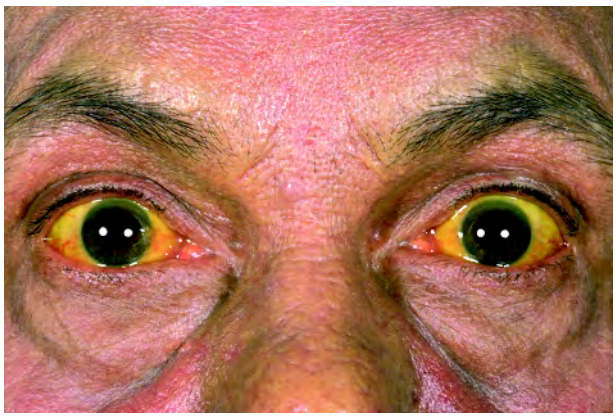
Jaundice

Definition

Jaundice is a condition in which a person's skin and the whites of the eyes are discolored yellow due to an increased level of bile pigments in the blood resulting from liver disease. Jaundice is sometimes called *icterus*, from a Greek word for "the condition."



Jaundice due to primary billary cirrhosis. *(© Medical-on-Line / Alamy)*

Description

In order to understand jaundice, it is useful to know about the role of the liver in producing bile. The most important function of the liver is the metabolic processing of "chemical" waste products like **cholesterol**, and excreting them into the intestines as bile. The liver is the premier "chemical" factory in the body—most incoming and outgoing chemicals pass through it. It is the first stop for all nutrients, toxins, and drugs absorbed by the digestive tract. The liver also collects chemicals from the blood for processing. Many of these outward bound chemicals are excreted into the bile. One particular substance, bilirubin, is yellow. Bilirubin is a product of the breakdown of hemoglobin, which is the protein inside red blood cells. If bilirubin cannot leave the body, it accumulates and discolors other tissues. The normal total level of bilirubin in blood serum is between 0.2 mg/dL and 1.2 mg/dL. When it rises to 3 mg/dL or higher, the person's skin and the whites of the eyes become noticeably yellow.

Bile is formed in the liver. It then passes into the network of hepatic bile ducts, which join to form a single tube. A branch of this tube carries bile to the gallbladder, where it is stored, concentrated, and released on a signal from the stomach. Food entering the stomach is the signal that stimulates the gallbladder to release the bile. The tube, which is called the common bile duct, continues to the intestines. Before the common bile duct reaches the intestines, it is joined by another duct from the pancreas. The bile and the pancreatic juice enter the intestine through a valve

called the Ampulla of Vater. After entering the intestine, the bile and pancreatic secretions together help in the process of digestion.

Causes and symptoms

There are many different causes for jaundice, but they can be divided into three categories based on where they start—before (pre-hepatic), in (hepatic), or after (post-hepatic) the liver. When bilirubin begins its life cycle, it cannot be dissolved in water. Thus, the liver changes it so that it is soluble in water. These two types of bilirubin are called unconjugated (insoluble) and conjugated (soluble). Blood tests can easily distinguish between these two types of bilirubin.

Hemoglobin and bilirubin formation

Bilirubin begins as hemoglobin in the blood-forming organs, primarily the bone marrow. If the production of red blood cells (RBCs) falls below normal, the extra hemoglobin finds its way into the bilirubin cycle and adds to the pool.

Once hemoglobin is in the red cells of the blood, it circulates for the life span of those cells. The hemoglobin that is released when the cells die is turned into bilirubin. If for any reason the RBCs die at a faster rate than usual, then bilirubin can accumulate in the blood and cause jaundice.

Hemolytic disorders

Many disorders speed up the death of red blood cells. The process of red blood cell destruction is called hemolysis, and the diseases that cause it are called hemolytic disorders. If red blood cells are destroyed faster than they can be produced, the patient develops **anemia**. Hemolysis can occur in a number of diseases, disorders, conditions, and medical procedures:

- Malaria. The malaria parasite develops inside red blood cells. When it is mature it breaks the cell apart and swims off in the blood. This process happens to most of the parasites simultaneously, causing the intermittent symptoms of the disease. When enough cells burst at once, jaundice may result from the large amount of bilirubin formed from the hemoglobin in the dead cells. The pigment may reach the urine in sufficient quantities to cause "blackwater fever," an often lethal form of malaria.
- Side effects of certain drugs. Some common drugs can cause hemolysis as a rare, but sudden, side effect. These medications include some antibiotic and antituberculosis medicines; drugs that regulate the heartbeat; and levodopa, a drug used to treat Parkinson's disease.
- Certain drugs in combination with a hereditary enzyme deficiency known as glucose–6–phosphate dehydrogenase (G6PD). G6PD is a deficiency that affects more than 200 million people in the world. Some of the drugs listed above are more likely to cause hemolysis in people with G6PD. Other drugs cause hemolysis only in people with this disorder.

KEY TERMS

Ampulla of Vater—The widened portion of the duct through which the bile and pancreatic juices enter the intestine. *Ampulla* is a Latin word describing a bottle with a narrow neck that opens into a wide body.

Anemia—A condition in which the blood does not contain enough hemoglobin.

Biliary system/bile ducts—The gall bladder and the system of tubes that carry bile from the liver into the intestines.

Bilirubin—A reddish pigment excreted by the liver into the bile as a breakdown product of hemoglobin.

Crigler-Najjar syndrome—A moderate to severe form of hereditary jaundice.

Erythroblastosis fetalis—A disorder of newborn infants marked by a high level of immature red blood cells (erythroblasts) in the infant's blood.

Gilbert's syndrome—A mild hereditary form of jaundice.

Glucose–6–phosphate dehydrogenase (G6PD) deficiency—A hereditary disorder that can lead to episodes of hemolytic anemia in combination with certain medications.

Hemoglobin—The red chemical in blood cells that carries oxygen.

Hemolysis—The destruction or breakdown of red blood cells.

Hepatic—Refers to the liver.

Icterus—Another name for jaundice.

Microangiopathic—Pertaining to disorders of the small blood vessels.

Pancreas—The organ beneath the stomach that produces digestive juices, insulin, and other hormones.

Sickle cell disease—A hereditary defect in hemoglobin synthesis that changes the shape of red cells and makes them more fragile.

Splenectomy—Surgical removal of the spleen.

Most important among these drugs are antimalarial medications, such as quinine, and vitamins C and K.

- Poisons. Snake and spider venom, certain bacterial toxins, copper, and some organic industrial chemicals directly attack the membranes of red blood cells.
- Artificial heart valves. The inflexible moving parts of heart valves damage RBCs as they flutter back and forth. This damage is one reason to recommend pig valves and valves made of other organic materials.
- Hereditary RBC disorders. There are a number of hereditary defects that affect the blood cells. There are many genetic mutations that affect the hemoglobin itself, the best known of which is sickle cell disease. Such hereditary disorders as spherocytosis weaken the outer membrane of the red cell. There are also inherited defects that involve the internal chemistry of RBCs.
- Enlargement of the spleen. The spleen is an organ that is located near the upper end of the stomach and filters the blood. It is supposed to filter out and destroy only worn out RBCs. If it has become enlarged, it filters out normal cells, as well. Malaria, other infections, cancers and leukemias, some of the hereditary anemias mentioned above, obstruction of blood flow from the spleen—all these and many more diseases can enlarge the spleen to the point where it removes too many red blood cells.
- Diseases of the small blood vessels. Hemolysis that occurs in diseased small blood vessels is called microangiopathic hemolysis. It results from damage caused by rough surfaces on the inside of the capillaries. The RBCs squeeze through capillaries one at a time and can easily be damaged by scraping against the vessel walls.
- Immune reactions to RBCs. Several types of cancer and immune system diseases produce antibodies that react with RBCs and destroy them. In 75% of cases, this reaction occurs all by itself, with no underlying disease to account for it.
- Transfusions. If a patient is given an incompatible blood type, hemolysis results.
- Kidney failure and other serious diseases. Several diseases are characterized by defective blood coagulation that can destroy red blood cells.
- Erythroblastosis fetalis. Erythroblastosis fetalis is a disease of newborns marked by the presence of too many immature red blood cells (erythroblasts) in the baby's blood. When a baby's mother has a different blood type, antibodies from the mother may leak into the baby's circulation and destroy blood cells. This reaction can produce severe hemolysis and jaundice in the newborn. Rh factor incompatibility is the most common cause.
- High bilirubin levels in newborns. Even in the absence of blood type incompatibility, the newborn's bilirubin level may reach threatening levels.

Normal jaundice in newborns

Normal newborn jaundice is the result of two conditions occurring at the same time—a pre-hepatic and a hepatic source of excess bilirubin. First of all, the baby at birth immediately begins converting hemoglobin from a fetal type to an adult type. The fetal type of hemoglobin was able to extract oxygen from the lower levels of oxygen in the mother's blood. At birth the infant can extract oxygen directly from his or her own lungs and does not need the fetal hemoglobin any more. So fetal hemoglobin is removed from the system and replaced with adult hemoglobin. The resulting bilirubin loads the system and places demands on the liver to clear it. But the liver is not quite ready for the task, so there is a period of a week or so when the liver has to catch up. During that time the baby is jaundiced.

In 2002, studies found that infants younger than eight weeks old with jaundice often had hidden (asymptomatic) urinary tract **infections**. Previous studies have shown that newborn jaundice may be an early sign of bacterial infections in infants. The study recommended that pediatricians routinely test young infants with jaundice for urinary tract infections.

Hepatic jaundice

Liver diseases of all kinds threaten the organ's ability to keep up with bilirubin processing. Starvation, circulating infections, certain medications, **hepatitis**, and **cirrhosis** can all cause hepatic jaundice, as can certain hereditary defects of liver chemistry, including Gilbert's syndrome and Crigler-Najjar syndrome.

Post-hepatic jaundice

Post-hepatic forms of jaundice include the jaundices caused by failure of soluble bilirubin to reach the intestines after it has left the liver. These disorders are called obstructive jaundices. The most common cause of obstructive jaundice is the presence of **gallstones** in the ducts of the biliary system. Other causes have to do with birth defects and infections that damage the bile ducts; drugs; infections; cancers; and physical injury. Some drugs—and **pregnancy** on rare occasions—simply cause the bile in the ducts to stop flowing.

Symptoms and complications associated with jaundice

Certain chemicals in bile may cause **itching** when too much of them end up in the skin. In newborns, insoluble bilirubin may get into the brain and do permanent damage. Long standing jaundice may upset the balance of chemicals in the bile and cause stones to form. Apart from these potential complications and the discoloration of skin and eyes, jaundice by itself is inoffensive. Other symptoms are determined by the disease producing the jaundice.

Diagnosis

Physical examination

In many cases, the diagnosis of jaundice is suggested by the appearance of the patient's eyes and complexion. The doctor will ask the patient to lie flat on the examining table in order to feel (palpate) the liver and spleen for enlargement and to evaluate any abdominal **pain**. The location and severity of abdominal pain and the presence or absence of **fever** help the doctor to distinguish between hepatic and obstructive jaundice.

Laboratory tests

Disorders of blood formation can be diagnosed by more thorough examination of the blood or the bone marrow, where blood is made. Occasionally a bone marrow biopsy is required, but usually the blood itself will reveal the diagnosis. The spleen can be evaluated by an ultrasound examination or a nuclear scan if the physical examination has not yielded enough information.

Imaging studies

Disease in the biliary system can be identified by imaging techniques, of which there are many. X rays are taken a day after swallowing a contrast agent that is secreted into the bile. This study gives functional, as well as anatomical, information. There are several ways of injecting x-ray dye directly into the bile ducts. It can be done through a thin needle pushed straight into the liver, or through a scope passed through the stomach that can inject dye into the Ampulla of Vater. CT and MRI scans are very useful for imaging certain conditions, such as cancers in and around the liver, or gallstones in the common bile duct.

Liver disease is usually assessed from blood studies alone, but again a biopsy may be necessary to clarify less obvious conditions. A liver biopsy is performed at the bedside. The doctor uses a thin needle to take a tiny core of tissue from the liver. The tissue sample is sent to the laboratory for examination under a microscope.

Assessment of jaundice in newborns

Newborns are more likely to have problems with jaundice if:

- They are premature.
- They are of Asian or Native American descent.
- They have been bruised during the birth process.
- They have lost too much weight during the first few days.
- They are born at a high altitude.
- The mother has diabetes.
- Labor had to be induceds.

Research is continuing to find noninvasive methods to determine bilirubin levels in newborns so that physicians did not have to rely on visual examination alone to determine which infants should receive blood tests. Once these measurements of skin pigment can be shown effective and cost-effective in clinical practice, they may become more available. Another study used this measurement method incorporated into home health visits to monitor babies within 24 hours of discharge from the hospital following birth.

Treatment

Jaundice is often early warning sign of serious liver damage. Alternative medicine treatments should not be used as a substitute for conventional medical treatment. Patients should contact their doctors for diagnosis and treatment immediately if experiencing signs and symptoms of jaundice. Alternative therapies may be helpful as complementary measures for patients who have an underlying disease that already has been diagnosed.

Nutritional therapy

Naturopaths or nutritionists may recommend the following dietary changes:

- Drinking fresh vegetable or fruit juices during the first several weeks after diagnosis and eating a diet consisting mostly of raw fruits and vegetables, seeds, and nuts during the next month. These fruits and vegetables are easy to digest and contain lots of antioxidants, vitamins and minerals. They help the body remove toxins from the blood, and decrease stress/strain on the liver for digestion/metabolism.
- Fasting intermittently.

- Eliminate alcohol from the diet for good, and avoiding foods that are processed and high in fat. These foods are bad for the liver.
- Drinking a cup of lemonade (without sugar) early in the morning to improve liver and bile function.
- Incorporating olive oil or lemon oil into the diet as a liver flush regimen.
- Taking nutritional supplements, such as multivitamins or minerals, vitamin C, vitamin B complex, other antioxidant-containing supplements, supplements containing alpha lipoic acid, protein supplements, essential fatty acids (EFAs), and digestive enzymes with bile (for patients having pale stools).

Traditional Chinese medicine

Depending on a patient's specific condition, an expert Chinese herbalist may prescribe herbal remedies that can help improve liver function. Animal studies have shown the following Chinese herbs may have liver protective effects:

- *Bupleurum chinense*
- *Phellodendron wilsonii*
- *Clementis chinensis*

Herbal therapy

Patients should consult an experienced herbalist for specific herbal treatments that may include **milk thistle** or **artichoke**.

Homeopathy

For homeopathic therapy, patients should consult a homeopathic physician who will prescribe specific remedies based on knowledge of the underlying cause.

Juice therapy

Juice therapy helps the liver detoxify toxins to be eliminated from the body. Patients should mix one part of pure juice with one part of water before drinking. Daily consumption of the following juices may be helpful:

- carrot and beet juice with a touch of radish or dandelion root juice
- grapes, pear, and lemon
- carrot, celery, and parsley
- carrot, beet, and cucumber

Aromatherapy

Essential oils of **rosemary**, lemon, and geranium may help improve liver function and relax the body. They can be given as inhalants, a soothing bath, or soak.

Other therapies

Other alternative treatments that may be help improve liver function include **fasting**, Ayurveda, **hydrotherapy**, and **acupuncture**.

Allopathic treatment

Jaundice in newborns

Newborns are the only major category of patients in whom the jaundice itself requires attention. If there is reason to suspect increased hemolysis in the newborn, the bilirubin level must be measured repeatedly during the first few days of life. If the level of bilirubin shortly after birth threatens to go too high, treatment must begin immediately. Exchanging most of the baby's blood was the only way to reduce the amount of bilirubin until a few decades ago. Jaundiced babies are now fitted with eye protection and placed under bright fluorescent blue lights. The light chemically alters the bilirubin in the blood as it passes through the baby's skin so that it may be more easily eliminated in the urine. In 2003, researchers tested a new drug called Stanate that showed promise in blocking bilirubin production. However, debate concerning the use of the drug for treatment of only those infants with jaundice or as a preventive measure was delaying its FDA approval and widespread use.

Hemolytic disorders

Hemolytic diseases are treated, if at all, with medications and blood transfusions, except in the case of an enlarged spleen. Surgical removal of the spleen (splenectomy) can sometimes cure hemolytic anemia. Drugs that cause hemolysis or arrest the flow of bile must be stopped immediately.

Hepatic jaundice

Most liver diseases have no specific cure, but the liver is so robust that it can heal from severe damage and regenerate itself from a small remnant of its original tissue.

Post-hepatic jaundice

Obstructive jaundice frequently requires a surgical cure. If the original passageways cannot be restored, surgeons have several ways to create alternate routes. To create alternate passageways, a surgeon will sew an open piece of intestine over a bare patch of liver. Tiny bile ducts in that part of the liver will begin to discharge their bile into the intestine, and pressure from the obstructed ducts elsewhere will find release in that direction. As the flow increases, the

ducts grow to accommodate it. Soon, all the bile is redirected through the open pathways.

Prevention

Erythroblastosis fetalis can be prevented by giving an Rh negative mother a gamma globulin solution called RhoGAM whenever there is a possibility that she is developing antibodies to her baby's blood. G6PD hemolysis can be prevented by testing patients before giving them drugs that can cause it. Medication side effects can be minimized by early detection and immediate cessation of the drug. **Malaria** can often be prevented by taking certain precautions when traveling in tropical or subtropical countries. These precautions include staying in after dark; using prophylactic drugs such as mefloquine; and protecting sleeping quarters with mosquito nets treated with insecticides and mosquito repellents. In 2003, new studies showed promise for a possible vaccine against malaria. Early trials showed that vaccination combination might stimulate T-cell activity against malaria, the best type of protection that researchers can hope to find. However, further studies will have to be done.

New research in 2002 linked a popular antidepressant drug paroxetine (Paxil) to several newborn complications, including jaundice. Although research is preliminary, pregnant women might want to discuss use of the drug with their physicians to prevent complications like jaundice in their newborn babies.

Jet lag

Definition

Jet lag is a commonplace condition marked by **fatigue**, **insomnia**, and irritability that is caused by air travel through a number of time zones. Some studies have shown that up to 90% of all international business travelers experienced at least a mild form of jet lag.

Description

Living organisms are accustomed to periods of night and day alternating at set intervals. Most of the human body's regulating hormones follow this cycle, known as circadian rhythm. The word circadian comes from the Latin, *circa*, meaning "about," and *dies*, meaning "day." These cycles are not exactly 24 hours long, hence the approximation indicated in "circa." Each chemical has its own cycle of highs and lows, interacting with and influencing the other cycles. Body temperature, sleepiness, thyroid function, growth hormone, metabolic processes, adrenal hormones, and

the sleep hormone **melatonin** all cycle with daylight. There is a direct connection between the retina (where light hits the back of the eye) and the part of the brain that controls all these hormones. Artificial light has some effect, but sunlight has much more. Disruption of circadian rhythms affects the sleep-wake cycles of night shift workers as well as travelers.

When people are without clocks in a compartment that is completely closed to sunlight, most of them fall into a circadian cycle of about 25 hours. Typically, all the regulating chemicals follow one another in order like threads in a weaving pattern. Every morning the sunlight resets the cycle, stimulating the leading chemicals and thus compensating for the difference between the 24-hour day and the 25-hour innate rhythm.

When traveling through a number of time zones, most people reset their rhythms within a few days, demonstrating the adaptability of the human body. Some people, however, have upset rhythms that last indefinitely.

Causes and symptoms

Traveling through a few time zones at a time is not as disruptive to circadian rhythms as traveling much greater distances can be. The foremost symptom of jet lag is altered sleep pattern: sleepiness during the day and insomnia during the night. Jet lag may also include **indigestion** and trouble concentrating. Individuals afflicted by jet lag alternate in and out of a normal day-night cycle.

Treatment

Exposure to bright morning sunlight cures jet lag after a few days in most people. A few will have prolonged sleep phase difficulties. For these individuals, there is a curious treatment that has achieved success. By forcing one's self into a 27 hour day, complete with the appropriate stimulation from bright light, all the errant chemical cycles will be able to catch up during one week.

When selecting an international flight, individuals should try to arrange an early evening arrival in their destination city. When people travel to a destination in the east, they can try going to bed and waking up a few hours earlier several days before their flight. If travel is to the west, going to bed and waking up later than usual can help the body start to adjust to the upcoming time change. More specific recommendations are available, tailored to whether individuals are traveling through 6 time zones, 7–9 zones, or 10 or more.

The following precautions taken during an international flight can help to limit or prevent jet lag:

- Stay hydrated. Drink plenty of water and juices to prevent dehydration. Beverages and foods with caffeine should be avoided because of their stimulant properties. Alcohol should also be avoided.
- Stretch and walk. As much movement as possible during a flight helps circulation, which moves nutrients and waste through the body and aids in elimination.
- Stay on time. Set watches and clocks ahead to the time in the destination city to start adjusting to the change.
- Sleep smart. Draw the shade and sleep during the evening hours in the destination city, even if it is still daylight outside the airplane. Earplugs and sleep masks may be helpful in blocking noise and light. Many airlines provide these items on international flights.
- Dress comfortably. Wear or bring comfortable clothes and slippers that will make sleeping during the flight easier.

Upon arrival in the destination city, individuals should spend as much time outdoors in the sunlight as possible during the day to reset their internal clock and lessen the symptoms of jet lag. Bedtime should be postponed until at least 10 p.m., with no daytime naps. If a daytime nap is absolutely necessary, it should be limited to no more than two hours.

To promote a restful sleeping environment in a hotel setting, travelers should request that the hotel desk hold all phone calls. Because sleeping in too late can also prolong jet lag, an early wake up call should be requested if an alarm clock is not available. If the hotel room is noisy, a portable white noise machine can help to block outside traffic and hallway noises. A room air conditioner or fan can serve the same purpose. The temperature in the room should also be adjusted for sleeping comfort.

New information shows that **exercise** at one's destination can also help. When headed westbound, travelers should exercise one hour in the evening. If going eastbound, they do best by exercising in the morning.

All **antioxidants** help to decrease the effects of jet lag. Extra doses of vitamins A, C, and E, as well as **zinc** and **selenium**, two days before and two days after a flight help to alleviate jet lag. Melatonin, a hormone which helps to regulate circadian rhythms, can also aid in combating jet lag. Melatonin is

available as an over-the-counter supplement in most health food stores and pharmacies. Reports show that the drug is safe for short-term use and recommend 5 mg between 10 p.m. and midnight at the destination to help one fall asleep and sleep better.

If weather prevents an individual from spending time in the sunlight, **light therapy** may be beneficial in decreasing jet lag symptoms. Light therapy, or phototherapy, uses a device called a light box, which contains a set of fluorescent or incandescent lights in front of a reflector. Typically, the patient sits for 30 minutes next to a 10,000-lux box (which is about 50 times as bright as an ordinary indoor light). Light therapy is safe for most people, but those with eye diseases should consult a healthcare professional before undergoing the treatment.

Allopathic treatment

In cases of short-term insomnia triggered by jet lag, a physician may recommend sleeping pills or prescription medication. Such medication should be taken only under the guidance of a healthcare professional.

As of 2008, a melatonin agonist known as LY 156735 was being investigated. An agonist is a drug that stimulates activity at cell receptors that are normally stimulated by such naturally occurring substances as melatonin. LY 156735 was found to speed up the re-adaptation time of volunteer subjects following a simulated 9-hour time shift.

Another area of research in the late 2000s involved the genes that encode the proteins governing circadian rhythms. Evidence suggested that differences among individuals in adaptability to time zone changes are to some extent genetically determined. Targeting the genes that affect this adaptability was hoped to yield new treatments for jet lag and other disorders of circadian rhythm.

Expected results

Jet lag usually lasts 24–48 hours after travel has taken place. In that short time period, the body adjusts to the time change, and with enough rest and daytime exposure to sunlight, it returns to normal circadian rhythm.

Prevention

Eating a high-protein diet that is low in calories before intended travel may help reduce the effects of jet lag.

KEY TERMS

Agonist—A medication that has an affinity for and stimulates the activity of cell receptors that are normally stimulated by naturally occurring substances, such as melatonin.

Circadian—Pertaining to biological rhythms occurring at approximately 24-hour intervals. Jet lag is caused by a disruption of the human body's circadian clock.

Hormone—A chemical made in one part of the body that has an effect on another part.

Melatonin—A hormone that helps to regulate circadian rhythms.

Jock itch

Definition

Also known as *tinea cruris*, jock itch is a growth of fungus in the warm, moist area of the groin.

Jock itch. *(© Custom Medical Stock Photo / Alamy)*

KEY TERMS

Bupleurum—An Asian plant used in traditional Chinese and Japanese medicines to treat infected or inflamed skin.

Saikosaponins—Chemical compounds found in bupleurum that have anti-inflammatory effects.

Tinea—A term that refers to any of several fungal infections of the skin, especially ringworm.

Tinea cruris—The medical term for jock itch.

Description

Fungal infections are named for the affected part of the body. *Cruris* is derived from the Latin word for leg, hence *Tinea cruris*, for the fungal rash affecting the area where the leg joins the pelvis. Fungi seem to thrive in dark, moist places. Jock itch has been found most often in males, especially those who wear athletic equipment and are exposed to public showers and locker rooms. It is also thought that some fungal **infections** may be spread by towels that may be inadequately cleansed between gym/spa users, but this has not been clearly documented.

Fungal infections can invade or spread to various other areas of the body, and are named for the affected body part. For example, *Tinea capitis* is a fungal infection of the head, usually resulting in red, itchy areas that destroy the hair in the affected area. A fungal infection of the skin on the arms, legs or chest is called *Tinea corporis*. **Athlete's foot** or *Tinea pedis* is a fungal infection in the moist skin fold between the toes. Fungal infection affecting the toenails is called *Tinea ungium*, and causes thickened, crumbly toenails.

Causes and symptoms

The mode of transmission of fungal infections is not clear, but it seems that some individuals are more prone to development of the infection than others. An average of one in five people develops fungal infection at some point during their lifetime. Fungal infection can also be carried by household pets, such as cats and dogs, or by farm animals. In animals, fungal infection manifests itself as a missing area of fur. In humans, as the fungus grows, it spreads to surrounding tissues in a circular fashion, with the skin in the middle returning to a normal appearance. The borders of the affected area may look red and scaly, and the individual may complain of intense **itching** and/or burning. Because the borders develop a raised appearance, there may appear to be a worm beneath the skin and be referred to as ringworm. There is, however, no worm affecting the skin or underlying tissue in cases of fungal infections, including jock itch.

Diagnosis

Often a case of jock itch can be identified based on the characteristic description previously described. If assessed by a conventional doctor, the area of affected skin may be scraped onto a glass slide for definitive diagnosis under the microscope. In order to determine the exact type of fungus present, a small piece of affected skin may be sent to a laboratory for further study or cultured via scraping.

Treatment

Topical treatments include poultices of **peppermint**, oregano, or **lavender**. **Tea tree oil**, diluted with a carrier oil of almond oil, can be applied to the rash several times per day. Cedarwood and jasmine oils can relieve itching when applied in the same manner. **Grapefruit seed extract** can be taken as a strong solution of 15 drops in 1 oz of water.

Bupleurum, or **Chinese thoroughwax**, is an Asian plant that has been used in **traditional Chinese medicine** and Japanese Kampo formulations to treat jock itch and other fungal skin infections. Bupleurum contains compounds known as saikosaponins, which have anti-allergic and anti-inflammatory effects.

A good remedy for jock itch is to wash the groin area with the diluted juice of a freshly squeezed lemon, which can help dry up the rash. A hair dryer on the cool setting can also be used on the area after showering to dry it thoroughly. A warm bath relieves itching in many patients. The affected area should kept clean and dry, and patients are advised to wear loose-fitting

pure cotton underwear. Fabrics that contain polyester or nylon hold moisture against the body.

Allopathic treatment

Typical conventional treatment for jock itch involves the use of an antifungal cream, spray, or powder twice a day for about two weeks. Two commonly used over-the-counter antifungal preparations are *clotrimazole* (Lotrimin) and *tolnaftate* (Tinactin). While the tendency to discontinue treatment once itching disappears is common, patients should use the antifungal preparation for a full two-week course in order to prevent recurrence of the infection. Doctors recommend continuing the treatment for a full week following clinical clearance of the infection.

Expected results

Most tinea infections resolve without scarring or spread of infection below the skin's surface. Inflammation, however, may require the use of a combination antifungal/steroid medication.

Prevention

Careful attention to skin hygiene, including the maintenance of clean, dry, and intact skin, is the most important step in preventing the development of fungal infection. Light clothing should be worn during warm weather, to decrease perspiration and allow dissipation of body heat. Clean and dry cotton underwear will wick perspiration away from the skin, and prevent jock itch from developing. Use baby powder to keep the area dry during **exercise**. Do not share towels at the gym. Dietary measures discussed under treatment will also prevent initial fungal infection and/or recurrence.

Jojoba oil

Description

Jojoba (pronounced ho-ho-ba) oil is a vegetable oil obtained from the crushed bean of the jojoba shrub (*Simmondsia chinenis*). The jojoba shrub is native to the Sonoran Desert of northwestern Mexico and neighboring regions in Arizona and southern California. It grows in dense stands throughout that region. The woody evergreen shrub may reach 15 ft (4.5 m) in height. Jojoba has flat gray-green leathery leaves and a deep root system that make it well adapted to desert heat and drought. It has a life span of 100–200 years, depending on environmental conditions. Jojoba grows best in areas with 10–18 in (25–45 cm) of annual rainfall where temperatures seldom fall below 25°F (-4°C) for more than a few hours at night. It can grow on many types of soils, including porous rocks, in slightly acid to alkaline soils, and on mountain slopes or in valleys.

Jojoba shrubs are dioecious, meaning plants are either male (staminate), producing pollen, or female (pistillate), producing flowers. The small flowers have no odor or petals and do not attract pollinating insects. The flowers are pollinated by wind in late March; the flowers develop into fruit by August, with full maturation occurring by October. The green fruit dries in the desert heat, its outer skin shriveling and pulling back to expose a wrinkled brown soft-skinned seed (referred to as a nut or bean) the size of a small olive. These nuts, which resemble coffee beans, contain a vegetable oil that is clear and odorless but less oily to the touch than traditional edible oils. The oil comprises half of the weight of the nut. There are about 1,700 seeds in a pound; 17 lb (6.3 kg) of jojoba seeds are required to produce one gallon of oil.

Native Americans have used jojoba for hundreds of years. In the 1700s, Father Junipero Serra, the founder of 21 California missions, noted in his diary

that the Native Americans were using the oil and the seeds for many different purposes: for treating sores, **cuts**, **bruises**, and **burns**; as a diet supplement and as an appetite suppressant when food was not available; as a skin conditioner, for soothing windburn and **sunburn**; as a cooking oil; as a hair or scalp treatment and hair restorative; and as a coffee-like beverage by roasting the seeds.

The chemical structure of jojoba oil is different from that of other vegetable oils. Rather than being an oil, it is actually is a polyunsaturated liquid wax that is similar to sperm whale oil, though without the fishy odor. It is made of fatty acids as well as esters composed entirely of straight chain alcohols. Both the acid and alcohol portions of jojoba oil have 20 or 22 carbon atoms, and each has one unsaturated bond. Waxes of this type are difficult to synthesize. As a wax, jojoba oil is especially useful for applications that require moisture control, protection, and emolliency. Jojoba oil is liquid at room temperature because of its unsaturated fatty acids. It does not oxidize or become rancid and does not break down under high temperatures and pressures. Jojoba oil can be heated to 370°F (188°C) for 96 hours without exhibiting degradation in general composition and carbon chain length. The stability shown by jojoba oil makes it especially useful for cosmetic applications.

When the United States banned the use of sperm whale oil (spermaceti wax) in 1974, the government began to fund efforts to investigate and cultivate jojoba as a replacement. Jojoba oil was found to be an adequate substitute for applications that had previously used sperm whale oil. The first commercial cultivation of jojoba was in the Negev Desert and Dead Sea areas of Israel, but by 1977, domestic cultivation had begun in the United States. In 2000, the International Jojoba Export Council expected the global jojoba production to increase 15% over a five-year period.

General use

Jojoba oil has many uses in a wide variety of industries. As a cosmetic, it is an effective cleanser, conditioner, moisturizer, and softener for the skin and hair. It is applied directly to the skin to soften the skin, to reduce wrinkles and stretch marks, to lighten and help heal scars, and to promote healthy scalp and hair. Jojoba oil is similar to, and miscible with, sebum, which is secreted by human sebaceous glands to lubricate and protect skin and hair. When sebum production decreases due to age, pollutants, or environmental stresses, jojoba oil can be used to replicate sebum oil. Jojoba oil can accumulate around hair roots, thereby conditioning hair and preventing it from becoming brittle and dull. If there is too much sebum buildup on the scalp, it dissolves and removes the sebum, leaving the hair clean. Jojoba oil as a solubilizing agent can also remove sticky buildup on hair from hair preparations as well as airborne particulates deposited on the hair. It forms a lipid layer on the skin, acting as a moisturizer, as well as penetrating and being absorbed by the outer layer of skin. It is widely used as an ingredient in shampoos, conditioners, facial, hand and body lotions, cuticle and nail care products, baby care lotions, creams, and oils, cleansers, moisturizers, bath oils and soaps, sunscreen lotions, and makeup products. Jojoba oil is also used as a base in the manufacture of perfume.

KEY TERMS

Noncomedogenic—A substance that contains nothing that would cause blackheads or pimples to form on the skin. Jojoba oil is noncomedogenic.

The potential therapeutic uses of jojoba oil include the treatment of **acne**, cold sores, and such skin diseases as **psoriasis**.

Jojoba oil is also a registered (licensed for sale) pesticide for use on crops. It is used to control white flies on all crops and powdery mildew on grapes and ornamentals. It is applied as a spray containing 1% or less final concentration of jojoba oil. It acts as a pesticide by forming a physical barrier between an insect pest and the leaf surface. Because of its low toxicity and its rapid degradation in the environment, jojoba oil does not pose a risk to non-target organisms or the environment; though as an oil, it should not be disposed of in lakes or other bodies of water.

Preparations

Jojoba oil is prepared by pressing the jojoba seeds to extract the oil, followed by filtration. It is then pasteurized to ensure product safety. Four grades of jojoba oil are produced: (1) a pure, natural golden grade, a golden-yellow color oil that is produced by the basic production process; (2) refined and bleached jojoba oil, with color removed by bleaching and filtration; (3) a decolorized/deodorized grade, which is used in cosmetics requiring colorless and odorless oils; and (4) a molecular distilled grade, an expensive formulation produced in minimal quantities, with its use having mostly been replaced with decolorized/deodorized jojoba oil.

Precautions

Jojoba oil is a nontoxic, noncomedogenic (does not clog pores), and hypoallergenic substance. It has been widely used for decades in cosmetics, with no reported adverse effects. If jojoba oil is ingested, most of it is eliminated in the feces, with little getting distributed in the body.

Side effects

No side effects are expected with the use of jojoba oil in recommended amounts, although allergic reactions are a rare possibility.

Interactions

Since jojoba oil does not oxidize or become rancid, it is added to other oils to extend their shelf life.

Journal therapy

Definition

Journal therapy is the purposeful and intentional use of a written record of one's own thoughts or feelings to further psychological healing and personal growth. It is often used as an adjunct to many **psychotherapy** and recovery programs. Healthcare practitioners maintain that written expression fills a very important role in the therapeutic process by providing a mechanism of emotional expression in circumstances in which interpersonal expression is not possible or viable.

Origins

People have kept journals and diaries to record dreams, memories, and thoughts since ancient times. Emotional expression has also long held a central role in the study and practice of psychology. Throughout history, psychologists have advocated the expression of emotions as essential for good mental and physical health. Since the early 1980s, interest in this topic has resulted in numerous research studies investigating the health benefits of expressive writing.

KEY TERMS

Art therapy—The use of art media to assess and treat an individual's development, abilities, personality, interests, concerns, or conflicts.

Psychodyamic—The scientific study of mental or conditional forces developing especially in early childhood and their effect on behavior and mental states.

Benefits

Journal writing produces a number of benefits in healthy people—among other things, it enhances creativity, helps cope with **stress**, and provides a written record of memorable life experiences. Likewise, some researchers have found that journal writing has a number of psychological and physical health benefits for people who are ill.

Aside from a reduction in physical symptoms of disease, the psychological benefits include reconciling emotional conflicts, fostering self-awareness, managing behavior, solving problems, reducing **anxiety**, aiding reality orientation, and increasing self-esteem. Writing therapy has been used as an effective treatment for the developmentally, medically, educationally, socially, or psychologically impaired and is practiced in mental health, rehabilitation, medical, educational, and forensic institutions. Populations of all ages, races, and ethnic backgrounds are served by writing therapy in individual, couple, family, and group therapy formats.

The therapeutic use of expressive writing allows individuals to confront upsetting topics, thus alleviating the constraints or inhibitions associated with not talking about the event. The psychological drain of the inhibition is believed to cause and/or exacerbate stress-related disease processes. Researchers have found that emotional expression facilitates cognitive processing of the traumatic memory, which leads to emotional and physiological change. Specifically, written emotional expression promotes integration and understanding of the event while reducing negative emotions associated with it.

Description

Journal writing and other forms of writing therapy are based on the premise that the mind and the body are inseparably joined in the healing process. Although there are many methods of conducting

journal writing therapy depending on the therapeutic technique of the psychologist or psychiatrist, the therapist often instructs the participant to write about a distressing or traumatic event or thought in one or more sessions.

Although researchers are uncertain about exactly how writing about traumas produces improvements in psychological well-being, traumatic stress researchers have pointed out that ordinary memories are qualitatively different from traumatic memories. Traumatic memories are more emotional and perceptual in nature. The memory is stored as a sensory perception, obsessional thought, or behavioral reenactment. It is associated with persistent, intrusive, and distressing symptoms, avoidance, and intense anxiety that results in observed psychological and biological dysfunction. Thus, one goal in treating traumatic memories is to find a means of processing them.

A narrative that becomes more focused and coherent over a number of writing sessions is often associated with increased improvement, according to several research studies. The memories become deconditioned and restructured into a personal, integrated narrative. Changes in psychological well-being after writing therapy may result from cognitive shifts about the trauma either during or after the writing process.

Preparations

In a health care setting, the participant often prepares for journal writing by receiving (from the therapist) a set of instructions regarding the length and focus of the writing session or sessions. Other instructions may include writing in a stream-of-consciousness fashion, without censorship or concern about grammar or style.

Precautions

It is advisable that journal therapy be conducted only by a licensed health professional, such as a certified **art therapy** practitioner or trained psychologist or psychiatrist. While journal writing classes available to the general public may perform a variety of useful functions, these classes are not intended to provide medical therapy. In journal therapy, the participant may, for example, uncover potentially traumatic, repressed, or painful memories. Therefore, a trained health professional may be necessary to supervise the process and treat these symptoms as they arise.

Side effects

There are no known side effects of journal or writing therapy.

Research and general acceptance

Therapeutic writing became an increasingly popular topic in the final decades of the twentieth century, not only among trained health care professionals, but also among self-improvement speakers without medical training. Seminars, workshops, and Internet sites purportedly offering therapy though expressive writing sprang up around the nation and gained popular acceptance. Despite the large body of research indicating that writing confers benefits on healthy people, the topic of writing therapy's affects on diseased individuals has not received a great deal of research attention. Although increasingly used by health care professionals as an adjunct to various therapeutic approaches, the practice has been criticized by some members of the health care community. Some researchers are distrustful of the findings that so much measurable improvement in health status can occur in just a few brief writing sessions.

In the United Kingdom, the focus of journal therapy has been on descriptive accounts and psychodynamic explanations for subjective improvements in the health status of participants. In the United States, on the other hand, the focus is on formal scientific research aimed at validating the impact of brief, highly standardized writing exercises on physical measures of illness. The research demonstrates that although physical measures of illness may change, the reasons for the change are not always clear.

In the United States, one study on the effects of writing about stressful experiences on symptom reduction in patients with **asthma** or **rheumatoid arthritis** found that after four months of writing therapy—in conjunction with standard pharmacotherapy—nearly half the patients enrolled in the study experienced clinically relevant improvement. A growing number of studies have documented symptom improvement in patients with psychiatric disorders as well, suggesting that addressing patients' psychological needs produces both psychological and physical health benefits.

Training and certification

Although journal therapy is often provided by certified instructors who receive variable amounts of training in a number of programs around the country, journal therapy is best administered by a licensed psychologist (who may also be an art therapist) or psychiatrist.

Educational, professional, and ethical standards for art therapists who conduct writing therapy are regulated by The American Art Therapy Association, Inc. The American Art Therapy Credentials Board,

Inc., an independent organization, grants postgraduate supervised experience. A registered art therapist who successfully completes the written examination administered by the Art Therapy Credentials Board qualifies as Board Certified (ATR-BC), a credential requiring maintenance through continuing education credits.

Juice therapies

Definition

Juice therapy involves the consumption of the juice of raw fruit or vegetables. A person may drink juice preventively to stay healthy, to treat a medical condition such as **cancer**, or to produce a certain outcome, such as strengthening the immune system. Three widely practiced juice therapies differ primarily in the amount of time that a person is involved in the therapy and whether other items are included in the person's diet.

Vitamins and minerals found in juices

Type of juice	Vitamins and minerals
Apple	Chromium, selenium, vitamin C
Asparagus	Folic acid, potassium, vitamins A, B_6, C, and K
Bok choy	Calcium
Broccoli	Folic acid, phosphorus, potassium, vitamins A, B_6, C, E, and K
Brussel sprouts	Folic acid, potassium, thiamine, vitamins B_6, C, and K
Cabbage	Calcium, chromium, manganese, vitamins B_6 and C
Cantaloupe	Beta-carotene, potassium, vitamin C
Carrots	Beta-carotene, zinc
Celery	Potassium, vitamins B_1, B_2, B_6, and C
Citrus fruits	Vitamin C
Collard greens	Calcium, vitamin K
Garlic	Manganese, selenium, vitamin B_6
Ginger	Zinc
Green peas	Zinc
Kale	Calcium, folic acid, vitamins B_6 and K
Orange	Folic acid, potassium, vitamin C
Papaya	Beta-carotene, vitamin A, C, and E
Peppers	Vitamin C
Spinach	Vitamins B_6 and E
Sweet peppers	Chromium
Tomatoes	Carotenes (especially lycopene), folic acid, niacin, vitamins C and K
Turnip	Calcium, copper, folic acid, manganese selenium, vitamin C
Turnip greens	Calcium, folic acid, manganese, vitamins B_6, C, and E

*Selenium amounts in plant foods vary greatly depending on the amount in the soil in which the plants are grown.

(Illustration by Corey Light. Cengage Learning, Gale)

For some people, adding fresh juice to their daily meal plan is sufficient. Others will embark on a juice fast for several days to cleanse their systems. Juice is also a major component of the so-called **Gerson therapy** diet that is used to treat cancer. This therapy usually starts with a stay of three to eight weeks in a clinic. Then therapy continues at home and may continue for years.

Origins

Fasting and juice consumption

The two components of most juice therapies, **fasting** and juice consumption, date back thousands of years. Fasting is a long-standing religious tradition described in the Bible and other ancient writings. The medicinal use of juice can be traced back thousands of years to India. Proponents of **Ayurvedic medicine**, a healing system, believed that drinking juice strengthens body tissues.

In the centuries that followed, people continued to recognize that eating fruit and vegetables produced health benefits. Much folklore and many sayings developed around the benefits of fruits and vegetables. Carrots were said to improve eyesight; and according to the adage, "An apple a day keeps the doctor away." During the twentieth century, fruit and vegetables became important components of healing therapy.

Gerson juice diet

During the 1940s, a German doctor, Max B. Gerson, developed a therapy using juice to treat his migraine headaches. He developed the therapy further and recommended it to people diagnosed with migraines, arthritis, **tuberculosis**, and cancer. His diet was based on the theory that excess **sodium** in a person's system disrupts the immune system and the functions of the liver, pancreas, and thyroid gland. Gerson developed a low-salt organic diet that focused on raw vegetable and fruit juices. The diet included nutritional supplements and coffee enemas, which he claimed, detoxified the liver and relieved **pain**. Since the therapy worked for Gerson, he recommended it to patients.

Advocates of juice therapies maintain that refraining from eating solid food boosts the body's ability to heal itself. Since the body is not spending time and energy on digesting complex high-fat food, it can concentrate on healing instead. Advocates also believe that all-juice **diets** can help the body eliminate toxins (poisons). This reasoning is typically the basis put forth in support of juice fasts.

Juicing

Another form of juice therapy known as juicing involves extracting the juice from raw fruit and vegetables. From the 1970s on, people like "Juiceman" Jay Kordich popularized the concept of drinking fresh juice to boost energy, lose weight, and achieve other health benefits. Kordich provided recipes and sold juice extractors that are also known as "juicers."

Kordich toured the country and talked about juice ingredients that seemed exotic to a public used to tomato juice and orange juice. He presented suggestions for new juice combinations, such as juiced potato, apple, carrot, and **parsley**. Kordich even provided various recipes that were aimed at producing specific results, such as weight loss or increased vitality. Through his infomercials and presentations, as well as those of other people who followed in his footsteps, the public became much more conscious of juice and its potential health benefits. One outgrowth of the interest in juices has been the establishment of chain stores such as Jamba Juice that sell primarily juice drinks.

Benefits

Research has shown that a diet rich in fresh fruits and vegetables reduces the risk of such chronic diseases such as **heart disease** and diabetes. This diet is also believed to reduce the risk of developing cancer. Furthermore, raw vegetables and fruit contain vitamins, food enzymes, minerals, **amino acids**, and natural sugars. Some of those nutrients are altered or lost in commercial juices sold in stores because, with few exceptions, these juices must be pasteurized (heat treated) to prevent spoilage. According to juice therapy advocates, however, the benefits of fresh juices extend beyond their nutritional content.

Proponents of juice therapies continue to study its benefits. In 2002, a physician reported to the American College of Cardiology that two cups of orange juice daily significantly lowered the blood pressure of hypertensive patients. A British study in the same year verified the positive effects of **cranberry** juice on urinary tract **infections**.

Juice is used in Ayurvedic treatment for such conditions as arthritis, **anemia**, and **constipation**. Juice is also a component of naturopathy, which is also known as the "whole body cure." A naturopathic doctor may prescribe a juice fast as part of treatment for arthritis, cancer, or **AIDS**. Supporters of juice fasting believe that the process releases a hormone that helps the body fight disease so that a juice fast strengthens the immune system. The fast also allows the naturopathic

physician to identify food sensitivities (allergens) as the patient begins eating food.

Juice fasting is also a part of **detoxification** therapy. It is part of the Gerson diet, a cancer therapy said to eliminate the build-up of toxins in the body by stimulating enzymes, improving the digestive system, and providing the correct balance of vitamins and minerals.

Description

Juice therapy can be as simple as extracting the juice from raw produce or as complicated as the Gerson diet. The therapies vary in the amount of commitment involved and the cost. Whether a therapy is covered by medical insurance will depend on the health plan. The costs of juicing or fasting at home are generally not covered. A juice fast administered as part of another treatment by a doctor or other health care provider might be covered. For Gerson therapy, some companies pay for part or all of the costs, according to the Gerson Institute Web site. Individuals interested in therapeutic juice fasting as part of treatment for a specific disease should check with their insurance company about coverage.

Gerson therapy

The Gerson therapy treatment was originally administered at a Gerson therapy clinic. Today, the institute does not operate facilities; instead since 1999, it has licensed such facilities as the Oasis of Hope Hospital in Tijuana, Mexico. The Gerson therapy treatment is based on drinking freshly pressed vegetable and fruit juice every hour. During a typical day at a Gerson clinic, a person would drink 13 glasses of raw carrot/apple and green-leaf vegetable juices. Vegetarian meals of organically grown food are served. During treatment, the patient receives coffee enemas during the evening to detoxify the blood and tissues. A stay at the Oasis of Hope is quite expensive and may not be covered by medical insurance.

Fasting

A juice fast can be undertaken at home with no professional guidance or under the direction of an alternative medicine practitioner such as a naturopathic doctor. The fast could also be part of the program at a retreat center.

Another juice therapy option is a short-term cleansing diet lasting two to three days. One popular fast involves consumption of fruit and vegetable juice for several days. In some plans, herbal tea and broth are allowed. Another variation is the raw food diet, which involves eating uncooked fruit and vegetables. Advocates claim the diet is useful in treating such conditions as heart disease and arthritis.

Juicing

Juicing involves the extraction of juice from raw fruit or vegetables. An extractor, fresh produce, and a commitment of time to juice the items are required. A blender is not strong enough to juice produce. Juice extractors are priced from about $120–$2,000. Juice should be consumed as soon as possible after extraction. When it is stored, juice loses some of its nutritional value.

BENEFICIAL JUICES. While most people know that orange juice is rich in **vitamin C**, the juices of other produce are believed to provide other health benefits. The wide selection of juices offers benefits that include the following:

- An 8-oz (240 ml) glass of carrot juice contains more than 10 times the recommended daily allowance of vitamin C.
- Fresh fruit and vegetable juices, including wheatgrass juice, are consumed for ulcers. Ulcer remedies include raw potato juice for peptic ulcers. For a duodenal ulcer, raw cabbage juice can be mixed with carrot and celery juice.
- Cranberries help prevent and treat urinary infections.
- Beet juice can be diluted to stimulate the liver.
- Garlic lowers the blood pressure and cholesterol.
- Cantaloupe juice can be consumed for stress.

Preparations

Individuals should consult a doctor or nutritionist before beginning a fast or treatment such as Gerson therapy. The medical professional can determine whether it is safe for the individual to undertake the fast, and recommend duration for the fast. The individual should also discuss with his or her healthcare provider any warning signs that indicate health problems are developing from the therapy. Prolonged fasting can be dangerous and knowing the signs of a possible problem can help prevent serious health consequences.

Precautions

Some precautions should be taken with each form of juice therapy. Juicing removes much of the necessary dietary fiber found in fruits and vegetables. Since an adult diet should contain 20–25 g of fiber per day, a person relying heavily on juice should find other sources of dietary fiber. Another caution is that carrot

greens, rhubarb greens, and apple seeds can be toxic and should not be juiced.

Some health professionals advise against fasting, a process they say can produce weakness, **fatigue**, anemia, and other conditions. Other health professionals believe that fasts are safe, but should not be undertaken by pregnant women, people who are diabetic, and those who have ulcers or a heart condition. In some cases, the doctor or practitioner may advise a supervised fast.

Another potential problem with juicing fresh fruit and some vegetables is that it can lead to the intake of considerable amounts of sugar. In some people, the sugar produces a quick rush of energy followed by a "crash." Although drinking juice can help individuals ensure that they get the recommended amounts of fruit and vegetables each day, consuming large amounts of fruit juice can lead to excessive sugar intake which can cause weight gain and increase the risk of type 2 diabetes.

Critics of the Gerson diet say that it has many dangerous side effects, including dehydration, electrolyte imbalance, constipation, infection, poor resistance to disease, excessive weight loss, inflammation of the colon, and in some cases even death. A person diagnosed with cancer should never undertake Gerson therapy instead of conventional cancer treatments such as chemotherapy. As of 2008, there were only two licensed Gerson centers in the world, 10-bed center in Tijuana, Mexico and a 3-bed center in California.

Side effects

The side effects of fasting can include weight loss, mental confusion, fatigue, electrolyte imbalance, constipation, **diarrhea**, and dehydration.

In Gerson therapy, diarrhea and **nausea** are considered part of the healing process. During the treatment, a person may experience flu-like symptoms, loss of appetite, weakness, and **dizziness**. Other side effects may include **feverblisters**, perspiration and **body odor**, intestinal cramping, and a painful feeling in tumors.

Research and general acceptance

The Gerson diet is highly controversial. Individuals who are proponents of the therapy have come forward with some studies they claim to be proof of its effectiveness. Members of the medical community have criticized these studies, however, for involving too few subjects, not being reproducible, and other methodological problems. According to the American Cancer Society, available scientific evidence does not support the health claims made by Gerson therapy practitioners. The Gerson diet is classified by the National Cancer Institute as not medically proven and potentially unsafe.

Both alternative and traditional medical practitioners accept the benefits of eating a diet that includes a wide variety of many different fruits and vegetables. Juicing, as part of a balanced, healthy diet, can be an excellent way for individuals to include fruits and vegetables in their diet. Juice fasts, however, especially those of long duration, are not widely accepted as beneficial, and many medical professionals warn against their potential dangers.

KEY TERMS

Ayurvedic medicine—A 5,000-year old system of holistic medicine developed on the Indian subcontinent. Ayurvedic medicine is based on the idea that illness results from a personal imbalance or lack of physical, spiritual, social, or mental harmony.

Training and certification

Although there is no official training in juice therapy as such, those who administer it may have training and certification in other disciplines. A naturopathic doctor or medical doctors will have medical training. Individuals staffing the Gerson Clinics have been trained in Gerson therapy. A trained nutritionist or dietitian may recommend juicing as a way to include more fruits and staffers at Gerson Clinics have been trained in that therapy.

KEY TERMS

Diuretic—A substance that promotes urination.

Infusion—An herbal tea created by steeping herbs in hot water. Generally, leaves and flowers are used in infusions.

Sitz bath—A bath in which only the hips and buttocks are soaked.

Stomachic—A substance that increases the appetite.

Juniper

Description

Juniper (*Juniperus communis*) is an evergreen shrub found on mountains and heaths throughout Europe, Southwest Asia, and North America. The tree grows to a height of 6-25 ft (2-8 m) and has stiff, pointed needles that grow to 0.4 in (1 cm) long. The female bears cones that produce small, round, bluish black berries, which take three years to fully mature.

Juniper belongs to the pine family (Cupressaceae). Juniper has diuretic, antiseptic, stomachic, antimicrobial, anti-inflammatory, and antirheumatic properties. The tree's therapeutic properties stem from a volatile oil found in the berries. This oil contains terpenes, flavonoid glycosides, tannins, sugar, tar, and resin. Terpinen-4-ol (a diuretic compound of the oil) stimulates the kidneys, increasing their filtration rate. The flavonoid amentoflavone exhibits antiviral properties. Test tube studies show that another constituent of juniper, desoxypodophyllotoxins, may act to inhibit the herpes simplex virus. The resins and tars contained in the oil benefit skin conditions such as **psoriasis**.

For more than 300 years, juniper berries have been a popular flavoring agent for gin. The word gin comes from the Dutch word for juniper, "geniver." In addition to being an ingredient in alcohol, juniper also has medicinal properties. Ancient Egyptian doctors used the oil as a laxative as far back as 1550 B.C. The Zuni Native American people used the berries to assist them in **childbirth**. Other Native Americans gathered juniper berries and leaves to treat **infections**, arthritis, and **wounds**. British herbalists used juniper to promote **menstruation**. Nineteenth-century American herbalists used juniper as a remedy for congestive heart failure, **gonorrhea**, and urinary tract infections.

Juniper has also been used as a traditional remedy for **cancer**, arthritis, **gas**, **indigestion**, **warts**, **bronchitis**, **tuberculosis**, **gallstones**, **colic**, heart failure, intestinal disease, **gout**, and back **pain**. The berries were often eaten to relieve rheumatism or to freshen bad breath. When treating patients, doctors often chewed juniper berries to prevent infection.

General use

Modern herbalists prescribe juniper to treat bladder infections, kidney disease, chronic arthritis, gout, rheumatic conditions, fluid retention, cystitis, skin conditions, inflammation, digestive problems, menstrual irregularities, and high blood pressure. The German Commission E has approved juniper berries for use in treating **heartburn** and dyspepsia (indigestion), belching, and other digestive disturbances.

Juniper is a powerful diuretic. The volatile oil contained in juniper is composed of compounds that stimulate the kidneys to remove fluid and bacterial waste products from the body. This is useful in conditions such as congestive heart failure, urinary infections, and kidney disease.

The oil also has antiseptic properties, which makes it a useful disinfectant treatment for urinary and bladder infections. The German Commission E reported that juniper caused an increase in urine flow

and smooth muscle contractions. Juniper may be combined with other herbs such as **uva ursi**, **parsley**, cleavers, or **buchu** to treat bladder infections. In fact, juniper may help treat bladder infections more effectively when combined with other herbs.

Juniper's anti-inflammatory properties help to relieve the inflammation, stiffness, and pain that are present in conditions like arthritis, rheumatism, and gout. The berries can be made into an ointment and rubbed on the affected joints and muscles. The tree needles may be crushed and added to a bath to ease aching muscles. Some people may find relief from the nerve, muscle, joint, and tendon pains of gout and **rheumatoid arthritis** by applying a compress made from an infusion of juniper berries.

Juniper is also warming to the digestive system and increases the production of stomach acid, stimulates the appetite, settles the stomach, and relieves gas.

A steam distillation process is used to extract the essential oil of juniper from the ripe, dried berries. This aromatic oil has a light, fruity fragrance that is psychologically uplifting during periods of low energy, **anxiety**, and general weakness. Applied topically, essential oil of juniper has a warming effect on the skin and helps to promote the removal of fluid and waste products from tissues. External applications also help relieve sore muscles, joint and lower back pain, and can be used to clear up **acne**, **eczema**, and **varicose veins**. To stimulate menstruation, juniper oil can be added to a carrier oil and used in a sitz bath or massage. Steam inhalation of the essential oil may also help relieve coughs and lung conditions such as bronchitis.

Consumers should use juniper oil sparingly and should not use more than the recommended dose. Six or more drops of juniper oil can have a toxic effect. Any **aromatherapy** essential oil should be diluted in a carrier oil such as almond or grapeseed oil before external use.

Preparations

The ripe, mature berries and needles from the tree are used in herbal medicine. Juniper is available in bulk form as whole berries, or as a supplement in the form of capsules or tinctures.

The recommended tincture dosage is 10-20 drops four times daily.

Teas are often taken to relieve digestive problems. To make a tea, 1 cup of boiling water is poured over 1 tablespoon of juniper berries. The mixture is covered and steeped for 10-20 minutes. One cup can be drunk two times daily. The tea should not be used for longer than two weeks at a time. A clean cloth may be soaked in the cooled mixture to create a compress.

Precautions

Juniper should be used only for short periods of time. High doses or prolonged use of juniper may irritate the kidneys and urinary tract, causing damage. People with kidney problems should not use this herb.

Juniper stimulates contractions of the womb. Pregnant women should not use juniper. Breastfeeding women also should not use juniper.

Juniper may increase blood sugar levels in diabetics. Therefore, diabetics should consult with their doctor before using juniper.

When taking juniper for a **bladder infection**, consumers should see their doctor if the infection is still present after several days of use, or if lower back pain, **fever**, or **chills** develop.

Side effects

External application of juniper oil may cause a skin rash.

People with **allergies** may experience allergy symptoms such as nasal congestion.

Side effects of juniper overdose include **diarrhea**, purplish urine, blood in the urine, kidney pain, intestinal pain, elevated blood pressure, and a quickened heartbeat. If these effects occur, consumers should stop taking juniper and call their doctor immediately.

Interactions

Consumers should use juniper cautiously with other diuretic drugs or substances because excessive fluid loss may occur.

Juvenile rheumatoid arthritis

Definition

Juvenile **rheumatoid arthritis** (JRA) includes a number of different conditions, all of which affect children and all of which have immune-mediated joint inflammation as their major manifestation. JRA is also known as juvenile idiopathic arthritis or JIA. The European League Against Rheumatism (EULAR) refers to the disorder as juvenile chronic arthritis (JCA).

Description

The skeletal system of the body is made up of different types of strong, fibrous material known as connective tissue. Bone, cartilage, ligaments, and tendons are all forms of connective tissue that have different compositions and different characteristics.

The joints are structures that hold two or more bones together. Some joints (synovial joints) allow for movement between the bones being joined (articulating bones). The simplest model of a synovial joint involves two bones, separated by a slight gap called the joint cavity. The ends of each articular bone are covered by a layer of cartilage. Both the articular bones and the joint cavity are surrounded by a tough tissue called the articular capsule. The articular capsule has two components: the fibrous membrane on the outside, and the synovial membrane (or synovium) on the inside. The fibrous membrane may include tough bands of fibrous tissue called ligaments, which are responsible for providing support to the joints. The synovial membrane has special cells and many capillaries (tiny blood vessels). This membrane produces a supply of synovial fluid that fills the joint cavity, lubricates it, and helps the articular bones move smoothly about the joint.

In JRA, the synovial membrane becomes intensely inflamed. Usually thin and delicate, the synovium becomes thick and stiff, with numerous infoldings on its surface. The membrane becomes invaded by white blood cells, which produce a variety of destructive chemicals. The cartilage along the articular surfaces of the bones may be attacked and destroyed, and the bone, articular capsule, and ligaments may begin to be worn away (eroded). These processes severely interfere with movement in the joint.

JRA specifically refers to chronic arthritic conditions that affect a child under the age of 16 years and that last for a minimum of three to six months. JRA is often characterized by a waxing and waning course, with flares separated by periods of without noted symptoms (remission). Some literature refers to JRA as juvenile rheumatoid arthritis, although most types of JRA differ significantly from the adult disease called rheumatoid arthritis, in terms of symptoms, progression, and prognosis.

Demographics

JRA is the most common chronic inflammatory disease in children, affecting about 50,000 children in the United States.

Causes and symptoms

A number of different causes have been sought to explain the onset of JRA. There appears to be a genetic link; the tendency to develop JRA sometimes runs in particular families, and certain genetic markers are more frequently found in patients with JRA and other related diseases. Research has shown that several autoimmune diseases, including JRA, share a common genetic link. In other words, patients with JRA might share common genes with family members who have other autoimmune diseases such as rheumatoid arthritis, systemic lupus, **multiple sclerosis**, and others.

Many researchers have looked for some infectious cause for JRA, but no clear connection to a particular organism has ever been made. JRA is considered by some to be an autoimmune disorder. Autoimmune disorders occur when the body's immune system mistakenly identifies the body's own tissue as foreign and attacks those tissues, as if trying to rid the body of an invader (such as a bacteria, virus, or fungi). While an autoimmune mechanism is strongly suspected, certain markers of such a mechanism (such as rheumatoid factor, often present in adults with such disorders) are rarely present in children with JRA.

Joint symptoms of arthritis may include stiffness, **pain**, redness, warmth of the joint, and swelling. Bone in the area of an affected joint may grow too quickly or too slowly resulting in limbs that are of different lengths. When the child tries to avoid moving a painful joint, the muscle may begin to shorten from disuse, which is called a contracture.

Symptoms of JRA depend on the particular subtype. According to criteria published by the American College of Rheumatology (ACR) in 1973 and modified in 1977, JRA is classified by the symptoms that appear within the first six months of the disorder:

- Pauciarticular JRA: The most common and the least severe type of JRA, affecting about 40–60% of all JRA patients, pauciarticular JRA affects fewer than four joints, usually the knee, ankle, wrist, and/or elbow. Other more general (systemic) symptoms are usually absent, and the child's growth usually remains normal. Very few children (less than 15%) with pauciarticular JRA end up with deformed joints. Some children with this form of JRA experience painless swelling of the joint. Others have a serious inflammation of structures within the eye, which if left undiagnosed and untreated could lead to blindness. This condition, known as uveitis, affects about 20% of children diagnosed with JRA. While many children have cycles of flares and remissions, in some children the disease completely and permanently resolves within a few years of diagnosis.
- Polyarticular JRA: About 50% of all cases of JRA are of this type. Polyarticular JRA is most common in children up to age three or after the age of 10 and affects girls more often than boys. Polyarticular JRA affects five or more joints simultaneously. This type of JRA usually affects the small joints of both hands and both feet, although other large joints may be affected as well. Some patients with arthritis in their knees experience a different rate of growth in each leg. Ultimately, one leg grows longer than the other. About half of all patients with polyarticular JRA have arthritis of the spine and/or hip. Others with polyarticular JRA have other symptoms of a systemic illness, including anemia (low red blood cell count), decreased growth rate, low appetite, low-grade fever, and a slight rash. The disease is most severe in those children who are diagnosed in early adolescence. Some of these children test positive for rheumatoid factor (RF), a marker present in other autoimmune disorders. RF is found in adults who have rheumatoid arthritis. Children who are positive for RF tend to have a more severe course, with a disabling form of arthritis that destroys and deforms the joints. This type of arthritis is thought to be the adult form of rheumatoid arthritis occurring at a very early age.
- Systemic onset JRA: Sometimes called Still's disease (after a physician who originally described it), this type of JRA occurs in about 10% of children with arthritis. Boys and girls are equally affected, and diagnosis is usually made between the ages of five and 10. The initial symptoms are not usually related to the joints. Instead, these children have high fevers; a rash; decreased appetite and weight loss; severe joint and muscle pain; swollen lymph nodes, spleen, and liver; and serious anemia. Some children experience other complications, including inflammation of the sac containing the heart (pericarditis), inflammation of the tissue lining the chest cavity and lungs (pleuritis), and inflammation of the heart muscle (myocarditis). The eye inflammation often seen in pauciarticular JRA is uncommon in systemic onset JRA. Symptoms of actual arthritis begin later in the course of systemic onset JRA, and they often involve the wrists and ankles. Many of these children continue to have periodic flares of fever and systemic symptoms throughout childhood. Some children go on to develop a polyarticular type of JRA.
- Spondyloarthropathy: This type of JRA most commonly affects boys aged eight years and older. The arthritis occurs in the knees and ankles, moving over time to include the hips and lower spine. Inflammation of the eye may occur occasionally but usually resolves without permanent damage.
- Psoriatic JRA: This type of arthritis usually shows up in fewer than four joints but goes on to include multiple joints (appearing similar to polyarticular JRA). Hips, back, fingers, and toes are frequently affected. A skin condition called psoriasis accompanies this type of arthritis. Children with this type of JRA often have pits or ridges in their fingernails. The arthritis usually progresses to become a serious, disabling problem.

Diagnosis

Diagnosis of JRA is often made on the basis of the child's collection of symptoms. Laboratory tests often show normal results. Some nonspecific indicators of inflammation may be elevated, including white blood cell count, erythrocyte sedimentation rate, and a marker called C-reactive protein. As with any chronic disease, **anemia** may be noted. Children with an extraordinarily early onset of the adult type of rheumatoid arthritis have a positive test for rheumatoid factor.

Treatment

Range-of-motion and muscle-strengthening exercises are among the best natural therapies for JRA. Research has shown that **exercise** can decrease inflammatory agents while increasing anti-inflammatory compounds in the body, thereby improving immune function. However, physical activity can be challenging when patients are experiencing symptoms of pain. Physical or occupational therapists can provide supervised exercises to teach proper technique, and these exercises should be practiced as recommended at home.

To reduce morning stiffness, the child can take a hot bath or shower or apply a heating pad.

Diet is also believed to play a role in treating JRA. A number of autoimmune disorders, including JRA, seem to have a relationship to food **allergies**. Patients may experience symptom relief after identifying and eliminating food allergens from the diet, which can trigger inflammation. Following a diet low in saturated fats may also help reduce the inflammatory response, which can be increased by a diet high in saturated fats. A strict vegetarian diet low in fats and free of glutens may also be helpful. Including foods rich in **calcium** and **vitamin D** is also important to build bone mass and reduce the risk of **fractures**.

Massage has been shown to benefit children with JRA by reducing **anxiety** and **stress**, reducing pain, and reducing morning stiffness.

Alternative treatments that have been suggested for arthritis include juice therapy, which can work to detoxify the body, helping to reduce JRA symptoms. Some recommended fruits and vegetables are carrots, celery, cabbage, potatoes, cherries, lemons, beets, cucumbers, radishes, and **garlic**. Tomatoes and other vegetables in the nightshade family (potatoes, eggplant, and red and green peppers) are discouraged. As an adjunct therapy, **aromatherapy** preparations include cypress, **fennel**, and lemon. Massage oils include **rosemary**, benzoin, **chamomile**, camphor, **juniper**, **eucalyptus**, and **lavender**. Other types of therapy that have been used are **acupuncture**, **acupressure**, and body work.

Also shown to be effective in some cases are the **essential fatty acids**: **omega-3 fatty acids** in **fish oil**, and the omega-6 fatty acid gamma liolenic acid (GLA) found in **borage oil**, current seed oil, and **evening primrose oil**. Several alternative medicine doctors suggest there may be some benefit in taking **cartilage supplements**, although no definitive studies had been done as of 2008 on this treatment. Anti-inflammatory spices such as **turmeric**, **ginger**, and **cayenne** may be helpful. Natural remedies such as **yucca**, **burdock root**, **horsetail**, **devil's claw**, sarsaparilla, and **white willow** bark also can be helpful since they have anti-inflammatory and analgesic properties.

Nutritional supplements that may be beneficial include large amounts of **antioxidants** (vitamins C, A, E, **zinc**, **selenium**, and flavonoids), as well as B vitamins and a full complement of minerals (including **boron**, **copper**, **manganese**). One study showed 1,800 International Units (IU) of **vitamin E** a day could be helpful in relieving symptoms. Other nutrients that assist in detoxifying the body, including **methionine**, cysteine, and other **amino acids**, may also be helpful. Constitutional **homeopathy** can also work to quiet the symptoms of JRA and bring about balance to the whole person.

Allopathic treatment

Treating JRA involves efforts to decrease the amount of inflammation, in order to preserve movement. Nonsteroidal anti-inflammatory agents (such as ibuprofen, naproxen, diclofenac, and celecoxib) are usually the first line of treatment for JRA to reduce inflammation. Analgesics, including acetaminophen and tramadol, may provide pain relief but do not reduce inflammation. Patients should ask their doctor about using analgesics in combination with their other arthritis medications. Steroid medications are effective but have many serious side effects with long-term use. Injections of steroids into an affected joint can be helpful. Steroid eye drops are used to treat eye inflammation. Drugs that act on the immune system may be added when NSAID monotherapy is not effective in treating symptoms. These include: methotrexate (Rheumatrex), azathioprine (Imuran), leflunomide (Arava), cyclosporine (Sandimmune), sulfasalazine (Azulfidine), and hydroxychloroquine (Plaquenil). Glucocorticoids are stronger medications that may be used in select cases of JRA in low doses for short-term treatment.

Tumor necrosis factor (TNF) antagonists represent a newer class of biologic drugs used to treat JRA. These drugs include etanercept (Enbrel); infliximab (Remicade), which is usually given with methotrexate; and adalimumab (Humira), a drug in this class approved by the U.S. Food and Drug Administration in February 2008. These drugs ease joint pain, reduce swelling, and improve mobility and may be associated with less severe side effects than other medications.

Physical therapy and exercises are often recommended in order to improve joint mobility and strengthen supporting muscles. Occasionally, splints are used to rest painful joints and to prevent or improve deformities.

Research has confirmed that the blood serum of patients with JRA contained elevated levels of interleukin-6, a cytokine (nonantibody protein) that is critical to regulation of the immune system and blood cell formation. Because interleukin-6 is also associated with inflammation, researchers have suggested that compounds inhibiting the formation of interleukin-6 may provide new treatment options for JRA.

Expected results

Treatment and continued physical activity can prevent loss of function, provide pain relief, and maintain joint mobility. Most children with JRA can attend

KEY TERMS

Autoimmune disorder—A condition marked by an overactive immune system; the body's immune system mistakenly identifies the body's own tissue as foreign and attacks those tissues, as if trying to rid the body of an invader.

Rheumatoid factor—An antibody found in approximately 80% of patients with adult onset rheumatoid arthritis. When RF is identified in children with juvenile rheumatoid arthritis, there is an increased risk of joint damage, and the child may require more aggressive treatments.

Synovial membrane—A layer of connective tissue that lines the insides of joints, tendon sheaths, and bursae. The synovial membrane produces synovial fluid, which has a lubricating function.

Tumor necrosis factor (TNF) antagonist—A substance that blocks the action of TNF, a naturally occurring protein in the body that helps cause inflammation.

a regular school and benefit from being with children of the same age. Special school accommodations may be available for children with JRA under Federal Act 504 of the Rehabilitation Act of 1973, which bans discrimination against disabled persons in programs that receive federal funds.

The prognosis for pauciarticular JRA is quite good, as is the prognosis for spondyloarthropathy. Polyarticular JRA carries a slightly worse prognosis. RF-positive polyarticular JRA carries a difficult prognosis, often with progressive, destructive arthritis and joint deformities. Systemic onset JRA has a variable prognosis, depending on the organ systems affected, and the progression to polyarticular JRA. About 1 to 5% of all JRA patients die of such complications as infection, inflammation of the heart, or kidney disease.

Prevention

Little is known about the causes of JRA; therefore, there are no recommendations available for how to avoid developing it.

K

Kali bichromium

Description

Kali bichromium is a bright orange, caustic, corrosive compound used in the manufacture of dye, photography, and batteries. It is also used as a homeopathic remedy. In **homeopathy**, **potassium** bichromate is diluted to the point where it no longer retains any poisonous or caustic qualities. Homeopaths usually abbreviate kali bichromium as kali bich. or as kali bi.

General use

Homeopathic medicine operates on the principle that "like heals like." This means that a disease can be cured by treating it with products that produce the same symptoms as the disease. These products follow another homeopathic law, the Law of Infinitesimals. In opposition to traditional medicine, the Law of Infinitesimals states that the lower a dose of curative, the more effective it is. To achieve a low dose, the curative is diluted many, many times until only a tiny amount, if any, remains in a huge amount of the diluting liquid.

In homeopathic medicine, kali bichromium is said to have an affinity for the mucous membranes and the skin. It is used primarily to treat stringy yellowish or greenish mucous discharges from any part of the body, including the nose, throat, larynx, vagina, urethra, and stomach. Its most common use is to treat colds that are accompanied by sinus congestion or evolve into sinusitis.

In these situations the patient feels pressure and fullness in the sinuses and experiences extreme **pain** at the root of the nose that improves when pressure is applied to the painful spot. Kali bichromium is also used to treat feelings of fullness and pressure in the middle ear and to treat sinus or migraine headaches that start at night.

In addition, kali bichromium is used to treat a sore throat with swollen tonsils, swollen neck, and a discharge of pus. In the mouth, ulcers or a dry, burning feeling are treated by kali bichromium when accompanied by intense pain at the root of the tongue or a dry, yellow-coated tongue.

Certain types of coughs are also treated with kali bichromium when the voice is rough and hoarse, and the **cough** is dry. If the cough worsens when breathing damp, cold air, worsens in the early hours of the morning, and is better in warm air, these are also indications to the homeopath that kali bichromium is an appropriate remedy.

Kali bichromium is used to treat joint pains that appear and disappear suddenly or wander to different spots in the body causing severe pain. These pains, like the cough, are improved by warmth.

Kali bichromium is sometimes used for relief of distress in the digestive system such as **nausea** and vomiting of yellow mucus and bile. In homeopathic terminology, the effectiveness of remedies is proved by experimentation and reporting done by famous homeopathic practitioners. Kali bichromium was proved as a **vomiting** remedy by Dr. John H. Clark (1853–1931).

In homeopathic medicine the fact that certain symptoms get better or worse under different conditions is used as a diagnostic tool to indicate what remedy will be most effective. Symptoms that benefit from treatment with kali bichromium get worse in the very early hours of the morning (2 a.m. to 5 a.m.), worsen in wet weather, are worse in the summer, are worse upon awaking, upon getting cold from undressing, and upon consuming alcohol (which often induces vomiting and **diarrhea** in patients that need this remedy). Symptoms improve with warmth, movement, pressure, and from eating. Patients needing kali bichromium tend to get cold easily.

Homeopathy also ascribes certain personality types to certain remedies. The kali bichromium personality is

KEY TERMS

Sinusitis—An inflammation of the sinuses with or without a mucus discharge.

Urethera—The tube that drains the bladder.

said to be listless with aversion to physical or mental **exercise**. People with kali bichromium personalities also tend to be rigid and inflexible, doing most activities such as eating, sleeping, and working on a rigid timetable. They are very detail oriented. Morally, they tend to be very proper, rigid, and conservative, which results in a narrow-minded, self-centered personality.

Preparations

Kail bichromium is prepared by extensive dilutions of what is called a mother tincture of potassium dichromate dissolved in an alcohol/water mixture. There are two homeopathic dilution scales, the decimal (x) scale with a dilution of 1:10 and the centesimal (c) scale where the dilution factor is 1:100. Once the mixture is diluted, shaken, strained, then re-diluted many times to reach the desired degree of potency, the final mixture is added to lactose (a type of sugar) tablets or pellets. These are then stored away from light. Kali bichromium is available commercially in tablets or pellets in strengths of 6x, 12x, 30x, 200x, 6c, 12c, 30c, and 200c.

Homeopathic and orthodox medical practitioners agree that by the time the mother tincture is diluted to strengths used in homeopathic healing, it is likely that very few if any molecules of the original remedy remain. Homeopaths, however, believe that these remedies continue to work through an effect called potentization that has not yet been explained by mainstream scientists.

Precautions

No particular precautions have been reported when using kali bichromium.

Side effects

When taken in the recommended dilute form, no side effects have been reported. However, concentrated quantities of this compound are corrosive.

Interactions

Studies on interactions between kali bichromium given in homeopathic doses and conventional pharmaceuticals are nonexistent.

Kampo medicine

Definition

Kampo (sometimes spelled kanpo) is a Japanese variant of Chinese traditional medicine that involves the extensive use of herbs. The name is derived from the Japanese symbols *kan*, which means China and *po*, which means medicine. Kampo treatment has become very much integrated in the Japanese health care system. It is widely available from hospitals and physicians there, and is the most popular form of complementary health care in contemporary Japan. Kampo herbal preparations are sold by many pharmacies in Japan, which, according to the World Health Organization (WHO), has the highest per capita consumption of herbal medicine in the world. In addition to herbal treatments, Kampo practitioners may also administer **acupuncture**, **moxibustion** (therapy using moxa, or **mugwort** herb), and manipulative therapy.

Origins

Oriental traditional medicine has employed herbs for almost 4,000 years. Much of the earliest literature about the subject comes from ancient China, where wealthy families hired herbalists and paid them only

when everyone in the family enjoyed good health. Kampo medicine is a form of **traditional Chinese herbalism**, which came to Japan about 16 centuries ago and was refined over the years by Japanese practitioners. At Shoso-in, a famous historical site in western Japan, a 1,200-year-old cache of medicinal herbs was discovered—stored in air-tight wooden boxes. Researchers found that many of those samples still retained full medicinal potency.

Western medicine started to enter Japan with Jesuit missionaries and Dutch traders during the 16th and 17th centuries, but never succeeded in fully displacing traditional practices. In recent years, a considerable resurgence of Kampo's popularity has occurred.

Benefits

Kampo preparations are used to treat a wide variety of conditions, including **eczema**, atopic **dermatitis**, and gynecological problems. Other applications include **allergies**, **rheumatoid arthritis**, chronic **hepatitis**, diabetic **retinopathy**, bronchial **asthma**, endometrial **cancer**, collagen disease, colds, **nausea**, high **cholesterol**, and even **bedwetting**.

Description

Like other forms of Oriental traditional medicine, Kampo is based on concepts quite foreign to Western medical thinking. These concepts include *In-You* (negative and positive); *Gogyou* (five lines); *Ki* (air); *Sui* (water); and *Ketu* (blood). Unlike Western medicine, which thinks largely in terms of diseases affecting specific organs, Kampo emphasizes identifying patterns of "whole body" symptoms.

Kampo herbal treatments are divided into three basic groups related to urination, to sweating, and to defecation. Most prescriptions consist of a combination of crude drugs, used to treat whatever disharmony is detected. Kampo remedies usually take longer to work than standard pharmaceuticals. A typical trial period for a new prescription is three months. Patients may continue taking some prescriptions for years. Examples of crude drugs used in Kampo preparations include glycyrrhiza (**licorice**), rhubarb, and ginseng.

Japan's medical regulators have recognized Kampo since the 1970s, and Kampo herbs are included in the list of reimbursable drugs under the country's national health insurance plan. During the 1990s and continuing into the new millennium, Japanese officials required recertification of a number of Kampo drugs, insisting that their safety and effectiveness be re-evaluated.

Japanese pharmacists are allowed to manufacture a limited number of drugs themselves. Of these licensed products, 50 percent are Kampo products, according to the Japan Pharmaceutical Association.

Precautions

As with all Oriental herbal remedies, persons should use only Kampo preparations obtained from a reliable source. Serious problems have arisen when Oriental herbal prescriptions were misidentified or contained adulterants. The Register of Chinese Herbal Medicine in the United Kingdom recommends that patent medicines mixing Western and Oriental herbs be avoided, together with any patent preparation containing heavy metals. Some patients have developed hepatitis after taking patent-medicine tablets based on traditional Oriental formulas. One investigation revealed that the tablets did not contain the complete herb, but rather a chemical isolated from a single herb. This practice contradicts the most basic principles of Oriental traditional medicine, which uses combinations of whole herbs.

Because of Kampo's complexity, self-treatment is usually not advised, and consultation with a knowledgeable practitioner is essential. Some patients have experienced serious, even fatal, kidney or liver problems after treatment with Oriental herbs. Anyone with a history of disease in those organs should not be treated without accompanying blood tests to monitor their function. It has also been suggested that patients who consume considerable amounts of alcohol should receive liver function tests. It is important that patients be monitored after starting Oriental herb treatments to check for signs of liver or kidney problems.

Side effects

Because Kampo and other forms of Oriental traditional medicine are so old, practitioners say that most side effects were identified long ago and so are easily avoided by an experienced practitioner. Some Oriental herbal preparations, however, are known toxins that continue to be prescribed because of their beneficial effects. These must be used with extreme care, employing only low doses under the direction of a highly competent and certified practitioner. In most cases, these preparations should be used only in a hospital setting. In addition, some people may have an allergic hypersensitivity to certain herbs.

Research and general acceptance

In Japan, Kampo treatment is studied and frequently prescribed by medical doctors. As many as 70

percent of Japanese gynecologists are said to employ Kampo, particularly in menopausal patients.

Training and certification

In Japan, Kampo drugs are widely available from medical doctors and pharmacists. In the rest of the world, Kampo preparations and practitioners are largely unregulated.

Kaposi's sarcoma

Definition

Kaposi's sarcoma (KS), also called multiple idiopathic hemorrhagic sarcoma, is a neoplastic disease associated especially with **AIDS**, usually affecting the skin and mucous membranes.

Description

Typically, raised lesions appear on the skin and in the mouth. These are quite disfiguring nodules or blotches and can be red or purple. The gastrointentinal track and the respiratory track can be involved with symptoms of coughing, **fever**, and inflammation and swelling.

Causes and symptoms

Kaposi's sarcoma (KS) is caused by human herpesvirus 8 (HHV8). Malignant cells are found in the tissues under the skin or mucous membranes that line the mouth, nose, and anus. KS causes red or purple patches on the skin and/or mucous membranes and spread to other organs, such as the lungs, liver, or intestinal tract. KS is seen in three forms:

- indolent
- lymphadenopathic
- AIDS related

The primary distinction between the three forms of KS is the rate of growth and the location of the lesions. In the past, the indolent form of Kaposi's sarcoma was the most common and was most often seen in men, over the age of 60 years, of Jewish or Italian ancestry, in African men, and in patients who had organ transplants or have had their immune systems impaired for other reasons. KS was frequently left untreated. Because of its slow growth, the **cancer** was not a threat to the patient. Since the 1980s, more cases with rapid growth have been observed, usually accompanied by AIDS (HIV disease).

The aggressive form of KS is seen in about one-third of patients with AIDS, and has become endemic in equatorial African. In African nations, aggressive KS is seen most often among young men and children.

Lymphadenophic KS affects the lymph nodes, as well as the skin structures.

Diagnosis

KS is traditionally diagnosed based on the red or purple patches on the skin or mucous membranes. A biopsy is usually performed in order to verify the diagnosis. Since other cancers may have a similar appearance to KS, it is often useful to test for the presence of human herpesvirus 8 in order to confirm the diagnosis.

Treatment

In indolent KS, localized treatment is often adequate. Superficial lesions may be removed surgically. Alternatives are radiation therapy, electrical curettage, in which the lesion is burned with an electrical current, or cryotherapy, in which a source of extreme cold, such as liquid nitrogen, is applied to the cancer in order to kill the cells.

Among patients who develop KS after an organ transplant, reduction in the dose of drugs used to control the immune response may be enough to control or

eliminate the cancer, although this procedure increases the risk of transplant rejection. One report from the University of Barcelona in Spain stated that a change of medication may resolve the problem of KS after transplantation.

In KS associated with AIDS, systemic chemotherapy is usually required.

The Gay Men's Health Crises (GMHC) has reviewed a number of alternative therapies that have been tried in KS, but none has shown consistently favorable results. Among the treatments mentioned were shark cartilage, herbal and purifying massage therapies to enhance immune function, and transcendental **meditation**. **Homeopathy** has been tried, but here too the results have not been reliable.

Allopathic treatment

KS cannot be cured in the usual sense of the term. However, treatments are available to deal with weakened immune systems that make possible the disease. Among individuals with HIV and AIDS diseases, drug "cocktails" to combat the human immunodeficiency virus (HIV) have produced improvement in KS symptoms in nearly half of all cases. Cryosurgery and radiation are sometimes used to remove the lesions associated with KS, but traditional surgery is generally not recommended because of dangerous side-effects.

Expected results

Expected results depend primarily on the underlying condition of the patient. Those patients who have classic, slow-growing KS may live many years, even in the absence of treatment. For patients with HIV/AIDS, a proposed staging system has divided patients into low and high risk groups, depending both on the extent of the sarcoma and their underlying immune function. Patients with well functioning immune systems, no AIDS associated opportunistic **infections**, and KS confined to the skin, have an estimated survival of about three years. Those with impaired immune systems, other infections, and more widespread KS, have an estimated survival of about one year. Overall survival depends on the patient's response to treatment.

A variety of other drugs is available for treating various aspects of KS. The antiviral drug vinblastine and **sodium** tetradecyl sulfate are sometimes injected directly into the lesions associated with KS. Systemic treatment for the disease is possible using the anti-cancer drugs doxorubicin and daunorubicin. Encouraging results with use of the anti-cancer drug paclitaxel (Taxol) and the anti-leukemia drug imatinib have also been reported.

KEY TERMS

Acquired immune deficiency syndrome (AIDS)—a disease in which the immune response is impaired. The disease is caused by the human immunodeficiency virus (HIV), which is spread by direct contact with body fluids such as blood and semen.

Lesion—A diseased patch of skin.

Sarcoma—A cancer arising from connective tissue such as skin.

Prevention

The United States Public Health Service (USPHS) guidelines for prevention of KS call for prophylactic administration of drugs that are effective against human herpesvirus-8. The primary drugs for this purpose are foscarnet and ganciclovir. In each case, the dose must be adjusted based on the patient's condition. While the USPHS recognizes that KS may affect children as well as adults, no formal recommendations for prevention had been published as of 2008.

Kava kava

Description

Kava kava (*Piper methysticum*) is a tropical shrub that grows throughout the Pacific Islands. Kava kava belongs to the pepper family (Piperaceae) and is also known as kava, asava pepper, or intoxicating pepper. It grows to an average height of 6 ft (1.83 m) and has large heart-shaped leaves that can grow to 10 in (25.4 cm) wide. A related species is *Piper sanctum*, a native plant of Mexico that is used as a stimulant.

Kava kava has been used as a medicinal herb for hundreds of years and used by Pacific Islanders to treat rheumatism, **asthma**, **worms**, **obesity**, headaches, **fungal infections**, leprosy, gonorrhea, vaginal **infections**, urinary infections, menstrual problems, migraine headaches, and **insomnia**. It was also used as a diuretic, an aphrodisiac, to promote energy, and to bring about sweating during colds and fevers. Pacific Islanders consume a kava kava drink at social, ritual, and ceremonial functions. It is drunk at ceremonies to commemorate marriages, births, and deaths; in meetings of village elders; as an offering to the gods; to cure illness; and to welcome honored guests. Pope John Paul II, Queen Elizabeth II, and Hillary Rodham Clinton have all drunk kava kava during their island visits.

The drink is prepared by grinding, grating, or pounding the roots of the plant, then soaking the pulp in cold water or coconut milk. Traditionally the root was chewed, spit into a bowl, and mixed with coconut milk or water. That practice is no longer the standard.

Captain James Cook has been accredited with the western discovery of kava kava during his journey to the South Pacific in the late 1700s. The first herbal products made from kava kava appeared in Europe in the 1860s. Pharmaceutical preparations became available in Germany in the 1920s. Currently, kava kava has received widespread attention because of its reputation to promote **relaxation** and reduce stress.

General use

Kava kava has been prescribed by healthcare providers to treat a wide range of ailments including

The root of the kava kava plant can be pressed into a muddy and bitter drink with relaxing benefits. The beverage is making a comeback in Hawaii amid a broader cultural renaissance in Hawaiian language, music and arts. *(Lucy Pemoni / AP Photo)*

Kava, leaves with inflorescences. *(© inga spence / Alamy)*

insomnia, nervousness, and stress-related **anxiety** and anxiety disorders. It is also reported to relieve urinary infections, **vaginitis**, fatigue, asthma, rheumatism, and **pain**.

The active ingredients in kava kava are called kavalactones and are found in the root of the plant. Kavalactones cause reactions in the brain similar to pharmaceutical drugs prescribed for depression and anxiety. Research has shown that kavalactones have a calming, sedative effect that relaxes muscles, relieves spasms, and prevents convulsions. Kavalactones also have analgesic (pain-relieving) properties that may bring relief to sore throats, sore gums, canker sores, and toothaches.

Kava kava is a strong diuretic that is reportedly beneficial in the treatment of **gout**, rheumatism, and arthritis. The effect of the herb relieves pain and helps remove waste products from the afflicted joints. Antispasmodic properties have shown to help ease menstrual cramps by relaxing the muscles of the uterus. Kava kava's antiseptic and anti-inflammatory agents may help relieve an irritable bladder, urinary tract infections, and inflammation of the prostate gland.

Preparations

Kava kava is available in dry bulk (powdered or crushed), capsule, tablet, tea, and tincture forms. Many of the products are made from the dried powder of the root. Western consumers have generally been advised to look for standardized extracts of kava kava that contain a 70% kavalactone content. On the other hand, a report submitted to the Committee of Safety of Medicines (CSM) of the United Kingdom in April 2002 indicates that many of the side effects reported in connection with kava kava are due to the high concentration of the herb in commercial standardized extracts. The report suggested that kava preparations made according to traditional methods are relatively safe. It is likely that controversy over kava kava will continue.

Precautions

Before 2002, the usual precautions regarding kava kava stated that it should not be used by pregnant or lactating women, or when driving or operating heavy machinery. The American Herbal Products Association (AHPA) advised consumers in 1997 not to take kava kava for more than three months at a time, and not to exceed the recommended dosages. In light of more recent findings, however, it would be prudent for many adults to completely avoid preparations of or products containing kava kava.

As of March 25, 2002, the United States Food and Drug Administration (FDA) recommended that people who have a history of liver disease or are taking medications that affect the liver should consult a physician before taking any preparations containing kava kava.

Side effects

Prior to 2002, most reports of side effects from kava kava concerned relatively minor problems, such as numbness in the mouth, headaches, mild **dizziness**, or skin **rashes**. Nineteenth-century missionaries to the Pacific islands noted that people who drank large quantities of kava kava developed yellowish scaly skin. A more recent study found the same side effect in test subjects who took 100 times the recommended dose of the plant.

As of 2002, however, kava kava has been associated with serious side effects involving damage to the liver, including **hepatitis**, **cirrhosis**, and liver failure. Most of the research on kava kava has been done in Europe, where the herb is even more popular than it is in the United States. By the late fall of 2001, there had been at least 25 reports from different European countries concerning liver damage caused by the plant. French health agencies reported one death and four patients requiring liver transplants in connection with kava kava consumption. On December 19, 2001, the MedWatch advisory of the U. S. Food and Drug Administration posted health warnings about the side effects of kava kava; and on January 16, 2002, Health Canada advised Canadians to avoid all products containing the herb. France banned the sale of preparations containing kava kava in February 2002. The U. S. National Center for Complementary and

Kava kava plant. *(Gilbert S. Grant / Photo Researchers, Inc.)*

Alternative Medicine (NCCAM) put two research studies of kava kava on hold while awaiting further action by the FDA. NCCAM advised consumers in the United States on January 7, 2002 to avoid products containing kava. On March 25, 2002, the FDA issued a consumer advisory and a letter to health care professionals concerning the risk of severe liver damage from the use of products containing kava kava. While the most recent actions on the part of the FDA stop short of banning kava products from the U. S. market, the agency asks consumers as well as medical practitioners to notify its MedWatch hotline of any liver damage or other injuries associated with using kava kava. The MedWatch toll-free number is (800) 332-1088.

In addition to causing liver damage, kava kava appears to produce psychological side effects in some patients. Beverages containing kava kava have been reported to cause anxiety, **depression**, and insomnia. In addition, kava kava has caused tremors severe enough to be mistaken for symptoms of **Parkinson's disease** in susceptible patients.

Interactions

Kava kava has been shown to interact with beverage alcohol and with several categories of prescription medications. It increases the effect of barbiturates and other psychoactive medications; in one case study, a patient who took kava kava together with alprazolam went into a coma. It may produce dizziness and other unpleasant side effects if taken together with phenothiazines (medications used to treat **schizophrenia**). Kava kava has also been reported to reduce the effectiveness of levodopa, a drug used in the treatment of Parkinson's disease.

Some interactions between kava kava and prescription medications, as well as some of the herb's side effects, have been attributed to synergy (combined effects) among the various chemicals contained in kava kava rather than to any one component by itself.

KEY TERMS

Analgesic—A medication or preparation given for pain relief.

Barbiturate—A group of drugs that have sedative properties. Barbiturates depress the body's respiratory rate, blood pressure, temperature, and central nervous system.

Diuretic—A substance that increases the flow of urine. Diuretics are given to lower the volume of liquid in the body.

Kavalactones—Medically active compounds in kava root that act as local anesthetics in the mouth and as minor tranquilizers

Sedative—A drug that has a calming and relaxing effect. Sedatives are used to aid sleep and ease pain, and are often given as mild tranquilizers.

Standardized extract—A product that contains a specific amount of the active ingredients of the herb.

Synergy—Combined action or effects. Some researchers think that the side effects and interactions reported for kava kava are related to synergy among the various compounds in the herb.

Kegel exercises

Definition

Kegel exercises (Kegels) are exercises designed to strengthen the muscles of the lower pelvic girdle, or pelvic floor—the pubococcygeal (PC) muscles. The PC muscles support the bladder, urethra, and urethral sphincter—the muscle group at the neck of the bladder that acts as a spigot for controlling urine flow into the urethra— and the vagina, uterus, and rectum. Anything that puts pressure on the abdomen can weaken or damage these pelvic muscles. Such conditions include **pregnancy**, **childbirth**, excess weight, hormonal changes, and **aging**. Kegel exercises enable the PC muscles to better withstand increases in intra-abdominal pressure (pressure inside the abdomen). They make the bladder, urethra, and vagina more resilient, and improve bladder control and sexual relations.

Thirteen to 20 million American women suffer from **urinary incontinence**, primarily stress urinary incontinence (SUI)—urine leakage while laughing, coughing, **sneezing**, standing up suddenly, or exercising. SUI occurs when intra-abdominal pressure increases and the urethral sphincter opens inappropriately. During pregnancy, the fetus puts pressure on the bladder and the sphincter may relax and leak. Postpartum incontinence may result from muscle and nerve damage during childbirth due to delivery of a large baby, prolonged labor, excessive pushing, a forceps delivery, or an episiotomy (an incision made during delivery to prevent tearing of maternal tissue). About 40% of American women suffer from incontinence after childbirth, and the incidence increases by about 12% following each birth. Childbirth also increases the risk for incontinence later in life. During **menopause**, as a result of lower levels of estrogen, women with SUI may have thinning of the lining of the outer urethra, a sensation of having to urinate often, and recurrent urinary tract **infections** (UTIs). Beginning Kegels in midlife can help prevent urinary incontinence later.

Origins

In the 1930s, Dr. Joshua W. Davies hypothesized that strengthening the PC muscles could improve bladder control by assisting the closure of the urethral sphincter. By 1948, Dr. Arnold M. Kegel, a Los Angeles-area obstetrician and gynecologist, was having his patients practice vaginal contractions in preparation for childbirth. That same year he invented the Kegel perineometer, or pelvic-muscle sensor, to help prevent urinary incontinence (leakage) following childbirth.

Kegel's perineometer was the first **biofeedback** machine designed for clinical use. Employing a vaginal

sensor, an air-pressure balloon, and a tire gauge, it enabled patients to verify that they were performing Kegel's correctly and to monitor their progress. The patients continued their practice at home. Kegel published numerous papers on his work and claimed to have cured incontinence in 93% of 3,000 patients. He produced a documentary movie to teach the procedure to other physicians. However, his perineometer was never marketed effectively and there was a widespread misconception that Kegels could not be performed without it. In the 1970s, more sensitive electromyography (EMG) perineometers became available for those with severely debilitated pelvic muscles.

Benefits

Kegel exercises strengthen the PC muscles and increase blood flow and nerve supply to the pelvic region, promoting or resulting in:

- increased pelvic support
- restoration of vaginal muscle tone and improved vaginal health
- protection from the physical stresses of childbirth
- restoration of sexual function and improved sexual response and pleasure
- increased vaginal-wall thickness and lubrication after menopause (cessation of menstruation)
- prevention or reversal of urinary leakage and rectal incontinence
- relief from pelvic pain or pain of vulvar vestibulitis (inflammation of the vaginal opening)

KEY TERMS

Biofeedback—An electronic monitoring technique for learning to control a body movement or function.

Electromyography (EMG)—The recording of electrical currents generated by muscle activity.

Incontinence—Inability to control the passage of urine or feces.

Perineometer—A device for measuring PC-muscle contraction.

Pubococcygeal (PC) muscles—The muscles of the lower pelvic girdle, or pelvic floor, which support the bladder, urethra, and urethral sphincter; the muscle group at the neck of the bladder that acts as a spigot for controlling urine flow into the urethra, vagina, uterus, and rectum.

Stress urinary incontinence (SUI).—Urine leakage upon straining, coughing, laughing, or sneezing.

Urethra—The tube that delivers urine from the bladder to the exterior.

Urethral sphincter—Circular muscle that controls the movement of urine from the bladder to the urethra.

Vaginal cone—A weighted cone held in the vagina for Kegel excercising.

Vulvar vestibulitis—Inflammation of the vestibule of the vulva or vagina.

Description

Locating the PC muscles

The PC muscles can be felt by:

- stopping and starting urine flow to identify the forward PCs
- squeezing the vagina to identify the back of the PCs
- squeezing around two fingers placed in the vagina
- imagining sucking a marble up the vagina
- preventing a bowel movement or the passing of gas by tightening the muscles around the anus

There is a pulling sensation when the correct muscles are contracted. Weaker and stronger contractions are practiced until the PC muscles can be squeezed at will.

Practicing Kegels

There are numerous suggestions for practicing Kegels, which include:

- Contracting the PC muscles three to 10 seconds and relaxing them three to 10 seconds for five to 15 repetitions, three to 12 times per day.
- Contracting the PC muscles strongly for one second then releasing for one second, 20 times, three times per day, speeding up the contractions until there is a fluttery sensation.
- While emptying the bladder, stopping the urine flow at least three seconds, 10 times during each urination, which provides 60–80 contractions per day. The complete **exercise** requires muscle contraction from back to front. It may take three to eight weeks for noticeable improvement. Once good muscle tone is achieved, Kegels may be performed just once a day.

The PC muscles can be exercised at almost any time—while lying down, sitting (in the car at a stop light, at work, etc.), squatting, standing, or walking—and varying the exercise position is said to be most effective. Sitting or standing adds weight to the exercise. It may be helpful to perform a Kegel squeeze before

coughing, standing up, or lifting a heavy object. It may also be helpful to incorporate Kegels into a daily routine and keep a log. It is recommended that pregnant women practice Kegels regularly before, as well as after, childbirth.

Squeezing with two fingers in the vagina will confirm that only the vaginal muscles are contracting. Placing a hand on the lower abdomen is a reminder to keep the belly soft and relaxed, to refrain from tightening other muscles such as the stomach, buttocks, or leg muscles, or to hold the breath, all of which increase intra-abdominal pressure, working against the Kegels.

Vaginal cones

Kegels can be performed by the ancient Chinese technique of placing a weighted cone in the vagina and holding it in place up to 15 minutes twice a day. The practice is initiated using the heaviest cone that can be held easily for one minute. The cones weigh from 15–100 gm (0.04–0.3 lb). Brands include FemTone Weights, Kegel Weights, Kegel Kones, and Perineal Exerciser. Sequentially heavier cones are used until a maintenance program is established. This method automatically uses the correct muscles. Some of these products require a doctor's prescription.

Biofeedback devices and electrical stimulation

Nerve damage may prevent some people from performing Kegels properly. Vaginal or anal sensors and EMG perineometers with computerized visual or auditory feedback displays can measure the PC contraction. A handheld over-the-counter product (called the Myself pelvic muscle trainer) costs about $90. Another device can send mild electrical impulses to help locate the PC muscles.

With a vaginal sensor and biofeedback monitor, two 20-minute sessions per day for seven to nine months—with a specific goal such as holding 45-microvolts for 60 seconds—can relieve vulvar vestibular **pain** in the majority of women.

Insurance may not pay for EMG biofeedback therapy; however Medicare will reimburse for it if conventional Kegel exercises have failed.

Preparations

Training may be provided before initiating a Kegels routine.

Precautions

A temporary loss of muscle and nerve function following childbirth may make Kegels more difficult.

Kegel exercises do not work if abdominal, thigh, or buttock muscles are contracted. Furthermore, such contractions can increase pressure on the bladder, aggravating incontinence. Vaginal cones are not recommended in the presence of infection, neurological damage, diuretic medicines, or **caffeine**.

Side effects

There are no side effects to Kegel exercises.

Research and general acceptance

When performed properly and consistently, Kegels are usually helpful. The United States Agency for Health Care Policy and Research recommends that behavioral methods, including Kegels and biofeedback, be utilized to treat urinary incontinence before initiating drugs or surgery. Randomized controlled studies have shown that as many as 50–90% of women can reduce or overcome SUI with Kegels alone. However, reports of effectiveness vary since many people do not receive proper Kegel instruction. Consistent use of vaginal cones can improve or cure incontinence within four to six weeks in 70% of women.

The use of Kegels to improve urinary incontinence in men has not been extensively studied, although many clinicians report improvement. One study found that after the removal of a cancerous prostate, men who performed Kegels twice a day regained bladder control faster than those who did not do the exercises.

Training and certification

Patient training in Kegel exercises can be performed by a knowledgeable healthcare provider.

Kelley-Gonzalez diet

Definition

The Kelley-Gonzalez diet consists of large amounts of raw fruits, juices, raw and steamed vegetables, cereals, and nuts. When combined with massive quantities of dietary supplements and freeze-dried pancreatic enzymes, together with a "detoxification" process involving coffee enemas, it is said to slow the growth of **cancer** tumors.

Origins

The Kelley-Gonzalez regimen is based on a belief that enzymes from the pancreas are capable, like chemotherapy, of killing cancer cells. The use of pancreatic enzymes to treat cancer was first proposed in 1906 by John Beard, a Scottish embryologist. This idea received some attention at the time but was largely abandoned after Beard died in 1923. During the 1960s, the concept was resurrected by William Donald Kelley, a controversial dentist from Grapevine, Texas. Kelley wrote a book titled *One Answer to Cancer* that outlined his five-pronged approach:

- Nutritional therapy: Beef pancreatic enzymes combined with numerous other dietary supplements.
- Diet: A carefully individualized diet, ranging all the way from vegetarian to all-meat.
- Detoxification: As few as three or as many as 52 weeks of enemas and laxative purging.
- Neurological stimulation: Various manipulations including chiropractic, osteopathic, mandibular, and physiotherapeutic.
- Spiritual therapy: Prayer and Bible reading.

In 1981, Nicholas Gonzalez, then a second-year medical student at Cornell University, began a five-year investigation of Kelley's work. Reviewing 10,000 patient records and interviewing 500 cancer patients, Gonzalez became convinced that many of Kelley's patients had survived significantly longer than would otherwise have been expected. "Despite the careful documentation and the five-year investment of time, my attempts at publication were met with scorn and ridicule," Gonzalez recalls. "It seemed no one in academic medicine could, at the time, accept that a nutritional therapy might produce positive results with advanced cancer patients."

In 1987, Gonzalez started practicing medicine in New York City and developing his own cancer regimen similar to Kelley's, except that he rejected the neurological and spiritual aspects of Kelley's treatment. In 1999, the journal *Nutrition and Cancer* published results from a pilot study of the Gonzalez regimen in 11 patients with inoperable, advanced pancreatic cancer. the results were promising enough to prompt the U.S. National Institutes of Health's (NIH) National Center for Complementary and Alternative Medicine (NCCAM) to sponsor a $1.4 million, seven-year, large-scale clinical study of the regimen. In the study, one group of patients received the standard chemotherapy,

KEY TERMS

Amebiasis—An infection or disease caused by amoebas.

Campylobacter—A bacterium that can invade the lining of the intestine.

Hyponatremia—Abnormally low levels of sodium in the blood, often related to dehydration.

Sepsis—The presence of pus-forming micro-organisms or their toxins in the blood.

and the other group followed the Kelley-Gonzalez regimen. The study accepted participants until 2005. The results have not yet been released.

Benefits

In his New York medical practice, Gonzalez uses his enzyme-based treatment on patients with pancreatic cancer, as well as a wide variety of other cancers. In addition, he uses variations of the Gonzalez regimen to treat a range of other illnesses, including **chronic fatigue syndrome**, arthritis, and **multiple sclerosis**.

Description

As currently practiced by Gonzalez, the regimen includes pancreatic enzymes taken orally every four hours and at meals for 16 days. Patients also take as many as 150 dietary supplements a day, including vitamins, minerals, **magnesium** citrate, papaya, trace elements, and glandular products from animals. Patients also receive frequent coffee enemas. They are placed on a strict diet including large quantities of fresh fruits, vegetable juices, cereals, and as many as 20 almonds a day. Red meat, white sugar, chicken, refined grain products, and soy are all forbidden. Fish is allowed only in limited quantities.

Precautions

The Kelley-Gonzalez diet is considered a highly experimental treatment for cancer, with only limited evidence of its effectiveness. It should therefore be undertaken only with competent medical advice and monitoring. Prospective patients should be aware that the diet requires considerable commitment and can almost be considered a full-time job. Initially, it can involve as many as eight enemas a day as well as preparing four servings of fresh carrot juice and taking dietary supplements 10 times a day.

Side effects

At least two deaths have been linked to coffee enemas, attributed to hyponatremia (**sodium** deficiency in the blood) and dehydration. With unqualified practitioners, a risk of contamination may result from unsanitary equipment used to administer enemas. For example, one outbreak of *Campylobacter* sepsis occurred among clients of a border clinic in Mexico that offered coffee enemas. In Colorado, an amebiasis outbreak was linked to fecal contamination of an enema-delivery system. Other side effects of the Kelley-Gonzalez treatment may include low-grade **fever**, muscle aches and pains, or **rashes**.

Research and general acceptance

For many years, the Kelley-Gonzalez Diet was rejected by orthodox medical practitioners. However, as described earlier, a 1999 pilot study by Gonzales has led to a clinical trial sponsored by the NIH. The results of that large-scale trial are not yet available.

Training and certification

Gonzalez offers his regimen from his medical practice in New York City. In a 1995 interview with *The Moneychanger,* he said that there are other practitioners "who say they do the Kelley therapy or the Gonzalez therapy, and I've never even met them."

Kelp

Description

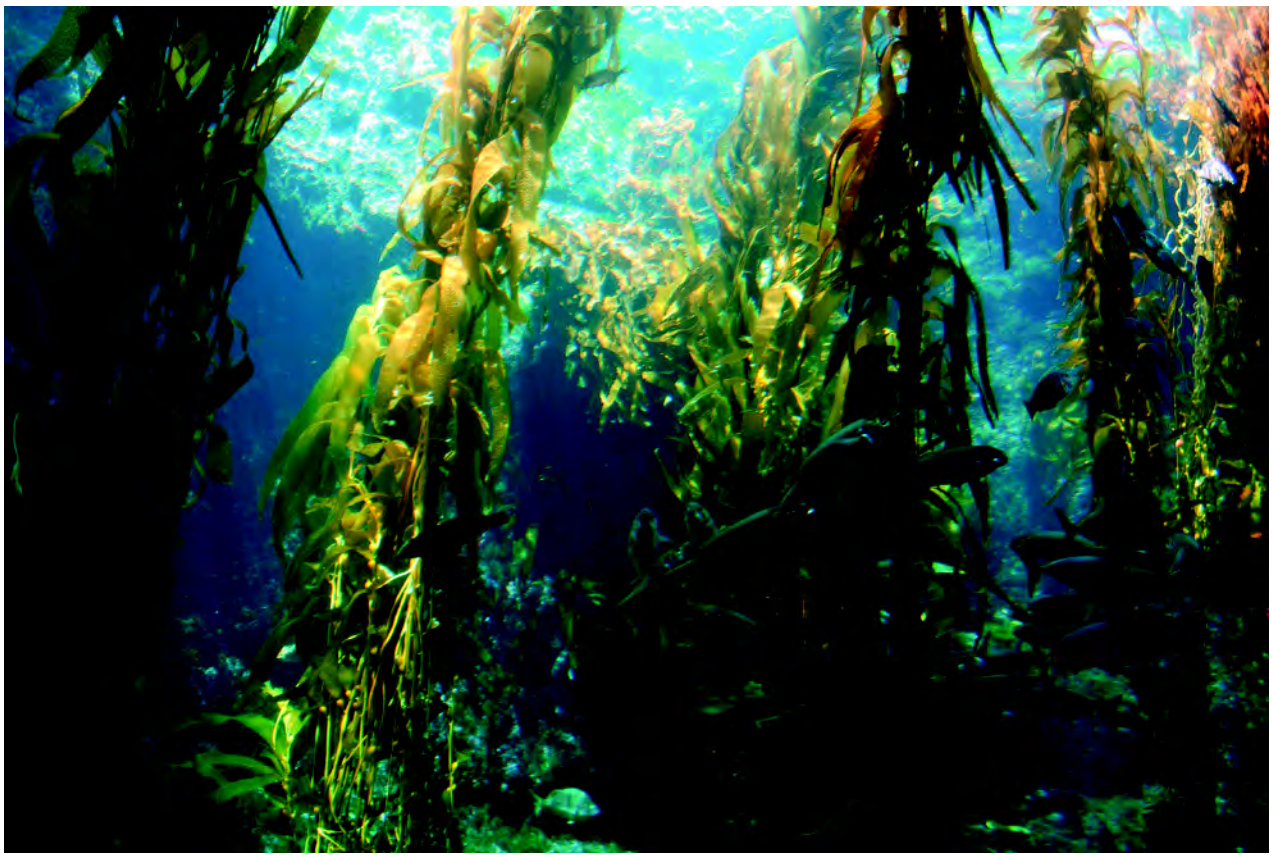
Kelp (*Fucus vesiculosus*) is a type of brown seaweed, moderate in size, that grows in regions with cold coastlines including those of the northwestern United States and northern Europe. There are several varieties of kelp: true kelp, which thrives in cool seas; giant kelp and bladder kelp, which grow in the North Pacific. Giant kelp is so named because it grows to 213 ft (65 m). Kelp anchors itself to rocky surfaces via tentacle-like roots. From these roots grows a slender stalk with long, leaf-like blades.

Kelp belongs to the Laminaria family. Other names for *Fucus vesiculosus* are kelpware, black-tang, bladderfucus, cutweed, and **bladderwrack**. The main constituents of kelp include phenolic compounds, mucopolysaccharides, algin, polar lipids, and glycosyl ester diglycerides. Kelp also contains protein, carbohydrates, and **essential fatty acids**.

Kelp contains approximately 30 minerals. It is a rich source of **iodine**, **calcium**, **sulfur**, and silicon. Other minerals include **phosphorus**, **iron**, **sodium**, **potassium**, **magnesium**, chloride, **copper**, **zinc**, **manganese**, barium, **boron**, **chromium**, lithium, nickel, silver, titanium, **vanadium**, aluminum, strontium, bismuth, chlorine, cobalt, gallium, tin, and zirconium. Kelp also contains vitamins C, E, D, K, and B complex. The highest concentrations of these vitamins and minerals are found in the tissues of kelp. Since kelp is such a valuable source of nutrients, it is often recommended as a dietary supplement, particularly for people with mineral deficiencies.

Origins

Different kinds of kelp have been eaten for nutritional value for over a thousand years. The Chinese used kelp and other types of seaweed as medicine as far back as 3,000 B.C. The Greeks used kelp to feed their cattle around the first century B.C. Kelp has been a staple food of Icelanders for centuries, and ancient Hawaiian nobles grew gardens of edible seaweed.



Kelp forest. West Coast, USA. *(© Papilio / Alamy)*

KEY TERMS

Diuretic—A substance that promotes urination.

Goiter—An enlargement of the thyroid gland.

Hypothyroidism—A condition resulting from an underactive thyroid gland.

Infusion—An herbal tea created by steeping herbs in hot water. Generally, leaves and flowers are used in infusions.

Kelp was also used in Europe and Great Britain as fertilizer to nourish soil and assist plant growth.

The largest consumer of kelp, however, has been Japan. The Japanese have incorporated kelp and seaweed into their **diets** for 1,500 years. During the seventh to ninth centuries, only the Japanese nobility consumed seaweed. In the seventeenth century, Japan began farming seaweed. The Japanese and other Asian cultures used kelp to treat uterine problems, genital tract disorders, and kidney, bladder, and prostate ailments.

Kelp is still an integral part of the Japanese diet. The Japanese include kelp in almost every meal, using it in salads or as a garnish, or cooking it in soups, sauces, and cakes. Noodles made from kelp are a staple of the Japanese diet. Until recently, kelp was eaten almost exclusively by the Japanese. Now the Western population is beginning to take note of this nutrient-rich seaweed. However, *Fucus vesiculosus* is not the kind of kelp that is eaten.

Eating dietary kelp may be responsible for the low rate of **breast cancer** among Japanese women, and also for the low rate of **heart disease**, respiratory disease, rheumatism, arthritis, high blood pressure, and gastrointestinal ailments. The occurrence of thyroid disease is also low in Japan.

General use

Many herbalist and naturopathic physicians recommend *Fucus vesiculosus* to treat thyroid disorders, arthritis, rheumatism, **constipation**, colds, high blood pressure, **colitis**, **eczema**, goiter, **obesity**, low vitality, poor digestion, nervous disorders, menstrual irregularities, glandular disorders, and water retention.

Fucus vesiculosus has a therapeutic effect on many systems of the body. It strengthens immune system function and increases resistance to infection and **fever**. Kelp is also beneficial to the nervous and endocrine systems. It enhances the function of the adrenal, thyroid, and pituitary glands, and supports brain health and function.

One of the main therapeutic uses of *Fucus vesiculosus* is for thyroid conditions such as **hypothyroidism** and goiter. Partly due to its high iodine content, this kind of kelp assists in the production of thyroid hormones, which help regulate the thyroid gland. People who don't eat dairy products, seafood, and salt may develop an iodine deficiency. This may result in low thyroid function. Kelp is a good source of iodine for those who may be deficient.

Thyroid hormones are also necessary to maintain a normal metabolism. *Fucus vesiculosus* helps boost metabolism, which helps to sustain normal weight (especially in people who are overweight because of a thyroid condition).

This type of kelp is also used to rid the body of and keep it from absorbing harmful chemicals, toxins, carcinogens, and such heavy metal pollutants as barium and cadmium. Algin, a fiber-like extract of kelp, helps prevent the body from assimilating these elements. Algin is used industrially in the production of tires and as an agent that prevents ice cream from crystallizing. Kelp also helps to prevent the body from absorbing radioactive elements such as strontium 90, a dangerous radioactive substance created by nuclear power plants. However, since *Fucus vesiculosus* absorbs toxic chemicals, it must be harvested from clean waters or it may contain toxins.

Kelp also reduces **cholesterol** levels by inhibiting bile acid absorption. The diuretic effect of kelp is beneficial to an irritated or infected bladder since it helps to flush out harmful bacteria. Kelp helps reduce inflammation in injured tissues and ease painful joints in rheumatism and **rheumatoid arthritis**. Kelp may also reduce an enlarged prostate in men, and is also used to strengthen fingernails, prevent **hair loss**, and regenerate hair if the follicle is still alive.

In addition to its medicinal uses, kelp contains natural **antioxidants** that make it useful to the food industry in retarding spoilage. The cosmetics industry is also studying the effects of a gel derived from kelp in improving the elasticity of human skin.

Preparations

The kelp used medicinally in modern times is generally harvested in kelp farms. These farms help preserve the natural balance of the sea, which is disrupted when large amounts of naturally growing seaweed are removed. Farming kelp also helps to ensure that the kelp retains its nutritional value. Kelp loses valuable nutrients when it is washed ashore. When

kelp is harvested, it is cut, dried, then ground into powder. It is this powder that is encapsulated or pressed into tablets.

Kelp is available in bulk form either dried or as a ground powder. It is also sold as granules, capsules, tablets, or tinctures. Granulated or powdered kelp can be added to food as a salt substitute.

The recommended daily dose for adults is 10–15 mg. Kelp can also be made into a tea. To create an infusion, 1 cup of boiling water is poured over 2-3 tsp of dried or powdered kelp. The tea is steeped for 10 minutes, and can be drunk three times daily.

Precautions

People should not gather wild kelp because it may contain contaminants absorbed from the sea.

People with high blood pressure or a history of thyroid problems should consult their healthcare practitioner before using kelp. The high sodium content of *Fucus vesiculosus* may make high blood pressure worse. Kelp isn't recommended for people on a low-sodium diet.

Excessive consumption of kelp can provide the body with too much iodine and interfere with thyroid function. Consumers should use it only as directed.

Side effects

There are no known side effects, but some people may be sensitive or allergic to kelp. Common allergic symptoms include mild stomachache.

Interactions

Fucus vesiculosus shouldn't be taken with thyroid medications.

Khella

Definition

Khella *(Ammi visnaga)* is a member of the *Apiaceae* family, whose familiar members include carrot and **parsley**. Khella is an herbaceous annual native to North Africa, and naturalized to Australia, North and South America, and throughout the Middle East. It is grown in the United States, Mexico, Argentina, and Chile, and cultivated commercially in the former Soviet Union, Egypt, Morocco, and Tunisia. Khella has been known since ancient times and is mentioned in the *Ebers papyrus*, one of the oldest known medical works dating from 1500 B.C. Khella, so named by the Moors of North Africa, has many other common names reflecting both its folk use and appearance, including false queen Anne's lace, toothpick plant, green mist lace, and honey plant. The herb is sometimes called bishop's weed, though this is also the common name for a related plant, *Ammi majus L.* The Greek physician Dioscorides, author of *De Materia Medica* called the herb "ammi," meaning "sand," perhaps reflecting the common habitat of the herb.

Khella thrives in sunny fields and among cultivated crops in well-drained, sandy soil. It reaches heights from 2 to 3 feet and may spread as wide as 4 feet. It is self-fertile and pollinated by insects. The fern-like, finely cut, toothed leaves grow from erect, round, and furrowed stems that branch toward the top. The stems bear small greenish-white flowers in a rounded and clustered compound umbel that gives the appearance of fine lacework. The flowers are androgynous, containing both male and female reproductive parts. In damp conditions, the compound umbels open up, and when dry they close with a nest-like appearance. The pedicels of the flowers are stiff when dry and pleasant tasting. They have been traditionally used as tooth cleansers. The seeds are tiny, smooth, ovate to oblong, and bitter.

Active Constituents

The medically active constituents in khella are present in the fruit and seeds. A primary active constituent, the furanocoumarin khellin, is found in the fatty oil of the seed and was first isolated in crystalline form in 1879. Other furanocoumarins are visnagin and khellol. Other compounds include the flavonoids **quercetin**, kaemperot, and isorhamnetin, and the **essential oils** camphor, terpineol, terpinen, and linalool oxides, as well as fixed oils, psoralens (methoxypsoralen), and protein.

General use

Khella acts therapeutically as a urinary tract antispasmodic, diuretic, hypoglycemic, lithontripic, selective coronary vasodialator, and bronchodilator. Khella has been used for decades as an effective remedy for various respiratory problems, including **asthma**, **bronchitis**, **emphysema**, and **whooping cough** and to treat arteriosclerosis and relieve the sharp **pain** of **angina** and pre-menstrual distress. An extract of the phytochemical khellin used as a topical gel has been shown to be helpful in treatment of vitiligo, a skin disease. Khella increases the sun sensitivity of melanocytes in the skin, thus stimulating repigmentation.

Khella's active constituents have been included in many commercial drug formulas used for dilating blood vessels. This use was based on research dating from the 1950s. However in 1994, the German Commission E, a committee of experts evaluating the safety and efficacy of herbs and herbal combinations, withdrew approval of khella for therapeutic use "due to the insufficiently proven efficacy of the drug and its pharmaceutical preparations, as well as the associated risks."

Khella was cultivated in the medicinal gardens of ancient Egypt where it was valued for relieving the pain and easing the passage of **kidney stones**. Its antispasmodic properties help relax bile duct constrictions and relax the muscle of the urethra, and khella has been shown to relax the coronary arteries thus improving the blood supply to the heart muscle.

Research

In 2001, scientists at Umm Al-Qura University in Saudi Arabia investigated the effect of *Ammi visnaga* seeds on experimentally induced kidney stones in albino rats. Daily oral treatment with 500 mg of the extract, according to researchers "highly reduced the incidence of nephrolithiasis (**calcium** oxalate deposition in the kidneys)." The seed extract also showed highly potent diuretic activity. The researchers offered a daily dosage of 60 ml of khella extract to human volunteers who complained of kidney stones. Researchers reported that "the patients confirmed the efficacy of *Ammi visnaga* treatment."

Preparations

Khella is commercially available in capsule form, as an essential oil, in liquid extract, tincture, and dried for use as a tea. For an infusion, individuals can use one teaspoon of crushed seeds per cup of water and steep for 25 minutes. Khella extract, standardized to contain a minimum of 12% of the phytochemical constituent khellin, is commercially prepared from the seeds with a dry seed/menstruum ratio of 1:3 using grain alcohol (60–65%) and distilled water. The recommended daily dosage is 120 to 160 mg.

KEY TERMS

Antispasmodic—Phytochemical agent that acts to relax muscular spasms, suppressing smooth muscle contractions and preventing or reducing incident of seizure.

Lithontripic—Phytochemical effect that acts to prevent the formation of kidney or gall stones and facilitates dissolution and removal when formed.

Melanocyte—The pigment-producing cell in the epidermis that produces malanin and determines skin color.

Vitiligo—A skin pigmentation disorder in which the melanocytes are destroyed leaving irregular patches of unpigmented skin, appearing most commonly on hands, feet, face and lips.

Precautions

Khella has been shown to have cumulative toxicity. Prolonged use may bring about **nausea** and **vomiting**, **headache**, **insomnia**, **constipation**, and vertigo. Externally, the sap of the plant may cause irritation and a painful skin rash. When used topically, particularly for prolonged periods, the phototoxic activity of khella may cause blistering in normal skin when exposed to the sun. Individuals should use this herb under the supervision of a healthcare professional as appropriate dosages will vary depending upon the condition being treated.

Contraindications

Khella should not be taken by patients using antiarrhythmics, anticoagulants, calcium channel blockers, and other antihypertensives. Khella may enhance the effects of these pharmaceuticals. Individuals should avoid using khella if they are pregnant or breast-feeding as effects are unknown. Khella may cause elevated liver function test results.

Clare Hanrahan

Kidney infections

Definition

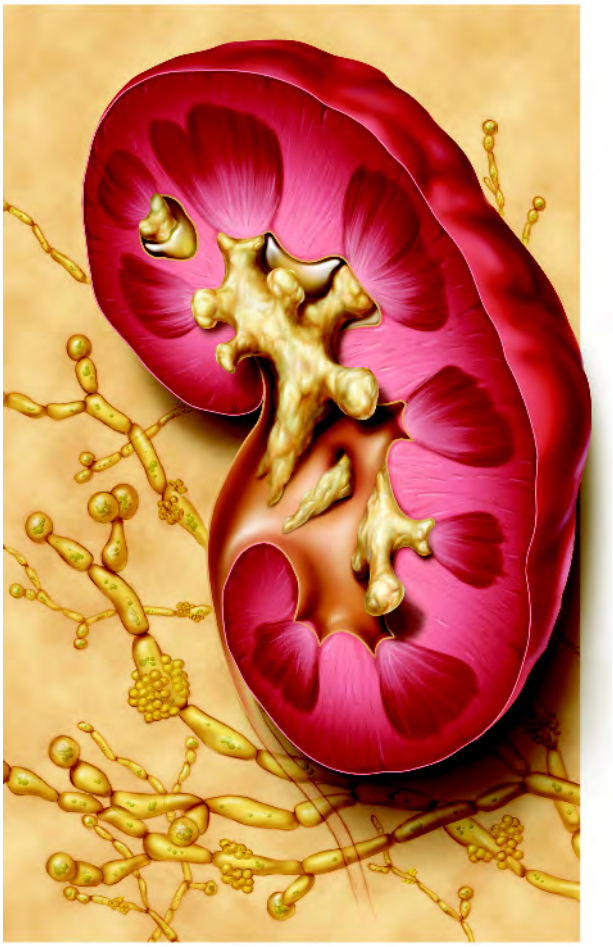
Kidney infection is a general term used to describe infection of the kidney by bacteria, viruses, or fungi. The infecting microbe may have invaded the kidney from the urinary bladder or from the bloodstream. The disease is characterized by **fever**, **chills**, back **pain**, and, often symptoms associated with **bladder infection**.

Description

The kidneys are bean-shaped organs located in the abdominal cavity on the right and left side of the lower back. As the principle part of the urinary system, the kidneys process the fluid component of blood (plasma) to maintain appropriate water volume and concentrations of chemicals (electrolytes). Urine is the waste product formed from this process. Urine flows from each kidney through a tube called a ureter to the urinary bladder, and is removed from the body through a tube called the urethra. The kidneys and ureters comprise the upper urinary tract, and the bladder and urethra comprise the lower urinary tract.

Kidney infection, also called pyelonephritis and upper urinary tract infection, occurs when microbes, usually bacteria, invade the tissues of the kidney and multiply. One or both kidneys may be infected. Infection originating directly from the bladder is called an ascending infection.

Inflammation occurs in response to the infection. As a result of the infection and inflammation, scarring and other tissue damage may occur. Most cases of acute kidney infection resolve without any permanent kidney damage. In severe cases, kidney damage is so extensive that the kidneys can no longer function, a state called renal failure.



Kidney infected with candida cast, yeast-like fungi. *(Brian Evans / Photo Researchers, Inc.)*

There are several types of kidney **infections**.

- Acute pyelonephritis: uncomplicated kidney infection which has a short and relatively severe course.
- Chronic pyelonephritis: long-standing disease associated with either active or inactive kidney infection.
- Emphysematous pyelonephritis: acute infection associated with gas in and around the kidney. This type almost always occurs in persons with diabetes.
- Pyonephrosis: acute or chronic pyelonephritis associated with blockage of the ureter.
- Renal and perinephric abscesses: abscesses (pockets of pus) in and around the kidney.

Kidney infections occur most often in adult women who are otherwise healthy. Urinary tract infections are uncommon in men until old age when bladder

catheterization and other urinary procedures are more commonly performed.

Causes and symptoms

Kidney infection is usually caused by bacteria, although infection by fungi (yeasts and molds) or viruses does occur. The bacteria *Escherichia coli (E. coli)* is responsible for about 85% of the cases of acute pyelonephritis. However, *E. coli* causes only 60% of the acute pyelonephritis cases in the elderly.

Other common causes include *Klebsiella*, *Enterobacter*, *Proteus*, *Enterococcus*, and *Pseudomonas* species. Infection by *Proteus* species can lead to the formation of **kidney stones**.

Kidney infection may also be caused by *Mycobacteria tuberculosis* or other Mycobacteria species or by the yeast *Candida*. Kidney infection also can be caused by Group B Streptococci in newborns.

Certain women are inherently more susceptible to urinary tract infections. Researchers have found that women who have recurrent infections possess certain markers on their blood cells. Also, the bacteria that commonly cause urinary tract infections stick more readily to the vaginal cells of women who have recurrent infections.

Other risk factors for developing kidney infections include:

- bladder catheterization, a common cause of bladder and kidney infections in hospitals.
- diabetes
- pregnancy
- urinary calculi (stone)
- urinary tract abnormalities
- urinary tract obstruction

The symptoms of kidney infection include fever, shaking chills, **nausea**, **vomiting**, and middle to lower back pain that may travel to the abdomen and groin. This pain may be severe. These symptoms may be preceded or accompanied by those associated with bladder infection—frequent, painful urination.

Infants and young children may have fever, irritability, straining on urination, and unusual urine odor. Fewer than half of newborns have fever associated with kidney infection, which makes diagnosis difficult.

In more than 20% of elderly patients with kidney infection, the presenting symptoms are gastrointestinal or pulmonary (lung). Also, one third of elderly patients do not develop fever.

Diagnosis

Kidney infections can be diagnosed by family physicians, obstetrics and gynecology (OB/GYN) doctors, and urologists (doctors who specialize in the urinary system). The diagnosis of kidney infection is based primarily on symptoms, urinalysis, and urine cultures. Blood tests may also be performed. Approximately 20% of patients have bacteria in the bloodstream, a condition called bacteremia. Urine dipsticks that detect signs of infection are often used right in the doctor's office. Urine also is examined with a microscope for the presence of bacteria and leukocytes (white blood cells). Urine culture can identify which microbe is causing the infection and may also be used to determine which antibiotic would be most effective.

Other diagnostic procedures may be used to look for signs of infection in the kidney. An x ray of the abdomen may be taken. Ultrasound, which uses sound waves to visualize internal organs, may be used to examine the bladder and kidney. Less routinely performed are intravenous urograms, computerized tomography (CT scan), and scintillation scans.

Treatment

Delays in the diagnosis and treatment of kidney infection can lead to permanent kidney damage. The person who suspects kidney infection should seek professional care immediately, as antibiotics are essential to control the infection. Alternative medicine may be used as an adjunct to the appropriate antibiotic treatment.

Dietary changes that may help to control and prevent kidney infection.

- Drinking 8–12 glasses of water daily helps to wash out bacteria, although this also may dilute antibacterial factors in the urine.
- Acidifying the urine by eating few alkaline foods such as dairy.
- Following a diet rich in whole grains, vegetables, and acidifying juices, such as citrus and cranberry.
- Eliminating high sugar foods.
- Drinking unsweetened cranberry juice to acidify the urine and provide the antimicrobial agent hippuric acid. In controlled studies, cranberry extract capsules did not provide the same benefit as cranberry juice. Studies have shown that cranberry juice helps suppress the growth of certain bacteria and reduces urinary tract infection by making it more difficult for bacteria to stick to the lining of the ureter and bladder.

- Ingesting at least one clove of garlic or up to 1,200 mg garlic as a tablet daily for its alleged anti-infective properties.

Magnesium supplementation may help prevent the formation of kidney stones and thus indirectly prevent kidney infection by preventing urinary tract blockage. **Zinc** may boost the immune system. A study in rats with ascending pyelonephritis found that the addition of vitamins A and E to standard antibiotic therapy significantly reduced kidney inflammation as compared to antibiotic treatment alone. This effect has not been tested in humans.

Traditional Chinese medicine treats pyelonephritis with **acupuncture**, herbals, and patent medicines. The Chinese patent medicine Zhi Bai Di Huang Wan (**Anemarrhena**, Phellodendron, and Rehmannia Pill) is often used to treat kidney infections and disease and bladder infections. The patient can take eight pills three times daily. Herbs such as *Semen Abutili seu Malvae, Semen plantaginis,* and *Herba lygodii japonici* are used to treat or prevent the formation of kidney stones.

In traditional Chinese medicine, treatment of urinary tract infection often uses one or more of the following herbs in doses of 30 g to 60 g taken once or twice daily. Patients should consult a traditional Chinese medical practitioner for the treatment best suited for them:

- Herba commelinae
- H. plantaginis
- H. patriniae
- H. salviae plebeiae
- H. hedyotis seu oldenlandiae
- H. taraxaci
- H. andrographis

Allopathic treatment

Initiating antibiotic therapy as soon as possible is critical to prevent or reduce damage to the kidneys. Historically, all pyelonephritis patients were treated in the hospital. This is no longer considered necessary. Responsible patients with mild kidney infection can be treated at home with antibiotics taken by mouth. Patients with high fever, vomiting, evidence of bacteria in the bloodstream, and/or dehydration should be hospitalized in order to receive intravenous (IV) antibiotics and fluids. Severe illness, either with or without complications, requires hospitalization for treatment.

The recommended treatment for acute pyelonephritis is two weeks of therapy with the antibiotic combination trimethoprim/sulfamethoxazole. Fluoroquinolones (Cipro, Noroxin, NegGram), ceftriaxone (Rocephin), or gentamicin are other choices. Fluoroquinolones should not be used by pregnant women or children. With treatment, symptoms normally resolve within two to three days. Patients must, however, take the full two-week course of antibiotics so that the infection does not recur.

Abscesses may be treated with percutaneous (by a needle through the skin) or surgical drainage. Emphysematous pyelonephritis may be treated with antibiotics, however, surgical removal of the kidney (nephrectomy) may be necessary (individuals can, however, live normally with only one kidney). Because of the 75% death rate, nephrectomy is the treatment of choice in people with diabetes who have emphysematous pyelonephritis. Kidney stones are most often treated with extracorporeal shock wave lithotripsy (ESWL). Shock (sound) waves are aimed at the stone. The energy in the shock waves causes the stone to vibrate and fragment into small pieces that can be more easily passed.

Expected results

Antibacterial therapy of kidney infection has a 90% cure rate. Severe or chronic infection can lead to kidney damage and renal failure. Renal failure requires hemodialysis, a process that uses a dialysis machine (an artificial kidney) to process the patient's blood and remove waste products several times a week. Patients with severe kidney damage require kidney transplantation.

Prevention

Researchers are trying to develop a vaccine for urinary tract infections (UTIs), but as of 2008, none were available in the United States. The key to preventing kidney infection is to promptly treat bladder infection. Measures taken to prevent bladder infection may prevent subsequent kidney infection. These include:

- drinking large amounts of fluid
- reducing intake of sugar
- voiding frequently and as soon as the need arises
- proper cleansing of the area around the urethra (females), especially after sexual intercourse
- acupuncture (effective in preventing recurrent lower UTIs in women)
- avoiding use of vaginal diaphragms and spermicidal jelly (females)

The primary preventive measure specifically for men is prompt treatment of prostate infections. Chronic prostatitis may go unnoticed but can trigger recurrent UTIs. In addition, men who require temporary catheterization following surgery can be given antibiotics to lower the risk of UTIs.

KEY TERMS

Ascending infection—Infection which begins in the urinary bladder and travels through the ureters up to the kidneys.

Electrolyte—ions in the body that participate in metabolic reactions. The major human electrolytes are sodium (Na+), potassium (K+), calcium (Ca 2+), magnesium (Mg2+), chloride (Cl-), phosphate (HPO4 2-), bicarbonate (HCO3-), and sulfate (SO4 2-).

Hemodialysis—The blood processing procedure used when kidney function is lost. Blood is removed from a vein, processed through a dialysis machine (artificial kidney), and put back into a vein.

Nephrectomy—Surgical removal of a kidney.

Percutaneous—Medical procedure that is performed through the skin using a needle. Abscess drainage and urinary stones may be treated percutaneously.

Pyelonephritis—Infection and inflammation of the kidney.

Renal failure—A state when the kidneys are so extensively damaged that they can no longer function.

Kidney stones

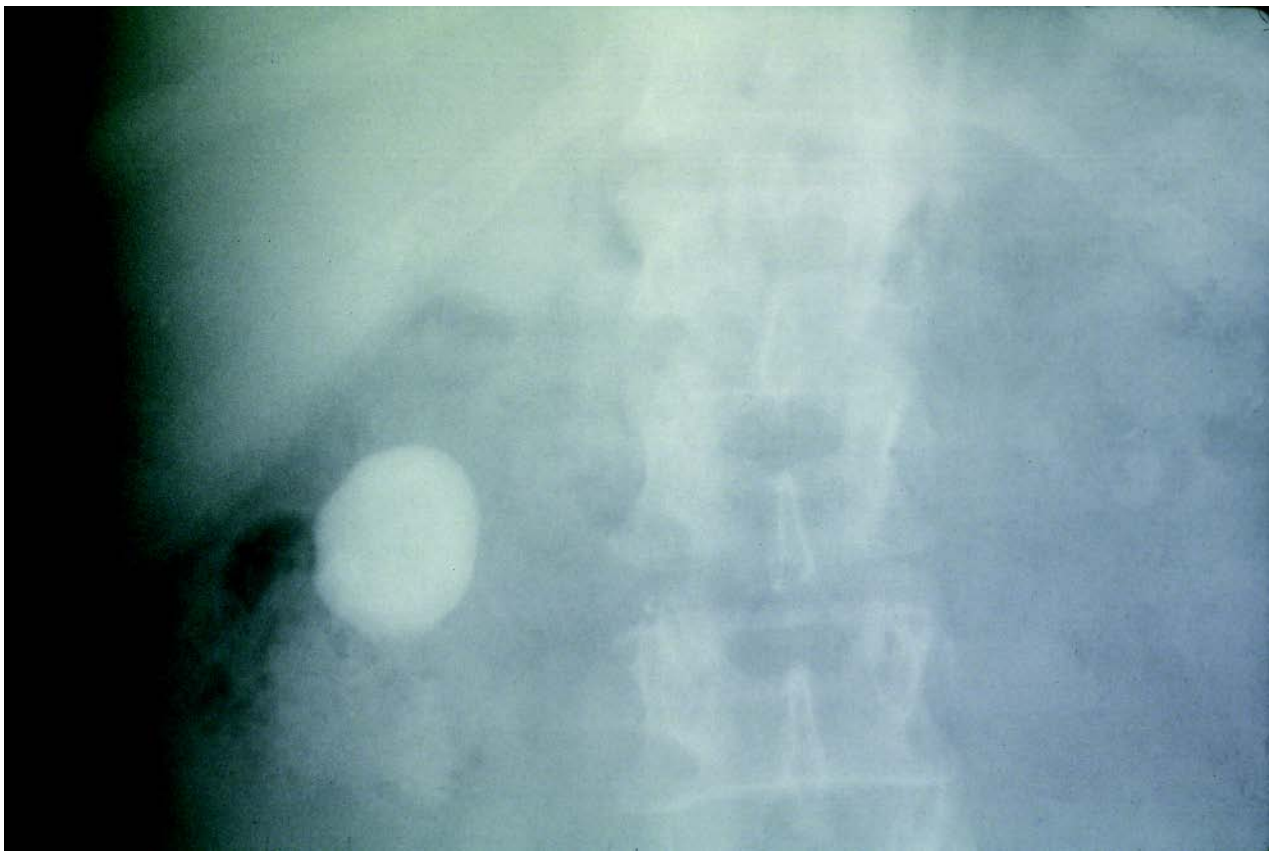
Definition

Kidney stones are solid accumulations of material that form in the tubal system of the kidney. Kidney stones cause problems when they block the flow of urine within the kidney or urinary tract. When the stones move through the ureter, they can cause severe **pain**.

Description

Urine is formed by the kidneys. Blood flows into the kidneys, and nephrons (specialized tubes) within the kidneys allow a certain amount of fluid from the blood, along with certain substances dissolved in that fluid, to flow out of the body as urine. Sometimes, a problem causes the dissolved substances to become solid again. Tiny crystals then form in the urine, meet, and cling together to create a larger solid mass called a kidney stone.

Many kidney stones are small enough that the kidney continues to function normally, and the stones never cause any pain. These are called "silent stones." Kidney stones cause problems when they interfere with the normal flow of urine. They can obstruct (block) the flow through the ureter. The kidney is not accustomed to experiencing any pressure. When pressure builds from backed-up urine, the kidney may swell (hydronephrosis). If the kidney is subjected to this pressure for some time, there may be damage to delicate kidney structures. When the kidney stone is



X ray showing a kidney stone. *(Custom Medical Stock Photo. Reproduced by permission.)*

lodged further down the ureter, the backed-up urine may also cause the ureter to swell (hydroureter). Because the ureter is a muscular tube, the presence of a stone makes the tube spasm, causing severe pain.

About 10% of all people have a significant kidney stone during their lifetime. Kidney stones are most common among white men over age 30, people who have previously had kidney stones, and people whose family members are prone to developing kidney stones. Eating a lot of animal protein and drinking too few fluids are also thought to contribute to the development of kidney stones.

Causes and symptoms

Kidney stones can be composed of a variety of substances. The most common types of kidney stones are described here.

Calcium stones

About 80% of all kidney stones are **calcium** stones. These stones are composed of either calcium and phosphate, or calcium and oxalate. People with calcium stones may have other diseases that cause them to have increased blood levels of calcium. These diseases include primary parathyroidism, sarcoidosis, **hyperthyroidism**, renal tubular acidosis, multiple myeloma, hyperoxaluria, and some types of **cancer**.

Struvite stones

Struvite stones account for 10% of all kidney stones. Struvite stones are composed of **magnesium** ammonium phosphate. These stones occur most often in patients who have had repeated urinary tract **infections** caused by certain types of bacteria. These bacteria produce a substance called urease that increases the urine pH and makes the urine more alkaline. This chemical environment allows struvite to settle out of the urine, forming stones.

Uric acid stones

About 5% of all kidney stones are uric acid stones. These occur when increased amounts of uric acid circulate in the bloodstream. When the uric acid content becomes very high, it can no longer remain

Kidney stone on a human finger tip. *(Stephen J. Krasemann / Photo Researchers, Inc.)*

dissolved and solid particles of uric acid settle out of the urine. A kidney stone is formed when these particles cling to each other within the kidney, slowly forming a solid mass. About half of all patients with this type of stone also have deposits of uric acid elsewhere in their bodies, commonly in the joint of the big toe. This painful disorder is called **gout**. Other causes of uric acid stones include chemotherapy for cancer, bone marrow disorders in which certain types of blood cells are over-produced, and an inherited disorder called Lesch-Nyhan syndrome.

Cystine stones

Cystine stones account for 2% of all kidney stones. Cystine is a type of amino acid, and people with this type of kidney stone have an abnormality in the way their bodies process **amino acids** in the diet.

Patients who have kidney stones usually do not have symptoms until the stone passes into the ureter. Before this, some people may notice blood in their urine. Once the stone is in the ureter, however, most people experience bouts of very severe pain. The pain is crampy, spasmodic, and intense. It usually begins in the flank region, the area between the lower ribs and the hip bone. As the stone moves closer to the bladder, a patient will often feel the pain radiating along the inner thigh. Women may feel the pain in the vulva, while men often feel pain in the testicles. **Nausea**, **vomiting**, frequent and painful urination, and blood in the urine are common. **Fever** and **chills** usually mean that the ureter has become obstructed, allowing bacteria to become trapped in the kidney and cause a kidney infection (pyelonephritis).

Diagnosis

Most often in a healthy adult, diagnosis of kidney stones is based on the patient's pattern of severe, distinctive pain. Diagnosis may include laboratory examination of a urine sample and an x-ray examination. During the passage of a stone, examination of the urine usually reveals blood. A number of imaging tests can, if necessary, be used to diagnose kidney stones. A plain x ray of the kidneys, ureters, and bladder may or may not reveal the stone. A series of x rays taken after injecting **iodine** dye into a vein is usually a more reliable way of seeing a stone. This procedure is called an intravenous pyelogram (IVP). The dye "lights up" the urinary system as it travels. In the case of an obstruction, the dye will be stopped by the stone or will only be able to get past the stone at a slow trickle. This test is not often used in the twenty-first century since less invasive imaging tests are available. An ultrasound can also be used to detect renal blockage. The use of computed tomography (CT) scans has been added to diagnose of some kidney stones.

When a patient is passing a kidney stone, the urine is strained through a special sieve to catch the stone. If the stone can be located (often it cannot), it can then be sent to a laboratory for analysis to determine the chemical composition of the stone. After the kidney stone has been passed, other tests may be done to understand the underlying condition that may have caused the stone to form. Collecting urine for 24 hours, followed by careful analysis of its chemical makeup, can often determine the reason for stone formation.

Treatment

It is believed that stones will pass more quickly if the patient is encouraged to drink large amounts of water (2–3 quarts per day). **Cranberry** (*Vaccinium macrocarpon*) juice has been a traditional remedy for the treatment and prevention of kidney stones. Although good-quality clinical trials have found that cranberry juice has some effect on urinary tract infections, its effectiveness in treating kidney stones is unproven.

Herbal remedies that have anti-lithic (stone-dissolving) action can assist in dissolving small kidney stones. These include gravel root (*Eupatorium purpureum*), hydrangea (*Hydrangea aborescens*), and wild carrot (*Daucus carota*). Starfruit (*Averrhoa carambola*) is recommended to increase the amount of urine a patient passes and to relieve pain.

A Chinese herbal practitioner may use herbs such as *Semen Abutili seu Malvae, Semen plantaginis,* and *Herba lygodii japonici* for urinary stones. Dietary

Human male calcium oxalate kidney stone. *(© Steve Sant / Alamy)*

KEY TERMS

Diuretic—A substance that removes water from the body by increasing urine production.

pH—A measure of the acidity of a fluid. On a scale of 1 to 14, a pH of 7 is neutral. Higher pH readings are alkaline and lower pH readings are acidic.

Ureter—A tube that carries urine from the kidney to the bladder.

changes can be made to reduce the risk of future stone formation and to facilitate the resorption of existing stones. Supplementation with magnesium, a smooth muscle relaxant, can help reduce pain and facilitate stone passing. **Guided imagery** may also be used to help relieve pain. Large stones may require conventional medical intervention.

Allopathic treatment

The pain associated with a kidney stone sends most patients to the emergency room, and a patient with a kidney stone will say that the most important aspect of treatment is adequate pain relief. Because the pain of passing a kidney stone is so severe, narcotic pain medications are usually required. If the patient is vomiting or unable to drink fluids because of the pain, it may be necessary to provide intravenous fluids and anti-emetics (drugs that stop vomiting). If symptoms and urine tests indicate the presence of infection, antibiotics are required.

Although most kidney stones pass on their own, some do not. The preferred method of treatment is extracorporeal shock wave lithotripsy (ESWL). Shock waves are aimed at the stone. The energy of the shock waves causes the stone to vibrate and fragment into small pieces that can be more easily passed. This procedure is generally done under light anesthesia because the shock waves cause pain. If the stone is lodged in the ureter, the urologist may insert a device into the ureter that can direct laser or ultrasound energy at the stone and pulverize it. If the stone is large and ESWL does not work, the stone may be removed by minimally invasive surgery.

Expected results

A patient's prognosis depends on the underlying disorder causing the development of kidney stones. In most cases, patients with uncomplicated calcium stones recover very well. About 60% of these patients, however, will have other kidney stones. Struvite stones are particularly dangerous because they may grow extremely large, filling the tubes within the kidney. These are called staghorn stones and will not pass out in the urine. They require surgical removal. Uric acid stones may also become staghorn stones.

Prevention

Prevention of kidney stones depends on the type of stone and the presence or absence of an underlying disease. In almost all cases, increasing fluid intake so that a person consistently drinks 2 to 3 quarts (liters) of water a day is an important preventative measure. Drinking a glass of lemonade made with real lemons or real lemon concentrate also helps increase the amount of citrate in the urine. Citrate makes it more difficult for kidney stones to form.

People with calcium oxalate stones do not need to reduce the amount of calcium in their diet but may reduce the amount of foods containing oxalate. These foods include rhubarb, star fruit, beets, beet greens, collards, okra, refried beans, spinach, Swiss chard, sweet potatoes, sesame seeds, almonds, and soy products. A vegan diet or one very low in animal products also is effective in preventing kidney stones, especially when combined with a very low salt diet.

People prone to form kidney stones may also be given medication to help prevent their formation. A thiazide diuretic can help prevent the formation of calcium stones. Allopurinol (Zyloprim, Aloprim) reduces the amount of uric acid blood and urine and helps prevent the formation of uric acid stones. Sturvite stones often form when the kidney becomes infected, so preventing infection also helps to prevent stone formation. Cystine stones are difficult to prevent.

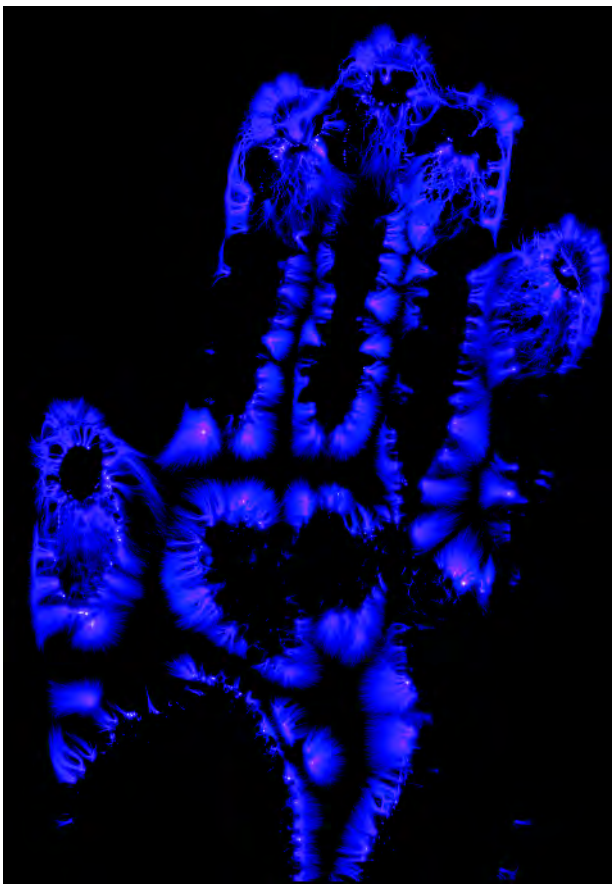
Kirlian photography

Definition

Kirlian photography creates a photographic image by placing the object or body part to be photographed on film or photographic paper and exposing it to an electromagnetic field.

Origins

Although experiments with photographing objects exposed to an electrical field are known to have been carried out as early as the 1890s, Kirlian photography is generally said to have originated with the work of a pair of Soviet scientists, Semyon and Valentina Kirlian, beginning around 1939. Over the next several decades at Kazakh State University, the Kirlians developed electrophotographic techniques which used neither a lens nor a camera. By the 1960s, their work had attracted public attention in the Soviet Union. Interest in Kirlian photography spread to the West during the 1970s, where attempts were made to replicate effects achieved in photographs of Alexei Krivorotov, a well-known psychic healer in the U.S.S.R. In the United States, studies were carried out with psychic healers at the Jerrey Society for Parapsychology and the UCLA Neuropsychiatric Institute.



Kirlian photograph of a hand. *(© Andrew Wakeford / Alamy)*

Benefits

The most common therapeutic use of Kirlian photography is as a diagnostic tool. Variations in the shapes, colors, and intensity of the images produced are said to provide clues to the patient's overall health and energy level and to indicate the presence or absence of disease, specific emotional states, and other physiological or psychological conditions.

Kirlian photograph of the palms of a woman's hands. *(© Photo Researchers, Inc. Reproduced by permission.)*

Description

Practitioners most often photograph the patient's hand (or, less frequently, the foot), which rests on a photographic medium placed over an electrically charged metal plate. During the approximately one-minute exposure, the patient may feel tingling in the exposed surface. After developing the image, the practitioner interprets its significance and, if necessary, refers the patient to a health-care provider for treatment. Kirlian photography is also sometimes used to assess the effectiveness of treatments (such as **acupuncture**) by comparing before and after photographs of the patient.

Research and general acceptance

Although some have speculated that Kirlian photography actually records the aura long said by some mystics and psychic healers to exist around human beings, this is not a generally accepted viewpoint. A scientific explanation of these dramatic images is that they result from interactions between charged particles created by the electromagnetic field used to form the images. A 1976 *Science* article concluded that moisture is a principal determinant of the form and color of human Kirlian photographs.

It has also been noted that variations in a variety of factors, including the amount of pressure on the plate, the voltage and frequency, and the exposure time, moisture, and temperature, can all influence the images produced.

For these reasons, as well as claims of unreliability and a lack of research data supporting its use, Kirlian photography is not recognized as a legitimate diagnostic tool by the mainstream medical community.

Nevertheless, individual practitioners and researchers continue to experiment with Kirlian photography for diagnosis, especially in Russia and Eastern Europe. It

has also been used for nonmedical purposes, such as detecting flaws in metal and determining the viability of seeds.

Knee pain

Definition

Knee **pain** refers to any aching or burning pain of the knee joint. Knee pain can be a symptom of numerous conditions and diseases including knee **stress**, **osteoarthritis**, injury, **gout**, infection, and **bursitis**.

Description

Knee pain is very common. Each year, millions of Americans visit the doctor for knee pain. It is the most frequent reason for visits to an orthopedist (bone and joint surgeon).

To understand the various causes of knee pain, it is important to know how the knee functions. The knee refers to the joint where the femur (thigh bone) meets the tibia (largest lower leg bone). In front of this joint lies the patella (knee cap). The joint is lined by a membrane called a synovial sac. The synovial sac produces synovial fluid which acts as a lubricant much in the way that oil lubricates the moving parts of machinery. Other tissues that make up the knee joint include cartilages, muscles, tendons, and ligaments. The upper end of the tibia has cartilaginous shock absorbers called "menisci" (meniscus). Other protective structures are the bursae, which cushion areas of friction in the joint. Most of the muscles involved with joint mobility originate in the thigh, cross the knee joint, and attach to the tibia.

The knee supports two to three times a person's body weight. It is a complex joint that allows for a considerable range in mobility. In addition to simple flexion (bending) and extension (straightening) movements, the knee joint is designed to allow for rotation, gliding, and rolling movements. To allow for complex mobility and joint stability, joint strength is sacrificed, making the knee very prone to injury.

X ray of an arthritic knee showing narrowing of the joint space with sclerotic changes in an 84 year old woman. *(© PHOTOTAKE Inc./ Alamy)*

Causes and symptoms

Knee pain is a symptom of many different diseases and conditions. Short-term knee pain may be the result of excess stress on the knee. Possible causes of knee pain include:

- Arthritis. Osteoarthritis (joint degeneration), rheumatoid arthritis (joint inflammation), and septic arthritis (joint infection) can cause knee pain.
- Bursitis. Inflammation of the bursae of the knee can cause knee pain. Bursitis can be caused by infection, gout, rheumatoid arthritis, injury, illness, or chronic irritation (crawling or kneeling)

KEY TERMS

Bursae—Sacs of fluid that serve to cushion areas of friction in joints.

Decoction—Concentration of an herb obtained by boiling it down.

Ligament—A fibrous band of tissue connecting cartilage or bones that serves to strengthen and support joints.

Meniscus—Crescent-shaped disks of cartilage located on the head of the tibia that serve as shock absorbers.

Tincture—A medicinal solution consisting of an herb and alcohol mixture.

- Cysts. A cyst is a fluid-filled sac. Cysts associated with the knee can cause swelling and knee pain or discomfort.
- Fracture. Breakage or crack in any of the bones associated with the knee joint can cause knee pain.
- Gout. A faulty chemical process leads to high levels of uric acid in the blood which causes inflammatory arthritis, crystal deposits in joints, joint destruction, and joint pain.
- Ligament injury or instability. The ligaments supporting the knee may be injured or strained by persons who participate in sports, particularly football, rugby, lacrosse, basketball, skiing, soccer, and volleyball. Other accidents can also cause ligament damage.
- Loose bodies. This condition refers to any loose objects that float around the knee and cause problems. They also are called "joint mice" because of their elusive nature.
- Meniscus conditions. Damage, usually in the form of a tear, to the menisci can be caused by degenerative changes associated with advancing age or sports-related injury. Sports that commonly cause menisci damage include football, basketball, soccer, tennis, lacrosse, and skiing.
- Osteonecrosis. Degeneration of the bones associated with the knee cause pain and deformity.
- Patellofemoral pain. Also known as anterior knee pain syndrome, this condition is characterized by pain around the knee cap. The exact cause of patellofemoral pain is unknown but is probably related to muscle inadequacy, lack of flexibility, rapid growth, or bone positioning.

Diagnosis

Knee pain can be diagnosed and treated by an orthopedic surgeon. Diagnosis is based primarily on medical history and physical exam. The diagnosis begins with a detailed medical history to fully characterize the knee pain. The knee will be bent to determine the range of motion and palpated (felt with the hands) to detect the presence of any abnormalities. The physical exam may include any of a number of different tests designed to detect injuries by manipulating the knee and leg. X rays may be taken. In some cases more advanced testing may be carried out using magnetic resonance imaging (MRI), computed tomography (CT), or contrast arthrography (x ray following injection of a contrast solution).

Treatment

Most alternative treatments for knee pain aim at reducing pain, inflammation, and stiffness. Persons experiencing long-term or severe knee pain should consult a physician to determine the underlying cause.

Herbals

Several herbal remedies are recommended to relieve knee pain. Some remedies are used externally, while others involve internal use of herbs.

The following herbs may relieve knee pain and/or associated symptoms when used externally:

- basil and sage oil rub: knee pain
- comfrey (*Symphytum officinale*) oil rub: joint stiffness and aching joints
- eucalyptus (*Eucalyptus globulus*) essential oil rub: swelling
- ginger (*Zingiber officinale*) root hot compress or bath: joint stiffness, arthritis, and degenerative joint disease
- lavender (*Lavandula officinalis*) essential oil rub: joint stiffness and aching joints
- mustard (*Sinapsis alba*) powder bath or paste (with alcohol): knee pain
- red pepper (*Capsicum*) lotion: arthritic pain and swelling
- St. John's wort (*Hypericum perforatum*) oil rub: joint stiffness and aching joints
- wintergreen (*Gaultheria procumbens*) oil rub: chronic pain

The following herbs may relieve knee pain and/or associated symptoms when used internally:

- celery (*Apium graveolens*) decoction or tincture: swollen joints and gout

- chamomile (*Matricaria recutita*): spasms and swelling
- deadly nightshade (*Atropa belladonna*) plaster: swollen joints
- devil's claw (*Harpagophytum procumbens*) tablets: swollen joints
- flaxseed (*Linus usitatissimum*) oil: lubricates joints
- feranium (*Pelargonium odoratissimum*): chronic pain
- jamaican dogwood (*Piscidia erythrina*): pain and swelling
- lemon (*Citrus limon*) juice: swollen joints
- prickly ash (*Zanthoxylum americanum*) tea: joint pain
- white willow (*Salix alba*) tablets or decoction: swollen joints and joint pain
- wild lettuce (*Lactuca virosa*): pain and swelling

Other remedies

Various other alternative treatments that can be helpful in relieving knee pain include:

- Acupressure. Pressing the Stomach 36 point located below the knee caps tones muscles and relieves joint pain anywhere in the body. Pressing the Spleen 9 points located below the kneecap on the inside of each leg relieves knee pain.
- Acupuncture. Inflammation and pain may be relieved by acupuncture. The large intestine meridian is the most effective channel for pain relief. A National Institutes of Health consensus panel found that acupuncture may be an effective treatment for osteoarthritis pain.
- Aromatherapy. Aromatherapy with essential oils is sometimes recommended. The essential oil of peppermint relieves pain and decreases inflammation. The essential oil of rosemary relieves pain and relaxes muscles.
- Chinese medicine. Knee sprain and contusion (bruise) are treated by application of *Shang Ke Xiao Yan Gao* (Relieve Inflammation Paste of Traumatology) and ingestion of *Die Da Wan* (Contusion Pill). Once the initial pain and swelling have been reduced, the patient can apply *Shang Shi Zhi Tong Gao* (Relieve Damp-Inducing Pain Medicinal Plaster).
- Exercise. Regular moderate exercise can reduce pain by improving the strength, tone, and flexibility of muscles. The endorphins released while exercising may also be helpful.
- Food therapy. Following a detoxification diet may restore nutritional balance to the body and relieve joint pain. Animal proteins may induce joint pain caused by inflammatory conditions, such as arthritis, so following a vegetarian diet may be helpful.
- Homeopathy. Rhus toxicodendron is recommended for joint and arthritis pain that is worse in the morning and relieved by warmth. Kali bichromicum is indicated for persistent, severe pain. Other homeopathic remedies can be designed for specific cases by a homeopathic practitioner.
- Hydrotherapy. A warm compress can relieve joint stiffness and dull pain. A cold compress or ice pack can relieve sharp, intense pain.
- Magnetic therapy. Magnetic fields may increase blood flow and block pain signals.
- Massage. Joint pain may be relieved by massaging the area above and below the painful joint. Massaging with ice packs may interfere with pain signals and replace them with temperature signals.
- Reflexology. Knee pain may be relieved by working the knee reflex points.
- Rolfing. This deep, sometimes painful, massage therapy may speed healing and reduce pain.
- Supplements. Knee pain may be relieved by taking vitamin C to promote healing, the B vitamins to balance the nervous system, which reduces pain, and calcium to increase bone strength.

Allopathic treatment

Knee pain may be relieved by taking nonsteroidal anti-inflammatory drugs such as acetaminophen (Tylenol), ibuprofen (Advil, Motrin), or naproxen (Aleve). More severe pain may be treated with prescription pain relievers such as tramadol or a narcotic. Additional treatment for knee pain depends upon the underlying cause and may include injection of drugs into the knee, surgery, wearing a brace, and/or physical therapy. Surgical treatment depends on the cause, but in the case of osteoarthritis, some patients face actual replacement of the joint. However, in 2002, a new device was introduced that postponed the need to replace an arthritic knee. The device is made of chrome and fits between the natural structures of the knee.

Expected results

Most causes of knee pain respond well to conservative treatments and resolve within 4–6 weeks. Knee pain caused by injury or disease may require surgery and lengthy rehabilitation.

Prevention

Strengthening the leg muscles may help prevent knee pain caused by overworking the joint. In addition, a stronger knee may prevent injury to the joint. Squats are an easy **exercise** that will strengthen the quadriceps (front thigh muscles) and hamstrings (back thigh muscles). The **yoga** warrior posture strengthens the muscles around the knee and increases range of motion.

Kneipp wellness

Definition

Kneipp wellness is a holistic system for overall health developed by Sebastian Kneipp, a nineteenth-century Bavarian priest. His approach includes aspects of **hydrotherapy**, herbalism, and aerobic **exercise**.

A couple at the Kneipp Wellness bathing village of Bad Mergentheim in Baden Württemberg, Germany. *(© mediacolor's/ Alamy)*

Origins

Sebastian Kneipp was born to a poor family in Stephansreid, Bavaria, on May 17, 1821. He initially took up his father's trade of weaving, but longed to become a priest. With help from a sympathetic clergyman, he was admitted to high school as a mature student, but after five years of intensive studies, Kneipp became seriously ill with pulmonary **tuberculosis**. At that time, the disease was usually fatal, but Kneipp came across an eighteenth-century book about hydrotherapy that inspired him during the winter of 1849 to immerse himself several times a week in the icy Danube River. These brief exposures to cold water seemed to bolster his immune system, because Kneipp's tuberculosis went into remission and he was able to continue his theological studies in Munich. There, he convinced some of his fellow students to join his experiments with hydrotherapy.

Kneipp was ordained as a priest in 1852. In that capacity, he began using hydrotherapy to help some of his poorer parishioners. He broadened his approach to include herbalism, exercise, and other elements, and toned down his initial enthusiasm for shocking the body with cold water. "I warn all against too-frequent application of cold water," he later wrote. "Three times I concluded to remodel my system and relax the treatment from severity to mildness and thence to greater mildness still." Kneipp's reputation grew after a number of dying patients recovered when he was called to administer last rites

KEY TERMS

Hydrotherapy—A family of therapies that treat illness by using water either externally or internally.

Phytotherapy—A form of treatment that uses plants or plant extracts either externally or internally.

and managed instead to restore them to health. In 1855 he was assigned to Worishofen, a village in the foothills of the Bavarian Alps that soon developed an international reputation as a place of healing. Kneipp summarized his teachings in two popular books, *My Water Cure* in 1886 and *So Sollt Ihr Leben (Thus Thou Shalt Live)* in 1889. Supporters of his techniques formed Kneipp Societies in Germany and the United States.

Father Kneipp was later named a monsignor by Pope Leo XIII. After his death in Worishofen on June 17, 1897, his wellness techniques became less popular, but interest in hydrotherapy increased again during the latter part of the twentieth century.

Benefits

Proponents of Kneipp therapy believe that it bolsters the immune system and results in improved overall wellness. In Germany, it is especially popular for treating **varicose veins**.

Description

Today, Kneipp physiotherapy is essentially a form of classical naturopathy. It is founded on five "pillars":

- Hydrotherapy. Hydrotherapy involves the use of hot and cold water to stimulate the nerves, blood vessels and internal organs. It uses baths, compresses, packs, and water jets.
- Phytotherapy. Plant therapy takes the form of medicinal herbs added to bath water and also administered as juices, lozenges, teas, or ointments, etc.
- Exercise therapy. This aspect of treatment involves long hikes, gymnastics, tennis, cycling, and other vigorous activities to amplify the effects of the water and herb therapies.
- Nutrition therapy, which employs a low-protein, high-fiber diet. Special Kneipp diets are also available for weight loss or such ailments as gout, diabetes, or metabolic problems.
- Health maintenance therapy. Patients in the Kneipp program are trained to adhere to their natural biorhythms.

Precautions

All forms of hydrotherapy may pose some risk of water-borne **infections**, and patients should make sure that baths and similar facilities are properly maintained and disinfected. In addition, persons with serious health problems should consult their physician before undertaking an exercise program.

Side effects

Side effects may vary, depending on the numerous herbs used in Kneipp therapy. When in doubt, it is best to consult a knowledgeable herbalist.

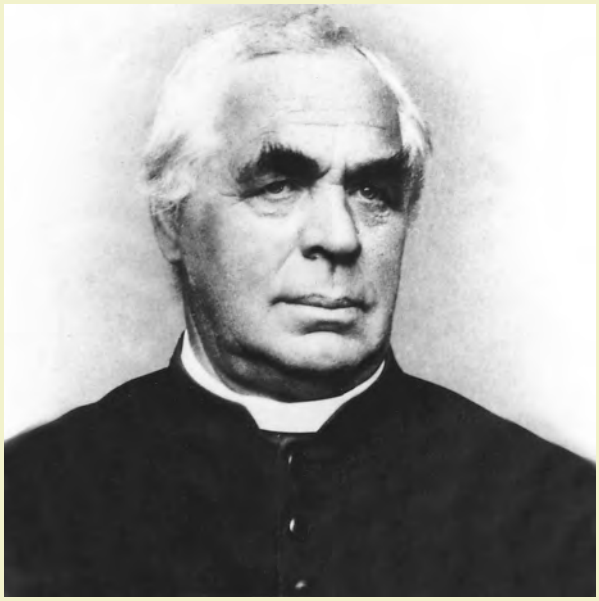
Research and general acceptance

Initially, Kneipp was rejected as a charlatan by the medical establishment. At one point, he was taken to court for quackery, although the judge acquitted him after learning from Kneipp about the shortage of physicians in Alpine villages. Kneipp is now recognized by naturopaths as a founding father of their discipline. The benefits of water are well-known to physiotherapists, but there is so far little conclusive evidence that Kneipp or other methods of hydrotherapy can increase the body's immunity. One German study published in 1977 found that immunological reactions to protein and bacterial antigens were significantly more intense in patients who had undergone Kneipp hydrotherapy, compared to a group of healthy volunteers. There is little doubt among medical doctors that patients should benefit from the vigorous exercise and **high-fiber diet** included in the Kneipp prescription for wellness.

Training and certification

The world center of Kneipp wellness is the village of Bad Worishofen in the foothills of the Bavarian Alps. There, the Kneipp *Kur* is offered by spas, physicians, and guest houses. Healer training is provided by the Sebastian Kneipp School of Physiotherapy. Elsewhere in the world, many adherents of Kneipp's writings treat themselves by using his techniques.

FATHER SEBASTIAN KNEIPP (1821–1897)



(Betmann/CORBIS. Reproduced by permission.)

Born in Stephansreid, Bavaria, Germany, of poor parents, Sebastian Kneipp's childhood was filled with labor, much of it learning weaving from his father. Even as a child, Kneipp wanted to become a priest. With the help of a priest who befriended him, Kneipp entered high school where he studied theology for five years. During this time, he contracted consumption (pulmonary tuberculosis), usually a fatal disease at that time. While ill, he read an eighteenth century book on hydrotherapy by Dr. Hahn. This caused him to bathe two or three times a week in the icy Danube River to stimulate his immune system. His tuberculosis went into remission, his health improved, and in 1850, he entered a seminary in Munich. He continued his hydrotherapy and convinced other theological students to practice it. Kneipp was ordained a priest in 1852. During the next few years, he was called to the bedsides of many patients to perform the last rites. Instead he successfully treated a number of the patients with hydrotherapy.

He perfected his own system of hydrotherapy and his successful treatment of the poor attracted much attention. People came from throughout Germany to be healed by Kneipp's hydrotherapy. His success fostered resentment from physicians and at one point, he was charged in German courts with quackery, where he was subsequently acquitted. In 1886, he published *My Water Cure*, which was translated into several languages and became popular throughout Europe. He continued to refine his treatment from one of severity to milder versions. It consisted of bathing in and drinking cold water, going to bed and rising early, long barefoot walks in wet grass, and simple meals consisting of little meat and lots of whole grain cereals. He continued his hydrotherapy practice at Wörishofen Monastery in the foothills of the Alps until his death. Kneipp's hydrotherapy is still practiced throughout the world, especially in Germany and the United States.

David Helwig

Kola nut

Description

The kola nut, or bitter cola, (*Cola vera, Cola acuminata, Cola nitida*) is a seed part from a tree from the Sterculiaceae family. The trees are native to Central and Western Africa, but are now found in the West Indies and Brazil, where they were introduced by African slaves. All three species are used as a stimulant and are prepared in the same manner. The kola tree grows to approximately 40 ft (12 m) in height, and has white to yellow flowers with spots that range from red to purple. The kola tree's leaves are 6–8 in long (15–20 cm) and the tree bears fruit that is shaped like a star. Inside the fruit, about a dozen round or square seeds can be found in a white seed shell.

General use

Kola nut, which contains high amounts of **caffeine**, helps combat **fatigue** and is most commonly used as a central nervous system stimulant that focuses on the cerebrospinal centers. It also contains theobromine, a stimulant found in chocolate as well as in **green tea**. Kola nut also contains tannins, phenolics, phlobaphens, kola red, betaine, protein, starch, fat, **thiamine**, **riboflavin**, and **niacin**. The *Journal of the American Medical Association* advocates the use of kola over other stimulants, because it is not addictive

Kola nut plant. *(©PlantaPhile, Germany. Reproduced by permission.)*

and does not lead to **depression**. Because kola nut is also a diuretic, its use has been suggested for those with renal diseases, cardiac or renal **edema** and rheumatic and rheumatoid conditions. Most people around the world are familiar with kola; many have tasted it and do not even know it. In the 1800s, a pharmacist in Georgia took extracts of kola, sugar and coca and mixed them with carbonated water. His accountant tasted it and called it "Coca Cola." Today, Coca-Cola still uses kola in its original recipe.

Respiratory conditions

Kola is widely used as a treatment for **whooping cough** and **asthma**, as the caffeine acts as a bronchodilator, expanding the bronchial air passages. A *Journal of American Medicine* cites a study of kola nut's effects on asthma that showed "the attack being cut short and the child's condition rapidly improved."

Gastrointestinal disorders

In Africa, the fresh nuts are chewed as a ceremonial greeting, as a stimulant, and to help aid digestion, as kola nut stimulates gastric acid production. Kola nuts are also known to improve the taste of food and act as an appetite suppressant.

Other conditions

The kola nut is also used to treat migraine headaches, because the caffeine and theobromine act as cerebral vasodilators (increase blood flow in the head) and, when used in a poultice, can be applied to external **cuts** and scrapes.

More recently, an ephedra/caffeine preparation made from kola nut extract and a Chinese medication known as Ma Huang was tested for safety and efficacy as part of a weight reduction program. The study indicated that the preparation improved the subjects' rate of weight loss and reduction in body fat without undesirable side effects.

The flavor of kola nut in cola beverages appears to be more effective than other flavors in disguising the taste of **activated charcoal** when the charcoal must be given as an antidote for accidental poisoning.

KEY TERMS

Bronchodilator—A medicine that relaxes the bronchial muscles and opens up the air passages to the lungs.

Cardiac arrythmia—The irregular beating of the heart.

Cotyledon—A seed leaf, from the embryo of a seed plant.

Theobromine—A stimulant that occurs naturally in chocolate as well as in kola nut. Foods and drinks containing theobromine are poisonous to domestic pets.

Vasodilator—A drug or nerve that causes blood vessels to widen.

Preparations

The part of the seed known as the kola nut is the cotyledon, which is also called the seed leaf. The cotyledons are white and bitter when they are fresh, but they turn reddish with almost no taste when they are dried. Fresh nuts are difficult to find outside of the tropical areas where they are grown. Sometimes, the nuts are sold at African markets in international cities, like Washington D.C. The dried cotyledons are 1–2 in (2.5–5 cm) long.

Dosage of kola nut should be 2–6 g per day, as 2.5–7.5 g of liquid extract or 10–30 g per day of tincture. Powdered cotyledons should be taken at 1-3 g per day, as a decoction, liquid extract, or tincture. For the decoction, boil 1-2 teaspoons in a cup of water and take three times a day. The liquid extract should be taken in a 1:1 solution of 60% alcohol at .6-1.2 ml three times a day. Tinctures in a 1:5 solution of 60% alcohol, with 1-4 ml of the cotyledons three times a day.

Precautions

Because of its use as a stimulant, kola nut should be used with caution. Patients should consult with their doctors, especially if they are taking other medications. Due to its caffeine content, kola nut should not be used by women who are pregnant or nursing a child. Also because of its caffeine content, it is not advisable for those suffering from **insomnia** or **anxiety** problems. In some cases, extreme restlessness and sleepnessness can occur. It should not be used by patients with a history of high blood pressure, heart trouble, palpitations, seizures, insomnia, **heart disease**, high **cholesterol**, or **stroke**. Research in Niger showed that the habitual chewing of kola nut can actually cause cardiac arrythmias, based on clinical trials using cats. Kola nut should not be used by those with stomach or duodenal ulcers because it increases gastric juice production and may add to gastrointestinal discomfort and disorders. Kola nut is also one of the top ten common food allergens, among cow's milk and chocolate. Kola nut is naturally very high in tannin, a white-to-yellow astringent powder that gets its name from its use as a textile and leather tanning agent. However, a University of Miami study shows that "tannins are increasingly recognized as dietary carcinogens and as antinutrients interfering with the system's full use of protein" and called for more studies correlating early death and regular kola nut use in third world countries. Kola nut should not be used long-term.

Kola nut and cola beverages should be kept away from dogs, cats, and other domestic animals. The theobromine in kola nut (and in chocolate as well) can be fatal to these pets because they metabolize it much more slowly than humans.

Side effects

Kola nut may cause insomnia, anxiety, nervousness, gastrointestinal problems, and tremors. If there is any indication of an overdose, **diarrhea**, **nausea**, and/or cramps may follow. Oral **blisters** have also been known to form.

Heavy use of kola nut or drinking large quantities of cola beverages has been associated with bone loss in adults and inhibition of bone formation in adolescents. Some practitioners are recommending that teenagers should restrict intake of soft drinks containing cola in order to lower their risk of **osteoporosis** in later life.

Interactions

Kola nut should not be used with muscle relaxants, heart medications, high blood pressure medication, nitrates and calcium-channel blockers.

Clinical experiments indicate that beverages containing cola increase the rate and extent of absorption of carbamazepine (Tegretol), a drug used to treat **epilepsy** and some forms of **bipolar disorder**. Kola nut has been reported to interact with tricyclic antidepressant medications and with MAO inhibitors. In general, patients taking any medication for anxiety or depression should consult their physician before taking preparations containing kola nut.

Kombucha

Description

Kombucha is a fermented beverage prepared from a mushroom (*Fungus japonicus*). Known as kombucha tea, the drink is touted for its health-promoting properties. It is also called Manchurian mushroom tea, Manchurian fungus tea, Kwassan, combucha tea, and champagne of life. During fermentation and preparation, the kombucha membrane becomes a tough, gelatinous cover composed of several different yeasts (one-celled fungi) and certain nontoxic bacteria derived from the air, similar to a sourdough bread starter. When the fungus is fermented in a mixture containing water, black or **green tea**, sugar, and vinegar (or other fermentation source), the microorganisms combine into a complex fermenting culture. This culture produces several compounds that have been considered health tonics over the centuries. Kombucha also contains several B vitamins and **vitamin C**. The tea is said to have a unique, pleasant taste. The membrane surface of the kombucha is also edible.

Kombucha tea. *(© Bon Appetit / Alamy)*

In China, kombucha tea has been utilized as a health beverage for thousands of years, dating back to before 200 B.C. It has been consumed for centuries in Japan, Korea, and Russia. In the early 1900s, use of the tea spread from Russia into other European countries including Germany, where it was touted as a health elixir for many years. In the 1950s and 1960s, German and Italian researchers claimed that kombucha tea exhibited strong anticancer properties, and it was promoted as a miracle cure for **cancer**. Alexander Solzhenitzyn, the Nobel Prize winning Russian author, reported that kombucha tea, which he began to drink during a prison term, cured his stomach cancer. Proponents of kombucha tea continue to tout its possible anticancer and immunity-enhancing properties. However, controlled studies have failed to display conclusive evidence as to its efficacy in treating various medical conditions.

General use

Kombucha tea is taken as a general health tonic. Claims are made for its use as a remedy for specific health conditions and diseases. It is used to introduce

KEY TERMS

Anthrax—A highly toxic strain of bacteria.

Intestinal flora—The beneficial bacteria that live in the digestive tract and aid digestion of food.

and improve healthy intestinal flora and bacteria, as an energy-enhancing tonic, and as a detoxifier in helping to remove pollutants. It is taken to strengthen the immune system after an illness, stimulate hair growth, improve arthritis and skin conditions, and as a health tonic for cancer and autoimmune deficiency syndrom (**AIDS**) patients.

Kombucha tea contains significant amounts of the B complex vitamins, as well as vitamin C and minerals. It contains a small amount of alcohol (higher than 1%), which is produced during fermentation, and small amounts of methylxanthine stimulants. Teas do not contain **caffeine**, but they do contain methylxanthine alkaloids, a similar stimulant.

There is no large body of scientific evidence that supports the strong claims made by advocates of kombucha tea. Some European studies have pointed to positive results in cancer cases, but further research is needed to confirm these results. Its proposed anticancer and **detoxification** effects have been attributed to certain chemicals in the tea. However, more recent tests have failed to validate the presence of these chemicals in the beverage. One study did confirm improvements in liver function after a three-week treatment. Research in Russia demonstrated antibiotic effects caused by kombucha tea. There are many testimonial claims that the tea increases vitality and overall well-being. In general, properly fermented foods have been shown to aid in the growth of beneficial intestinal flora, reduce the growth of harmful yeasts and bacteria in the digestive tract, and improve digestion and absorption. Some testimonial claims have also been made by cancer and AIDS patients.

Preparations

Kombucha tea is available in several forms. Kits include the fungi and all ingredients, as well as directions to make the brew at home. The fungi may also be purchased separately. Dried kombucha is available in capsule form.

Making the tea from scratch is a process similar to preparing yogurt, sauerkraut, and other fermented foods. Instructions should be followed carefully. Particular care should be taken to maintain the cleanliness of the tea-making process, to avoid contamination by mold or unhealthy bacteria (a cause of health problems in those drinking poor quality kombucha). **Smoking** in the same room as the mixture may contaminate it. Mold typically appears as green, pink, or black blotches in the culture, and should be thoroughly removed and discarded. The fermentation process is generally successful if the kombucha skin remains firm and rubbery. Care should be taken if the membrane becomes crumbly or discolored. On average, the fermentation of kombucha tea takes 12–14 days. After fermentation, new batches can be easily made from the existing culture.

When using the supplement in pill form, consumers can follow the manufacturer's recommended dosages. Users of the tea can drink up to three cups of the beverage per day, with food or between meals.

Historically, kombucha was consumed as a tea. The health benefits of other forms of the supplement have not been compared with the original therapeutic beverage. There are reports of consumer illness from home prepared kombucha. This may have been due to tea that was too old, infected with molds or other contaminants, or had other problems. Consumers must be alert to the risks of home prepared fermentation methods.

Precautions

Several precautions concerning kombucha tea have been issued. Because the beverage is fermented at home, there is the risk that the liquid can become contaminated by dangerous bacteria such as anthrax. People with compromised immune systems must be extremely careful not to consume contaminated fermentations. Due to the high acidity of the drink, the tea should not be placed in metal containers or in pottery that has a lead glaze finish. There have been reported cases of **lead poisoning** and anthrax due to drinking kombucha tea that has been improperly prepared. The United States Food and Drug Administration (FDA) issued a warning concerning the danger of lead poisoning from improperly made kombucha tea. Kombucha tea is not recommended for pregnant or nursing mothers.

Side Effects

Consumption of kombucha tea has been observed to cause stomach upset, yeast **infections**, allergic reactions, **nausea**, and **headache**. Persons with stomach ulcers may find that kombucha increases their symptoms. Due to harmful bacteria that can survive in the culture, ingesting contaminated tea can be dangerous or fatal.

Interactions

Kombucha tea is high in acidity, and should not be consumed by those taking medications that make them susceptible to increased gastrointestinal acidity. The tea contains a small amount of alcohol, and should not be consumed with any medications that interact unfavorably with alcohol. The tea should not be taken by people with stabilized **alcoholism**, to avoid aggravating the condition.

Some people report general and specific improved health from moderate use of kombucha tea. These reports await final validation by current research. There are risks associated with the use of poor quality or contaminated kombucha. Its use may be contraindicated in those who have medical conditions or require certain medications.

Douglas Dupler

Kudzu

Description

Kudzu, whose botanical name is *Pueraria lobata*, is a member of the Fabaceae legume family. It is also known as Ge-gen, kudzu vine, mile-a-minute vine, foot-a-night vine, and the vine-that-ate-the-South. The latter names refer to this vine's property of rapid growth. This perennial trails, climbs, and winds its rough vines around tree poles and anything else it touches. It grows in shady areas, mountain areas, fields, roadsides and forests in China, Japan, and the southern United States, more so in the latter because when imported, its native insects did not tag along. Kudzu was first seen in the United States as an ornamental plant at the 1876 Philadelphia Centennial Exposition. During the Depression, the United States Department of Agriculture (USDA) imported kudzu for erosion control. In 1972, the USDA classified kudzu as a weed because the plant can reach 60 ft (18.29 m) in a single growing season. In June and July, the vines sport purple flowers and in autumn, the leaves shed.

The kudzu root, which can grow to the size of a human being, has a history of use in Chinese medicine. Kudzu contains daidzein, an isoflavone, and daidzin and puerarin, isoflavone glycosides. The isoflavone amount can range from 1.77–12.08%, based on kudzu's growing conditions. The highest isoflavone is puerarin with daidzin and daidzein next in isoflavone amounts. A study at the University of Michigan compared legumes for their sources of the isoflavones of genistein and daidzein. The results showed the kudzu root as a good nutritional source of those two components.

The root also supports bacteria that grab nitrogen from the atmosphere and put it in the soil. This factor may explain kudzu's rapid growth and its success in feeding Angora goats raised by Tuskegee University researcher Dr. Errol G. Rhoden.

General use

Traditional uses

Traditional Chinese medicine has used kudzu, whose Chinese name is *ge gan*, for centuries. Kudzu's medicinal uses were first recorded in Shen Nong's herbal text, published around A.D. 100. Chinese medicine recommends kudzu for what it calls *wei*, or superficial syndrome, referring to a mild disease that appears just below the body's surface and is accompanied by a **fever**. Chinese medicine also indicates using kudzu for thirst, headaches (migraine and other types of headaches), **neck pain** from **hypertension**, **angina**, **allergies**, **diarrhea**, and speeding the progression of **measles** in children. In general, kudzu is used as a demulcent, or medication given to soothe irritated mucous membranes.

Cardiovascular disease

One alternative practitioner has stated that because kudzu improves the body's flow of blood and levels of oxygen and opens heart vessels, it might help the cardiovascular system. Another researcher, James Duke, refers to a Chinese clinical study that showed that kudzu can benefit angina sufferers. For a period of 1–6 months, 71 participants took 10–15 gm of kudzu root extract. The results indicated that 29 people had significant improvement, 20 had an

KEY TERMS

Demulcent—A substance or medication given to soothe irritated or inflamed mucous membranes. Kudzu is used as a demulcent in traditional Chinese medicine.

Daidzein—An isoflavone contained in kudzu that appears to be useful in treating alcoholism.

Ethanol—Another name for the alcohol found in alcoholic drinks.

Extract—A concentrated form of the herb made by pressing the herb with a hydraulic press, soaking it in water or alcohol, then allowing the excess water or alcohol to evaporate.

Tincture—A liquid herbal preparation, made by soaking the herb in alcohol or a mixture of alcohol and water.

intermediary amount of improvement, and the remaining 22 showed no improvement or only a slight improvement.

Duke cites another Chinese study showing that kudzu can lower blood pressure. For a period of 2–8 weeks, 52 people drank about 8 tsp of kudzu root in a tea. Seventeen people had their blood pressure decrease substantially, while the other 30 had some relief from hypertension.

Alcoholism

It is the Chinese medicinal use of kudzu in treating **alcoholism**, however, that is the focus of many studies on kudzu. In 1989, two associate research professors in the psychiatry department at the University of North Carolina tested rats for their alcohol cravings. In 1991 an organic chemist tested a tea containing seven herbs including kudzu on drunken rats. The rats had been injected with alcohol; when they ingested the herbal tea, their motor movements became more coordinated.

In further studies conducted in 1992, the rats were allowed to drink alcohol for an hour each day. The rats gulped down an enormous amount of alcohol; however, after a week, when the herbal mixture containing kudzu was given to them 15 minutes before their happy hour, they drank much less alcohol. In another study, the rats were allowed to drink alcohol for the first 24 hours, then deprived for the next 24 hours. On day three, the rats' alcohol intake increased from 20% to 30%. Once injected with the herbal mixture, however, the rats either drank a normal or less than normal amount.

A 1995 study was also conducted at Harvard University using hamsters, because hamsters naturally choose alcohol over water. Thirty hamsters were given either daidzein, an active ingredient in kudzu; or disulfiram (Antabuse), a compound that stops ethanol craving in humans. Nine more hamsters were allowed to drink as much alcohol as they wanted without anything added. Hamsters receiving daidzein dropped their alcohol intake by 70% and those receiving disulfiram had 80% less alcohol intake. The researchers concluded that daidzein takes a less toxic metabolic route than disulfiram.

A double-blind random clinical study using human subjects was conducted at the Veterans' Affairs Medical Center in Prescott, Arizona. Thirty-eight middle-aged men suffering from chronic alcoholism were given either 1.2 g of kudzu root extract (21 men) or 1.2 g of a placebo (17 men) twice daily for a month. The results of this test showed no significant difference in sobriety or alcohol cravings in either group.

Preparations

The problems of manufacturing kudzu root as a drug to treat alcoholism and other disorders were outlined in an article on traditional Chinese medicine by Dr. James Zhou. Zhou says that herbs lose their natural balance when manufacturers purify, refine, and treat them with chemicals. The daidzein in kudzu could treat alcoholism, but the purification process destroys the isoflavone balance. Because it is the isoflavone puerarin in kudzu that stops cardiovascular damage impairment and may prevent an alcoholic side effect, liver damage, Zhou believes that the herb should be given in its natural state.

For angina pectoris, practitioners of traditional Chinese medicine recommend 30–120 mg of standardized tablets of kudzu root two to three times daily. Ten mg of a standardized tablet equals 1.5 g of the pure root. Tinctures of 1–2 ml three to five times daily are recommended in place of tablets. To help lower cravings for alcohol, the recommended dosage is 3–5 g of kudzu root three times daily or 3–4 ml of tincture three times daily. The *All-In-One-Guide to Natural Remedies and Supplements* recommends drinking kudzu tea to combat alcoholism. An alternative form of treatment involves taking 1500-mg supplements or cubes before or after the alcohol. The 1500 mg can be divided equally into three daily doses.

Kudzu also comes in supplements combined with **St. John's wort** to treat the symptoms of alcoholism. One capsule is taken with each meal on a daily basis.

Kudzu leaves can also be used in cooking, for example in quiches and as a deep-fried dish.

Precautions

Kudzu should not be taken by pregnant and lactating women. In traditional Chinese practice, people who sweat too much or have cold in their stomach should avoid kudzu because it is given for "wind-heat" illnesses.

Side effects

No toxic side effects or damage to the liver have been reported from kudzu.

Interactions

Kudzu should not be taken in conjunction with prescription drugs. As with all medicinal supplements, it is best to check with a health care provider before taking kudzu.

Labyrinth walking

Definition

A labyrinth is a patterned path, often circular in form, used as a walking **meditation** or spiritual practice. A labyrinth's walkway is arranged in such a way that the participant moves back and forth across the circular form through a series of curves, ending at the labyrinths's heart or center. It is unicursal, which means that it has only one entrance and leads in only one direction. Although the word "maze" is often used as a synonym for labyrinthmazes are multicursal in design; the user has to make choices at many points along the path. Mazes often have more than one entrance, and usually contain many wrong turns and dead ends.

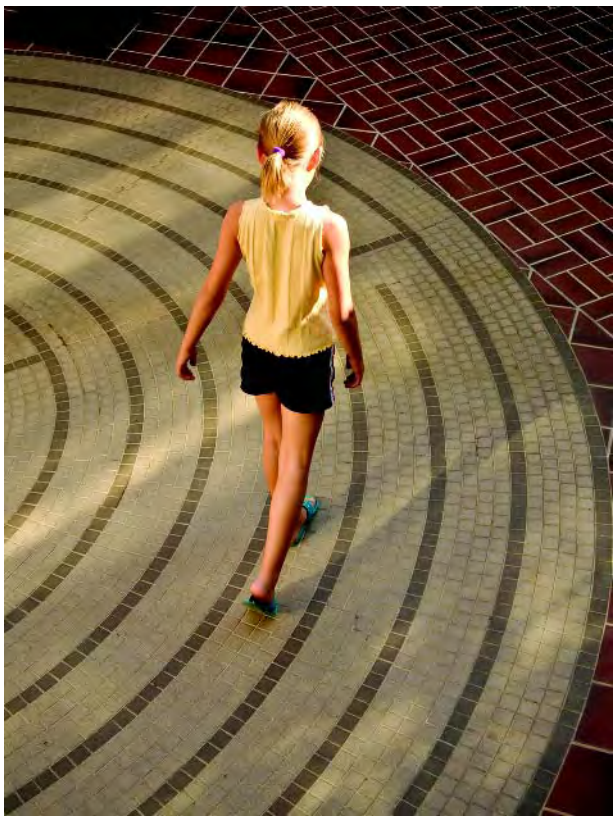
The English word labyrinth is derived from the Greek word *labyrinthos*, which in turn may come from *labrys*, the word for the double-headed axe associated with the Minoan culture on the island of Crete that was at its height around 1650 B.C.. According to the Greek historian Herodotus (c. 450 B.C.), King Minos of Crete asked an Athenian architect and inventor named Daedalus to build a house with winding passages for the Minotaur, a monster that his queen had borne after having intercourse with a bull. This mythical Cretan labyrinth was actually a maze rather than a true labyrinth, as it was intended to prevent those who entered it as human sacrifices to the Minotaur from escaping.

Origins

The unicursal designs associated with labyrinths are thought to predate constructed labyrinths. Pottery estimated to be 15,000 years old painted with labyrinthine patterns has been discovered in the Ukraine. The oldest known constructed labyrinths were built in ancient Egypt and Etruria (central Italy) around 4500 B.C., perhaps to prevent evil spirits from entering tombs. It was thought that the evil spirits were repelled by the planned order of the labyrinth's design. Other labyrinths were made by the Romans as mosaic patterns on the floors of large houses or public buildings. These mosaic labyrinths were usually square or rectangular in shape. The Romans also constructed turf labyrinths in fields or other open areas as a test of skill for horseback riders. Traces of Roman turf labyrinths have been found all over Europe.

Labyrinths have been found in many cultures around the world, including ancient India, Spain, Peru, and China. Members of the Tohono O'odham and Pima tribes in southern Arizona have made baskets for centuries decorated with the so-called "man in the maze" design. The labyrinth pattern woven into the basket represents the path to the top of a local sacred mountain known as Baboquivari. More than five hundred ancient stone labyrinths have been identified in Scandinavia. Most are located near the coast, and are thought to have been used for rituals intended to guarantee good fishing or protection from storms.

The best-known labyrinths in the West, however, are those dating from the Middle Ages. They were built as substitutes for going on a pilgrimage to Jerusalem, a journey that was physically or economically impossible for most Christians in Western Europe during this period. Cathedrals were designated as pilgrimage shrines, and labyrinths were embedded in the stone floors of the cathedrals as part of the shrine's design. The labyrinth on the floor of Chartres Cathedral in France was installed around A.D. 1200, and a similar labyrinth in Amiens Cathedral was made around the same time. Tracing the path through the labyrinth, often on the knees, was for many pilgrims the final act of devotion on the pilgrimage. The circuitous journey to the center of the labyrinth represented the many turnings in the journey of life, a journey that required the Church's guidance and support. Medieval labyrinths were circular in shape, the circle being a universal symbol of wholeness, completion, and unity.



This girl walks on a labyrinth, or a patterned path used for walking meditation or spiritual practice. *(Ginna Fleming / Alamy)*

KEY TERMS

Left brain—The left cerebral hemisphere, which controls activity on the right side of the body in humans. The left brain is thought to be specialized for language use and mathematical calculation; it is also associated with logical analysis, fact-based decisions, and planning or organization. A maze is considered a left-brain puzzle.

Mantra—A sacred word or formula that is repeated as an incantation to focus the mind and spirit, or to induce a mystical state.

Maze—A network of paths or passages intended to confuse, with numerous choices at different points. Unlike a labyrinth, a maze often has high walls intended to block the visitor's line of sight.

Right brain—The right cerebral hemisphere, which controls activity on the left side of the body in humans. It is associated with spatial and nonverbal concepts, intuition, emotions, and creativity. Labyrinth walking is thought to stimulate the right brain.

Unicursal—A curve or series of curves that forms one path, without branching or splitting. A true labyrinth is unicursal in design.

By the seventeenth century, however, many cathedral labyrinths were removed or destroyed. There is some disagreement among scholars regarding the reasons for their removal. Some experts think that the labyrinths were removed because the cathedral clergy had forgotten their history and original purpose, while others speculate that they were destroyed to prevent children from playing on them during Mass and disturbing worship. Another factor was the growth of rationalism in the seventeenth century and the hostility toward religion that emerged during the French Revolution at the end of the eighteenth century. The labyrinths were regarded as remnants of "superstition" and therefore offensive to "enlightened" people.

The contemporary revival of interest in labyrinth walking began in the early 1990s, when Dr. Lauren Artress, a psychotherapist who was on the Special Ministries staff of Grace Cathedral (Episcopal) in San Francisco, attended a Mystery Seminar led by Jean Houston, who describes herself as "a scholar and researcher in human capacities," and directs the Foundation for Mind Research in Pomona, New York. Dr. Houston presented the labyrinth as a tool for spiritual growth that would lead the seminar participants to their spiritual center. She had taped the forty-foot-wide pattern of the Chartres Cathedral labyrinth on the floor of the meeting room. Dr. Artress felt drawn to return to the labyrinth later that night and found walking through it a powerful experience. She then made a pilgrimage to Chartres itself in 1991, followed by further research into the history and significance of labyrinths. After returning to the United States, Dr. Artress made a canvas version of the Chartres labyrinth for use in the San Francisco cathedral. It was introduced to the public on December 30, 1991, and was used twice a month until 1995, when a permanent outdoor labyrinth made of terrazzo stone was laid down in the cathedral's outdoor garden.

Benefits

In general, labyrinth walking is said to benefit participants by allowing a temporary suspension of so-called left-brain activity—logical thought, analysis, and fact-based planning—and encourage the emergence of the intuition and imaginative creativity associated with the right brain. Lauren Artress has said,

"The labyrinth does not engage our thinking minds. It invites our intuitive, pattern-seeking, symbolic mind to come forth. It presents us with only one, but profound, choice. To enter a labyrinth is to choose to walk a spiritual path."

In addition to helping people open themselves to the nonrational parts of the psyche, labyrinth walking puts them in touch with simple body rhythms. Because labyrinth walking involves physical movement, participants may find themselves becoming more mindful of their breathing patterns, the repetition of their footfalls, and the reorientation of the entire body that occurs as they move through the circular turns within the labyrinth. More particularly, the overall pattern of movement in labyrinth walking—first inward toward the center of the labyrinth and then outward on the return path—holds deep symbolic meaning for many people.

Specific benefits that some people have experienced as a result of labyrinth walking include:

- answers to, or insights, personal problems or circumstances
- a general sense of inner peace or calm
- emotional healing from past abuse or other traumas
- a sense of connection to, or unity with, past generations of pilgrims or family ancestors
- reawakened interest in their specific religious tradition
- greater awareness of their own feminine nature or the feminine principle in nature, often associated with circular shapes and patterns
- stimulation of their imagination and creative powers
- improved ability to manage chronic pain
- faster healing following an injury or surgical procedure

Description

Labyrinth construction and design

Contemporary labyrinths are constructed from a wide variety of materials in outdoor as well as indoor settings. In addition to being made from canvas, mosaic flooring, or paving stones, labyrinths have been woven into patterned carpets, outlined with stones, bricks, or hedgerows, or carved into firmly packed earth. Most modern labyrinths range between 40 and 80 feet in diameter, although larger ones have also been made.

One classification scheme categorizes labyrinths as either left- or right-handed, according to the direction of the first turn to be made after entering the labyrinth. The entrance to the labyrinth is known as the mouth, and the walkway itself is called the path. Classical labyrinths are defined as having a simple path with an equal number of turns and counterturns. Labyrinths are also classified by the number of circuits in their design, a circuit being one of the circles or rings surrounding the center of the labyrinth. The labyrinth in Chartres Cathedral, for example, is a classical eleven-circuit labyrinth. Three- and seven-circuit classical labyrinths have been constructed in many parts of the United States, while one labyrinth in Denmark has 15 circuits.

Walking the labyrinth

The actual procedure of labyrinth walking is divided into three phases or stages: the journey inward, a pause for **prayer** or meditation at the center, and the return journey. There are no rules or guidelines for the pace or speed of labyrinth walking, although participants are asked to be respectful of others who may prefer a slower pace, and to move around them as gently as possible. Some people choose to dance, run, crawl on their hands and knees, or walk backwards in the labyrinth. With regard to pausing in the center of the labyrinth, people's behavior varies depending on the size of the labyrinth. Labyrinths based on the Chartres model have six "petals" or semicircular spaces surrounding the center, which allows several people to remain for a few minutes to pray, contemplate, or meditate. Smaller labyrinths may have room for only one person at a time in the center, and it is considered courteous to remain there only briefly.

Labyrinth walking can be incorporated into such ritual events as weddings, funerals, and anniversary celebrations, or such personal events as completing one's schooling, taking a new job, or moving to a new area. Some published guides to labyrinth walking include meditations to be used for labyrinth walking during **pregnancy**, or for blessing ceremonies at different seasons of the year.

Preparations

Although one need not be a member of any specific faith or religious tradition to participate in labyrinth walking, spiritual preparation is considered an important part of the activity. Although the walk itself is informal and relatively unstructured, most participants find that a period of quietness to focus their attention on their journey is essential. Some also recommend clarifying one's intention for the walk beforehand; that is, participants should ask themselves whether they are seeking spiritual guidance, healing, closer fellowship with God, discernment, blessing, or the fulfillment of some other purpose. The use of prayers or mantras is suggested as a way to calm and "center" one's spirit at the beginning of and during the walk.

Participants are advised to wear comfortable shoes and clothing for labyrinth walking so that they will not be distracted by physical discomfort or concerns about their appearance. They will be asked to remove their shoes, however, if the labyrinth is made of canvas or woven into a rug; thus it is a good idea to bring along a pair of clean cotton socks or soft-soled slippers.

Precautions

There are no special precautions needed for labyrinth walking other than allowing sufficient time for the experience. Most people find that the walk takes about 45 minutes or an hour, but some take two to three hours to complete their journey. It is best to plan a labyrinth walk for a day or evening without a tight time schedule.

Side effects

No physical or psychological side effects have been reported from labyrinth walking.

Research and general acceptance

Little research has been done within the mainstream or alternative medical communities on labyrinth walking in comparison to other forms of treatment. As of 2004, however, it appeared to be generally accepted as a form of mind-body therapy or spiritual practice that has few if any associated risks and offers spiritual benefits to many people.

Since the mid-1990s, growing numbers of churches and retreat centers in the United States and Canada have built or installed labyrinths. Some communities have also built outdoor labyrinths for the general public. In the early 2000s, health spas and tourist resorts have added labyrinths to their facilities in order to attract visitors interested in wellness programs. A labyrinth locator is available on the web site of The Labyrinth Society.

Training and certification

The Labyrinth Society (TLS), which was founded in 1999, hosts an annual meeting that includes workshops and speakers on labyrinth construction as well as the spiritual aspects of labyrinth walking. TLS does not, however, offer licensing or training programs as of 2004; its membership code of ethics states, "Membership or leadership in this Society does not serve as qualifying evidence of any level of proficiency or ability relating to labyrinths and their uses and shall not be so represented." Membership in TLS is open to anyone interested in "inspir[ing] possibilities and creat[ing]connections through the labyrinth."

Lachesis

Description

Not all products used in alternative healing come from plants. Lachesis is the venom of the bushmaster snake, *Lachesis mutus*. It is used in homeopathic medicine.

L. mutus is a tropical snake that lives in the jungles of Central and South America, growing to a length of 12 feet (3.6 m). It is the largest poisonous pit viper in the Western hemisphere, and second in size in the world only to the king cobra. *L. mutus* is related to the familiar North American rattlesnake.

A large bushmaster can have fangs more than 1 in (2.5 cm) long. Its venom is deadly and kills rapidly by inhibiting nervous impulses or slowly by interfering

Lachesis is the venom of the bushmaster snake, Lachesis mutus. *(© blickwinkel / Alamy)*

with blood clotting and accelerating the destruction of red blood cells. The bushmaster is also called the surucucu (sometimes spelled surukuku).

General use

Homeopathic medicine operates on the principle that "like heals like." This means that a disease can be cured by treating it with substances that produce the same symptoms as the disease, while also working in conjunction with the homeopathic law of infinitesimals. In opposition to traditional medicine, the law of infinitesimals states that the *lower* a dose of curative, the more effective it is. To achieve a low dose, the curative is diluted many, many times until only a tiny amount remains in a huge amount of the diluting liquid.

In homeopathic terms, fresh *L. mutus* venom was "proved" as a remedy by Constantine Hering around 1830. Although born in what is now Germany, Hering is considered to be the founder of American **homeopathy**. In 1827 he went to Surinam, South America, to conduct biological research for his government. In experimenting with lachesis venom in an attempt to find a homeopathic inoculation for smallpox, he accidentallypoisoned himself with a small amount of venom. This led him to his "proof" that lachesis was a homeopathic remedy. Ever the curious scientist, Hering later accidentally paralyzed his right side by continuing to test higher and higher doses of lachesis on himself.

Lachesis is used in homeopathy to treat a wide range of symptoms. These fall into the following general categories of:

- menstrual and menopausal complaints
- throat and mouth complaints
- fear, paranoia, and associated mental complaints
- nervous system complaints
- circulatory complaints

All these complaints exhibit certain patterns or modalities that indicate they should be treated with lachesis. These symptoms may:

- worsen after sleep and upon awakening
- worsen in the spring
- worsen after drinking hot beverages, taking hot baths, or direct exposure to the sun
- worsen if touched or if the body is constricted by tight clothes
- worsen with alcohol consumption
- produce surging waves of pain
- move from the left side to the right side of the body
- result in a mottled, engorged, congested face
- result in a very sensitive neck
- improve from eating
- improve from the onset of bodily discharge
- improve from exposure to cold and fresh air

In homeopathy, certain remedies are thought to be especially effective in people with specific personality and physical traits. The "lachesis personality" tends to be egocentric, self-important, unstable, and jealous.They may be possessive. This personality type often talks about doing great things, but rarely follows through. Physically, lachesis types tend to be overweight and bloated. They often have red hair and freckles.

Lachesis is a major homeopathic remedy for **hot flashes** associated with **menopause**. It is also used to treat premenstrual and menstrual symptoms such as **premenstrual syndrome** (PMS), menstrual **pain**, and short menses.

Throat and mouth complaints are also treated with lachesis. A **sore throat** that worsens when hot liquids are swallowed is a good example of the type of throat complaint for which lachesis is considered appropriate. Similarly, so is a sore throat with left-sided pain or pain in the left ear, and a purplish, engorged throat, swollen gums, tongue, and foul-tasting saliva. The throat, neck, and larynx are extremely sensitive to touch.

Lachesis is used to alleviate certain mental or emotional symptoms. These include suspicion and distrust that can border on paranoia, extreme talkativeness that reflects nervousness and restless, **depression**, petty jealousy, and unsociability.

Circulatory complaints treated with lachesis include:

- swollen and engorged veins that give the skin a bluish cast
- varicose veins
- nose bleeds
- slow-to-heal, bluish wounds
- a throbbing sensation in various parts of the body
- weak, irregular rapid pulse
- palpitations
- fainting

The main nervous system complaint treated by lachesis is cluster headaches. These are headaches that produce pulsating waves of pain, often on the left side, or beginning on the left side then moving to the right. They often precede **menstruation** and improve once menses begins. Petit mal seizures and **angina** are also treated with lachesis.

Other complaints that lachesis is said to alleviate include stomach pains, appendicitis, **vomiting**, and gastrointestinal complaints, anal spasms, bleeding **hemorrhoids**, and cravings for alcohol, coffee, and shellfish.

Preparations

Fresh venom is commercially prepared in a very highly diluted form. It is available in tablets or liquid and is known as lachesis 12X. It can be taken with other complementary homeopathic remedies.

Precautions

No particular precautions have been reported when using lachesis, however, caution must be taken when using this—and any homeopathic treatment. Individuals should consult a licensed homeopath or physician.

KEY TERMS

Angina—Any painful spasm that leaves one feeling choked or suffocated. In common usage, angina usually refers to chest pain associated with a heart spasm.

Petit mal seizures—A less severe form of epileptic seizure.

Side effects

When taken in the recommended dilute form, no side effects have been reported. However, concentrated quantities of the venom cause paralysis and hemorrhaging, and can be fatal.

Interactions

Studies on interactions between lachesis given in homeopathic doses and conventional pharmaceuticals are nonexistent.

Lacto-ovo vegetarianism

Definition

Lacto-ovo vegetarians do not eat meat but do include dairy products (lacto) and eggs (ovo) in their **diets**.

Origins

The term "vegetarian" was coined in 1847 by the founders of the Vegetarian Society of Great Britain, although **vegetarianism** as a way of life had existed for thousands of years. The founders of the Vegetarian Society were lacto-ovo vegetarians.

One of the central values that motivated vegetarians is that food choices should not require the death or suffering of animals. Thus, many vegetarians avoid meat but eat dairy products and eggs (on the grounds that store-bought eggs are unfertilized). Some people argue, however, that eating eggs may prevent the life of an animal, so some vegetarians are lacto-vegetarians. **Veganism**, another type of vegetarianism, follows a diet that uses no animal products at all.

Some of the world's oldest religious traditions have advocated vegetarianism as a means to both physical and spiritual health. In the Christian tradition, Trappist monks of the Roman Catholic Church are vegetarian, as are Seventh Day Adventists, who form a group large enough that many studies have been performed on them to determine the health benefits of lacto-ovo vegetarianism. Some vegetarians maintain that there is evidence that Jesus and the early Christians were vegetarians as well. In ancient India, the idea of *ahimsa* developed, which means "not doing harm." Followers of this creed believe that living in a manner that reduces the suffering of other living beings, including animals, is necessary to reach higher levels of spiritual wellness. According to Hinduismm, there is an endless cycle of rebirth and lives until souls reach nirvana. The presence of souls on all levels of animal life precludes meat eating.

The **yoga** system of living and health recommends vegetarianism because its dietary practices are based on the belief that healthy food contains prana. Prana is the universal life energy, which yoga experts believe is abundant in fresh fruits, grains, nuts, and vegetables, but absent in meat because it comes from an animal that has been killed. Some Buddhists are vegetarian because of their spiritual belief in the oneness of all life. Other traditional cultures, such as those in the Middle East and the Mediterranean regions, have evolved diets that consist mainly of lacto-ovo vegetarian foods. The **Mediterranean diet**, which a Harvard study declared to be one of the world's healthiest, is primarily although not strictly lacto-ovo vegetarian.

The list of famous vegetarians forms an illustrious group. The ancient Greek philosophers, including Socrates, Plato, and Pythagoras, advocated vegetarianism. Other famous vegetarians include Leonardo da Vinci, Sir Isaac Newton, the physician Albert Schweitzer, writer George Bernard Shaw, musician Paul McCartney, and champion triathlete Dave Scott. Albert Einstein, although not a strict vegetarian himself, stated that a vegetarian diet would be an evolutionary step forward for the human race.

Vegetarianism in the United States has generally consisted of a small but vocal number of adherents. It has its roots in the mid-1800s, when some people began to question accepted health and dietary practices. In 1839, Sylvester Graham, who invented the graham cracker from whole wheat flour, wrote *Lectures on the Science of Human Life*. A few decades later, Ralph Waldo Emerson and Henry David Thoreau both advocated vegetarianism. In 1883, Howard Williams published *The Ethics of Diet*, which promoted vegetarianism. Williams's book influenced many people around the world, including Russian author Leo Tolstoy and Indian political leader the Hindu Mahatma Gandhi. But vegetarianism remained largely unpopular in the United States during the nineteenth century.

In the twentieth century, vegetarianism steadily gained followers in the United States, although it met considerable resistance from the meat industry and general public. By the 1960s, the consumption of meat in the United States had increased significantly from consumption levels at the turn of the century. Meat and dairy foods made up two of the four recommended food groups designed by the United States government. Some researchers claimed that meat was fundamental to health, while a growing minority of nutritionists began to correlate the meat-heavy U.S. diet with rising rates of **heart disease**, **cancer**, and diabetes.

In 1971, Frances Moore Lappe published her landmark book, *Diet for a Small Planet,* which proposed that vegetarians could obtain a complete source of dietary protein by combining particular foods such as rice and beans. Until that time it was believed by U.S. nutritionists that only meat could supply adequate protein. The book sold millions of copies. Lappe's book argued that meat-centered diets are unhealthy for both people and the environment, and it stressed that meat-eating perpetuated hunger worldwide because animals raised for food consume so much grain. Millions were converted to vegetarianism by this book.

Vegetarianism steadily gained acceptance as an alternative to the meat-and-potatoes regimen of the traditional American diet. Several factors contributed to the U.S. trend toward vegetarianism. Outbreaks of **food poisoning** from meat products, as well as increased concern over such additives in meat as hormones and antibiotics, led many people and professionals to

question the safety of meat products. People also became aware of unethical treatment of animals in the meat industry. Then too the environmental impact of an agricultural system based on meat production was examined more closely. Some argued that raising of livestock causes soil erosion, water contamination and shortages, pollution, deforestation, and an inefficient use of natural resources.

The growing health consciousness of Americans is probably the most important reason for the surge of interest in vegetarianism. **Nutrition** experts argue that the high rates of heart disease, cancer, and diabetes are directly related to poor dietary habits, particularly a diet high in **cholesterol** and saturated fat and low in fiber. Nutritionists have repeatedly shown in studies that a healthy diet consists of plenty of fresh vegetables and fruits, complex carbohydrates such as whole grains, and foods that are high in fiber and low in cholesterol and saturated fat. The vegetarian diet fulfills all these criteria.

In alternative medicine, vegetarianism is a cornerstone dietary therapy, used in Ayurvedic treatment, **detoxification** therapies, the Ornish and Wigmore diets, and in treatments for many chronic conditions, including heart disease, diabetes, and cancer.

Benefits

Lacto-ovo vegetarianism is sometimes recommended as a dietary therapy for a variety of conditions, including heart disease, cancer, diabetes, **stroke**, high cholesterol, **obesity**, **osteoporosis**, **hypertension**, **gout**, **gallstones**, **kidney stones**, ulcers, **colitis**, **hemorrhoids**, **premenstrual syndrome**, **anxiety**, and **depression**. Lacto-ovo vegetarianism is an economical and easily implemented preventive practice. It does, however, require self-education regarding how to fashion an adequate diet for those who adopt it.

Preparations

It is generally recommended that a vegetarian diet be adopted gradually, to allow people's bodies and lifestyles time to adjust to new eating habits and food intake. Some nutritionists have designed transition diets to help people become vegetarian in stages. Many Americans eat meat products at nearly every meal, and the first stage of a transition diet is to replace meat in just a few meals a week with wholly vegetarian dishes. Then, particular meat products can be slowly reduced and eliminated from the diet and replaced with vegetarian foods. Red meat can be reduced and then eliminated, followed by pork, poultry, and fish. Individuals should be willing to experiment with transition diets and need patience when learning how to combine vegetarianism with such social activities as dining out. Many vegetarian cookbooks are available to help vegetarians prepare meals at home.

The transition to vegetarianism can be smoother for those who make informed choices regarding dietary practices. Nutritional guidelines include decreasing fat intake, increasing fiber, and emphasizing fresh fruits, vegetables, legumes, and whole grains while avoiding processed foods and sugar. Other helpful health practices include reading food labels and understanding such basic nutritional concepts as daily requirements for protein, fats, and nutrients. Would-be vegetarians can experiment with meat substitutes, foods that are high in protein and essential nutrients. Many meat substitutes are readily available, such as tofu and tempeh, which are soybean products that are high in protein, **calcium**, and other nutrients. Veggieburgers can be grilled like hamburgers, and vegetarian substitutes for turkey and sausage have surprisingly realistic textures and tastes.

Precautions

Adopting a lacto-ovo vegetarian diet does not automatically mean an improvement in health. One of the advantages of lacto-ovo vegetarianism is that eggs and dairy products are good sources of the protein, vitamins, and minerals for which vegetarians may have special requirements. Both eggs and dairy products, however, are generally high in calories and contain cholesterol and saturated fat. Studies have shown that some vegetarians consume higher than recommended quantities of fat, and some vegetarians have high cholesterol levels. The lacto-ovo vegetarian diet is most healthful when it uses eggs and low-fat dairy products sparingly to supplement a diet rich in whole grains, fruits, vegetables, and legumes. Another option for lacto-vegetarians is to use only egg whites (which contain no fat) and nonfat dairy products when high cholesterol and fat consumption are problems. Vegetable sources of saturated fat include avocados, nuts, and some cooking oils.

In general, a well-planned lacto-ovo vegetarian diet is healthful and safe and contains all the nutrients needed by the body. Vegetarians who eat few animal products, however, should be aware of particular nutrients that may be lacking in non-animal diets. These are protein, **vitamin A**, **vitamin B_{12}**, **vitamin D**, calcium, **iron**, **zinc**, and **essential fatty acids**. Furthermore, pregnant women, growing children, and people with certain health conditions have higher requirements for these nutrients.

Vegetarians should be aware of getting complete proteins in their diets. A complete protein contains all of the essential **amino acids**, which are proteins that are essential to the diet because the body cannot make them. Meat and dairy products generally contain complete proteins, but many vegetarian foods such as grains and legumes contain incomplete proteins, lacking one or more of the essential amino acids. Vegetarians can overcome this difficulty by combining particular foods in order to create complete proteins. In general, combining legumes such as soy, lentils, beans, and peas with grains such as rice, wheat, or oats forms complete proteins. Eating dairy products or nuts with grains also makes complete proteins. Oatmeal with milk combines to make a complete protein, as does peanut butter on whole wheat bread. Proteins do not necessarily need to be combined in the same meal, but generally they should be combined over a period of a few days.

Getting enough vitamin B_{12} may be an issue for some vegetarians, although this vitamin is present in both eggs and dairy products. Vitamin supplements that contain vitamin B_{12} are recommended, as are fortified soy products and nutritional yeast. Research has indicated that vitamin B_{12} deficiency is a risk for vegetarians, especially vegans. Those choosing a vegetarian diet should watch carefully to ensure they get enough active vitamin B_{12} from diet and supplements. Deficiency of this vitamin poses particular risk to pregnant women and nursing mothers.

Vitamin D can be obtained in dairy products, egg yolks, fortified foods, and sunshine. Calcium can be obtained in dairy products, enriched tofu, seeds, nuts, legumes, dairy products, and dark green vegetables, including broccoli, kale, spinach, and collard greens. Iron is found in raisins, figs, legumes, tofu, whole grains (particularly whole wheat), potatoes, and dark green leafy vegetables. Iron is absorbed more efficiently by the body when iron-containing foods are eaten with foods that contain **vitamin C**, such as fruits, tomatoes, and green vegetables. Zinc is abundant in eggs, nuts, pumpkin seeds, legumes, whole grains, and tofu. For vegetarians who eat no fish, getting enough omega-3 essential fatty acids may be an issue, and such supplements as **flaxseed** oil should be considered as well as eating walnuts and canola oil. Vegetarians may also consider buying organic foods, which are grown without the use of synthetic chemicals, as another health precaution.

Research and general acceptance

Walter Willett, chair of the Department of Nutrition at Harvard University and professor of epidemiology and nutrition, has extensively studied the effects of diet on health. His research has shown that about 82 percent of heart attacks, about 70 percent of strokes, more than 90 percent of type 2 diabetes, and more than 70 percent of colon cancer can be prevented with proper nutrition as part of a healthy lifestyle. In addition, he and his colleagues have found that greater meat consumption is associated with a higher prevalence of degenerative arthritis and soft tissue disorders. In addition, a healthy lifestyle that includes low meat intake has been shown to increase longevity.

One major epidemiological study of vegetarianism was done at Loma Linda University in California. Epidemiology is the study of how diseases affect populations as a whole. Researchers analyzed data from over 25,000 people in the Seventh Day Adventist Church, who are lacto-ovo vegetarians. These vegetarians had 14% of the chance of dying from heart disease that meat-eating Americans faced. The Adventists also had significantly longer life expectancy. From this study, researchers estimated that eating meat just once a day triples the risk of dying from heart disease by age 64. It should be noted, however, that Seventh Day Adventists typically do not smoke or drink alcohol, and may have healthier lifestyles in general, affecting rates of heart disease. A study in England analyzed more than 10,000 vegetarians and meat eaters, and researchers concluded there was a direct relationship between the amount of meat consumed and the chances of getting heart disease. Other studies have been performed on population data from World War II. In Norway during the war, the death rate from heart disease and strokes dropped significantly concurrent with the drop in consumption of meat.

Many studies have concentrated on the benefits of eating fruits and vegetables and have shown that eating more fruits and vegetables helps decrease the risk of cancer. Other studies have shown that diets high in fiber, which vegetarian diets tend to be, reduce the risk for heart disease, cancer, and other conditions, including digestive disorders, appendicitis, and osteoporosis (bone loss).

A lacto-ovo vegetarian diet, as prescribed by Dean Ornish, has been shown to improve heart disease and reverse the effects of **atherosclerosis**, or hardening of the arteries. Ornish's diet was used in conjunction with **exercise**, **stress** reduction, and other holistic methods. Ornish allowed only the use of egg whites and nonfat dairy products in his low-fat vegetarian diet. Ornish's groundbreaking clinical research demonstrated that coronary heart disease can be reversed with comprehensive lifestyle changes.

KEY TERMS

Ayurvedic treatment—A holistic system of medicine from India that focuses on using physical, psychological, and spiritual therapies to achieve a mind-body balance and optimal health.

Cholesterol—A steroid fat found in animal foods that is also produced in the body from saturated fat for several important functions. Excess cholesterol intake is linked to many diseases.

Complex carbohydrates—Nutrients that are broken down by the body into simple sugars for energy, found in grains, fruits, and vegetables.

Detoxification—The process of eliminating or neutralizing toxins in the body, thereby enabling the body to heal itself and restore health.

Legumes—A group of plant foods that includes beans, peas, and lentils, which are high in protein, fiber, and other nutrients.

Organic food—Food grown without the use of synthetic pesticides and fertilizers.

Saturated fat—Fat that is usually solid at room temperature, found mainly in meat and dairy products but also in vegetable sources such as some nuts and seeds, and avocados.

Unsaturated fat—A type of fat found in plant foods that is typically liquid (oil) at room temperature. Unsaturated fats are the most commonly recommended dietary fats.

Lactobacillus species

Definition

Lactobacillus is a genus of Gram–positive anaerobic bacteria that get their name from the fact that they convert lactose to lactic acid by the process of fermentation. Lactose is a disaccharide sugar, similar

Scanning electron microscope image of lactobacillus acidophilus bacteria. *(Dennis Kunkel / Phototake, Reproduced by permission.)*

to sucrose (ordinary table sugar), that consists of one molecule of glucose and one molecule of galactose bonded to each other. The genus consists of more than 100 species, many of which consist of two or more **strains**. Probably the best known member of the genus is "L. acidophilus"

Description

Lactobacillus is a member of a larger group of bacteria known as lactic acid bacteria (LAB), so named because they convert carbohydrates to lactic acid. Lactobacillus differs from other members of the LAB group in that they are homofermentive, that is, they produce lactic acid only as their primary (>85%) metabolic product. Other LAB produce other fermentative products, such as ethanol (ethyl alcohol), acetic acid, and carbon dioxide in addition to lactic acid. Lactobacillus bacteria are an important component of the gut flora in humans; they are also found in the female genital system. The term gut flora refers to all the bacteria and other microorganisms that live in the human intestinal system and that, for the most part, are benign and play useful roles in the digestive process. Their beneficial function is to some extent a result of their production of lactic acid, which provides an acidic environment in which disease–causing microorganisms are less able to survive. Lactobacillus also occur in many environments other than the human digestive and genital systems, specifically, in any condition in which dead or decaying plant material is available as a food source.

The lactobacilli are of special interest to researchers, at least partly because of their relatively simple genetic and biochemical structure. As of 2008, the genomes of three species, "L. plantarum ", "L. johnsonii", and "L. acidophilus" had been completely sequenced, while the genomes of at least four other members of the genus were at least partially determined.

Uses

Historically, lactobacillus bacteria have played a very important role in many kinds of food production. They are used in the manufacture of cheese and yogurt; sauerkraut, pickles, and kimchi; beer, wine, and cider; and silage, fermented plant matter used as feed for domestic animals. Two common species used in food production are "L. casei" and "L. brevis".

The basic principle behind the use of lactobacilli as dietary supplements is that the human digestive system consists of a finely balanced mixture of beneficial ("good") and harmful ("bad") bacteria. Beneficial bacteria contribute to and support many biochemical reactions that promote growth and development, while harmful bacteria attack systems, leading to disease. In healthy individuals, the body maintains a proper balance between "good" and "bad" bacteria. Any number of conditions may cause a disruption in this balance that can result in disease. For example, the use of antibiotics to treat an infectious disease may result in the destruction of beneficial as well as harmful bacteria. Without the benefit of "good" bacteria to keep "bad" bacteria under control, other diseases may develop. For this reason, health care workers routinely recommend that patients on antibiotics supplement the bacteria in their digestive system by eating yogurt containing a lactobacillus to maintain a proper bacterial balance in their digestive systems.

The most common use of lactobacilli in medicine is as **probiotics**. A probiotic is a dietary supplement consisting of microorganisms thought to have potentially beneficial effects in the digestive system of humans and other animals, with the potential for preventing the growth of pathogenic (disease–causing) organisms. The lactobacillus most widely used for this purpose is "L. acidophilus". A number of diseases and disorders for which "L. acidophilus" has been recommended, with greater or lesser scientific support, include:

- acne
- cancer
- cardiovascular disease
- constipation
- Crohn's disease
- diverticulitis
- heartburn
- indigestion
- stomach ulcers
- ulcerative colitis
- urinary tract infections
- vaginal yeast infections
- weakened immune system

The scientific validity of claims such as these is the subject of considerable research. In November 2005, the National Center for Complementary and Alternative Medicine (NCCAM) held a conference of researchers to determine the current state of knowledge about the use of probiotics in general. The conference reported that there is "encouraging evidence" for claims

that support the use of probiotics in the treatment of a number of conditions, including treatment for:

- diarrhea, for which the evidence is strongest of any condition
- urinary tract and genital tract infections
- irritable bowel syndrome
- bladder cancer (reduction in the risk of recurrence)
- pouchitis (a condition that develops after surgery for removal of the colon)
- atopic dermatitis (eczema) in children

The conference report also concluded that "in studies of probiotics as cures, any beneficial effect was usually low; a strong **placebo effect** often occurs; and more research . . . is needed in order to draw firmer conclusions."

Side effects

Probiotics have been used extensively for many years, with few or no generally recognized side effects. However, well–controlled scientific studies on the subject are largely absent and need to be undertaken to gain a better understanding for the potential of such effects. Some moderate side effects of using probiotics like lactobacilli are already well known and include bloating, **gas**, and **indigestion**. Theoretically, the introduction of bacteria into the digestive system could result in infectious disease, but virtually nothing is known as to the practical likelihood of such an event.

Interactions

Scientists have hypothesized a number of possible interactions between lactobacillus and various herbs and drugs. Alcohol and antibiotics, for example, may be toxic to lactobacillus and should, therefore, not be taken at or near the same time that a probiotic is ingested. Another hypothesis suggests that lactobacillus thrives in a digestive environment that is only moderately acidic, so that taking a antacid prior to using a probiotic will increase the efficacy of the lactobacillus. Some evidence suggests also that lactobacillus may extend the period over which some drugs remain in the body. As an example, a probiotic may magnify the effects of a drug such as lorazepam, one of whose side effects is drowsiness. Herbal practitioners sometimes recommend that certain foods be taken in conjunction with lactobacillus because they are especially efficient at promoting the growth of the bacteria. These foods include asparagus, bananas, **garlic**, Jerusalem artichokes, and onions. At this point, scientific evidence to support any of the side effects is almost completely lacking.

KEY TERMS

Disaccharide—A type of sugar that consists of two simpler (monosaccharide) sugars.

Gram–positive bacteria—Bacteria that turn purple in the Gram staining process. They lack a secondary outer membrane that allows dye to enter and stain the bacterial cell.

Gut flora—A term used to describe all of the microorganisms living in the digestive system.

Lactic acid bacteria (LAB)—Bacteria that convert carbohydrates to lactic acid as a major metabolic product.

Probiotic—A dietary supplement consisting of microorganisms with potential beneficial effects in the digestive system of humans and other animals and potential blocking effects on pathogenic organisms.

Laryngitis

Definition

Laryngitis is caused by inflammation of the larynx, often resulting in a temporary loss of voice.

Description

When air is breathed in, it passes through the nose and the nasopharynx or through the mouth and the oropharynx. These are both connected to the larynx, a tube made of cartilage. The vocal cords, responsible for setting up the vibrations necessary for speech, are located within the larynx.

The air continues down the larynx to the trachea. The trachea then splits into two branches, the left and right bronchi (bronchial tubes). These bronchi branch into smaller air tubes that run within the lungs, leading to the small air sacs of the lungs (alveoli).

Either food, liquid, or air may be taken in through the mouth. While air goes into the larynx and the respiratory system, food and liquid are directed into the tube leading to the stomach, the esophagus. Because food or liquid in the bronchial tubes or lungs could cause a blockage or lead to an infection, the airway must be protected. The epiglottis is a leaf-like piece of cartilage extending upwards from the larynx. The epiglottis can close down over the larynx when someone is eating or drinking, preventing these substances from entering the airway.

KEY TERMS

Decoction—An herbal tea created by boiling herbs in water. Roots, bark, and seeds are used in decoctions; boiling the herbs brings out their medicinal properties.

Infusion—System for releasing the herbal essence of herbal leaves and flowers. It is similar to brewing tea.

Tincture—A method of preserving herbs in alcohol.

In laryngitis, the tissues below the level of the epiglottis are swollen and inflamed. This causes swelling around the area of the vocal cords and they can't vibrate normally. Hoarse sounds or loss of voice are characteristic of laryngitis. Laryngitis is a very common problem, and often occurs during an upper respiratory tract infection (cold).

Causes and symptoms

Laryngitis is primarily caused by overuse of the voice, a condition faced by people ranging from teachers to performers. Other causes of laryngitis include:

- strain on the larynx from talking or singing for long periods
- shouting or cheering for an extended time
- allergies
- colds or cough
- smoking
- alcohol consumption
- atmospheric conditions like dust in the air
- anxiety
- underactive thyroid
- growths on the larynx

However, the primary medical cause of laryngitis is a viral infection. The same viruses that cause the majority of simple colds are responsible for laryngitis. In extremely rare cases, more harmful bacteria or the bacteria that causes **tuberculosis** (TB) may cause laryngitis. In people with faulty immune systems (like AIDS patients), **infections** with fungi may be responsible for laryngitis.

Symptoms usually begin with a cold. The person may have a sore, scratchy throat, as well as a **fever**, runny nose, aches, and **fatigue**. Difficulty swallowing sometimes occurs, and the patient may have a ticklish **cough** or wheeze. Most characteristically, the patient suffers voice loss or the voice will sound strained, hoarse, and raspy.

In extremely rare cases, the swelling of the larynx may cause symptoms of airway obstruction. This is more common in infants because the diameter of their airways is so small. In that case, the baby may have a greatly increased respiratory rate and exhibit loud, high-pitched sounds with breathing (called stridor).

Diagnosis

Laryngitis is easily recognizable. People realize they can't speak or that their voices are hoarse. In most cases, they know the cause. Laryngitis could be the next phase of the flu or the result of cheering too energetically during a football game. In addition to being an easily recognizable condition, laryngitis is a self-limiting condition that goes away on its own. In most cases, laryngitis can be treated at home.

However, a doctor should be consulted if the laryngitis occurs for no apparent reason or if hoarseness lasts for more than two weeks. A doctor may diagnose another condition such as an underactive thyroid. Symptoms of underactive thyroid include tiredness, **constipation**, aches, and dry skin.

Diagnosis is usually made by learning the history of a cold that is followed by hoarseness. The throat usually appears red and somewhat swollen. Listening to the chest, neck, and back with a stethoscope (an instrument used to hear heart and lungs sounds) may reveal some harsh wheezing sounds when the person breathes.

With chronic laryngitis, TB may be suspected. Using an instrument called a laryngoscope, a doctor can examine the airway for redness, swelling, small bumps of tissue called nodules, and irritated pits in the tissue called ulcerations. Special skin testing (TB testing) will reveal if the person has been exposed to TB.

Treatment

Alternative treatments for laryngitis include various herbal therapies, as well as **reflexology**, homeopathy, **relaxation**, and exercise . Resting the voice is especially important, as is consulting a doctor or practitioner if symptoms last for more than two weeks.

Practitioners who treat laryngitis include naturopathic doctors and ayurvedic doctors. **Naturopathic medicine** focuses on whole body health care; the ayurvedic practitioner concentrates on maintaining balance between the body and the world.

Acupuncture or accupressure, elements of **traditional Chinese medicine** (TCM), may provide some relief. A TCM practitioner may prescribe Throat Inflammation Pills, which are also known as Laryngitis Pills. The pill is an over-the-counter Chinese formula. The usual dosage for adults is 10 pills taken three times daily. This is a short-term treatment and should be stopped after three days.

An ayurvedic practitioner could prescribe an infusion of mint, **ginger**, or cloves, as well as a milk decoction or **licorice** root powder.

Herbal remedies

Numerous herbals can be used to treat laryngitis. Herbal lozenges and throat sprays can provide immediate relief to a raw throat. Herbs that are effective for laryngitis include **thyme**, **horehound**, cardamom, plantain, cinnamon, and **eucalyptus**. Commercial cough medicines that are effective include herbs such as **anise**, **fennel**, and **peppermint**. A person can gargle with warm salt water and slippery elm bark, wild cherry, and mallow.

Echinacea tincture taken in water is recommended to boost the immune system. The tincture consists of 10 drops (1/8 teaspoon or 5/8 ml) of the herb in a glass of water. This mixture is taken frequently, or 5 ml three to four times a day. Antiviral herbs such as usnea, **lomatium**, and ligusticum may help speed recovery.

Poke should be taken as a last resort. It's a strong herb that should be taken only in small amounts and under the direction of a healthcare professional. However, there are many other herbs that can be purchased as packaged cold and throat remedies or used to prepare home treatments.

HYDROTHERAPY. A person can use a vaporizer for relief by inhaling steam. A natural version of the vaporizer is a boiling pot of water with herbs or **essential oils** added. The amount of these ingredients varies. A small handful of **sage** or eucalyptus leaves may be added to the water. When using essential oils, 1-2 teaspoons (4.5-10 g) of an oil such as sage, eucalyptus, **lavender**, benzoin, frankincense, thyme, or sandalwood are added. The pot is removed from the stove and the ingredients are allowed to steep. The person places a towel over the head for a tent-like effect, leans over the pot, and breathes in steam through the mouth.

HERBAL TEAS. Commercial products like horehound tea will provide relief. For brewing tea at home, 1 cup (250 ml) of boiling water is poured over 1-2 teaspoons (4.5-10 g) of an herb. The tea is steeped for about 10 minutes and then strained. Generally, up to 3 cups of tea may be drunk daily.

Helpful herbs for teas include capsicum (cayenne), which is used to treat conditions caused by a cold or flu. Capsicum tea might be a painful treatment if

inflammation is severe. Ginger root helps with chest congestion. Other useful herbs include cardamom, eucalyptus, spearmint, **rosemary**, sweet Annie, **nutmeg**, lavender, bee balm, peppermint, tansy, mallows, and **mullein**.

GARGLES. A home gargle is prepared like herbal tea. One cup (250 ml) of boiling water is poured over 1-2 teaspoons (4.5-10 g) of an herb. This mixture is steeped for about 10 minutes and then strained. The solution is gargled for about 10 seconds, and repeated every three to four hours. Herbs recommended for gargling include **coltsfoot**, garden **raspberry**, golden seal, mullein, **plantain**, red sage, **yarrow**, licorice, and **slippery elm**.

Other home remedies

A range of other home remedies will bring relief to laryngitis and its symptoms. These include:

- Drinking more liquids and eating raw fruit and vegetables.
- Eating certain foods. Candied ginger, honey, lemon, and pineapple juice are soothing. Spicy foods with ingredients like garlic, cayenne pepper, horseradish, mustard, or ginger are helpful.
- Using vitamins. They can also help the immune system. The recommended dosages are 1,000-3,000 mg of vitamin C and 10,000-20,000 I.U. of vitamin A (beta carotene).
- Using a compress. A compress is a form of hydrotherapy that starts by placing a warm washcloth on the neck. Next, a long cotton cloth is soaked in cold water. After the cloth is wrung out, it is wrapped around the neck. Then a long piece of wool flannel such as a scarf is wrapped around the wet cloth. The flannel is secured with a safety pin and remains in place for at least 30 minutes. The compress can be worn overnight.
- Relaxing and exercising. Since anxiety can cause laryngitis, both relaxation techniques and physical exercise can reduce stress.
- Breathing deeply. Deep breaths and breathing exercises can make the respiratory system stronger.

Reflexology

Reflexology is a healing method that involves the manipulation of certain parts of the body to bring about balance. For laryngitis, the reflexology focus is on the throat, lung, chest, lymphatic system, and diaphragm points on both feet. Also recommended is manipulation of all points on the sides and bottoms of the toes.

Homeopathy

Homeopathy is a healing method that is based on the theory that "like cures like." The potency of a homeopathic remedy is indicated by an "x." This indicates the number of times that one part of a remedy was diluted in nine parts of a dilutant. Distilled water is the preferred dilutant. The potency of a remedy can also be expressed as "c," the number of times one part of the remedy was diluted in 99 parts of a dilutant.

Homeopathic remedies for laryngitis include:

- Aconite (6x or 12x). It's taken every two hours at the very start of a cold or when the voice is lost and the person has a dry cough. If there is no improvement after four or five hours, another remedy such as spongia tosta is taken.
- Spongia tosta (12x). It's taken four times daily for laryngitis combined with a dry throat.
- Arnica (6x or 12x). It's taken hourly when loss of voice is caused by overuse or trauma.

Allopathic treatment

Treatment of a simple, viral laryngitis relieves the symptoms. Gargling with warm salt water, using **pain** relievers such as acetaminophen, using a vaporizer to create moist air, and resting will help the illness resolve within a week. Over-the-counter remedies such as throat sprays and lozenges may provide relief.

For an infant who is clearly struggling for air, a doctor may put in an artificial airway for a short period of time. This is very rarely needed.

When a doctor is consulted, antibiotics may be prescribed. The person with an underactive thyroid could be prescribed a thyroid hormone supplement. An individual with tubercular laryngitis is treated with a combination of medications used to treat classic TB. For people with fungal laryngitis, a variety of antifungal medications are available.

Expected results

The prognosis for people with laryngitis is excellent because it is a self-limiting condition. Recovery is complete, usually within a week. In the meantime, alternative remedies can provide relief.

Prevention

Prevention of laryngitis is the same as for any upper respiratory infection. People should wash their hands frequently and thoroughly, and should avoid contact with people who might be sick. However, even with relatively good hygiene practices, most people

will get about five to six colds per year. It is unpredictable which of these may lead to laryngitis.

Resting the voice is important, particularly for people like teachers, politicians, or actors who talk for long periods. Not speaking for a time is one way to rest the voice. Before giving a lengthy speech or attending an exciting championship game, herbal remedies can be used preventively to soothe the larynx. If **anxiety** provokes laryngitis, a person should practice a relaxation technique or **exercise** to reduce **stress**.

In all cases, **smoking** should be avoided. Since alcohol can irritate the throat, consumption may need to be limited.

Lavender

Description

Lavender is a hardy perennial in the Lamiaciae, or mint, family. The herb is a Mediterranean native. There are many species of lavendula which vary somewhat in appearance and aromatic quality. English lavender, *L. augustifolia*, also known as true lavender, is commercially valuable in the perfume industry and is a mainstay of English country gardens. French lavender, *L.stoechas*, is the species most probably used in Roman times as a scenting agent in washing water. The species *L. officinalis* is the official species used in medicinal preparations, though all lavenders have medicinal properties in varying degrees.

This fragrant, bushy shrub has been widely cultivated for its essential oil. The tiny, tubular, mauve-blue blossoms grow in whorls of six to ten flowers along square, angular stems and form a terminal spike. These flower spikes stretch upward beyond the

French lavender. *(© blickwinkel / Alamy)*

12-18 inch (3.6-5.4 m) height of the shrub, blooming from June to August. The blossoms are well liked by bees and a good source of honey. The needle-like, evergreen, downy leaves are a light, silver-gray. They are lanceolate, opposite, and sessile, and grow from a branched stem. The bark is gray and flaky. The herb thrives in full sun and poor soil. Ancient Greeks and Romans used lavender blossoms to scent bath water, a common use that gave the herb its name, derived from the Latin *lavare*, meaning to wash.

General use

Lavender is best known and loved for its fragrance. The herb has been used since ancient times in perfumery. As an aromatic plant, lavender lifts the spirits and chases melancholy. Taking just a few whiffs of this sweet-smelling herb is said to dispel **dizziness**. Traditionally, women in labor clutched sprigs of lavender to bring added courage and strength to the task of childbearing. A decoction of the flower may be used as a feminine douche for leucorrhoea. The dried blossoms, sewn into sachets, may be used to repel moths and to scent clothing, or may be lit like incense to scent a room. Because of its fumigant properties, the herb was hung in the home to repel flies and mosquitoes, and strewn about to sanitize the floors. Lavender essential oil was a component of smelling salts in Victorian times.

The essential oil of certain lavender species has a sedative, antispasmodic, and tranquilizing effect. Lavender has been long valued as a **headache** remedy. It can be taken in a mild infusion, or can be rubbed on the temples, or sniffed like smelling salts to provide relief from headaches caused by **stress**. Lavender oil is antiseptic, and has been used as a topical disinfectant for **wounds**. In high doses, it can kill many common bacteria such as typhoid, diphtheria, streptococcus, and pneumococcus, according to some research. The essential oil has also been used as a folk treatment for the bite of some venomous snakes. When used in **hydrotherapy** as part of an aromatic, Epsom salt bath, the **essential oils** of some species will soothe tired nerves and relieve the **pain** of **neuralgia**. They are also used topically on **burns** and have been shown to speed healing. It is also a fine addition to a foot bath for sore feet. Lavender essence makes a pleasant massage oil for kneading sore muscles and joints. Acting internally, lavender's chemical properties increase the flow of bile into the intestines, relieving **indigestion**. Its carminative properties help expel intestinal **gas**. Lavender is an adjuvant and may be used in combination with other herbs to make a tonic cordial to strengthen the nervous system.

KEY TERMS

Adjuvant—A characteristic of an herb that enhances the benefits of other ingredients when added to a mixture.

Carminative—A property of an herb that assists in relieving intestinal gas.

Coumarins—These blood-thinning plant chemicals break down red blood cells. Coumarins are responsible for the fresh- mown lawn aroma that some herbs exude.

Flavonoids—There are numerous phytochemicals known as flavones. Most exert a pharmacological effect, depending on their type. Flavonoids are one type of flavone.

Sessile— A botanical term to describe a leaf that emerges from the plant stem without a stalk.

Tannins—These astringent plant chemicals are the medicinal constituent of an herb that enables it to facilitate healing of wounds.

Volatile or essential oils—Simple molecules that give the plant its scent. When applied to the skin, volatile oil extracts are absorbed into the bloodstream through the fatty layer of the skin.

A 2002 report from Korea showed that **aromatherapy** massage with lavender oil and **tea tree oil** on patients undergoing hemodialysis for kidney failure received relief from the **itching** the treatment often causes.

Preparations

The medicinal properties of lavender are extracted primarily from the oil glands in the leaf and blossom. The plant contains volatile oil, tannins, coumarins, flavonoids, and triterpenoids as active chemical components. These phytochemicals are the plant constituents responsible for the medicinal properties. Lavender's volatile oil is best when extracted from flowers picked before they reach maximum bloom and following a long period of hot and dry temperatures. The flower spikes dry quickly when spread on a mat in an airy place away from direct sun.

Distilled oil: The essential oil of lavender is extracted by steam distillation. Just a few drops of this essential oil are effective for topical applications. Commercial distillations of this essential oil are readily available.

Lavender tea: An infusion of the fresh or dried flowers and leaf can be made by pouring a pint of

boiling water over one ounce of the dry leaf and flower, or two ounces fresh herb, in a non-metallic pot. It can be steeped (covered) for about ten minutes, strained and sweetened to taste. It should be drunk while still warm. Lavender tea may be taken throughout the day, a mouthful at a time, or warm, by the cup, up to three cups per day. Lavender works well in combination with other medicinal herbs in infusion.

Lavender oil extract: In a glass container, one ounce of freshly harvested lavender flowers can be combined with 1-1/2 pints of olive oil, sufficient to cover the herb. It should be placed in a sunny windowsill for about three days and shaken daily. After three days, the mixture should be strained through muslin or cheesecloth. More fresh flowers should be added and the process repeated until the oil has the desired aromatic strength. Lavender extract can be safely used internally to treat migraines, and nervous indigestion. A few drops on a sugar cube can speed headache relief. Externally, a small amount of lavender oil, rubbed on sore joints, can relieve rheumatism. The essential oil has also been used to minimize scar tissue when applied to burned skin.

Lavender sachet: Dried lavender blossoms and leaves can be sewn into a small cloth bag to scent linens and deter insects. The bag may be placed beneath the pillow as an aromatherapy.

Lavender vinegar: Fresh leaves and blossoms may be steeped in white vinegar for seven days, then strained and stored in a tightly capped bottle.

Precautions

Lavender has a long history of use as an essential oil and as a mildly sedative tea. When taken in moderation the tea is safe. It is important to note that, as with all essential oils, high or chronic doses of lavender essential oil are toxic to the kidney and liver. Infants are even more easily overdosed than adults.

Interestingly, lavender's relaxant effects were put to the test in a 2002 study on aromatherapy's effects on improved mental or physical performance. It seems that study subjects who smelled lavender actually did worse on mental tests than those who smelled nothing at all. So those choosing to use lavender's soothing effects should perhaps choose the timing carefully.

Side effects

No known side effects.

Interactions

As an adjuvant, lavender can enhance the helpful properties of other herbs when used in combination. **Lemon balm** (*Melissa officinalis*) leaves can be combined with lavender as a headache infusion. For cramping, an infusion of lavender and **valerian** (*Valeriana officinalis*) makes a soothing tea. Lavender's pleasant scent works well to cover disagreeable odors of other herbs in medicinal combinations. A tonic cordial can be made by combining fresh **rosemary** (*Rosmarinus officinalis*) leaves, cinnamon, **nutmeg**, and sandlewood with the lavender blossoms and steeping the mixture in brandy for about a week.

Lazy eye

Definition

Lazy eye, or amblyopia, is an eye condition in which disuse causes reduced vision in an otherwise healthy eye. The affected eye is called the *lazy* eye.

Man with a lazy eye. *(Custom Medical Stock Photo. Reproduced by permission.)*

This vision defect occurs in 2–3% of American children. If not corrected before age eight, amblyopia will cause significant loss of stereoscopic vision, the ability to perceive three-dimensional depth.

Description

In some children, one eye functions better than the other. When a child begins to depend on the stronger eye, the weaker eye can become progressively weaker. Eventually, the weaker eye grows "lazy" from disuse. If left untreated beyond the early child-development years (from birth to seven years old), vision in the affected eye will be underdeveloped due to lack of use.

The impairment of vision in the lazy eye occurs in three phases. In the first (suspension) phase, the brain turns the weaker eye on and off. In the second (suppression) phase, the brain turns off the lazy eye indefinitely. At this point, the eye still has usable vision and can function well if the other eye is covered. In the last (amblyopia) phase, which occurs after age seven, the eye loses all the sensitivity that is essential for good vision because it has not been used for so long.

Lazy eye is a visual problem with potentially serious consequences. If left untreated, the affected child may have permanent loss of vision in the lazy eye. Because of loss of vision in one eye, these children cannot see three-dimensional images very well—all images appear flat. They also have problems with depth perception. This has serious consequences in their future ability to work in professions that require good vision in both eyes. Affected children also have increased risk of blindness should something happen to the good eye.

Causes and symptoms

The following are probable causes of lazy eye:

- Strabismus, or misalignment of a child's eyes (crossed eyes). This is the most frequent cause of lazy eye. Approximately half of all children with crossed eyes will develop a lazy eye. In children with crossed eyes, the images do not coordinate, thus confusing the brain. Therefore, the brain will suppress the image that comes from one eye and predominantly use the image from the stronger eye.

KEY TERMS

Anisometropia—An eye condition in which the eyes have unequal refractive power.

Nystagmus—An involuntary, rapid movement of the eyeball, usually from side to side.

Refraction—The deviation of light when passing obliquely through the media of the normal eye and resulting in the focusing of images on the retina.

Refractive power—The degree of refraction of an eye.

Strabismus—Failure of the two eyes to direct their gaze at the same object simultaneously due to muscle imbalance.

- Anisometropia (unequal refractive power). In this case, there is difference in image quality between the two eyes because one eye is severely nearsighted or farsighted. In other words, one eye focuses better than the other. The brain will mostly use the clearer image from the good eye. The other eye will become underdeveloped due to neglect.
- Congenital cataract. The lazy eye can not see well because its lens is already cloudy at birth.
- Ptosis (drooping eyelid). Vision in the lazy eye is blocked or impaired by the drooping eyelid.
- Corneal scarring. The image quality of the affected eye is poor due to scarring in the cornea.

The following are risk factors for amblyopia:

- Rubella (German measles) or other infections in the mother during pregnancy
- premature birth
- other family members with vision problems in childhood

Lazy eye may not present obvious symptoms. For this reason, it is important for small children to have regular eye examinations.

Diagnosis

Diagnosis of amblyopia is often made during visual screening during routine infant check-ups and in the preschool years (aged three to five). Premature babies need to have more frequent eye exams during early childhood to prevent this and other vision problems. A new photoscreening instrument that has been recently introduced appears to significantly increase the accuracy of diagnosis of these eye problems.

Treatment

The following alternative methods may complement conventional treatment of lazy eye. However, they are not replacements for conventional treatments. Because their effectiveness is not proven, parents should consult their child's ophthalmologist about the appropriate use of these methods (if any) in their child's overall eye treatment program.

Orthoptics (eye exercises)

Eye exercises can be helpful. Orthoptic exercises are designed to help the eyes move together and assist the fusing of the two images seen by the eyes. It can help correct faulty vision habit due to misalignment of the eyes and can teach the child to use both eyes effectively and comfortably. This form of therapy can be used before or after eye-realignment surgery to improve results.

Vision therapy

Vision training is a form of physical therapy for the brain and the eyes. It is a more extensive form of eye exercise and requires more frequent visits.

Acupuncture

One study shows that **acupuncture** treatment may be effective in treating anisometropia, a condition in which one eye focuses much better than the other. Acupuncture can reduce the differences in refractive powers between the eyes so that both eyes can have similar image quality. This helps reduce the amblyopia problem. However, its long-term effectiveness remains unknown.

Allopathic treatment

In order to treat lazy eye, the doctor has to identify and treat underlying causes. Depending on these underlying causes, the doctor may recommend surgical or nonsurgical treatments, as discussed below.

Refractive error correction

If both eyes need vision correction, children are given prescription glasses for better focus and to prevent misalignment of the eyes.

Forcing the use of the lazy eye

In many children with amblyopia, only one eye has a focusing problem or weak muscles. In order to force the affected eye to work, the doctor will cover the strong eye with a patch for most of the day for at least several weeks. Sometimes, this treatment requires as

long as a year. The eye patch forces the lazy eye to work and thus, strengthens its vision and its muscles. This is the most common method used to treat lazy eye. To prevent the strong eye from becoming weaken due to disuse, the child is allowed to remove the patch so that he can see with the good eye for at least a few hours each day.

Another way to force the lazy eye to work harder is to use eye drops or ointment to blur the vision in the strong eye so that the child has to use the lazy eye to see. This method is not often used because it is associated with more adverse effects.

Surgical treatments

If the problem is caused by imbalances of the eye muscles and is not treatable with nonsurgical methods, the eye muscles can be realigned surgically to help the eyes coordinate better. Sometimes more than one surgery is required for the correction. Eye patch, glasses, or orthoptic exercises may be necessary following surgery to help the child use both eyes effectively. Long-term follow-up of surgical treatment indicates that it is highly effective in correcting the problem.

In patients whose amblyopia is caused by a congenital cataract in one eye, the cloudy lens is surgically removed and replaced by an intraocular lens. However, after surgery—even with eye glasses or contact lenses—this eye will still have poorer image quality than the good eye. Thus, the risk for amblyopia remains high. Therefore, nonsurgical treatment for lazy eye is often started after cataract surgery.

For a child whose vision is affected by a drooping eyelid, ptosis surgery is needed.

Expected results

With early diagnosis and treatment, children with amblyopia are expected to restore the sight in the lazy eye. However, if left untreated, the weak eye never develops adequate vision and the person may become functionally blind in that eye.

Prevention

Most cases of lazy eye are congenital, occurring since birth. However, if diagnosed early, vision loss in the affected eye can be prevented.

Lead poisoning

Definition

Lead poisoning occurs when a person swallows, absorbs, or inhales lead in any form. The result can be damaging to the brain, nerves, and many other parts of the body. Acute lead poisoning, which is somewhat rare, occurs when a person ingests a relatively large amount of lead over a short period of time. Chronic lead poisoning—a common problem in children—occurs when small amounts of lead are taken in over a longer period. The Centers for Disease Control and Prevention (CDC) defines childhood lead poisoning as a whole-blood lead concentration equal to or greater than 10 mcg/dL.

Description

Lead can damage almost every system in the human body, and it can also cause high blood pressure (**hypertension**). It is particularly harmful to the

Sources of lead poisoning

Source	Description
Paint	Lead-based paint can be a hazard in older homes. Children eat peeling paint, or come in contact with it during remodeling projects.
Dust and soil	Contamination of soil is usually caused by paint, leaded gasoline, pollution from industrial sites, and smelters.
Foods	Lead can be found in imported canned foods, leaded crystal, and some ceramic dishware.
Activities	Activities such as pottery, stained glassmaking, and furniture refinishing can heighten exposure to lead.
Drinking water	Homes built before 1930 may contain lead water pipes. Newer homes may also contain copper pipes with lead solder.
Traditional remedies & cosmetics	Certain ayurvedic medications, traditionally from India and other Southern Asian countries, may contain lead. Also litargirio (a peach -colored powder used mainly in the Dominican Republic) contains high levels of lead, and the FDA warns against its usage. Kohl is another traditional cosmetic frequently containing high levels of lead.

(Illustration by Corey Light. Cengage Learning, Gale)

developing brain of fetuses and young children. The higher the level of lead in a child's blood, and the longer this elevated level lasts, the greater the chance of ill effects. Over the long term, lead poisoning in a child can lead to learning disabilities, behavioral problems, and mental retardation. At very high levels, lead poisoning can cause seizures, coma, and even death. In one of the rare studies of its kind, the National Center for Environmental Health reported in 2003 that there were about 200 deaths from lead poisoning in the United States between 1979 and 1998. Most of the deaths were among males (74%), African Americans (67%), adults over the age of 45 (76%), and southerners (70%).

Of much greater concern than mortality due to lead poisoning is the number of children who have elevated levels of lead in their blood. Many children are exposed to lead through peeling paint in older homes. Others are exposed through dust or soil that has been contaminated by old paint or past emissions of leaded gasoline. Since children between the ages of 12 and 36 months are apt to put objects in their mouths, they are more likely than older children to take in lead. Pregnant women who come into contact with lead can pass it along to their fetuses.

More than 80% of American homes built before 1978 have lead-based paint in them, according to the Centers for Disease Control and Prevention (CDC). The older the home, the more likely it is to contain lead paint, and the higher the concentration of lead in the paint is apt to be. Some homes also have lead in the water pipes or plumbing. People may have lead in the paint, dust, or soil around their homes or in their drinking water without knowing it, since lead cannot be seen, smelled, or tasted. Because lead does not break down naturally, it can continue to cause problems until it is removed.

Efforts to promote public awareness of lead poisoning problems have had marked success in the United States. The percentage of children under the age of six with unacceptably high concentrations of lead in their blood dropped from 7.6% in 1997 to 1.2% in 2006. In 2008, the CDC expressed confidence that it was approaching the federal government's goal of eliminating childhood lead poisoning by the year 2010.

Causes and symptoms

Before scientists knew how harmful it could be, lead was widely used in paint, gasoline, water pipes, and many other products. In the 2000s, house paint is almost lead-free, gasoline is unleaded, and household plumbing is no longer made with lead materials. Still, remnants of the old hazards remain. Following are some sources of lead exposure:

- Lead-based paint. The most common source of exposure to large amounts of lead among preschoolers, paint chips from older homes that have fallen into disrepair are eaten by children. They may also chew on painted surfaces, such as windowsills. In addition, paint may be disturbed during remodeling.
- Dust and soil. These can be contaminated with lead from old paint or past emissions of leaded gasoline. In addition, pollution from operating or abandoned industrial sites and smelters can find its way into the soil, resulting in soil contamination.
- Drinking water. Exposure may come from lead water pipes, found in many homes built before 1930. Even newer copper pipes may have lead solder. Also, some new homes have brass faucets and fittings that can leach lead.
- Jobs and hobbies. A number of activities can expose participants to lead. These include making pottery or stained glass, refinishing furniture, doing home repairs, and using indoor firing ranges. When adults take part in such activities, they may inadvertently expose children to lead residue that is on their clothing or on scrap materials.
- Food. Imported food cans often have lead solder. Lead may also be found in leaded crystal glassware and some imported ceramic or old ceramic dishes (e.g., ceramic dishes from Mexico). A 2003 study of cases of lead poisoning in pregnant women found that 70% of the patients were Hispanics, most of whom had absorbed the lead from their pottery. In addition, food may be contaminated by lead in the water or soil.
- Folk medicines. Certain folk medicines (for example, alarcon, alkohl, azarcon, bali goli, coral, ghasard, greta, liga, pay-loo-ah, and rueda) and traditional cosmetics (kohl, for example) contain large amounts of lead. Also, certain Chinese and Tibetan herbal remedies and techniques are contaminated with lead and other heavy metals, such as mercury.
- Moonshine whiskey. Lead poisoning from drinking illegally distilled liquor is still a cause of death among adults in the southern United States.
- Gunshot wounds. Toxic amounts of lead can be absorbed from bullets or bullet fragments that remain in the body after emergency surgery. The use of lead in some kinds of ammunition has been banned in the United States, and substitutes for lead in other types of ammunition were being developed as of 2008.
- Imported toys. In 2006, the U.S. Consumer Products Safety Commission announced that a number of toy products imported from China were contaminated with lead paint. One of the worst such episodes occurred in 2007 when more than 1.5 million "Thomas & Friends" wooden railway toys painted with lead were recalled. As of 2008, the scope of this problem had not yet been fully determined, nor had adequate methods for controlling the importation of contaminated toys been established.

Chronic lead poisoning

Some evidence suggests that lead may be harmful to children even at low levels that were once thought to be safe, and the risk of damage rises as blood levels of lead increase. The symptoms of chronic lead poisoning take time to develop, however. Children can appear healthy despite having high levels of lead in their blood. Over time, though, problems such as the following may arise:

- learning disabilities
- hyperactivity
- mental retardation
- slowed growth
- hearing loss
- headaches

Scientists also know that certain genetic factors increase the harmful effects of lead poisoning in susceptible children; however, these factors were not completely understood as of 2008.

Lead poisoning is also harmful to adults, who may develop high blood pressure, digestive problems, nerve disorders, **memory loss**, and muscle and joint **pain**. In addition, it can lead to difficulties during **pregnancy**, as well as cause reproductive problems in both men and women.

In the 2000s, chronic exposure to lead in the environment was found to speed up the progression of kidney disorders in patients without diabetes.

Acute lead poisoning

Acute lead poisoning, while less common, shows up more quickly and can be fatal. In such cases, children are almost always affected. Symptoms such as the following may occur:

- severe abdominal pain
- diarrhea
- nausea and vomiting
- weakness of the limbs
- seizures
- coma

Diagnosis

A high level of lead in the blood can be detected with a simple blood test. In fact, testing is the only way to know for sure if children without symptoms have been exposed to lead, since they can appear healthy even as long-term damage occurs. The CDC recommends testing all children at 12 months of age and, if possible, again at 24 months. Testing should start at six months for children at risk for lead poisoning. Based on these test results and a child's risk factors, the doctor decides whether further testing is needed and how often. In some states, more frequent testing is required by law.

Evidence is emerging to indicate that even lower doses of lead than previously thought can cause neurological damage in children. It may be that virtually no level of lead is safe and that measures need to be taken to remove lead from the environment. As of 2008 in the United States, the CDC recommended that lead blood levels in children not exceed 10 mcg/dL.

Children at risk

Children with an increased risk of lead poisoning include those who have the following features:

- live in or regularly visit a house built before 1978 in which chipped or peeling paint is present, particularly poor children in sub-standard housing
- live in or regularly visit a house that was built before 1978 where remodeling is planned or underway
- have a brother or sister, housemate, or playmate who has been diagnosed with lead poisoning
- have the habit of eating dirt or have been diagnosed with pica
- live with an adult whose job or hobby involves exposure to lead
- live near an active lead smelter, battery-recycling plant, or other industry that can create lead pollution

Adults at risk

Testing is also important for adults whose job or hobby puts them at risk for lead poisoning, including the following:

- glazed pottery or stained glass making
- furniture refinishing
- home renovation
- target shooting at indoor firing ranges
- battery reclamation
- precious metal refining
- radiator repair
- art restoration

Treatment

In the event of emergency poisoning, patients or parents should call 911 or the poison hotline at (800) 222-1222. The first step in treating lead poisoning is to avoid further contact with lead. For adults, this usually means making changes at work or in hobbies. For children, it means finding and removing sources of lead in the home. In most states, the public health department can help assess the home and identify lead sources.

If the problem is lead paint, a professional with special training should remove it. Removal of lead-based paint is not a do-it-yourself project. Scraping or sanding lead paint creates large amounts of dust that can poison people in the home. This dust can stay around long after the work is completed. In addition, heating lead paint can release lead into the air. For these reasons, lead paint should be removed only by a professional who knows how to do the job safely and has the equipment to clean up thoroughly. Occupants, especially children and pregnant women, should leave the home until the cleanup is finished.

Medical professionals should take all necessary steps to remove bullets or bullet fragments from patients with gunshot injuries.

Nutritional therapy

While changes in diet are no substitute for medical treatment, they can complement the **detoxification** process. The following nutritional changes are recommended:

- Increased consumption of fresh vegetables, fruits, beans, nuts, whole grains, and seeds.
- Increased consumption of soluble fibers, such as pears, apples, oatmeal, oat bran, rye flour, dried beans, guar gum, pectin, and psyllium.
- Increased consumption of sulfur-containing foods, such as eggs, garlic, and onions. Garlic has been used successfully to reduce lead poisoning in animals.
- Taking high-potency multivitamin/mineral supplements (1 tablet a day).
- Taking additional supplements of vitamin C, B-complex vitamins, iron, calcium, zinc, L-lysine, L-cysteine, and

L-cysteine supplements. These vitamins, minerals, and amino acids help reduce the amount of lead that the body absorbs. Iron is especially important, since people who are deficient in this nutrient absorb more lead. Thiamine, a B-complex vitamin, has been used to treat lead poisoning in animals.

- A 2002 report stated that eating tofu may lower lead levels in the blood since it is rich in calcium.
- Using a filter to prevent lead contamination in the water. Drinking lots of water (at least eight glasses per day) to help the body excrete the toxin.
- Committing to a three-day fast at the end of every season. Fasting is the oldest method of detoxification. During fasting, patients should take supplements and drink four glasses of juice a day to assist the cleansing process and to prevent exhaustion.

Herbal therapy

Milk thistle (*Silybum mariannum*) protects the liver and assists in the detoxification process by increasing **glutathione** supply in the liver. Glutathione is the enzyme involved primarily in the detoxification of toxic heavy metals including lead.

Homeopathy

Homeopathic medicines can be administered once the source is removed, to help correct any imbalances brought on by lead toxicity.

Allopathic treatment

The American Association of Poison Control Centers maintains a nationwide toll-free hotline for prevention and treatment of poisonings. The number is (800) 222-1222. In the case of any suspected poisoning emergency, they can be contacted 24 hours a day.

Chelation therapy

If blood levels of lead are high enough, the doctor may also prescribe **chelation therapy**. This process involves the use of chemicals that bind to lead and help the body pass it in urine at a faster rate. The four most popular chemical agents used for this purpose, either alone or in combination, are edetate **calcium** disodium (EDTA calcium), dimercaprol (BAL), succimer (Chemet; DMSA), and penicillamine (Cuprimine, Depen). EDTA calcium and BAL are given through an intravenous line or in shots, whereas succimer and penicillamine are given orally. (Although many doctors prescribe penicillamine for lead poisoning, this use of the drug has not been approved by the Food and Drug Administration.)

Expected results

If acute lead poisoning reaches the stage of seizures and coma, there is a high risk of death. Even if the person survives, there is a good chance of permanent brain damage. The long-term effects of lower levels of lead can also be permanent and severe. However, if chronic lead poisoning is detected early, these negative effects can be limited by reducing future exposure to lead and getting proper medical treatment.

Prevention

Many cases of lead poisoning can be prevented. These steps can help:

- Keep the areas where children play as clean and dust-free as possible.
- Wash pacifiers and bottles when they fall to the floor, and wash stuffed animals and toys often.
- Make sure children wash their hands before meals and at bedtime.
- Mop floors and wipe windowsills and other chewable surfaces, such as cribs, twice a week with a solution of powdered dishwasher detergent in warm water.
- Plant bushes next to an older home with painted exterior walls to keep children at a distance.
- Plant grass or another ground cover in soil that is likely to be contaminated, such as soil around a home built before 1960 or located near a major highway.
- Have household tap water tested to find out if it contains lead.
- Use only water from the cold-water tap for drinking, cooking, and making baby formula, since hot water is likely to contain higher levels of lead.
- If the cold water has not been used for six hours or more, run it for several seconds, until it becomes as cold as it will get, before using it for drinking or cooking. The more time water has been sitting in the pipes, the more lead it may contain.
- Individuals who work with lead in their jobs or hobbies ought to change their clothes before they go home.
- Do not store food in open cans, especially imported cans.
- Do not store or serve food in pottery meant only for decorative use.
- Arrange for the house to be inspected for lead. Many state health departments will do this.
- Be aware of the status of imported toys that may have unacceptably high levels of lead.

KEY TERMS

Chelation therapy—Treatment with chemicals that bind to a poisonous metal and help the body pass it in urine at a faster rate.

Dimercaprol (BAL)—A chemical agent used to remove excess lead from the body.

Edetate calcium disodium (EDTA calcium)—A chemical agent used to remove excess lead from the body.

Penicillamine (Cuprimine, Depen)—A drug used to treat medical problems (such as excess copper in the body and rheumatoid arthritis) and to prevent kidney stones. It is also sometimes prescribed to remove excess lead from the body.

Pica—An abnormal appetite or craving for non-food items, often such substances as chalk, clay, dirt, laundry starch, or charcoal.

Succimer (Chemet) or DMSA—A drug used to remove excess lead from the body.

Learning disorders

Definition

Learning disorders are academic difficulties experienced by children and adults of average to above-average intelligence. People with learning disorders have difficulty with reading, writing, mathematics, or a combination of the three. These difficulties significantly interfere with academic achievement or daily living.

Description

Learning disorders, or disabilities, affect approximately 2 million children between the ages of six and 17 (5% of public school children), although some experts think the figure may be as high as 15%. These children have specific impairments in acquiring, retaining, and processing information. Standardized tests place them well below their IQ range in their area of difficulty. The three main types of learning disorders are reading disorders, mathematics disorders, and disorders of written expression. The male: female ratio for learning disorders is about 5: 1.

Reading disorders

Reading disorders are the most common type of learning disorder. Children with reading disorders have difficulty recognizing and interpreting letters and words (**dyslexia**). They are not able to recognize and decode the sounds and syllables (phonetic structure) behind

KEY TERMS

Dyslexia—An inability to read, write, or spell words in spite of the ability to see and recognize letters. Dyslexia is an autosomal dominant disorder thst occurs more frequently in males.

IQ—Intelligence quotient; a measure of intellectual functioning determined by performance on standardized intelligence tests.

Phonics—A system to teach reading by teaching the speech sounds associated with single letters, letter combinations, and syllables.

written words and language in general. This condition lowers accuracy and comprehension in reading.

Mathematic disorders

Children with mathematics disorders (dyscalculia) have problems recognizing and counting numbers correctly. They have difficulty using numbers in everyday settings. Mathematics disorders are typically diagnosed in the first few years of elementary school when formal teaching of numbers and basic math concepts begins. Children with mathematics disorders usually have a co-existing reading disorder, a disorder of written expression, or both.

Disorders of written expression

Disorders of written expression typically occur in combination with reading disorders or mathematics disorders or both. The condition is characterized by difficulty with written compositions (dysgraphia). Children with this type of learning disorder have problems with spelling, punctuation, grammar, and organizing their thoughts in writing.

Causes and symptoms

Learning disorders are thought to be caused by neurological abnormalities that trigger impairments in the regions of the brain that control visual and language processing and attention and planning. These traits may be genetically linked. Children from families with a history of learning disorders are more likely to develop disorders themselves. In 2003 a team of Finnish researchers reported finding a candidate gene for developmental dyslexia on human chromosome 15q21.

Learning difficulties may also be caused by such medical conditions as a traumatic brain injury or brain **infections** such as encephalitis or **meningitis**.

The defining symptom of a learning disorder is academic performance that is markedly below a child's age, grade capabilities, and measured IQ. Children with a reading disorder may confuse or transpose words or letters and omit or add syllables to words. The written homework of children with disorders of written expression is filled with grammatical, spelling, punctuation, and organizational errors. The child's handwriting is often extremely poor. Children with mathematical disorders are often unable to count in the correct sequence, to name numbers, and to understand numerical concepts.

Diagnosis

Problems with vision or hearing, mental disorders (**depression**, attention-deficit/hyperactivity disorder), mental retardation, cultural and language differences, and inadequate teaching may be mistaken for learning disorders or complicate a diagnosis. A comprehensive medical, psychological, and educational assessment is critical to making a clear and correct diagnosis.

A child thought to have a learning disorder should undergo a complete medical examination to rule out an organic cause. If one is not found, a psychoeducational assessment should be performed by a psychologist, psychiatrist, neurologist, neuropsychologist, or learning specialist. A complete medical, family, social, and educational history is compiled from existing medical and school records and from interviews with the child and the child's parents and teachers. A series of written and verbal tests are then given to the child to evaluate his or her cognitive and intellectual functioning. Commonly used tests include the Wechsler Intelligence Scale for Children (WISC-III), the Woodcock-Johnson Psychoeducational Battery, the Peabody Individual Achievement Test-Revised (PIAT-R), and the California Verbal Learning Test (CVLT). Federal legislation mandates that this testing is free of charge within the public school system.

Treatment

Once a learning disorder has been diagnosed, an individual education plan (IEP) is developed for the child in question. IEPs are based on psychoeducational test findings. They provide for annual testing to measure a child's progress. Students with learning disorders may receive special instruction within a regular general education class or they may be taught in a special education or learning center for a portion of the day.

Common strategies for the treatment of reading disorders focus first on improving a child's recognition of the sounds of letters and language through phonics training. Later strategies focus on comprehension, retention, and study skills. Students with disorders of written expression are often encouraged to keep journals and to write with a computer keyboard instead of a pencil. Instruction for students with mathematical disorders emphasizes real-world uses of math, such as balancing a checkbook or comparing prices.

Ensuring that the child has proper **nutrition** can help in the treatment of learning disorders. Those who do not receive the proper doses that they need may require changes in their **diets**, or supplements are taken. Supplements that may help with learning disorders are **fish oil**, flax oil, primrose oil, and **omega-3 fatty acids**. Eliminating food additives, like colors and preservatives, as well decreasing the child's consumption of refined sugars, can also be helpful.

Meditation is also beneficial. It helps to slow the mind down and take in the surroundings while focusing on the task at hand.

Herbal remedies may also help to focus the mind. **St. John's wort** and *Ginkgo biloba* are used to treat **attention-deficit hyperactivity disorder** (ADHD). Ginkgo is a blood thinner and those considering taking it should consult a doctor beforehand.

Expected results

The high school dropout rate for children with learning disabilities is almost 40%. Children with learning disabilities that go undiagnosed or are improperly treated may never achieve functional literacy. They often develop serious behavior problems as a result of their frustration with school; in addition, their learning problems are often stressful for other family members and may strain family relationships. The key to helping these students reach their fullest potential is early detection and the implementation of an appropriate individualized education plan. The prognosis is good for a large percentage of children with reading disorders that are identified and treated early. Learning disorders continue into adulthood, but with proper educational and vocational training, an individual can complete college and pursue a challenging career. Studies of the occupational choices of adults with dyslexia indicate that they do particularly well in people-oriented professions and occupations, such as nursing or sales.

Lecithin

Definition

Lecithin was discovered in 1850 by Maurice Gobley, who isolated it in egg yolks and identified it as the substance that allows oil and water to mix. The name is derived from the Greek word *lekithos*, which means "yolk of egg." Lecithin is a naturally occurring fatty substance found in several foods, including soybeans, whole grains, and egg yolks. It is often used as an emulsification agent in processed foods. It can be taken in various forms as a nutritional supplement, often derived from soybeans. The body breaks lecithin down into its component parts: **choline**, phosphate, glycerol, and fatty acids. The body's highest concentration of lecithin is found in the vital organs, where it makes up about 30% of the dry weight of the brain and nearly two-thirds of the fat in the liver.

General use

Lecithin acts as an emulsifier and helps the body in the absorption of fats. Some studies suggest that soy lecithin improves the metabolism of **cholesterol** in the digestive system. Therefore, lecithin has been touted as a treatment for high cholesterol. It has also been said to be a treatment for neurologic and liver disorders. Promoters claim that supplemental lecithin can be used to help lower cholesterol and deter **memory loss**. Some proponents of lecithin warn that the low fat and low cholesterol **diets** that many Americans follow may lower the amount of lecithin that they consume, creating a deficit and necessitating supplemental lecithin. As Americans eat fewer eggs, meats, and dairy products, the amount of choline that they consume may be less than required. Choline is the key element in lecithin that researchers believe may have a beneficial effect on cholesterol and memory.

Lecithin has been identified as a possible resource for lowering blood cholesterol because of its reputation as a source of polyunsaturated fats. In addition, choline helps the liver metabolize fat and form lipoproteins. However, as of 2008, there was scant evidence to support the use of lecithin in lowering cholesterol. Researchers in some studies have found a drop in cholesterol levels, while others have found no drop in cholesterol levels at all. A group of researchers from the Netherlands who summarized findings in the *American Journal of Clinical Nutrition* concluded that many studies of the effects of lecithin had faulty methods, and the few good studies proved that lecithin was not effective in lowering cholesterol. Subsequently, a group of American researchers solved part of the mystery concerning the fact that eggs, which are packed with cholesterol, do not impact people's cholesterol much if eaten in moderation. The reason seemed to be the lecithin found in eggs that reduces cholesterol's absorption in the bloodstream. Generally speaking, the role of lecithin in reducing blood cholesterol appears to be minimal.

Lecithin is also considered to be of possible benefit to brain function, and supporters claim that it may help prevent **Alzheimer's disease**. Promoters indicate that the choline in lecithin may have the ability to penetrate the blood-brain barrier and impact the production of acetylcholine, a neurotransmitter that facilitates brain function. They claim that long-term use of lecithin as a dietary supplement could help minimize memory loss. However, studies on the use of lecithin for the treatment of Alzheimer's disease have found that it has no marked benefit.

Preparations

Lecithin is derived from soy and is available in capsule, liquid, and granule form. Consumers should not use a synthetic form of the supplement (choline chloride) but should seek one that contains natural phosphatidyl choline. Lecithin from soybeans generally contains about 76% phosphatidycholine. Studies of supplements sold in health food stores show that most contain minimal levels of pure lecithin. In fact, a person might get the same benefit from eating a handful of peanuts. The American Heart Association and the College of Physicians and Surgeons of Columbia University have described lecithin supplements as an expensive and probably unnecessary way of increasing unsaturated fatty acids in one's diet.

Precautions

Consumers should be aware that most nutritional supplements are not regulated by the Food and Drug Administration (FDA) for product safety or effectiveness. Because lecithin is not considered an essential nutrient, as of 2008, no Recommended Daily Allowance (RDA) has been established for this nutrient.

Side effects

There are no major side effects for lecithin as a supplement. In high doses (more than 25 g per day), lecithin can cause sweating, upset stomach, **diarrhea**, **nausea**, and **vomiting**. Pregnant or nursing women and children should avoid the supplement because it has not been adequately tested for safety.

KEY TERMS

Emulsification—The process by which two immiscible liquids are dispersed into each other.

Fatty acid—A long-chain carboxylic acid found in fats, oils, and other lipids.

Neurotransmitter—A chemical that carries a message from the end of one neuron (nerve cell) to the beginning of a second neuron.

Ledum

Description

Ledum is an evergreen shrub, *Ledum palustre*. This plant grows wild in Canada, northern Europe, and the cooler regions of North America as far south as Wisconsin and Pennsylvania, reaching a height of 1–6 ft (0.3–2 m). It has narrow, dark, aromatic leaves with hairy or wooly undersides. The leaves, either dried or fresh, are used primarily in homeopathic healing, but have also been used in Native American and Russian folk medicine.

During the American Revolution when the British imposed a tax on imported tea, the American colonists used ledum as a tea substitute. Other names for ledum include marsh tea, Labrador tea, wild **rosemary**, James's tea, and *ledum latifolium*.

General use

Homeopathic medicine operates on the principle that "like heals like." This saying means that a disease can be cured by treating it with products that produce the same symptoms as the disease. These products follow another homeopathic law, the Law of Infinitesimals. In opposition to traditional medicine, the Law of Infinitesimals states that the lower a dose of curative, the more effective it is. To achieve a low dose, the curative is diluted many, many times until only a tiny amount, if any, remains in a huge amount of the diluting liquid.

Ledum groenlandicum. *(Erin Paul Donovan / Alamy)*

In homeopathic terminology, the effectiveness of remedies is proved by experimentation and reporting done by famous homeopathic practitioners. Ledum was proved as a remedy by the German founder of **homeopathy**, Dr. Samuel Hahnemann (1775–1843).

In homeopathic medicine, ledum is used first and foremost as a first-aid remedy to prevent infection. It is taken internally for:

- bruises, especially bruises that are improved by the application of cold
- insect stings and animal bites
- puncture wounds, cuts, grazes, and scrapes
- black eyes and other eye injuries

Other homeopathic uses for ledum include the treatment of stiff and painful joints, especially when the **pain** begins in the feet and ankles and moves upward. Ledum is also used for sprained ankles. According to some homeopathic practitioners, ledum is said to take away the craving for alcohol.

Since 1995, ledum has been touted as a homeopathic remedy for **Lyme disease**. Originally prescribed by a holistic veterinarian in Connecticut to treat the symptoms of Lyme disease in horses, dogs, and cats, ledum in the 1M potency is now recommended by some alternative practitioners as a treatment for Lyme disease in humans. There are several anecdotal reports of its success in treating this painful disease.

KEY TERMS

Antioxidants—Enzymes that bind with free radicals to neutralize their harmful effects on living tissue. Ledum appears to be a rich source of antioxidants.

Decoction—Decoctions are made by simmering an herb, then straining the solid material out.

Lyme disease—A chronic, recurrent inflammatory disease carried by deer ticks and caused by a spirochete.

In homeopathic medicine the fact that certain symptoms get better or worse under different conditions is used as a diagnostic tool to indicate what remedy will be most effective. Symptoms that benefit from treatment with ledum get worse with warmth and are also worse at night. Symptoms improve with the application of cold.

Homeopathy also ascribes certain personality types to certain remedies. The ledum personality is said to be discontented and self-pitying. People with the ledum personality may be irritable, angry, impatient, worried, and want to be left alone. People in need of ledum often have restless, disturbed sleep marked by bad dreams.

Ledum is also used in Native American and Russian folk healing. In Russian, ledum is called *bogulnik*. Both these cultures use decoctions or infusions of ledum to treat coughs, **bronchitis**, and bronchial **asthma**. According to historical records, the famous Swedish botanist Karl Linneaus (1707–1778) was the first to record using ledum for sore throats and coughs.

In addition, Russian folk medicine uses ledum mixed with butter to make an ointment that is applied externally to treat scabby **dandruff**, skin **infections**, **bruises**, **wounds**, and bleeding. Used externally, it is believed to act as an antibiotic and an anti-fungal to reduce infection.

Mainstream medical researchers have studied ledum within the field of environmental medicine. Some Russian animal studies from the mid-1990s indicated that ledum offers some protection against radiation damage to the digestive system and the formation of red blood cells. A Canadian study completed in the summer of 2002 reported that ledum is a highly accurate indicator of high environmental concentrations of lead.

Ledum is also being studied for its beneficial effects when eaten as a vegetable. A 2002 report from the School of Pharmacy at the University of London states that ledum has a high level of antioxidant activity, and shows promise as a treatment for **gout**, diseases related to **aging**, and central nervous system disorders.

Preparations

Ledum is prepared by picking the leaves, small twigs, and flowers in the late summer. These can be used fresh or dried to make an infusion (tea) or a decoction. For homeopathic remedies, the dried plant material is ground finely then prepared by extensive dilutions. There are two homeopathic dilution scales, the decimal (x) scale with a dilution of 1:10 and the centesimal (c) scale where the dilution factor is 1:100. Once the mixture is diluted, shaken, strained, then re-diluted many times to reach the desired degree of potency, the final mixture is added to lactose (a type of sugar) tablets or pellets. These are then stored away from light. Ledum is available commercially in tablets in many different strengths. Dosage depends on the symptoms being treated.

Homeopathic and orthodox medical practitioners agree that by the time the initial remedy solution is diluted to strengths used in homeopathic healing, it is likely that very few if any molecules of the original remedy remain. Homeopaths, however, believe that these remedies continue to work through an effect called potentization that has not yet been explained by mainstream scientists.

As an infusion for treating respiratory distress and coughs, 1 oz (30 g) of dried leaves is added to 1 qt (1 L) of boiling water.

Precautions

Puncture wounds from rusty nails, needles, animal **bites**, and similar implements can be serious and may result in **tetanus**. When treating puncture wounds with ledum, patients should make sure their tetanus immunizations are current, monitor their healing, and seek traditional medical help at the first sign of infection.

People who bruise very easily should consult a physician, as this condition is sometimes caused by blood disorders and other serious conditions.

Side effects

Ledum taken in the standard homeopathic dilutions has not been reported to cause side effects. A tea made from ledum has been safely taken for centuries.

Interactions

Studies of interactions between ledum and conventional pharmaceuticals are nonexistent.

Lemon balm

Description

Lemon balm is a citrus-scented, aromatic herb. It is a perennial member of the Lamiaceae (formerly Labiatae), or mint, family and has proven benefit to the nervous system. This lovely Mediterranean native, dedicated to the goddess Diana, is bushy and bright. Greeks used lemon balm medicinally over 2,000 years ago. Honey bees swarm to the plant. This attraction inspired the generic name, melissa, the Greek word for honeybee. Romans introduced lemon balm (*Melissa officinalis*) to Great Britain where it became a favorite cottage garden herb. The plant has been naturalized in North America.

Lemon balm. *(© foodfolio / Alamy)*

Lemon balm grows in bushy clumps to 2 ft (0.6 m) tall and branches to 18 in (45.7 cm). It thrives in full sun or partial shade in moist, fertile soil from the mountains to the sea. The heart-shaped, deeply-veined leaves exude a pleasant lemon scent when brushed against or crushed. They have scalloped edges and square stems. The tiny white or golden blossoms grow in the leaf axils, and bloom from June through October. The plant is hardy, self-seeding, and spreads easily in the right soil conditions. The plant has a short rhizome, producing the erect, downy stems. The essential oil content appears to be highest in the uppermost third of the plant.

General use

Lemon balm is a soothing, sedative herb that can relieve tension and lift **depression**. An infusion of this citrus-scented herb will improve digestion, reduce **fever**, ease spasms, and enhance **relaxation**. The plant has antihistaminic properties and helps with **allergies**. Lemon balm infusions, taken hot, will induce sweating. Lemon balm has been used for centuries to calm the mind, improve memory, and sharpen the wit. A daily infusion of lemon balm is said to promote longevity. It is a helpful herb in cases of hyperthyroid activity, palpitations of the heart, and tension **headache**. It can relieve pre-menstrual tension and menstrual

KEY TERMS

Antioxidant—An enzyme or other organic substance that is able to counteract the damaging effects of oxidation in living tissue. The flavonoids in lemon balm appear to have some antioxidative efficacy.

Essential oil—Another term for volatile oil; the aromatic oil that can be obtained by steam distillation from plant parts. Most essential oils are composed of terpenes and their oxygenated derivatives.

Flavonoids—A class of water-soluble plant pigments that have antiviral and other healing qualities. The flavonoids in lemon balm are the source of its antihistaminic effectiveness.

Sedative—A medication or preparation given to calm or soothe nervousness or irritability. Lemon balm has sedative properties.

Volatile oil—The fragrant oil that can be obtained from a plant by distillation. The word "volatile" means that the oil evaporates in the open air.

cramping. It helps promote good digestion, relieve flatulence, and **colic**, and can ease one into a restful sleep. Lemon balm has antiviral and antibacterial properties. Used externally as a skin wash, this gentle herb can ease the sting of insect **bites**, soothe **cold sore** eruptions (herpes simplex), and treat sores and **wounds**. Lemon balm's highly aromatic qualities make it a good insect repellent. It is also valued in **aromatherapy** to relax and soothe a troubled mind. Fresh leaves are often added to salads, or used with fish, mushroom, and cheese dishes. In France, the herb is used in making cordials, and is called *Tea de France*.

Apart from its traditional medicinal uses, lemon balm is used to flavor vermouth and other alcoholic beverages as well as some soft drinks.

Lemon balm contains volatile oils, including citral, citronella, eugenol, and other components as well as flavonoids, triterpenoids, rosmarinic acid, polyphenols, and tannin. Several new flavonoids were discovered in lemon balm in 2002. Flavonoids are a group of water-soluble plant pigments that have antiviral and antioxidative qualities.

Preparations

Lemon balm leaves and flowers are used in medicinal remedies. The herb is at its best when used fresh from the harvest. The leaves may be picked throughout the summer, but the flavor is at its prime just before flowering. When the plant is dried for storage, the volatile oils diminish, reducing the medicinal potency of the herb. Freezing the fresh harvest is a good way to preserve the leaves for later use.

To create a tea, place two ounces of fresh lemon balm leaves in a warmed glass container; bring 2.5 cups of fresh, nonchlorinated water to the boiling point; add it to the herbs; cover; and infuse the tea for about 10 minutes. Once strained, the tea can be consumed warm. The prepared tea will store for about two days in the refrigerator. Lemon balm infusion is a gentle and relaxing tea. It may be enjoyed by the cupful three times a day.

Lemon balm combines well with the leaves of **peppermint** (*Mentha piperita*), and **nettle** (*Urtica dioica*), and the flowers of **chamomile** (*Matricaria chamomilla*).

Precautions

Lemon balm has been used safely for thousands of years. However, pregnant women and individuals with **hypothyroidism** should avoid use unless under consultation with a physician. Use caution when harvesting because of the likely presence of bees.

Side effects

The sedative effect of lemon balm means that it can depress the central nervous system when given in high doses. In addition, it has been reported that persons with **glaucoma** should avoid using essential oil of lemon balm, as it can raise the pressure inside the eye.

Interactions

Lemon balm should be used in lower dosages when combined with other herbs, particularly such other sedative herbs as **valerian**. In addition, lemon balm should not be taken together with prescription sedatives or alcohol, as it can intensify their effects.

Lemon balm has been reported to interfere with the action of thyroid hormones. Persons taking any medication containing thyroid hormones should not take lemon balm.

A physician should be consulted before taking lemon balm in conjunction with any other prescribed pharmaceuticals.

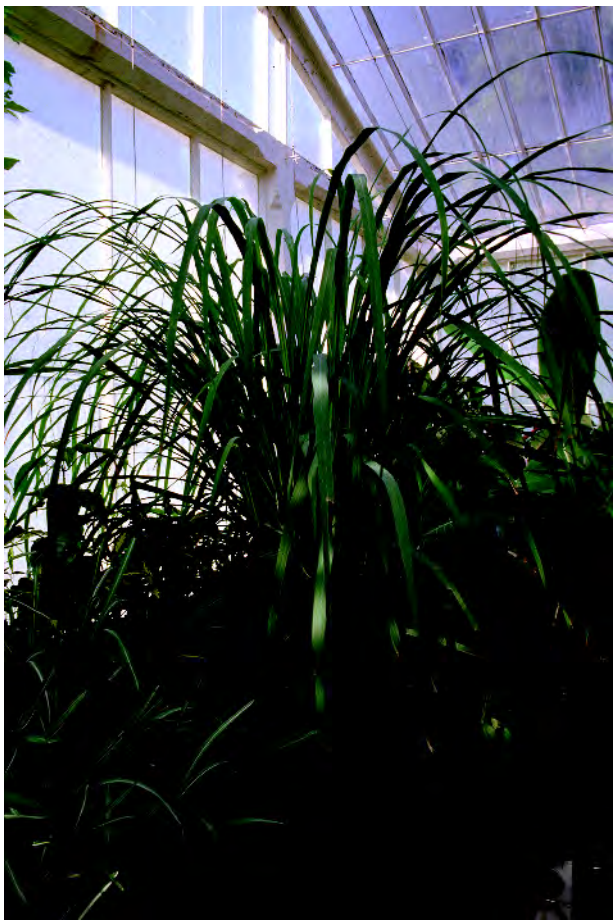
Lemongrass

Description

Resembling a gigantic weed, lemongrass is an aromatic tropical plant with long, slender blades that can grow to a height of 5 ft (1.5 m). Believed to have a wide range of therapeutic effects, the herb has been used for centuries in South America and India and has also become popular in the United States. Aside from folk medicine, lemongrass is a favorite ingredient in Thai cuisine and dishes that boast a tangy, Asian flavor. While there are several species of lemongrass, *Cymbopogon citratus* is the variety most often recommended for medicinal purposes. Native to Southeast Asia, lemongrass can also be found growing in India, South America, Africa, Australia, and the United States. Only the fresh or dried leaves of lemongrass, and the essential oil derived from them, are used as a drug. *Cymbopogon citratus*, which belongs to the Poaceae family of plants, is also referred to as West Indian lemongrass.

Not to be confused with **lemon balm**, which is an entirely different herb, lemongrass is considered by herbalists to have several useful properties, including antibacterial, antifungal, and fever-reducing effects.



Large lemongrass plant. *(©PlantaPhile, Germany. Reproduced by permission.)*

Some of these claims have been supported by animal and laboratory studies. In one test-tube investigation, published in the medical journal *Microbios* in 1996, researchers demonstrated that lemongrass was effective against 22 strains of bacteria and 12 types of fungi. Scientific research has also bolstered the herb's reputation as an analgesic and sedative. A study conducted in rodents suggests that myrcene, a chemical found in the essential oil of *Cymbopogon citratus*, may act as a site-specific **pain** reliever. Unlike aspirin and similar analgesics, which tend to alleviate pain throughout the body, myrcene seems to work only on particular areas. A study involving people indicates that lemongrass may also affect the way the body processes cholesterol.

More recently, lemongrass has been shown to have antimutagenic properties; that is, researchers have found that it is able to reverse chemically induced mutations in certain strains of bacteria.

While they may not be aware of it, most Americans have already tried lemongrass in one form or

KEY TERMS

Analgesic—Any substance that functions as a pain reliever.

Aromatherapy—The use of fragrances, often derived from essential oils, to improve emotional and physical well-being.

Astringent—An agent that helps to contract tissue and prevent the secretion of internal body fluids such as blood or mucus. Astringents are typically used to treat external wounds or to prevent bleeding from the nose or throat.

Citral—A pale yellow liquid drived from lemongrass used in making perfumes and to flavor food.

Essential oil—A general term describing a wide variety of plant-derived oils. They are often used to make soaps and perfumes; candies, soft drinks, processed foods, and other foods and beverages; and certain drugs and dental products.

Lemon balm—A herb with antiviral properties that is also used to alleviate anxiety or insomnia. The botanical name for lemon balm is *Melissa officinalis.*

Myrcene—A compound found in the essential oil of lemongrass that has pain-relieving properties.

Neuralgia—Nerve pain.

Placebo—A sugar pill or inactive agent often used in the control group of a medical study.

another. Citral, a key chemical found in *Cymbopogon citratus*, is an ingredient in a variety of foods and beverages (including alcohol). It can be found in candies, puddings, baked goods, meat products, and even in certain fats and oils. Citral is a pale yellow liquid that evaporates rapidly at room temperature. Like other **essential oils**, lemongrass is also used as a fragrance enhancer in many perfumes, soaps, and detergents.

General use

While not approved by the Food and Drug Administration (FDA), lemongrass reportedly has a wide variety of therapeutic effects. Because the herb has not been studied extensively in people, its effectiveness is based mainly on the results of animal and laboratory studies as well as its centuries-old reputation as a folk remedy. Lemongrass is one of the most popular plant medicines in Brazil, where it is used to treat nervous disorders and stomach problems. In the Amazon, lemongrass is highly regarded as a sedative tea.

When taken internally, lemongrass has been recommended for **stomachaches**, **diarrhea**, **gas**, bowel spasms, **vomiting**, **fever**, the flu, and headaches and other types of pain. The herb (or its essential oil) may be applied externally to help treat **acne**, **athlete's foot**, lower back pain, **sciatica**, **sprains**, tendinitis, **neuralgia**, and rheumatism. To treat circulatory disorders, some authorities recommend rubbing a few drops of lemongrass oil on the skin of affected areas; it is believed to work by improving blood flow. Like many essential oils, lemongrass is also used in aromatherapy.

The link between lemongrass and **cholesterol** was investigated by researchers from the Department of Nutritional Sciences, University of Wisconsin, who published their findings in the medical journal *Lipids* in 1989. They conducted a clinical trial involving 22 people with high cholesterol who took 140-mg capsules of lemongrass oil daily. While cholesterol levels were only slightly affected in some of the participants—cholesterol was lowered from 310 to 294 on average—other people in the study experienced a significant decrease in blood fats. The latter group, characterized as responders, experienced a 25-point drop in cholesterol after one month, and this positive trend continued over the course of the short study. After three months, cholesterol levels among the responders had decreased by a significant 38 points. Once the responders stopped taking lemongrass, their cholesterol returned to previous levels. It should be noted that this study did not involve a placebo group, which is usually used to help measure the effects of the agent being studied (in this case, lemongrass oil).

Considered an antiseptic and astringent, essential oil of lemongrass is also used by some people to cleanse oily skin and help close pores. Some herbalists recommend mixing a few drops of lemongrass with a normal portion of mild shampoo to combat greasy hair. Lemongrass essential oil can also be used as a deodorant to curb perspiration.

Last but not least, the herb has a strong reputation as an insect repellent. It is an important ingredient in several products designed to keep bugs at bay. Some authorities recommend rubbing the crushed herb directly on exposed areas of skin to avoid insect **bites** when enjoying the great outdoors.

The relative safety and stability of lemongrass oil has recommended it to pharmaceutical researchers who are testing new methods of quantitative analysis. Lemongrass oil has been used to demonstrate the

superiority of near-infrared spectroscopy to older methods of determining the chemical content of plant oils.

Preparations

The optimum daily dosage of lemongrass, which is available as fresh or dried herb or as lemongrass oil, has not been established with any certainty. Because lemongrass has been recommended for so many different purposes, and can be used internally and externally, consumers are advised to consult a doctor experienced in the use of alternative remedies to determine proper dosage. There is a significant difference between the external use of a few drops of essential oil, and the use of larger amounts of the herb in a tincture or tea.

Lemongrass tea can be prepared by steeping 1–2 tsp of the herb (fresh or dried) in a cup of boiling water. The mixture should be strained after 10–15 minutes. The tea is generally taken several times a day. In *Heinerman's Encyclopedia of Healing Herbs & Spices*, John Heinerman recommends using one cup of lemongrass tea every four hours to reduce fever. In the *Green Pharmacy*, prominent herbalist James Duke recommends drinking one to four cups of lemongrass tea a day to benefit from its anti-fungal properties. The used tea bags can also be applied externally as fungi-fighting compresses, according to the author.

To alleviate gas or persistent vomiting, Heinerman recommends a dose of 3–6 drops of lemongrass oil (the *Cymbopogon citratus* variety). It may be placed on a sugar cube or mixed with 1 tsp of real vanilla flavor before swallowing. For sciatica, lower back pain, sprains, tendinitis, and rheumatism, the author suggests rubbing 10 drops of the essential oil onto the skin of the affected areas.

Precautions

Lemongrass is not known to be harmful when taken in recommended dosages, though it is important to remember that the long-term effects of taking the herb (in any amount) have not been investigated. The essential oil should not be used internally by children, women who are pregnant or breast-feeding, or people with liver or kidney disease.

In rare cases, lemongrass essential oil has caused allergic reactions when applied to the skin. To minimize skin irritation, dilute the oil in a carrier oil such as safflower or sunflower seed oil before application. As with all essential oils, small amounts should be used, and only for a limited time.

Avoid getting lemongrass (herb or oil) in the eyes. Citral has been reported to irritate the respiratory tract in sensitive people as well as the eyes and skin.

Side effects

When taken internally in recommended dosages, lemongrass is not associated with any bothersome or significant side effects. Cases have been reported, however, in which people have developed skin **rashes** after drinking lemongrass tea.

Interactions

Lemongrass is not known to interact adversely with any drug or dietary supplement.

Leukemia

Definition

Leukemia is a **cancer** that starts in the organs that make blood, namely the bone marrow and the lymph system. Depending on specific characteristics, leukemia can be divided into two broad types: acute and chronic. Acute leukemias are the rapidly progressing leukemias, while the chronic leukemias progress more slowly. The vast majority of childhood leukemias are of the acute form.

Description

The cells that make up blood are produced in the bone marrow and the lymph system. The bone marrow is the spongy tissue found in the large bones of the body. The lymph system includes the spleen (an organ in the upper abdomen), the thymus (a small organ beneath the breastbone), and the tonsils (an organ in the throat). In addition, the lymph vessels (tiny tubes that branch like blood vessels into all parts of the body) and lymph nodes (pea-shaped organs that are found along the network of lymph vessels) are also parts of the lymph system. The lymph is a milky fluid that contains cells. Clusters of lymph nodes are found in the neck, underarm, pelvis, abdomen, and chest.

The cells found in the blood are the red blood cells (RBCs), which carry oxygen and other materials to all tissues of the body; white blood cells (WBCs) that fight infection; and platelets, which play a part in the clotting of the blood. The white blood cells can be further subdivided into three main types: granulocytes, monocytes, and lymphocytes.

The granulocytes, as their name suggests, have particles (granules) inside them. These granules contain special proteins (enzymes) and several other substances that can break down chemicals and destroy microorganisms, such as bacteria. Monocytes are the second type of white blood cell. They are also important in defending the body against pathogens.

The lymphocytes form the third type of white blood cell. There are two main types of lymphocytes: T lymphocytes and B lymphocytes. They have different functions within the immune system. The B cells protect the body by making "antibodies." Antibodies are proteins that can attach to the surfaces of bacteria and viruses. This "attachment" sends signals to many other cell types to come and destroy the antibody-coated organism. The T cells protect the body against viruses. When a virus enters a cell, it produces certain proteins that are projected onto the surface of the infected cell. The T cells recognize these proteins and make certain chemicals that are capable of destroying the virus-infected cells. In addition, the T cells can destroy some types of cancer cells.

The bone marrow makes stem cells, which are the precursors of the different blood cells. These stem cells mature through stages into either RBCs, WBCs, or platelets.

KEY TERMS

Antibodies—Proteins made by the B lymphocytes in response to the presence of infectious agents, such as bacteria or viruses, in the body.

Biopsy—The surgical removal and microscopic examination of living tissue for diagnostic purposes.

Chemotherapy—Treatment with drugs that act against cancer.

Computerized tomography (CT) scan—A series of x rays that resemble slices or cross-sections of anatomy, forming detailed images of specific areas.

Cytokines—Chemicals made by the cells that act on other cells to stimulate or inhibit their function. Cytokines that stimulate growth are called growth factors.

Immunotherapy—Treatment of cancer by stimulating the body's immune defense system.

Lumbar puncture—A procedure in which the doctor inserts a small needle into the spinal cavity in the lower back to withdraw some spinal fluid for testing. Also known as a "spinal tap."

Magnetic resonance imaging (MRI)—A medical procedure using a magnet linked to a computer to image areas inside the body.

Maturation—The process by which stem cells transform from immature cells without a specific function into a particular type of blood cell with defined functions.

Radiation therapy—Treatment using high-energy radiation from x-ray machines, cobalt, radium, or other sources.

Remission—Disappearance of a disease as a result of treatment. Complete remission means that all disease is gone. Partial remission means that the disease is significantly improved by treatment, but residual traces of the disease are still present.

Chronic leukemias

In chronic leukemias, the cancer starts in the blood cells made in the bone marrow. The cells mature and only a few remain as immature cells. However, even though the cells mature and appear normal, they do not function as normal cells. Depending on the type of white blood cell that is involved, chronic leukemia can be classified as chronic lymphocytic leukemia or chronic myelogenous leukemia.

Chronic leukemias develop very gradually. The abnormal lymphocytes multiply slowly, but in a poorly regulated manner. They live much longer and thus their numbers build up in the body. The two types of chronic leukemias can be easily distinguished under the microscope. Chronic lymphocytic leukemia (CLL) involves the T or B lymphocytes. B cell abnormalities are more common than T cell abnormalities. T cells are affected in only 5% of the patients. The T and B lymphocytes can be differentiated from the other types of white blood cells based on their size and by the absence of granules inside them. In chronic myelogenous leukemia (CML), the cells that are affected are the granulocytes.

Chronic lymphocytic leukemia (CLL) often shows no early symptoms and may remain undetected for a long time. Chronic myelogenous leukemia (CML), on the other hand, may progress to a more acute form.

Acute leukemias

In acute leukemia, the maturation process of the white blood cells is interrupted. The immature cells (or "blasts") proliferate rapidly and begin to accumulate in various organs and tissues, thereby affecting their normal function. This uncontrolled proliferation of the immature cells in the bone marrow affects the production of the normal red blood cells and platelets as well.

Acute leukemias are of two types: acute lymphocytic leukemia and acute myelogenous leukemia. Different types of white blood cells are involved in the two leukemias. In acute lymphocytic leukemia (ALL), the T or B lymphocytes become cancerous. The B cell leukemias are more common than T cell leukemias. Acute myelogenous leukemia, also known as acute nonlymphocytic leukemia (ANLL), is a cancer of the monocytes and/or granulocytes.

Leukemias account for 2% of all cancers. Because leukemia is the most common form of childhood cancer, it is often regarded as a disease of childhood. However, leukemias affect nine times as many adults as children. Half of the cases occur in people who are 60 years of age or older. The incidence of acute and chronic leukemias is about the same. According to the estimates of the American Cancer Society (ACS), approximately 29,000 new cases of leukemia were diagnosed in 1998. Internationally, leukemia is the fourth most common cancer among people age 15 to 19 years old.

Causes and symptoms

Leukemia strikes both sexes and all ages and its cause is mostly unknown. However, chronic leukemia has been linked to genetic abnormalities and environmental factors. For example, exposure to ionizing radiation and to certain organic chemicals, such as benzene, is believed to increase the risk for getting leukemia. A 2003 study from the Electric Power Research Institute showed possible links between metallic drainpipes and childhood baths. Chronic leukemia occurs in some people who are infected with two human retroviruses (HTLV-I and HTLV-II). An abnormal chromosome known as the Philadelphia chromosome is seen in 90% of those with CML. The incidence of chronic leukemia is slightly higher among men than women.

Acute lymphoid leukemia (ALL) is more common among Caucasians than among African-Americans, while acute myeloid leukemia (AML) affects both races equally. The incidence of acute leukemia is slightly higher among men than women. People of Jewish ancestry have a higher likelihood of getting leukemia. A higher incidence of leukemia has also been observed among persons with Down syndrome and some other genetic abnormalities.

A history of diseases that damage the bone marrow, such as aplastic **anemia**, or a history of cancers of the lymphatic system puts people at a high risk for developing acute leukemias. Similarly, the use of anticancer medications, immunosuppressants, and the antibiotic chloramphenicol also are considered risk factors for developing acute leukemias.

The symptoms of leukemia are generally vague and non-specific. A patient may experience all or some of the following symptoms:

- weakness or chronic fatigue
- fever of unknown origin
- weight loss that is not due to dieting or exercise
- frequent bacterial or viral infections
- headaches
- skin rash
- non-specific bone pain
- easy bruising
- bleeding from gums or nose

- blood in urine or stools
- enlarged lymph nodes and/or spleen
- abdominal fullness

Diagnosis

Like all cancers, leukemias are best treated when found early. There are no screening tests available. If the doctor has reason to suspect leukemia, he or she will conduct a thorough physical examination to look for enlarged lymph nodes in the neck, underarm, and pelvic region. Swollen gums, enlarged liver or spleen, **bruises**, or pinpoint red **rashes** all over the body are some of the signs of leukemia. Urine and blood tests may be ordered to check for microscopic amounts of blood in the urine and to obtain a complete differential blood count. This count will give the numbers and percentages of the different cells found in the blood. An abnormal blood test might suggest leukemia, however, the diagnosis has to be confirmed by more specific tests.

A doctor may perform a bone marrow biopsy to confirm the diagnosis of leukemia. During the biopsy, a cylindrical piece of bone and marrow is removed, generally from the hip bone. These samples are sent to the laboratory for examination. In addition to diagnosis, the biopsy is also repeated during the treatment phase of the disease to see if the leukemia is responding to therapy.

A spinal tap (lumbar puncture) is another procedure that the doctor may order to diagnose leukemia. In this procedure, a small needle is inserted into the spinal cavity in the lower back to withdraw some cerebrospinal fluid and to look for leukemic cells.

Standard imaging tests, such as x rays, computed tomography scans (CT scans), and magnetic resonance imaging (MRI) may be used to check whether the leukemic cells have invaded other areas of the body, such as the bones, chest, kidneys, abdomen, or brain. A gallium scan or bone scan is a test in which a radioactive chemical is injected into the body. This chemical accumulates in the areas of cancer or infection, allowing them to be viewed with a special camera.

Treatment

Alternative therapies should be used only as complementary to conventional treatment, not to replace it. Before participating in any alternative treatment programs, patients should consult their doctors concerning the appropriateness and the role of such programs in the overall cancer treatment plan. Appropriate alternative treatments can help prolong a patient's life or at least improve quality of life, prevent recurrence of tumors or prolong the remission period, and reduce adverse reactions to chemotherapy and radiation.

The effectiveness of most anti-cancer drugs used to treat leukemia can be reduced when patients take mega doses of antioxidants. These **antioxidants**, in patients not undergoing chemotherapy, can be very helpful in protecting the body against cancer. However, taken during chemotherapy, these antioxidants protect the cancer cells from being killed by treatment. Because high-dose supplementation of antioxidants can interfere with conventional chemotherapy treatment, patients should only take them at dosages much above the recommended daily allowance (RDA).

Dietary guidelines

The following dietary changes may be helpful:

- Avoiding fatty and spicy foods, which may be harder to digest.
- Eating new and exciting foods. Tasty foods stimulate appetite so that patients can eat more and have the energy to fight cancer.
- Increasing consumption of fresh fruits and vegetables. They are nature's best sources of antioxidants, as well as vitamins and minerals.
- Eating multiple (five or six) meals per day. Small meals are easier to digest.
- Establishing regular eating times and not eating around bedtime.
- Avoiding foods that contain preservatives or artificial coloring.
- Monitoring weight and eating adequate calories and protein.

Nutritional supplements

A naturopath or nutritional physician may recommend some of the following nutritional supplements to boost a patient's immune function and help fight cancer:

- Vitamins and minerals. Vitamins that are of particular benefit to cancer patients include beta-carotene, B-complex vitamins, (especially vitamin B_6, vitamins A, C, D, E and K. The most important minerals are calcium, chromium, copper, iodine, molybdenum, germanium, selenium, tellurium, and zinc. Many of these vitamins and minerals are strong antioxidants. However, patients should not take mega doses of these supplements without first consulting their doctor. Significant adverse or toxic effects may occur at high dosage, which is especially true for minerals. It is prudent to avoid use of antioxidants when

undergoing chemotherapy or radiation therapy since these treatments kill the cancer by producing oxidants. Antioxidants can undermine the effectiveness of treatment.

- Other nutritional supplements that may help fight cancer and support the body include essential fatty acids (fish or flaxseed oil), flavonoids, pancreatic enzymes (to help digest foods), hormones such as DHEA, melatonin or phytoestrogens, rice bran, and mushroom extracts. It is best to check with a nutritional physician or other licensed provider when adding these supplements.

Traditional Chinese medicine

Conventional treatment for leukemia is associated with significant side effects. These adverse effects can be reduced with Chinese herbal preparations. Patients should consult an experienced herbalist who will prescribe remedies to treat specific symptoms that are caused by conventional cancer treatments.

Juice therapy

Juice therapy may be helpful in patients with cancer. Patients should mix one part of pure juice with one part of water before drinking. Daily consumption of the following juice may be helpful by reducing toxic burden to the liver:

- carrot and beet juice with a touch of radish or dandelion root
- grapes, pear, and lemon
- carrot, celery, and parsley
- carrot, beet, and cucumber juices

Homeopathy

There is conflicting evidence regarding the effectiveness of **homeopathy** in cancer treatment. Because cancer chemotherapy may suppress the body's response to homeopathic treatment, homeopathy may not be effective during chemotherapy. Therefore, patients should wait until after chemotherapy to try this relatively safe alternative treatment.

Acupuncture

Acupuncture is the use of needles on the body to stimulate or direct the meridians (channels) of energy flow in the body. Acupuncture has not been shown to have any anticancer effects. However, it is an effective treatment for **nausea**, a common side effect of chemotherapy and radiation.

Other treatments

Other therapies that may help the leukemia patient include **meditation**, **qigong**, **yoga**, and **t'ai chi**, all of which can aid in **stress** reduction. Guided imagery can increase immune function and decrease **pain** and nausea.

Allopathic treatment

There are two phases of treatment for leukemia. The first phase is called induction therapy. The main aim of the treatment is to reduce the number of leukemic cells as far as possible and induce a remission in the patient. Once the patient shows no obvious signs of leukemia (no leukemic cells are detected in blood tests and bone marrow biopsies), the patient is said to be in remission. The second phase of treatment is then initiated. This is called continuation or maintenance therapy; the aim in this case is to kill any remaining cells and to maintain remission for as long as possible.

Chemotherapy is the use of drugs to kill cancer cells. It is usually the treatment of choice and is used to relieve symptoms and achieve long-term remission of the disease. Generally, combination chemotherapy, in which multiple drugs are used, is more efficient than using a single drug for treatment.

In 2002, scientists announced the discovery of a gene that triggers the death of leukemia cells. Identification of this gene can lead to better targeting of chemotherapy drugs (that involve a **vitamin A** derivative) for acute promyelocytic leukemia (APL). Another advancement in leukemia treatment occurred in the same year. A new drug was found to cancel the effects of mutations of a gene known as the main culprit in AML, an aggressive, treatment-resistant form of leukemia. Further study was needed on both new discoveries, but they were thought important to improving treatment of two forms of leukemia. Later in 2002, Gleevec, a new antileukemia drug that even proved successful at treating chronic myeloid leukemia, was heralded in clinical trials.

Because leukemia cells can spread to all the organs via the blood stream and lymph vessels, surgery is not considered an option for treating leukemias.

Radiation therapy, which involves the use of x rays or other high-energy rays to kill cancer cells and shrink tumors, may be used in some cases. For acute leukemias, the source of radiation is usually outside the body (external radiation therapy). If the leukemic cells have spread to the brain, radiation therapy can be given to the brain.

Bone marrow transplantation (BMT) is a process in which the patient's diseased bone marrow is replaced with healthy marrow. There are two methods of bone marrow transplant. In an allogeneic bone marrow transplant, healthy marrow is taken from a donor whose tissue is either the same as or very closely resembles the patient's tissue. First, the patient's bone marrow is destroyed with very high doses of chemotherapy and radiation therapy. Healthy marrow from the donor is then given to the patient through a needle in a vein to replace the destroyed marrow.

In the second type of bone marrow transplant, called an autologous bone marrow transplant, some of the patient's own marrow is taken out and treated with a combination of anticancer drugs to kill all abnormal cells. This marrow is then frozen and saved. The marrow remaining in the patient's body is destroyed with high-dose chemotherapy and radiation therapy. The marrow that was frozen is then thawed and given back to the patient through a needle in a vein. This mode of bone marrow transplant is currently being investigated in clinical trials.

Biological therapy or immunotherapy is a mode of treatment in which the body's own immune system is harnessed to fight the cancer. Substances that are routinely made by the immune system (such as growth factors, hormones, and disease-fighting proteins) are either synthetically made in a laboratory or their effectiveness is boosted and they are then put back into the patient's body. This treatment mode is also being investigated in clinical trials all over the country at major cancer centers.

Expected results

Like all cancers, the prognosis for leukemia depends on the patient's age and general health. According to statistics, more than 60% of leukemia patients survive for at least one year after diagnosis.

Acute myelocytic leukemia (AML) has a poorer prognosis rate than acute lymphocytic leukemias (ALL) and the chronic leukemias. In the last 15 to 20 years, the five-year survival rate for patients with ALL has increased from 38% to 57%.

Interestingly enough, since most childhood leukemias are of the ALL type, chemotherapy has been highly successful in their treatment. This is because chemotherapeutic drugs are most effective against actively growing cells. Due to the new combinations of anticancer drugs being used, the survival rates among children with ALL have improved dramatically. Eighty percent of the children diagnosed with ALL now survive five years or more, as compared to 50% in the late 1970s.

According to statistics, in chronic lymphoid leukemia, the overall survival for all stages of the disease is nine years. Most of the deaths in people with CLL are due to **infections** or other illnesses that occur as a result of the leukemia.

In CML, if bone marrow transplantation is performed within one to three years of diagnosis, 50-60% of the patients survive three years or more. If the disease progresses to the acute phase, the prognosis is poor. Less than 20% of these patients go into remission.

Prevention

Most cancers can be prevented by changes in lifestyle or diet, which will reduce risk factors. However, in leukemias, there are no such known risk factors. Therefore, at the present time, there are no real prevention recommendations for leukemia. People who are at an increased risk for developing leukemia because of proven exposure to ionizing radiation or exposure to the toxic liquid benzene, and people with Down syndrome, should undergo periodic medical checkups. Some experts recommend limiting toxic exposures, eating a whole foods diet, refraining from **smoking**, exercise, and fluids, and even intermittent **fasting** as possible prevention measures. In 2003, new research found that adult women who took aspirin two or more times a week had a 50% lower risk of developing adult leukemia. Scientists continue to work on a possible vaccine for leukemia. They made some progress in 2002, discovering a gene transfer model that might trigger immunity against leukemia cells.

KEY TERMS

Crabs—An informal term for pubic lice.

Endemic—A condition that is always present in a given population, such as human lice infestation.

Insecticide—A pesticide that kills insects.

Lindane—An organic chloride, neurotoxic insecticide that kills lice.

Malathion—An organic phosphate, neurotoxic insecticide that kills lice.

Neurotoxin—A chemical compound that is toxic to the central nervous system.

Nit—The egg sac laid by adult female lice.

Pediculicide—Any substance that kills lice.

Pediculosis (plural, pediculoses)—A lice infestation.

Permethrin—A synthetic pyrethroid for killing lice.

Petroleum jelly or ointment—Petrolatum, a gelatinous substance obtained from oil that is used as a protective dressing.

Piperonyl butoxide—A liquid organic compound that enhances the activity of insecticides.

Pyrethrin, pyrethroid—Naturally-occurring insecticide extracted from chrysanthemum flowers. It paralyzes lice so that they cannot feed.

Lice infestation

Definition

A lice infestation, or pediculosis, is caused by parasites living on human skin. Lice are tiny, wingless insects with sucking mouthparts that feed on human blood and lay eggs on body hair or in clothing. Lice **bites** can cause intense **itching**.

Description

There are three related species of human lice that live on different parts of the body:

- Head lice, *Pediculus humanus capitis*
- Body lice, *Pediculosis humanus corpus*
- Pubic lice, *Phthirus pubis,* commonly called "crab") lice

Pediculosis capitis is an infestation of head lice. A body lice infestation is called pediculosis corporis. Pediculosis palpebrarum or Phthiriasis palpebrarum, caused by crab lice, is an infestation of the eyebrows and eyelashes.

Lice infestations are not usually dangerous. However, head lice infestations present a serious public health problem because they spread easily among schoolchildren. In general, lice infestations occur in crowded, unsanitary facilities, including prison, military, and refugee camps. Lice infestations also occur frequently among the homeless.

Lice are transmitted through personal contact or infected clothing, bedding, or towels. Pubic lice are sexually transmitted. Lice do not jump, hop, or fly and they do not live on pets.

Head lice infestations are extremely common among children in schools, childcare facilities, camps, and playgrounds. They are the second most common communicable health problem in children, after the **common cold**, and appear to be on the increase. Six to 12 million American children get head lice every

year. In developing countries, more than 50% of the general population may be infested. Head lice can affect anyone, regardless of race, sex, socio-economic class, or personal hygiene. However children aged three to ten and their families are most affected. Girls and women are more susceptible than boys and men. Although African American children are much less likely to have head lice than white or Hispanic children, the incidence is increasing, particularly in black children with thick, kinky hair or hair extensions or wraps. In Africa, head lice have adapted their claws to the curly, elliptical hair shafts of blacks. In developing countries, head lice infestations are a significant cause of contagious bacterial **infections**. Neither frequent brushing nor shampooing nor hair length affects the likelihood of head lice infestation.

Head lice live and crawl on the scalp, sucking blood every three to six hours. Their claws are adapted for clinging to hair or clothing. Adult head lice can be silvery-white to reddish-brown. They are about the size of a sesame seed, about 0.6 inches (1–4 mm.) long. Female lice lay their eggs in sacs called nits that are about 0.04 inches (1 mm.) long and are glued to shafts of hair close to the scalp. During her one-month lifespan, a female louse may lay more than 100 eggs. The nymphs hatch in three to 14 days and must feed on blood within one day. Nymphs are smaller and lighter in color than adults and become sexually mature after 9 to 12 days. Head lice cannot survive without a human host for more than a few days at most.

Body lice lay their nits in clothing or bedding. Occasionally the nits are attached to body hair. Body lice nits are oval and yellow to white in color. They may not hatch for up to 30 days. Nymphs mature in about 7 days. Body lice can live without human contact for up to 10 days.

Body lice infestations are usually associated with poor personal hygiene, as may occur during war or natural disasters or in cold climates. Body lice can carry and transmit disease-causing organisms, including those for epidemic typhus, relapsing **fever**, and trench fever. Trench fever is self-limiting. However, typhus and relapsing fever have mortality rates of five to 10 percent. The elderly are most vulnerable to these diseases.

Pubic lice can survive for one to two weeks without human contact and occasionally are transmitted through infected bedding, towels, or clothing. Pubic lice have large front legs and look like tiny crabs. Females are larger than males. Nits hatch in about one week and the nymphs mature in about seven days. Although pubic lice do not carry diseases, they often are found in association with other sexually transmitted diseases.

Causes and symptoms

Lice are endemic in human populations, spreading by personal contact or contact with infested clothing or other personal items. Lice also can be transmitted when unaffected clothing is stored with infested items. Among children, head lice are commonly transmitted by the sharing of hats, combs, brushes, hair accessories, headphones, pillows, and stuffed toys.

Lice infestations are characterized by intense itching caused by an allergic reaction to a toxin in the lice saliva. The itching can interfere with sleep and concentration. Repeated bites can lead to generalized skin eruptions or inflammation. Scratching or scraping at the bites can cause **hives** or abrasions that may lead to bacterial skin infections. Swelling or inflammation of the neck glands are common complications of head lice.

Body lice bites first appear as small red pimples or puncture marks and may cause a generalized skin rash. Intense itching can result in deep **scratches** around the shoulders, flanks, or neck. If the infestation is not treated, complications may develop, including **headache**, fever, and skin infection with scarring. Crab lice in children may be an indication of sexual activity or abuse.

Diagnosis

Lice usually are diagnosed by the itching. However, itching may not occur until several weeks after infestation, if at all. The tickling caused by moving lice may be noticeable. Definite diagnosis requires identification of lice or their nits.

Head lice may cause irritability in children. Scalp irritations or sores may be present. Although head lice in children are usually limited to the scalp, in adults, head lice can spread to eyebrows, eyelashes, mustaches, and beards. An adult louse may be visible as movement on the scalp, especially around the ears, nape of the neck, and center line of the crown—the warmest parts of the head. Since less than 20 mature lice may be present at a given time during infestation, the nits often are easier to spot. Nits vary in color from grayish-white to yellow, brown, or black. They are visible at the base or on the shaft of individual hairs. Applying about 10 ounces (280 grams) of isopropyl (rubbing) alcohol to the hair and rubbing with a white towel for about 30 seconds releases lice onto the towel for identification.

Body lice appear similar to head lice, however they burrow into the skin and are rarely seen except on clothing, where they lay their nits in seams. Over time, body lice infestations can lead to a thickening and discoloring of the skin around the waist, groin, and upper thighs. Scratching may cause sores that become infected with bacteria or fungi.

Pubic lice usually appear first on genital hair, although they may spread to other body hair. In young children, pubic lice are usually seen on the eyebrows or eyelashes. Pubic lice appear as brown or gray moving dots on the skin. There are usually only a few live lice present and they move very quickly away from light. Their white nits can be seen on hair shafts close to the skin. Although pubic lice sometimes produce small, bluish spots called maculae ceruleae on the trunk or thighs, usually it is easier to spot scratching marks. Small, dark-brown specks of lice excretion may be visible on underwear.

Since pediculicides (medications for treating lice) are usually strong insecticides with potential side effects, it is important to rule out other causes of scratching and skin inflammation. The oval-shaped head lice nits can be distinguished from **dandruff** because they are glued at an angle to the hair shaft. In contrast, flat, irregularly shaped flakes of dandruff shake off easily. A healthcare professional needs to distinguish between body lice and scabies—a disease caused by skin mites—and between pubic lice and **eczema**, a skin condition.

Treatment

Most treatments apply to all types of lice infestation and, particularly with head lice, treatments are an area of great controversy. The questionable safety and effectiveness of allopathic (fighting disease with remedies that produce effects different from those produced by the disease) treatments has spurred the search for alternative therapies. With any type of treatment, itching may not subside for several days.

Head lice

Most authorities believe that head lice should be treated immediately upon discovery.Before beginning any treatment:

- Test a small scalp section for allergic reactions to the medication
- A vinegar rinse helps loosen nits
- Wash hair with regular shampoo

Treatments for applying to the scalp and hair include:

- Olive oil or petroleum ointment to smother the lice. Cover the head with a shower cap, four to six hours per day for three to four days
- Olive oil (three parts) and essential oil of lavender (one part)
- Herbal shampoos or pomades
- A mixture of paw paw, thymol, and tea tree oil
- A combination of coconut oil, anise, and ylang ylang
- Other mixtures of essential oils
- RID Pure Alternative, a nontoxic, hypoallergenic, dye and fragrance-free product
- A spray containing phenethyl propionate, cedar oil, peppermint oil, and sodium lauryl sulfate (LiceFreee)
- Cocamide DEA (a lathering agent), triethanolamine (a local irritant), and disodium EDTA (a chelator), (SafeTek)is both a nontoxic pediculicide and a conditioner for combing out lice and nits

Cutting the hair or shaving the head may be effective. Aromatherapies also are available. Infested eyelashes and eyebrows should be treated with petroleum jelly for several days and the nits should be plucked off with tweezers or fingernails.

Body lice

Treatment for body lice is a thorough washing of the entire body and replacing infected clothing. Clothing and bedding should be washed at 140°F (60°C) and dried at high temperature, or dry-cleaned.

Pubic lice

A common herbal treatment for pubic lice consists of:

- Oil of pennyroyal (*Mentha pulegium*, 25%
- Oil of garlic (*Allium sativum*, 25%
- Distilled water, 50%

The mixture is applied to the pubic hair once a day for three days. Anyone with pubic lice should be tested for other sexually transmitted diseases.

Nit Removal

Neither alternative nor allopathic treatments will kill all lice nits. Hair and pubic lice nits must be removed manually to prevent re-infestation as the eggs hatch. Manual removal alone may effectively treat a lice infestation.

Before removing nits, one of the following procedures may be used:

- 50% vinegar rinse to loosen the nits
- wiping individual locks of hair from base to tip with a cloth soaked in vinegar
- 8% formic acid solution applied to the hair for 10 minutes, rinsed out, and towel-dried
- catching live lice with a comb, tweezers, fingernails, or by sticking them with double-sided tape
- enzymatic lice-egg remover

Furthermore:

- Hair should be clean, damp, and untangled
- Hair conditioner should not be used on hair treated allopathically
- Remove clothing and place a towel between the hair and shoulders
- Divide hair into square-inch (six sq.-cm.) sections. Clips or elastics can be used to divide long hair

Nits are manually removed with:

- Any fine-toothed comb, including pet flea combs
- A specialized nit comb (LiceMeister, LiceOut)
- A battery-powered vibrating or anti-static comb
- Tweezers
- Baby safety scissors
- Fingernails

To comb out nits:

- Comb along each hair section from scalp to tip
- Between each passing, dip the comb in water and wipe with a paper towel to remove lice and nits
- Hold the comb to the light to be sure it is clean
- If necessary, clean comb with a tooth or fingernail brush or dental floss
- Work under a good light, with a magnifying glass if necessary
- Do not rush. Long, thick hair may take an hour to comb out thoroughly
- Wash towels and clothing after combing
- Repeat at least twice a week for at least two weeks

Re-infestation

Re-infestation occurs often with all types of lice due to:

- Ineffective or incomplete treatment
- Chemical-resistant lice
- Failure to remove live nits
- Failure to treat all infected household members, playmates, or partners
- Failure to remove nits from clothing, bedding, towels, or other items
- Re-infestation from another source

Re-infestation with body or pubic lice can be prevented by washing underclothes, sleepwear, bedding, and towels in hot, soapy water and drying with high heat for at least 20 minutes. Clothing infected with body lice should be ironed under high heat. Sexual partners should be treated for public lice simultaneously and should re-examine themselves for several days.

To prevent head lice re-infestation:

- Repeat lice checks and nit removal daily until none are found
- Notify school, camp, or daycare, and parents of playmates
- Check and if necessary treat household members, playmates, schoolmates, school or daycare staff, and others in close contact with an infestation
- Treat combs and brushes with rubbing alcohol, Lysol, or soapy water above 130°F (54°C)
- Wash all bedding, clothing, headgear, scarves, and coats with soapy water at 130°F (54°C) and dry with high heat for at least 20 minutes
- Wash or vacuum stuffed animals and other toys
- Vacuum all helmets, carpets, rugs, mattresses, pillows, upholstery, and car seats
- Remove the vacuum cleaner bag after use, seal in a plastic bag, and place in the outside garbage
- Non-washable items should be dry cleaned or sealed in a plastic bag for up to four weeks
- Lice pesticide sprays for inanimate objects are toxic and are not recommended
- Repeat treatment if necessary

Allopathic treatment

All types of lice are treated allopathically with insecticidal lotions, shampoos, or cream rinses. However, experts disagree about the effectiveness and/or safety of pediculicides. Pediculicides do not kill nits, so nit removal and a second application in seven to 10 days may be necessary. Pediculicides can be poisonous if used improperly or too frequently and overuse can lead to the proliferation of chemically resistant lice. The residue may remain on the hair for several weeks and can cause skin or eye irritations.

Pediculicides should not be used:

- Near broken skin, eyes, or mucous membranes
- In the bathtub or shower

- By pregnant or nursing women or children under two
- By those with allergies, asthma, epilepsy, or some other medical conditions

Pyrethroids

All U.S. Food and Drug Administration (FDA)-approved non-prescription pediculicides contain relatively safe and effective pyrethroids. Insecticidal pyrethrins (0.33%) (RID, A-200) are extracts from chrysanthemum flowers. Permethrin (1%)(Nix) is a more stable synthetic pyrethrin. Pyrethroid pediculicides usually also contain 4% piperonyl butoxide.

To treat with pyrethroids:

- Apply for specified time, usually 10 minutes.
- Thoroughly rinse out.
- Do not wash hair for one or two days after treatment.
- Do not use cream rinse, hair spray, mousse, gels, mayonnaise, or vinegar before or within one week after treatment. These products may reduce pediculicide effectiveness

During the 1990s, as schools began requiring children to be lice and nit-free, the use of pyrethroids rose significantly and the FDA began receiving reports of ineffectiveness. The FDA ordered new labeling of pyrethroid pediculicides on the outside of the carton, in simpler language, and with more information, to take effect in 2005–2006. Permethrin sprays for treating mattresses, furniture, and other items are not recommended.

Other insecticides

Prescription insecticides are used when other lice treatments fail or cannot be used.These pesticides include:

- Malathion (0.5% in Ovide), a neurotoxic organophosphate, was withdrawn from the U.S. market due to an increase in malathion-resistant lice and re-introduced in 1999. It is foul-smelling and flammable. Sometimes infested clothing is treated with a 1% malathion powder
- Lindane (1% or higher) (Kwell), an organochloride neurotoxin, can induce seizures and death in susceptible people, even when used according to the directions. In 2003 the FDA required new labeling and a reduction in bottle size
- Ivermectin (Stromectol), an oral treatment for intestinal parasites, is effective against head lice but has not been approved for that use by the FDA

Infested eyelashes are treated with a thick coating of prescription petroleum ointment, applied twice daily for ten days.

Prognosis

Despite the presence of chemically resistant lice and the thoroughness required to prevent re-infestation, essentially all lice infestations can be eradicated eventually.

Prevention

Prevention of lice infestation depends on adequate personal hygiene and the following public health measures:

- Avoid sharing combs, brushes, hair accessories, hats, towels, or bedding
- Check hair and scalp weekly for lice and nits
- Limit sexual partners

Regular lice checks in schools and "no nit" reentry policies have not been shown to be effective. The American Academy of Pediatrics, the Harvard School of Public Health, and the National Association of School Nurses recommend their elimination, although many healthcare professionals disagree.

Scientists have identified both the gene that enables head and body lice to digest blood and the gene that helps lice combat deadly infections, with the potential for new treatments and preventions for lice infestation.

Licorice

Description

Licorice, *Glycyrrhiza glabra*, is a purple and white flowering perennial, native of the Mediterranean region and central and southwest Asia. It is cultivated

Common licorice. *(© blickwinkel / Alamy)*

widely for the sweet taproot that grows to a depth of four ft (1.2 m). Licorice is a hardy plant that thrives in full sun or partial shade and prefers rich, moist soil. It may grow to a height of 3-7 ft (1-2 m). The wrinkled, brown root has yellow interior flesh and is covered with a tangle of rootlets branching from the stolons. The aerial parts of the plant are erect and branching with round stems that become somewhat angular near the top. The leaves are alternate, odd, and pinnate, dividing into as many as eight pairs of oblong leaflets. Licorice blossoms in late summer. The sweet-pea like flowers grow in clusters forming in the angle where the stem joins the branch. The maroon colored seed pods are about 1-2 in (3-5 cm) long and contain one to six kidney-shaped seeds.

Licorice is a sweet and soothing herb that has been appreciated for its medicinal qualities for thousands of years. Hippocrates named the herb *glukos riza*, or sweet root. Several species of this member of the Leguminosae, or pea, family, are used medicinally. *Glycyrrhiza glabra*, also known as sweet wood or sweet licorice, is cited first in most herbals. Chinese licorice, *G. uralenis* or *G. viscida*, known as the peacemaker,

was included in the Chinese classic herbal *Pen Tsao Ching* over 2,000 years ago, and is believed to promote longevity. An American variety, *G. lepidota* or wild licorice, was a common Native American remedy and was also used by early settlers. Dominican friars brought the herb to England in the sixteenth century. The abbess Hildegard of Bingen added licorice to her materia medica, and this well-loved herb was a favorite of German and English herbalists.

General use

The medicinal benefits of licorice root have been studied extensively, and its use in traditional medicine is well documented. Licorice is an expectorant, helpful in the treatment of upper respiratory tract catarrh. The root extract is demulcent, and commonly used as a component of many medicinal syrups and drops providing relief to a **sore throat** and for coughs. The glycoside glycyrrhizin, found in the root, is more than 50 times as sweet as sucrose. Glycyrrhizin, which becomes glycyrrhizic acid when ingested, has been credited with much of the pharmacological action of licorice. The herb is also effective as a mild laxative, cleansing the colon. Licorice is a liver tonic and is used as an anti-inflammatory medicine, useful in the treatment of arthritis. Along with other herbs, licorice is used to treat **muscle spasms**. It also acts to reduce stomach acid and relieves **heartburn**. Other active chemical constituents in licorice root include asparagine, flavonoids and isoflavonoids, chalcones, coumarins, sterols, and triterpenoid saponins. Studies have shown that licorice also stimulates the production of interferon.

Licorice preparations have been used in the healing of peptic ulcers. The demulcent action of the root extract coats and soothes the ulcerated tissue. Licorice also has a beneficial effect on the endocrine system and is helpful in treatment of problems with the adrenal gland, such as Addison's disease. Phytochemicals in the root act similarly to and stimulate the secretion of the body's natural adrenal cortex hormone, aldosterone. This sweet herb also has antibacterial action and is beneficial in treatment of **hypoglycemia**. Licorice increases bile flow and acts to lower blood **cholesterol** levels. Licorice root, when boiled to extract its sweetness, has been used traditionally in candy making. Commercially it is a flavoring in beer, soft drinks, and tobacco. Singers chew the root to ease throat irritation and to strengthen their voice. Many women's herbal formulas include licorice for its estrogenic properties as an aid to normalize and regulate hormone production during **menopause**; however, some recent studies indicate that licorice does not have the estrogenic qualities that have been attributed to it. Licorice is frequently used in medicinal compounds with other herbs. In Chinese medicine, this herb is always used in compound, as it can minimize the bitter taste of some herbal components, and help to blend and harmonize the entire mixture.

KEY TERMS

Apoptosis—Cell suicide or self-destruction. Licorice contains a compound that induces apoptosis in some types of human cancer cells.

Decoction—A herbal extract prepared by boiling the plant material for some time.

Demulcent—A type of medication given to soothe the stomach lining or other irritated mucous membrane. Licorice extract can be used as a demulcent.

Expectorant—A substance or medication given to bring up phlegm or mucus from the respiratory tract.

Glycyrrhizin—A sweet-tasting compound in licorice root that has a number of beneficial effects on the cardiovascular and digestive systems.

Tincture—A herbal preparation made by soaking the roots, leaves, or other parts of the plant in alcohol or a mixture of alcohol and water.

More recently, licorice has been found to offer some protection against cardiovascular disease. A team of Israeli researchers found that licorice root extract added to the diet lowers blood cholesterol levels as well as the rate of oxidation in cardiovascular tissue.

Licorice also shows promise as a possible chemopreventive against **cancer**. Glycyrrhizin, the glycoside credited with many of the beneficial effects of licorice, appears to inhibit the growth of cancer cells as well. In addition, a new polyphenol compound isolated from licorice root has been found to induce apoptosis, or self-destruction, in human prostate and breast tumor cells.

Preparations

The dried root is used in medicinal preparations. Harvest the taproot of three- to four-year-old plants in late autumn. Washed and dried, the root may be stored intact until needed for a preparation.

Decoction: Combine one teaspoonful of dried root, powdered or diced, for each cup of non-chlorinated water. Bring to boil, lower heat and simmer for 10-15

minutes. Dosage is three cups per day. Prepare fresh decoction daily.

Tincture: Combine one part dried root, powdered or diced, with five parts of brandy or vodka in a glass container. A 50/50 alcohol to water ratio is optimal. Seal the container with an airtight lid. Leave to macerate in a darkened place for two weeks. Shake daily. Strain the mixture through a cheesecloth or muslin bag and pour into a dark bottle for storage up to two years. Dosage is one to three milliliters of the tincture three times a day.

Precautions

People should avoid using licorice in large doses for long periods of time. This herbal remedy should be used for no longer than four to six weeks without medical advice. Pregnant women should not use the herb. Persons with high blood pressure or kidney disease should not use licorice, nor should those with cholestatic liver disorders or **cirrhosis**.

Side effects

Excessive use of the herbal extract may raise blood pressure, cause water retention, **headache**, and **potassium** loss; however, for persons on high potassium, low-sodium **diets**, this may not be a problem. Licorice taken in its natural form, such as chewing the root, may mitigate the side effect of water retention because of the high presence of the plant constituent asparagine. **Deglycyrrhizinated licorice** extract is commercially available for treatment of peptic ulcer and eliminates side effects possible with other licorice preparations.

Interactions

When licorice is used while taking thiazide diuretic medications, this may exacerbate potassium loss. Sensitivity to **digitalis** glycosides may increase with loss of potassium.

Light therapy

Definition

Light therapy, or phototherapy, is the administration of doses of bright light in order to treat a variety of sleep and mood disorders. It is most commonly used to re-regulate the body's internal clock and/or relieve **depression**.

Origins

Light, both natural and artificial, has been prescribed throughout the ages for healing purposes. Sunlight has been used medicinally since the time of the ancient Greeks; Hippocrates, the father of modern medicine, prescribed exposure to sunlight for a number of illnesses. In the late nineteenth and early twentieth centuries, bright light and fresh air were frequently prescribed for a number of mood and **stress** related disorders. In fact, prior to World War II, hospitals were regularly built with

Types of light therapy

Type	Description	Condition/disease
Back of knee	The area behind the knee, known as the popliteal region, contains photoreceptors that can adjust the body's circadian rhythms.	Seasonal affective disorder (SAD), jet lag
Colored	Different colored light has therapeutic effects on the body. Depending on the condition, the colored light can be projected as a beam on a specific area or as a floodlight that covers the whole body.	Used in conjunction with accupuncture (but they are not lasers), or on its own
Cold laser	Very low-intensity laser beams are directed at the body.	Used in laser acupunture to treat pain, stress tendinitis, etc.
Full spectrum, non - UV	Full spectrum light that does not emit UV rays.	Skin diseases, rashes, jaundice, and seasonal affective disorder (SAD)

(Illustration by Corey Light. Cengage Learning, Gale)

solariums, or sun rooms, in which patients could spend time recuperating in the sunlight.

In the 1980s, light therapy began to make an appearance in the medical literature as a treatment for **seasonal affective disorder**, or SAD. Today, it is widely recognized as a front-line treatment for the disorder.

Benefits

Light therapy is most often prescribed to treat seasonal affective disorder, a form of depression most often associated with shortened daylight hours in northern latitudes from the late fall to the early spring. It is also occasionally employed to treat such sleep-related disorders as **insomnia** and **jet lag**. Recently, light therapy has also been found effective in the treatment of such nonseasonal forms of depression as **bipolar disorder**. One 2001 study found that bright light reduced depressive symptoms 12–35% more than a placebo treatment in nine out of 10 randomized controlled trials.

When used to treat SAD or other forms of depression, light therapy has several advantages over prescription antidepressants. Light therapy tends to work faster than medications, alleviating depressive symptoms within two to 14 days after beginning light therapy as opposed to an average of four to six weeks with medication. And unlike antidepressants, which can cause a variety of side effects from **nausea** to concentration problems, light therapy is extremely well tolerated. Some side effects are possible with light but are generally not serious enough to cause discontinuation of the therapy.

There are several other different applications for light therapy, including:

- Full-spectrum/UV light therapy for disorders of the skin. A subtype of light therapy that is often prescribed to treat skin diseases, rashes, and jaundice.
- Cold laser therapy. The treatment involves focusing very low-intensity beams of laser light on the skin, and is used in laser acupuncture to treat a myriad of symptoms and illnesses, including pain, stress, and tendinitis.
- Colored light therapy. In colored light therapy, different colored filters are applied over a light source to achieve specific therapeutic effects. The colored light is then focused on the patient, either with a floodlight which covers the patient with the colored light, or

KEY TERMS

Dawn simulation—A form of light therapy in which the patient is exposed while asleep to gradually brightening white light over a period of an hour and a half.

Lux—The International System unit for measuring illumination, equal to one lumen per square meter.

Neurotransmitter—A chemical in the brain that transmits messages between neurons, or nerve cells.

Seasonal affective disorder (SAD)—A mood disorder characterized by depression, weight gain, and sleepiness during the winter months. An estimated 4 6% of the population of Canada and the northern United States suffers from SAD.

Serotonin—A neurotransmitter that is involved in mood disorders as well as transmitting nerve impulses.

with a beam of light that is focused on the area of the illness.

- Back of knee light therapy. A 1998 report published in the journal *Science* reported that the area behind the human knee known as the popliteal region contains photoreceptors that can help to adjust the body's circadian rhythms. The authors of the study found that they could manipulate circadian rhythms by focusing a bright light on the popliteal region. Further studies are needed to determine the efficacy of this treatment on disorders such as SAD and jet lag.

Description

Light therapy is generally administered at home. The most commonly used light therapy equipment is a portable lighting device known as a light box. The light box may be a full-spectrum box, in which the lighting element contains all wavelengths of light found in natural light (including UV rays), or it may be a bright light box, in which the lighting element emits non-UV white light. The box may be mounted upright to a wall, or slanted downwards towards a table.

The patient sits in front of the box for a prescribed period of time (anywhere from 15 minutes to several hours). For patients just starting on the therapy, initial sessions are usually only 10–15 minutes in length. Some patients with SAD undergo light therapy session two or three times a day, others only once. The time of day and number of times treatment is administered depends on the physical needs and lifestyle of the individual patient. If light therapy has been prescribed for the treatment of SAD, it typically begins in the fall months as the days begin to shorten, and continues throughout the winter and possibly the early spring. Patients with a long-standing history of SAD are usually able to establish a time-table or pattern to their depressive symptoms, and can initiate treatment accordingly before symptoms begin.

The light from a slanted light box is designed to focus on the table it sits upon, so patients may look down to read or do other sedentary activities during therapy. Patients using an upright light box must face the light source, and should glance toward the light source occasionally without staring directly into the light. The light sources in these light boxes typically range from 2,500–10,000 lux (in contrast, average indoor lighting is 300–500 lux; a sunny summer day is about 100,000 lux).

Light boxes can be purchased for between $200 and $500. Some healthcare providers and healthcare supply companies also rent the fixtures. This gives a patient the opportunity to have a trial run of the therapy before making the investment in a light box. Recently, several new light box products have become available. Dawn simulators are lighting devices or fixtures that are programmed to turn on gradually, from dim to bright light, to simulate the sunrise. They are sometimes prescribed for individuals who have difficulty getting up in the morning due to SAD symptoms. Another device known as a light visor is designed to give an individual more mobility during treatment. The visor is a lighting apparatus that is worn like a sun visor around the crown of the head. Patients with any history of eye problems should consult their healthcare professional before attempting to use a light visor.

Preparations

Full-spectrum light boxes do emit UV rays, so patients with sun-sensitive skin should apply a sun screen before sitting in front of the box for an extended period of time.

Precautions

Patients with eye problems should see an ophthalmologist regularly both before and during light therapy. Because UV rays are emitted by the light box, patients taking photosensitizing medications should consult with their healthcare provider before beginning treatment. In addition, patients with medical conditions that make them sensitive to UV rays should

also be seen by a healthcare professional before starting phototherapy.

Patients beginning light therapy for SAD may need to adjust the length, frequency, and timing of their phototherapy sessions in order to achieve the maximum benefits. Patients should keep their healthcare provider informed of their progress and the status of their depressive symptoms. Occasionally, additional treatment measures for depression (i.e., antidepressants, herbal remedies, **psychotherapy**) may be recommended as an adjunct, or companion treatment, to light therapy.

Side effects

Some patients undergoing light therapy treatments report side effects of eyestrain, headaches, insomnia, **fatigue**, **sunburn**, and dry eyes and nose. Most of these effects can be managed by adjusting the timing and duration of the light therapy sessions. A strong sun block and eye and nose drops can alleviate the others. Long-term studies have shown no negative effects to eye function of individuals undergoing light therapy treatment.

A small percentage of light therapy patients may experience hypomania, a feeling of exaggerated, hyperelevated mood. Again, adjusting the length and frequency of treatment sessions can usually manage this side effect.

Research and general acceptance

Light therapy is widely accepted by both traditional and complementary medicine as an effective treatment for SAD. The exact mechanisms by which the treatment works are not known, but the bright light employed in light therapy may act to readjust the body's circadian rhythms, or internal clock. Other popular theories are that light triggers the production of serotonin, a neurotransmitter believed to be related to depressive disorders, or that it influences the body's production of **melatonin**, a hormone that may be related to circadian rhythms. A recent British study suggests that dawn simulation, a form of light therapy in which the patient is exposed to white light of gradually increasing brightness (peaking at 250 lux after 90 min) may be even more effective in treating depression than exposure to bright light. Dawn simulation is started around 4:30 or 5 A.M., while the patient is still asleep.

Wide-spectrum UV light treatment for skin disorders such as **psoriasis** is also considered a standard treatment option in clinical practice. However, such other light-related treatments as cold laser therapy and colored light therapy are not generally accepted, since few or no scientific studies exist on the techniques.

Training and certification

Psychiatrists, psychologists, and other mental healthcare professional prescribe light therapy treatment for SAD. Holistic healthcare professionals and light therapists who specialize in this treatment are also available; in some states, these professionals require a license, so individuals should check with their state board of health to ensure their practitioner has the proper credentials. Light therapy for skin disorders should be prescribed by a dermatologist or other healthcare professional with expertise in skin diseases and light therapy treatment.

Linoleic acid

Description

Linoleic acid is a colorless to straw-colored liquid polyunsaturated fatty acid with the chemical formula ($C_{18}H_{32}O_2$) of the omega-6 series. Linoleic and another fatty acid, gamma-linolenic, or gamolenic, produce compounds called prostaglandins. Prostaglandins are substances found in every cell, are needed for the body's overall health maintenance, and must be replenished constantly. Linoleic acid is an essential fatty acid, which means that the body cannot produce it, so it must be obtained in the diet.

Linoleic acid is an important fatty acid, especially for the growth and development of infants. Fatty acids help to maintain the health of cell membranes, improve nutrient use, and establish and control cellular metabolism. They also provide the raw materials that help in the control of blood pressure, blood clotting, inflammation, body temperature, and other body functions. Fatty acids are consumed in the greatest quantities in the synthesis of fat. Although many people are encouraged to consume less fat in their **diets**, fat is still an important component of a healthy body. Fat stores the body's extra calories, helps insulate the body, and protects body tissues. Fats are also an important energy source during **exercise**, when the body depends on its calories after using up available carbohydrates. Fat helps in the absorption and transport through the bloodstream of the fat-soluble vitamins A, D, E, and K.

Conjugated linoleic acid (CLA) is a naturally occurring mixture of various isomers of linoleic acid with conjugated double bonds. The isomers of CLA have different shapes, functions, and benefits. CLA supplements, or fats containing CLA, generally contain a mixture of these isomers. Although CLA is present in many foods and can be synthesized from linoleic acid, it is made naturally in the stomach, especially in ruminant animals. (Ruminants are animals that regurgitate food and chew it, known as "chewing the cud." Cows and sheep are ruminants.) For this reason, CLA is found primarily in dairy and beef products, as well as other foods derived from ruminant animals. Many people have likely decreased their intake of CLA for two reasons. First, people in the 2000s are typically eating less beef and dairy fat in their diets. Second, many cattle are fed grain diets, which are lower in linoleic acid than the grass on which they would naturally feed, so there is less CLA in beef raised in the meat industry and in dairy foods. It is possible to increase the CLA in milk by adding a linoleic acid supplement to livestock feed. The supplement also increases lean tissue and decreases fat in the animals and induces dairy cattle to produce more milk.

Borage is a source of linoleic acid. *(© David Noton Photography / Alamy)*

Linoleic acid is found in **fish oil**, meat, milk, and other dairy products. It is also a constituent of many vegetable oils, including **evening primrose oil**, sunflower oil, and safflower oil. Commercially produced linoleic acid is used in margarine, animal feeds, emulsifying agents, soaps, and drugs.

General use

As mentioned, CLA supplements, or fats containing CLA, generally contain a mixture of CLA isomers. Plant oils, though they contain little CLA, are a rich source of linoleic acid. While linoleic acid may be taken as a supplement to help with certain conditions, the supplement will not necessarily increase CLA levels in the body.

Anticarcinogenic

One particular isomer in CLA, known as cis-9, trans-11, is linked to anticancer benefits. Studies with animals have shown CLA to reduce breast, prostate, stomach, colorectal, lung, and skin cancers. The CLA may slow the growth of cells that give rise to **cancer**. A human study has shown an association between linoleic acids and a decreased risk for **prostate cancer**. In addition, a study done in 2001 on human **breast cancer** cells grown in a laboratory medium showed that linoleic acid works to reduce tumor size through its effects on a gene that controls the rate of apoptosis, or cell self-destruction.

Cystic fibrosis

Infants with cystic fibrosis (CF) often have poor weight gain and growth and an inability to absorb fats. Some research suggests that infants with CF can benefit from formula with a high linoleic acid content because it optimizes **nutrition**, growth, and feeding efficiency.

Multiple sclerosis

Multiple sclerosis (MS) is a disease in which demyelination (loss of myelin sheath material) occurs. (The myelin sheath is a fatty substance that surrounds and insulates the axon of some nerve cells.) This condition leads to disruptions in nerve impulse transmission. Linoleic acid is believed to be helpful because myelin is composed of **lecithin**, which is made of linoleic and other fatty acids. Many diets recommended for MS patients include supplements. Patients supplementing with linoleic acid show a smaller increase in disability and reduced severity and duration of attacks than those with no linoleic acid supplement. Evening primrose oil is beneficial because of its specialized fatty-acid content, including linoleic acid. Doses of sunflower seed oil or evening primrose oil to provide 17 grams linoleic acid per day may be beneficial.

Pregnancy

One study indicated that low doses of linoleic acid and **calcium** can reduce the incidence of preeclampsia in high-risk women. (Preeclampsia is the development of **hypertension** with increased protein in the urine or accumulation of watery fluid in cells or tissues or both, due to pregnancy.) Another study showed, however, that linoleic acid consumption can have a negative effect on fetal growth. Pregnant women should talk to their doctors before taking linoleic acid or any other supplement.

Diet and nutrition

CLA helps regulate how the body accumulates and retains fat. It has been shown to reduce body fat, improve muscle tone, improve nutrient usage, and reduce the appetite by improving the way the body extracts energy from less food. These properties are useful for individuals trying to lose weight or tone muscles and also for people with nutrient absorption disorders and other digestive problems. The CLA isomer linked with reducing body fat and increasing lean muscle mass is trans-10, cis-12.

Skin care

Linoleic acid helps relieve flaky, itchy, or rough skin and maintain smooth, moist skin. A tablespoon of linoleic acid-rich foods or oils may be added on a daily basis to help improve and moisturize skin. Linoleic acid may also help with skin disorders such as atopic **eczema**. Evening primrose oil is taken to help with skin, hair, and nail repair.

Other uses

Animal research suggests that CLA supplementation may limit food allergy reactions and improve glucose tolerance. It is also used as a nutritional supplement for allergic respiratory disease, circulation, arthritis, and inflammatory problems. CLA is a potent antioxidant and may help reduce plaque formation in arteries and thus help prevent **heart disease**. Evening primrose oil helps to reduce arthritis **pain** and **depression**. It also helps to control diabetes, liver and kidney damage due to alcohol, and several symptoms of **premenstrual syndrome** (PMS).

Linoleic acid appears to have at least one negative effect on the human body, however. It appears to increase a person's risk of developing age-related **macular degeneration** (ARMD), a disease of the eye that leads to a progressive loss of vision and eventual blindness.

Preparations

Evening primrose oil is a fixed oil obtained from the seeds of *Oenothera biennis* or other spp. (Onagraceae). It contains about 72% linoleic acid and 9% gamolenic acid. Typical doses expressed as gamolenic acid are 320 or 480 mg daily, taken in two or three doses. Safflower oil is the refined fixed oil obtained from the seeds of the safflower, or false (bastard) **saffron**, *Carthamus tinctorius* (Compositae). It contains about 75% linoleic acid as well as various saturated fatty acids.

KEY TERMS

Age-related macular degeneration (ARMD)—An eye disease that appears to be related to high levels of linoleic acid in the body. ARMD is characterized by progressive and permanent loss of vision.

Apoptosis—The programmed self-destruction of a cell, which takes place when the cell detects some damage to its DNA. Apoptosis is sometimes called "cell suicide." The antitumor activity of linoleic acid is related to its effects on a gene that controls the rate of apoptosis.

Atopic eczema—Inflammation of the skin caused by allergic reaction.

Cystic fibrosis (CF)—A disorder of the exocrine glands that affects many organs of the body, especially the sweat glands and glands in the lungs and pancreas.

Isomers—Molecules that have the same molecular formula, but different configurations.

Multiple sclerosis (MS)—A disease caused by demyelination, or loss of myelin sheath material, which is essential in nerve impulse transmission.

Omega-6 fatty acid—A fatty acid with its first double bond at the sixth carbon in its carbon chain.

Phenothiazines—A parent compound for the synthesis of some antipsychotic compounds.

CLA is available in beef and dairy products, but to avoid eating too many fatty animal foods, supplements may be taken. CLA comes in capsules and softgels that range in potency from 600 to 1,000 mg. A specialist should be consulted to determine what is most appropriate.

Precautions

CLA appears to be safe and nontoxic at supplemental levels. However, using evening primrose oil as a supplement for linoleic acid can cause symptoms of undiagnosed temporal lobe **epilepsy** and should be used with caution in patients with a history of epilepsy.

Side effects

CLA may cause gastrointestinal upset in isolated cases, and evening primrose oil can cause minor gastrointestinal upset and **headache**.

Interactions

People who take epileptogenic drugs (drugs which cause epilepsy), in particular phenothiazines, may have interactions with evening primrose oil and should talk to their doctor before using a supplement.

Lipase

Definition

Lipase is an enzyme that is used by the body to break down dietary fats (lipids), especially triglycerides, into a form that can be absorbed in the intestines.

Description

Lipase is not found in foods; rather it is naturally manufactured in the pancreas. Small amounts are produced in the stomach and secreted in the saliva. The pancreas also makes two other groups of **digestive enzymes**: protease and amylase. The pancreas is a glandular organ near the stomach that secretes digestive juices into the small intestine and releases the hormones insulin, glucagon, and somatostatin into the bloodstream. Lipase appears in the blood together with another enzyme called amylase following damage to or diseases affecting the pancreas. It was once thought that abnormally high lipase levels were associated only with diseases of the pancreas. Other conditions are in the 2000s known to be associated with high lipase levels, especially kidney failure and intestinal obstruction. Diseases involving the pancreas, however, produce much higher lipase levels than diseases of other organs. Lipase levels in pancreatic disorders are often 5–10 times higher than normal.

Lipase levels are determined by a blood test. The lipase blood test is most often used in evaluating inflammation of the pancreas (**pancreatitis**), but it is also useful in diagnosing kidney failure, intestinal obstruction, **mumps**, and peptic ulcers. Doctors often order amylase and lipase tests at the same time to help distinguish pancreatitis from ulcers and other disorders in the abdomen. If the patient has acute (sudden onset) pancreatitis, the lipase level usually rises somewhat later than the amylase level—about 24–48 hours after onset of symptoms—and remains abnormally high for 5–7 days. Because the lipase level peaks later and remains elevated longer, its determination is more useful in late diagnosis of acute pancreatitis. However, lipase levels are not as useful in diagnosing chronic pancreatic disease.

Although fat digestion is not concentrated in the stomach, gastric lipase will digest egg yolk and cream in the stomach, since they are already emulsified fats. For fat to be digested properly, the liver needs to first emulsify the large fat molecules, and bile breaks it down to small droplets, allowing the lipase to start its work. Fat digestion in the small intestine is reliant on a pancreatic secretion called pancreatin containing lipase as well as protease and amylase. In some vegetarian **diets**, very little bile is produced since the liver is not stimulated to produce bile, with the result that the large fat molecules are not properly emulsified, making it difficult for the lipase to bind. This pattern leads to incomplete or reduced fat absorption. A shortage of lipase in the body may lead to high **cholesterol**, difficulty in losing weight, a tendency towards diabetes, high urine sugar levels—which some believe can lead to arthritis, bladder problems, gall stones, **hay fever**, prostate problems, and heart problems. With too little lipase, the cell membranes' permeability is inefficient, and nutrients cannot enter the cell, while wastes cannot leave it. There is also a tendency among people suffering from lipase deficiency to have a problem with electrolyte balance. **Muscle spasms** and a spastic colon are also reported as symptoms of lipase deficiency. People suffering with a spastic colon may be lipase deficient as well as people with vertigo (Meniere's disease), which is **dizziness** made worse by movement.

General use

Lipase supplements, which usually contain protease enzymes and amylase, are used to treat people with pancreatic insufficiency, meaning the pancreas does not make enough of these enzymes to aid in food digestion. It is also used to treat **celiac disease** and gluten intolerance. It is used infrequently to treat **indigestion** caused by a deficiency of pancreatic enzymes. Several scientific studies have shown its effectiveness in treating pancreatic insufficiency, celiac disease, **irritable bowel syndrome**, and indigestion. There is a lack of scientific evidence that lipase is effective in treating other conditions. However, it is used by some healthcare professionals to help treat cystic fibrosis, Crohn's disease (chronic inflammation, usually of the lower intestinal tract), lactose intolerance, **rheumatoid arthritis**, and lupus.

Celiac disease and gluten intolerance

Celiac disease and gluten intolerance are basically the same condition. Gluten intolerance is the body's inability to break down or digest gluten and can range from mild to moderate. Celiac disease is a condition of the digestive system in which the body produces antibodies that attack the gluten. These antibodies damage the lining of the small intestine and interfere with the absorption of nutrients from food. It is in the severe range of gluten intolerance. As of 2007, the only treatment for celiac disease was a **gluten-free diet**. Gluten is primarily found in products that contains wheat, rye, barley, or oats. It helps to make bread rise and gives many foods a smooth, pleasing texture. In addition to the many obvious places gluten can be found in a normal diet, such as breads, cereals, and pasta, there are many hidden sources of gluten. These include ingredients added to foods to improve texture or enhance flavor and products used in food packaging. Gluten may even be present on surfaces used for food preparation or cooking. An estimated three million Americans have celiac disease but only about

3% of them have been diagnosed, according to the American Academy of Allergy, **Asthma**, and Immunology. Lipase, in combination with other pancreatic enzymes, enhances the benefits of a gluten-free diet for people with celiac disease and gluten intolerance.

Lipase is also used to treat pancreatic insufficiency, a condition in which food cannot be normally processed by the body, and insulin secretion may be inadequate. Studies have shown that taking 1.5 grams of 9X pancreatin with each meal can help people with pancreatic insufficiency to better digest food.

Preparations

Lipase supplements usually contain other enzymes that help digest carbohydrates and protein. In the United States, the supplement pancreatin contains lipase, amylase, and protease. A government standard is used to rate lipase supplements and is denoted as USP units. The standard government measurement for pancreatin is 25 USP units of amylase, 2 USP units of lipase, and 25 USP units of protolytic (protease) enzymes. So a lipase supplement that has a label indicating that it is "9X pancreatin" is nine times stronger than the government standard. Lipase supplements are usually made from enzymes found in animals, although there are a few supplements that use lipase and other pancreatic enzymes derived from plants.

Recommended dosage

Pancreatin supplements usually contain 6,000 LU (lipase activity units) of lipase. The recommended dosage for adults is one to two capsules or tablets three times a day. Dosages for children should be determined by a pediatrician.

Precautions

Lipase supplements should be taken under the supervision of a qualified health care professional. It should not be taken by pregnant women or women who are nursing without approval from their physician.

Side effects

There are no known adverse side effects associated with lipase supplements.

Interactions

Lipase can interact with the anti-obesity drug orlistat (Xenical). Studies have shown orlistat interferes with the activity of lipase supplements. Orlistate is prescribed to treat **obesity** and works by blocking the ability of lipase to break down fats. Also, the dietary supplement betaine should not be taken with lipase supplements, since it can destroy lipase and other enzymes.

KEY TERMS

Celiac disease—A disorder caused by sensitivity to gluten that makes the digestive system unable to deal with fat.

Enzyme—Any complex chemical produced by living cells that is a catalyst for biochemical reactions.

Lupus—Either of two inflammatory diseases affecting connective tissue, one largely confined to the skin, the other affecting the joints and internal organs.

Pancreas—A large elongated glandular organ that is near the stomach and secretes juices into the small intestine and the hormones insulin, glucagon, and somatostatin into the bloodstream.

Pancreatitis—Inflammation of the pancreas.

Triglycerides—Natural fat found in human tissue that in high levels can increase the risk of heart disease and stroke.

Vertigo—Dizziness made worse by movement.

Ken R. Wells

Live cell therapy *see* **Cell therapy**

KEY TERMS

Anaphylaxis—An abnormal reaction to a substance that the body considers as dangerous or foreign.

Autogenous vaccine—A vaccine made of dead bacteria from a patient's own body.

Sepsis—Bacterial poisoning causing destruction of body tissues.

Livingston-Wheeler therapy

Definition

Developed by Virginia Livingston-Wheeler, a U.S. medical doctor, this complex vaccine and nutrition-based **cancer** therapy assumed that cancer was caused by *Progenitor cryptocides*, a bacterium said to become active only when the body's immune system is weakened or stressed.

Origins

Livingston-Wheeler discovered *Progenitor cryptocides* during the 1940s. In the following decade, she formed her hypothesis that cancer is caused by this bacterium, and developed a vaccine against it. In 1969, she founded what became the Livingston Foundation Medical Center in San Diego. In the years since then, this center claimed to have treated thousands of patients.

Livingston-Wheeler died in 1990, but her clinic continued to offer the Livingston protocol to about 500 patients a year until the clinic closed in 2004.

Benefits

An analysis by Livingston-Wheeler showed an 82 percent survival rate among 62 of her patients with confirmed diagnoses of various cancers. Of those 62 patients, 37 survived three years or longer. A later, independent study, however, found no significant difference between survival rates among her patients and those at a university cancer center offering conventional therapy. This study, which included 78 pairs of patients, was published in a 1991 issue of the prestigious *New England Journal of Medicine*. The American Cancer Society concluded that no scientific evidence existed to support the claims that the Livingston-Wheeler therapy was an effective treatment for cancer. Although versions of the Livingston protocol were also offered to patients with lupus, arthritis, scleroderma, **allergies**, and stress-induced syndromes, the American Cancer Society also noted that no scientific evidence supported the therapy's use for those or any other diseases.

Description

The treatment was commenced during a 10-day period at the Livingston Foundation Medical Center in San Diego, and continued by the patient afterward at home. In addition to vaccines, the Livingston treatment also often employed vitamins, **digestive enzymes**, sheep spleen extract, liver extract, antibiotics, a vegetarian diet, and **detoxification**. Traditional drug therapy was also used, so long as it continued to enhance the body's immune system. A staff psychologist taught patients strategies for managing emotional trauma. In addition, visualization techniques were used to improve the immune response. The Livingston Center also offered a two-day annual "immunological diagnostic program" focused on preventative health.

Preparations

At the beginning of the 10-day program, patients underwent a physical examination and diagnostic tests including blood counts, electrolytes, chemistry, urinalysis, thyroid and liver function, tumor markers, and hormone levels.

Precautions

In a fact sheet on Livingston-Wheeler therapy, the U.S. National Cancer Institute strongly urged cancer patients "to remain in the care of qualified physicians who use accepted methods of treatment or who are participating in carefully conducted clinical trials (treatment studies). The use of unconventional methods may result in the loss of valuable time and the opportunity to receive potentially effective therapy

and consequently reduce a patient's chance for cure or control of cancer." The U.S. Congressional Office of Technology Assessment (OTA) also warned, "As with any injection into the body of a foreign substance, the injection of the autogenous vaccine carries the associated risk of sepsis or anaphylaxis. Some risk of contamination in the preparation of the material is also possible, depending on the processes and procedures used to make and assure the sterility of the vaccines manufactured at the clinic." In addition, the OTA cautioned that "whole blood transfusion, even with directed donors' blood, carries a small risk of transmitting various infectious agents." and warned that injecting extracts of sheep liver and spleen, "carries certain risks associated with all types of cellular treatment."

Side effects

One University of Pennsylvania study found that self-reported quality of life among patients at the Livingston-Wheeler clinic was actually lower than among patients receiving conventional cancer care at the university's cancer center. Reported side-effects include malaise, slight **fever**, aching, tenderness at the site of vaccine injections, and appetite problems.

Research and general acceptance

In 1990, the Livingston clinic was ordered by California officials to stop using its vaccines on cancer patients, after a state panel of cancer experts and consumers concluded there was no conclusive scientific evidence proving they were safe and effective. The American Cancer Society also advised against the Livingston protocol. In addition, an article in CA: A Cancer Journal for Clinicians asserted that the premise for the Livingston-Wheeler treatment was faulty: the bacterium *Progenitor cryptocides* does not exist. It stated, "Careful research using modern techniques . . . has shown that there is no such organism and that Livingston-Wheeler has apparently mistaken several different types of bacteria, both rare and common, for a unique microbe."

Training and certification

The Livingston protocol and products were offered exclusively through the Livingston Foundation Medical Center in San Diego through its closure in 2004. During its operation, the center stated that it "is not affiliated with any other clinic, physician, research organization, or business entity anywhere in the world."

Lobelia

Description

Lobelia inflata, also known as Indian tobacco, wild tobacco, pukeweed, emetic weed, **asthma** weed and gagroot, is native to North America and can commonly be found growing wild over much of the United States. Lobelia derives its name from Matthias de Lobel, a sixteenth-century Flemish botanist. The erect stem reaches a height of between 6 in (15 cm) and several feet. The many small blue flowers appear in midsummer and are visible through late fall. The stem is hairy, and the plant contains a milk-like sap.

Worldwide, there are more than 200 species of lobelia, growing predominantly in the temperate and tropical zones. Some species found at high elevations in mountainous areas of Asia and Africa may achieve a height of up to 15 ft (5.5 m). At the other end of the size spectrum, the dwarf lobelia (*Lobelia erina*) is sometimes cultivated as a small ornamental or hanging plant.

General use

This powerful plant has the distinction of being simultaneously a stimulant (for the respiratory system) and a general relaxant. This unusual combination may help account for the remarkably diverse assortment of ailments for which lobelia is used.

To begin with, lobelia is commonly associated with the treatment of lung-related ailments such as

Edging Lobelia. *(© Arco Images / Alamy)*

asthma, **bronchitis**, coughs, **pneumonia**, colds and flu, and other upper-respiratory problems.

Perhaps not surprisingly, then, this well-established medicinal plant has a special relationship with the (also long-established) practice of **smoking**. In some Native American cultures, lobelia was smoked as a treatment for lung diseases, which presumably led early European naturalists to dub the plant Indian tobacco. Considering the plant's value as an overall tonic for the lungs, this practice stands in marked contrast to contemporary use of tobacco (which many Native American cultures also used) as a plant to be smoked. Even more intriguingly, lobelia is commonly used as an aid to stopping smoking, sometimes in combination with **cramp bark**. One of the alkaloids in lobelia, lobeline, has effects on humans similar to those of nicotine and can be helpful in treating the symptoms of nicotine withdrawal. These same properties may perhaps also explain the use of the plant to treat hangovers and **alcoholism**. Recent research, however, has questioned the usefulness of lobeline in smoking cessation programs; a German study published in 2000 concluded that lobeline "cannot be recommended" as a treatment for nicotine dependence.

KEY TERMS

Amphetamines—A group of drugs that stimulate the central nervous system. They are used medically to counteract depression, but are often used illegally as stimulants.

Beta-amyrin palmitate—A compound found in lobelia that has antidepressant properties.

Diuretic—A medication given to increase the body's output of urine.

Dopamine—A chemical in the brain that governs movement and emotions. Amphetamines trigger the release of dopamine, while lobeline opposes its effects.

Emetic—A medication given to induce vomiting.

Expectorant—A drug given to help bring up mucus or phlegm from the respiratory tract.

Hypokalemia—An abnormally low level of potassium in the bloodstream.

Lobeline—An alkaloid compound found in lobelia that resembles nicotine in its pharmacological effects. It has been studied by researchers in the field of tobacco addiction and drug abuse.

Methamphetamine—A form of amphetamine that is a potent stimulant of the central nervous system and is highly addictive. Slang terms for methamphetamine include "meth," "ice," "speed," and "chalk."

Nonsteroidal anti-inflammatory drugs (NSAIDs)—A term used for a group of pain-relieving medications that also reduce inflammation when used over a period of time. NSAIDs are often given to relieve the pain of osteoarthritis.

More recently, lobeline has attracted the attention of researchers as a possible treatment for methamphetamine addiction. Lobeline appears to oppose the action of dopamine, a brain chemical that regulates movement and emotion, and that is released by the effects of methamphetamine on the brain. Although reports published in 2001 and 2002 are promising, this use of lobeline has not yet reached the stage of clinical trials in humans.

Some Native Americans also used red lobelia to treat both intestinal **worms** and **syphilis**. Among the Shoshone of the American West, lobelia tea was brewed and used for its emetic and cathartic properties.

Lobelia is also commonly used as an emetic (i.e., to induce **vomiting**). This latter fact makes an interesting connection with the ancient "doctrine of signatures," which holds that a plant's appearance offers clues to its use: Lobelia inflata has been said to have "stomach-shaped" flowers.

Although it can be effective alone, lobelia is also commonly used in conjunction with other herbs. Among these are **coltsfoot**, **ephedra**, grindelia, lungwort, and **skullcap**.

In **homeopathy**, lobelia is used in ways similar to its herbal applications: more specifically, in cases of severe **nausea**, vomiting, asthma, **emphysema**, and dry **cough**, and in the treatment of **heart disease** (**angina** pectoris and cardialgia).

Externally, lobelia is used in connection with a variety of problems, including insect **bites** and poison ivy; **bruises**, **sprains** and arthritis; and ringworm.

Preparations

Lobelia is used both internally and externally, in various forms. The entire above-ground portion of the plant, including the seed pods, is harvested in late summer and fall, after it flowers. The leaves and seeds of the plant can be used to make a tincture. The dried herb can also be smoked or used as a tea. Prepared as a salve, it is appropriate for external use. All portions of the plant that are above ground are medicinally useful, including the stem.

Lobelia's chemical composition has been studied to a significant extent. It consists of various alkaloids (notably lobeline, as mentioned above), chelidonic acid, isolobeline, lobelic acid, lobeline, **selenium** and **sulfur**, among other substances.

Perhaps because of the plant's widespread and long-standing use for a diverse range of conditions, some of lobelia's pharmacological qualities have been investigated in the laboratory, including its action on the lungs and the antidepressant effect of a component isolated from the leaves known as beta-amyrin palmitate. A 1996 Russian study of 196 species of medicinal plants identified lobelia as being exceptionally high in **chromium** content, making it potentially useful for treating a chromium deficiency in humans.

Precautions

The effects of lobelia are unusually dose-specific; in other words, this plant can have widely varying effects—both in kind and intensity—depending on the amount taken. Herbal authorities differ markedly in their assessment of the plant's overall safety; some consider it relatively harmless. On the other hand, the Food and Drug Administration (FDA) has issued warnings to consumers in 1993 and 1998 about the potentially dangerous side effects of lobelia, and the Australian government has declared it unsafe for human consumption.

As with any medicinal herb, users are advised to consult with qualified health-care professionals before attempting any form of self-treatment. People using any form of medication should make sure that all their caregivers are aware of any herbs they may also be taking.

More specifically, women who are either pregnant or nursing should not take lobelia. The herb is contraindicated in cases of heart disease, pneumonia, shock, stomach ulcers, ulcerative **colitis**, esophageal reflux, **diverticulitis**, and high blood pressure.

Reports of toxic effects of lobelia in children have led American pediatricians to warn people against giving the herb to children as a treatment for asthma. This warning is particularly urgent in areas of the Southwest where folk medicines containing lobelia are frequently used.

Some writers also report that lobelia sap is highly toxic to livestock.

Side effects

In small doses, lobelia can have a soothing, sedative effect. In larger doses, it induces vomiting. The plant's well-established use in connection with lung disorders is due, in part, to its expectorant effects.

In potentially toxic doses, lobelia produces nausea, pronounced weakness, sweating, speeding heartbeat (tachycardia), sensory disturbances and **diarrhea**. In some people, even very small doses can cause nausea and vomiting. Signs of an overdose of lobelia include profuse sweating, low blood pressure, convulsions, respiratory **depression**, paralysis, coma, and death.

Interactions

Lobelia has been reported to have adverse interactions with several groups of drugs. It may potentiate (intensify) the effects of medications given to control blood pressure. It interferes with the action of drugs given to control diabetes. Lobelia increases the risk of loss of **potassium** from the body (hypokalemia) if it is taken together with diuretics or corticosteroids. Aspirin and NSAIDs appear to increase the risk of toxic reactions to lobelia.

Lomatium

Description

The name lomatium generally refers to *Lomatium dissectum*, one of the numerous species and varieties of the *Lomatium* genus that is native to western North America. Lomatium is a member of the Apiaceae (carrot) family and grows in the northwestern United States and southwestern Canada. Like many wild plants that have attracted the attention of commercial interests, lomatium is presently threatened with extinction over parts of its range.

In the wild, lomatium grows in rocky soil and reaches a height of 3 ft (0.9 m). The entire lomatium plant is edible, and numerous Native American groups regarded the lomatium plant as a food source and medicinal remedy. For cultivation as an herbal remedy, lomatium roots are unearthed during the months between early spring and fall. Roots are washed and dried for several days. The roots are then sliced and allowed to dry again. When dried correctly, lomatium is said to keep its medicinal properties for 2–3 years. Lomatium's antimicrobial activity is due to the tetronic acids and glucoside of luteolin that it contains. Other ingredients include the resin, which causes rash in some people, and coumarins, which could possibly cause rash as well. The coumarins, however, are being investigated for their possible usefulness in treating HIV infection.

Lomatium is also known as Indian biscuit root, biscuit root, desert **parsley**, desert parsnip, fern-leafed lomatium, ferula dissoluta, Indian desert parsnip, Indian parsnip, leptaotaenia dissecta, tohza, toza, and wild carrot.

General use

Many Native American groups recognized the value of lomatium as a source of nourishment and medicinal remedy. Lomatium root was peeled, dried, and ground into flour to make sweet-tasting biscuits. Lomatium seeds were eaten raw or roasted, or ground into flour for baking.

Native Americans chewed on the root to treat a range of respiratory **infections**. Lomatium was used for conditions including cold, flu, **bronchitis**, tuberculosis, hay fever, **asthma**, and **pneumonia**. Lomatium was also used in a tobacco mixture. The herb was smoked during rituals, and healers used the smoke to treat respiratory infections. Lomatium was used when the Native Americans were exposed to tuberculosis and other diseases that Europeans brought to North America.

When the world faced the **influenza** pandemic of 1917–18, Americans tried remedies such as castor oil, tobacco, aspirin, and morphine. American herbalists recommended use of lomatium, and the remedy was used with reported success, especially in the Southwest.

KEY TERMS

Coumarins—A group of crystalline compounds found in lomatium that may be useful in treating HIV infection.

Infusion—A liquid extract of an herb prepared by steeping or soaking plant parts in water or another liquid.

Potentiate—To intensify the effects of another herb or prescription medication.

Tincture—A method of preserving herbs with alcohol or water.

Wildcrafting—The art of gathering or harvesting herbs or other plants from their native wild environment for human use.

Contemporary uses of lomatium

Lomatium is currently used as an antiviral remedy to treat colds, coughs, and infections. The herb is also known for boosting the immune system and reducing inflammation.

Lomatium can relieve chest **pain** and stomach upset that frequently accompany the flu. It has also been used for conditions such as asthma, **hay fever**, mononucleosis, infective bronchitis, **tuberculosis**, and the early stages of **tonsillitis**. Other uses of lomatium include treatment of skin infections, **cuts**, and sores. A health practitioner might recommend the use of lomatium for a person diagnosed with fibromyalgia, a muscular inflammatory condition. Causes of **fibromyalgia** are not known, but are thought by some to be connected to viruses. Symptoms include an impaired immune system, chronic pain, and **fatigue**.

The future of lomatium

Lomatium was among the plants placed on Montana's plant protection list in April 1999. The state enacted a law that placed a three-year moratorium on the wildcrafting of lomatium, wild echinacea, butterroot, and sundew that grow on state land. Wildcrafting is the harvesting of herbal plants in the wild. Plants like lomatium face the risk of becoming endangered because of increased popularity and usage of herbal remedies, and reduction of habitat due to development.

A moratorium on wildcrafting is one way to protect plants in the short term. Long-term solutions include habitat protection and cultivation of herbs in home gardens and on commercial farms. Several organizations, such as United Plant Savers (www.plantsavers.org), are intent on protecting medicinal plants in the wild and increasing their availability.

Preparations

Lomatium is available as an extract, as a tincture, and in capsule form. Fresh root extract in an alcohol solution is believed to be the most effective remedy.

Lomatium tea, an infusion, is made by pouring one cup of boiling water over 1–2 tsp. of the dried herb. The mixture is steeped for 25 minutes and then strained. Lomatium tea can be taken three times a day.

Lomatium contains a resin that can cause a painful rash in some people. To avoid this rash, people can use "lomatium isolates," which are extracts with the resins removed. The extract can be taken at a dosage of 1–3 ml each day. In tincture form, the daily dosage is generally 10–30 drops taken one to four times per day. Children who are ill with colds or flu can be given lomatium capsules.

Precautions

Before beginning herbal treatment, people should consult a physician or health practitioner. A knowledgeable herbalist can give advice about dosages. Consultation is important because high doses of lomatium can cause nausea and an itchy rash that covers the entire body. Lower doses can also cause rash in people who are sensitive to lomatium resin. A person should first take a small amount of tincture to test for a rash reaction. The rash will go away in one to six days after discontinuing use of lomatium.

Lomatium and other herbal remedies are not regulated by the United States Food and Drug Administration (FDA) in the same way that prescription drugs are regulated. This difference means that the effectiveness of lomatium has not been scientifically tested. In addition, supplements are not standard in their ingredients or dosages. Women who are pregnant or nursing should not use lomatium, because its safety for these conditions has not been determined.

Side effects

Although lomatium is generally believed to be safe, the herb has been reported to cause a skin rash. A high dosage of the herb may result in **nausea**.

Interactions

Lomatium has been reported to potentiate (intensify the effects of) two groups of drugs, anticoagulants (blood thinners) and immunostimulants (drugs given to boost the immune system).

Lomilomi

Definition

The term Lomilomi literally means "to break up into small pieces with the fingers." It is a type of healing massage that is traditionally practiced in the Hawaiian Islands. Lomilomi is also called "loving hands" massage.

Origins

This form of massage incorporates both physical and spiritual ritual components. Lomilomi originated in the South Pacific and is practiced mainly in the Hawaiian islands, although in the 2000s, lomilomi had grown in popularity and practitioners could also be found in most other states, as well as Australia, Canada, Japan, and the United Kingdom.

When Captain Cook and other European explorers disembarked on the islands of Polynesia, the indigenous people healed their aches and pains with therapeutic massage. Experts in lomilomi also knew how to use it in **childbirth** and to treat congestion, inflammation, rheumatism and other musculoskeletal disorders, **asthma**, and **bronchitis**. They also applied lomilomi to babies and children to strengthen them and mold their features for physical beauty.

In times past, lomilomi was practiced mainly among family members. There were various orders of medical priests, known as kahunas. The one who specialized in massage was the kahuna lomilomi. One member of the family would be trained by a village kahuna. This person would then pass the training on to the next generation. Kahunas trained practitioners in the physical aspects of massage, and they taught that an important aspect of the healing process is the transfer of positive thoughts from the lomilomi practitioner to the client in a way that channels energy, called mana or life force and releases a sense of well being. One goal of lomilomi is to unblock energy flow and allow it to move in a new direction. Unlike traditional lomilomi practitioners, some modern practitioners tend to concentrate more on the physical rather than the spiritual aspects of this therapy.

The best-known school for training lomilomi practitioners was run by Margaret Machado, known to her students as Aunty Margaret, on the island of Hawaii. Machado was born in the early 1900s and learned traditional lomilomi techniques from her grandfather. Her daughter, Nerita Machado, continued the family lomilomi teaching tradition.

Benefits

Lomilomi cleanses and relaxes the body, both physically and spiritually in order to achieve internal harmony. It increases circulation, relaxes tension spots, and relieves **pain**.

Description

A lomilomi massage generally begins with clients relaxing on a table and opening themselves to a

healing state of mind. Some practitioners begin by using heated lomi stones to increase blood flow to certain areas of the body.

The traditional stroke of the lomilomi practitioner is out and away from the body. This touch is both deep and gentle, resembling in some ways **Swedish massage**. Unlike Swedish massage, however, lomilomi practitioners use their elbows and forearms and incorporate some vigorous deep tissue techniques. The forearm movement is typically applied across the grain of the long muscles of the back. There is no set pattern to the massage.

Sometimes lomi sticks are used to relieve facial tension or when deeper massage is needed in a specific part of the body. Lomilomi practitioners traditionally used indigenous oils prepared from coconut and leuki trees. The oil is worked into the skin in a rhythmic 1-2-3, 1-2-3, 1-2-3 movement. At its best, lomilomi releases healing energy that flows from the practitioner to the client.

Modern lomilomi massage varies in the length of time spent with the client time and may dispense with many of the traditional ritual preparations. Costs of this therapy are not typically covered by insurance. Many of the luxury resorts and spas in Hawaii have a practitioner trained in lomilomi on their staff.

Preparations

In traditional lomilomi, the client may drink herbal teas to cleanse the body internally before the massage. The body is also cleansed externally with red clay or salt. In some cases time is alternated between a steam hut and plunges in cold water to increase circulation before beginning the massage. Much of this preparation is dispensed with by modern practitioners.

Precautions

There are no particular precautions to be observed when receiving this therapy. Like many therapies, lomilomi is most effective when the client is in a receptive frame of mind to accept healing.

Side effects

No undesirable side effects had been reported as of 2008. Most clients report feel a reduction in **stress** and a general sense of well being. Others report specific relief of pains such as headaches and backaches.

Research and general acceptance

There are relatively few practitioners of lomilomi, so little controlled research had been done on its effectiveness as of the late 2000s. However, lomilomi has been an accepted part of native Hawaiian culture for hundreds of years.

KEY TERMS

Kahuna—A traditional Hawaiian village leader responsible for physical and spiritual healing; some specialize in herbs, others in massage.

Training and certification

The Hawaiian Lomilomi Association offers certification to practitioners who have received training from any of their approved lomilomi instructors. There are three levels of certification, each of which requires an increased amount of instruction and supervised experience. These certification levels are certified lomilomi therapist, licensed lomilomi therapist, and lomilomi clinical practitioner. This last category requires a 10-year apprenticeship under an approved advanced master lomilomi practitioner and 20 years of experience. Hawaii also has licensing requirements that massage therapists are required to meet.

Lou Gehrig's disease

Definition

Lou Gehrig's disease, or amyotrophic lateral sclerosis (ALS), is a neurodegenerative disease of unknown cause that breaks down tissues in the nervous system and affects the nerves responsible

for movement. Its common name comes from the professional baseball player whose career was ended because of it.

Description

Lou Gehrig's disease is a disease of the motor neurons, those nerve cells reaching from the brain to the spinal cord (upper motor neurons) and the spinal cord to the peripheral nerves (lower motor neurons) that control muscle movement. In Lou Gehrig's disease, for unknown reasons, these neurons die, leading to a progressive loss of the ability to move virtually any of the muscles in the body. The disease affects "voluntary" muscles, those controlled by conscious thought, such as the arm, leg, and trunk muscles. Lou Gehrig's disease, in and of itself, does not affect sensation, thought processes, the heart muscle, or the "smooth" muscle of the digestive system, bladder, and other internal organs. Most sufferers retain function of their eye muscles, as well.

"Amyotrophic" refers to the loss of muscle bulk, a cardinal sign of ALS. "Lateral" indicates one of the regions of the spinal cord affected, and "sclerosis" describes the hardened tissue that develops in place of healthy nerves. Lou Gehrig's disease affects approximately 50,000 people in the United States, with about 5,000 new cases each year. The onset usually begins between the ages of 40 and 70, although younger onset is possible. Men have a slightly higher chance of developing the disease than women.

Causes and symptoms

Causes

The symptoms of Lou Gehrig's disease are caused by the death of motor neurons in the spinal cord and brain. Normally, these neurons convey electrical messages from the brain to the muscles to stimulate movement in the arms, legs, trunk, neck, and head. As motor neurons die, the muscles cannot be moved as effectively, and weakness results. In addition, lack of stimulation leads to muscle wasting, or loss of bulk. Involvement of the upper motor neurons causes spasms and increased tone in the limbs, and abnormal reflexes. Involvement of the lower motor neurons causes muscle wasting and twitching (fasciculations).

Although many causes of motor neuron degeneration have been suggested for Lou Gehrig's disease, none has yet been proven responsible. Results of recent research have implicated toxic molecular fragments known as free radicals. Some evidence suggests that a cascade of events leads to excess free radical production inside motor neurons, leading to their death. Why free radicals should be produced in excess amounts is unclear, as is whether this excess is the cause or the effect of other degenerative processes. Additional agents within this toxic cascade may include excessive levels of a neurotransmitter known as glutamate, which may overstimulate motor neurons, thereby increasing free-radical production, and a faulty **detoxification** enzyme known as SOD–1, for superoxide dismutase type 1. The actual pathway of destruction is not known, however, nor is the trigger for the rapid degeneration that marks Lou Gehrig's disease. Further research may show that other pathways are involved, perhaps ones even more important than this one. Autoimmune factors or premature **aging** may play some role, as could viral agents or environmental toxins.

Two major forms of ALS are known: familial and sporadic. Familial Lou Gehrig's disease accounts for about 10% of all Lou Gehrig's disease cases. As the name suggests, familial Lou Gehrig's disease is believed to be caused by the inheritance of one or more faulty genes. About 15% of families with this type of Lou Gehrig's disease have mutations in the gene for SOD–1. SOD–1 gene defects are dominant, meaning only one gene copy is needed to develop the disease. Therefore, a parent with the faulty gene has a 50% chance of passing the gene along to a child. Sporadic Lou Gehrig's disease has no known cause. While many environmental toxins have been suggested as causes, to date no research has confirmed any of the candidates investigated, including aluminum and metal dental fillings. As research progresses, it is likely that many cases of sporadic Lou Gehrig's disease will be shown to have a genetic basis, as well. A third type, called Western Pacific Lou Gehrig's disease occurs in Guam and other Pacific islands. This form of the disease combines symptoms of both ALS and Parkinson's disease.

KEY TERMS

Aspiration—Inhalation of food or saliva.

Bulbar muscles—Muscles of the mouth and throat responsible for speech and swallowing.

Fasciculations—Involuntary twitching of muscles.

Motor neuron—A nerve cell that controls a muscle.

Voluntary muscle—A muscle under conscious control; contrasted with smooth muscle and heart muscle.

Symptoms

The earliest sign of Lou Gehrig's disease is most often weakness in the arms or legs, at first usually more pronounced on one side than the other. Loss of function is usually more rapid in the legs among people with familial Lou Gehrig's disease, and in the arms among those with sporadic Lou Gehrig's disease. Leg weakness may first become apparent by an increased frequency of stumbling on uneven pavement, or an unexplained difficulty climbing stairs. Arm weakness may lead to difficulty grasping and holding a cup, for instance, or loss of dexterity in the fingers.

Less often, the earliest sign of Lou Gehrig's disease is weakness in the *bulbar* muscles, those muscles in the mouth and throat that control chewing, swallowing, and speaking. A person with bulbar weakness may become hoarse or tired after speaking at length, or speech may become slurred.

In addition to muscle weakness, the other cardinal signs of Lou Gehrig's disease are muscle wasting and persistent twitching, which is known as fasciculation. These are usually noticed after weakness in muscles becomes obvious. Fasciculation is also common in people without the disease, and is virtually never the first sign of Lou Gehrig's disease.

While initial weakness may be limited to one region, Lou Gehrig's disease almost always progresses rapidly to involve virtually all the voluntary muscle groups in the body. Later symptoms include loss of the ability to walk, to use the arms and hands, to speak clearly or at all, to swallow, and to hold the head up. Weakness of the respiratory muscles makes breathing and coughing difficult, and poor swallowing control increases the likelihood of inhalation of food or saliva (aspiration). Aspiration increases the likelihood of lung infection, which is often the cause of death. With a ventilator and scrupulous bronchial hygiene, a person with Lou Gehrig's disease may live much longer than the average, although weakness and wasting will continue to erode any remaining functional abilities. Most people with Lou Gehrig's disease continue to retain function of the extraocular muscles that control movement of the eyes, allowing some communication to take place with simple blinks or through use of a computer–assisted device.

Diagnosis

The diagnosis of Lou Gehrig's disease begins with a complete medical history and physical exam, plus a neurological exam to determine the distribution and extent of weakness. An electrical test of muscle function, called an electromyogram, or EMG, is an important part of the diagnostic process. Various other tests, including blood and urine tests, x rays, and CT scans, may be done to rule out other possible causes of the symptoms, such as tumors of the skull base or high cervical spinal cord, thyroid disease, spinal arthritis, **lead poisoning**, or severe vitamin deficiency. Lou Gehrig's disease is rarely misdiagnosed following a careful review of all these factors.

Treatment

There is no cure for Lou Gehrig's disease, and no treatment that can significantly alter its course. There are many things that can be done, however, to help maintain quality of life and to retain functional ability even in the face of progressive weakness.

Two studies published in 1988 suggested that amino–acid therapies may provide some improvement for some people with Lou Gehrig's disease. While individual patient reports claim benefits for megavitamin therapy, herbal medicine, and removal of dental fillings, for instance, no evidence suggests that these offer any more than a brief psychological boost, often followed by a more severe letdown when it becomes apparent the disease has continued unabated. However, once the causes of Lou Gehrig's disease are better understood, alternative therapies may be researched more intensively. For example, if damage by free radicals turns out to be the root of most of the symptoms, antioxidant vitamins and supplements may be used more routinely to slow the progression of Lou Gehrig's disease. Or, if environmental toxins are implicated, alternative therapies with the goal of detoxifying the body may be of some use. In 2002, the Food and Drug Administration (FDA) granted approval for one company to begin trials on use of **creatine**, an amino acid dietary supplement, to treat ALS. Preliminary data from trials show that creatine might slow progression of Lou Gehrig's disease, but research remains to be completed before approval of the supplement for treatment of ALS.

A physical therapist works with the patient and family to implement **exercise** and stretching programs to maintain strength and range of motion, and to promote general health. Swimming may be a good choice for people with Lou Gehrig's disease, as it provides a low–impact workout to most muscle groups. One result of chronic inactivity is contracture, or muscle shortening. Contractures limit a person's range of motion, and are often painful. Regular stretching can prevent contracture.

An occupational therapist can help design solutions for movement and coordination problems, and

provide advice on adaptive devices and home modifications. Speech and swallowing difficulties can be minimized or delayed through training provided by a speech-language pathologist. This specialist can also provide advice on communication aids, including computer-assisted devices and simpler word boards. Nutritional advice can be provided by a nutritionist. A person with Lou Gehrig's disease often needs softer foods to prevent jaw exhaustion or choking. Later in the disease, **nutrition** may be provided by a gastrostomy tube inserted into the stomach.

Allopathic treatment

As of early 2002, only one drug had been approved for treatment of Lou Gehrig's disease. Riluzole (Rilutek) appears to provide on average a three-month increase in life expectancy when taken regularly early in the disease, and shows a significant slowing of the loss of muscle strength. Riluzole acts by decreasing glutamate release from nerve terminals. Experimental trials of nerve growth factor have not demonstrated any benefit. No other drug or vitamin currently available has been shown to have any effect on the course of Lou Gehrig's disease. However, in 2002, researchers had identified how a common drug prescribed for **acne** could slow the progression of cell death in the brain that causes ALS. The drug, called minocycline, can safely be taken orally. Scientists are now working on a combination of minocycline with other drugs to better target a more powerful therapy for Lou Gehrig's disease patients.

Mechanical ventilation may be used when breathing becomes too difficult. Modern mechanical ventilators are small and portable, allowing a person with Lou Gehrig's disease to maintain the maximum level of function and mobility. Ventilation may be administered through a mouth or nose piece, or through a tracheostomy tube. This tube is inserted through a small hole made in the windpipe. In addition to providing direct access to the airway, the tube also decreases aspiration. While many people with rapidly progressing Lou Gehrig's disease choose not to use ventilators for lengthy periods, they are increasingly used to prolong life for a short time.

The progressive nature of Lou Gehrig's disease means that most patients will eventually require full-time nursing care. This care is often provided by a spouse or other family member. While the skills involved are not difficult to learn, the physical and emotional burden of care can be overwhelming. Caregivers need to recognize and provide for their own needs, as well as those of the patient, to prevent **depression** and burnout. Throughout the disease, a support group can provide important psychological aid to the patient, and also act as a caregiver as they come to terms with the losses that Lou Gehrig's disease inflicts. Support groups are sponsored by both the Lou Gehrig's Disease Society and the Muscular Dystrophy Association.

Expected results

Lou Gehrig's disease usually progresses rapidly, and leads to death from respiratory infection within three to five years in most cases. The slowest disease progression is seen in those who are young and have their first symptoms in the limbs. About 10% of people with Lou Gehrig's disease live longer than eight years.

Prevention

There is no known way to prevent Lou Gehrig's disease or to alter its course.

Low back pain

Definition

Low back **pain** (LBP) is a common complaint, second only to cold and flu as a reason why patients seek care from their family doctor. It may be a limited musculoskeletal symptom or caused by a variety of diseases and disorders that affect or extend from the lumbar (lower) spine. Low back pain is sometimes accompanied by **sciatica**, which is pain that involves the sciatic nerve and is felt in the lower back, the buttocks, the backs and sides of the thighs, and possibly the calves. More serious causes of LBP may be accompanied by **fever**, night pain that awakens a person from sleep, loss of bladder or bowel control, numbness, burning urination, swelling, or intense sharp pain.

Description

Low back pain is a symptom that affects 80% of Americans at some point in their life with sufficient severity to cause absence from work. It is a common reason for visits to primary care doctors, and is estimated to cost the U.S. economy more than $100 billion every year in lost wages, lost productivity, and direct healthcare costs. About one-third of the nation's disability-related costs are associated with LBP, a condition primarily affecting individuals between the ages of 30 and 50.

The most common cause of low back pain is lumbar strain. The structures of the normal lumbar region of the spine include the lumbar vertebrae, discs between each vertebrae, ligaments, muscles and muscle tendons, the spinal cord within the vertebrae and nerves extending outward from the spine through vertebral foramina (openings in the bone). The lumbar vertebrae are distinct from the cervical (neck area) and thoracic (upper back) vertebrae, being generally thicker for greater weight bearing support, and resting atop the sacrum (tailbone), the triangular shaped bone between the buttocks.

The discs between each vertebrae of the spine cushion and absorb the shock that might otherwise be transmitted through the spine. Occasionally, the discs may rupture or herniate outward through their fibrous sheath, or covering, putting pressure on the nerves. Nerve pressure on the sciatic nerve (sciatica) may be the cause of or add to LBP. Nerve pain from other local organs may also cause LBP, in which case diagnosis and treatment is more involved, usually much more serious, and may indicate a life-threatening condition.

Risks for low back pain are increased with fracture and **osteoporosis**, narrowing of the spinal canal within the vertebrae (stenosis), spinal curvatures, **fibromyalgia**, osteo- and **rheumatoid arthritis**, **pregnancy**, **smoking**, **stress**, age greater than 30, or disease or illness of the organs of the lower abdomen.

In addition to dividing low back pain into three categories based on duration of symptoms—acute, sub-acute or chronic—low back pain may be described in the following terms:

- Localized. In localized pain the patient feels soreness or discomfort when the doctor palpates, or presses on, a specific surface area of the lower back.
- Diffuse. Diffuse pain is spread over a larger area and comes from deep tissue layers.
- Radicular. The pain is caused by irritation of a nerve root and radiates from the area. Sciatica is an example of radicular pain.
- Referred. The pain is perceived in the lower back, but actually is caused by inflammation or disease elsewhere, such as the kidneys or other structures of or near the lower abdomen, including the intestines, appendix, bladder, uterus, ovaries or the testes.

Causes and symptoms

Acute and sub-acute pain

Lumbar strain or sprain is the most common cause of acute low back pain. The pain usually does not extend into the leg and usually occurs within 24 hours of heavy lifting or overuse of the back muscles. The pain is often localized and may be accompanied by **muscle spasms** or soreness to touch. The patient usually feels better when resting. Symptoms of acute LBP may be accompanied by stiffness (guarding), **constipation**, poor sleep and trouble finding a comfortable position, difficulties walking and other limits on normal range of motion.

Acute strain may follow a sudden movement, especially a lifting and simultaneous twisting motion; however, injury is usually preceded by overuse or lack of **exercise** and tone, especially of the opposing muscles (the abdominals, for example), improper use, long periods of sitting or standing in one position, poor vertebral alignments or conditions compromising **nutrition** of the supportive structures. Acute low back pain due to lumbar strain (approximately 60% of sufferers) usually resolves with a week with conservative therapies, including reducing but not eliminating all activity.

Sub-acute pain is associated with a duration of six to twelve weeks, by which time 90% of individuals

experiencing low back pain and injury return to work. This category accounts for one-third of all disability-related costs. LBP persisting beyond three months is considered chronic.

Chronic pain

Chronic low back pain has several possible causes.

MECHANICAL. Chronic strain on the muscles of the lower back may be caused by **obesity**, pregnancy, or job-related stooping, bending, or other stressful postures. Construction, truck driving accompanied by vibration, jack hammering, sand blasting and other sources of chronic trauma strain to the back or nerve pressure may also contribute.

MALIGNANCY OR OTHER SERIOUS ILLNESS. Low back pain at night that is not relieved by lying down may be caused by a tumor in the cauda equina (the roots of the spinal nerves controlling sensation in and movement of the legs) or metastasized **cancer** that has spread to the spine from the prostate, breasts, or lungs. The risk factors for the spread of cancer to the lower back include a history of smoking, sudden weight loss, and age over 50. Kidney problems, such as **kidney stones**; ovarian and uterine problems, including fibroids; **endometriosis**; premenstrual water retention; and **ovarian cysts**; chronic constipation; sluggish or enlarged colon; benign tumors; bone **fractures**; aneurysm of the aorta; herpes zoster **shingles**; intra-abdominal infection or bleeding secondary to Coumadin therapy; osteomyelitis; **tuberculosis** of the spine (Pott's disease); and sepsis of the vertebral discs, all may be associated with pain to the lower back. Additional symptoms may include night sweats, being awakened at night by pain, weakness, numbness, muscle fatigue or poor coordination which progressively worsens, burning on urination, redness or swelling over the area of pain, changes in bowel or urinary patterns, and malaise.

ANKYLOSING SPONDYLITIS. **Ankylosing spondylitis** is a form of arthritis that causes chronic pain in the back. The pain is made worse by sitting or lying down and improves when the patient stands up. It is most commonly seen in males between the ages of sixteen and thirty-five. Ankylosing spondylitis is often confused with mechanical back pain in its early stages. Other symptoms include morning stiffness, a positive family history, and positive lab results for HLA-B27 antigen (an autoimmune marker), and an increased sedimentation (Sed) rate of the blood. This condition may have food allergy-related components, such as an allergy to wheat, worsened by drinking beer.

HERNIATED SPINAL DISC. Disc herniation is a disorder in which a spinal disc begins to bulge outward between the vertebrae. Herniated or ruptured discs are a common cause of chronic low back pain in adults. Pressure imposed on adjacent nerves results in pain that may worsen with movement, coughing, **sneezing**, or intra-abdominal strain, and may be accompanied by numbness of the skin in the area served by the nerve (dermatome). Deep tendon reflexes (DTRs) may be reduced, and the straight leg raising test may be positive. The crossed straight leg raising test, which is more specific to herniated disc, may also be positive.

PSYCHOGENIC. Back pain that is out of proportion to a minor injury or that is unusually prolonged may be associated with a somatoform disorder or other emotional disturbance. Psychosocial factors such as loss of work, job dissatisfaction, legal problems, and financial compensation issues are some of the non-organic factors that may be associated or causative. Psychogenic symptoms of LBP are usually diffuse, non-localized, and may include other stress related symptoms. A set of five tests called the Waddell tests may be used to help diagnose LBP of psychogenic origin.

Low back pain with leg involvement

Low back pain that radiates down the leg usually indicates involvement of the sciatic nerve. The nerve can be pinched or irritated by herniated discs, tumors of the cauda equina (the nerve roots of the spine), abscesses in the space between the spinal cord and its covering, spinal stenosis, and compression fractures. Some patients experience numbness or weakness of the legs, as well as pain. There may be spasming of muscles stimulated by the involved nerve and a positive leg raising test.

Diagnosis

The diagnosis of low back pain can be complicated. Most cases are initially evaluated by primary care physicians or other health practitioners, rather than by specialists.

Initial workup

PATIENT HISTORY. The doctor will ask the patient specific questions about the location of the pain, its characteristics, its onset, and the body positions or activities that make it better or worse. If the pain seems to be referred from other organs, the doctor may ask about a history of diabetes, peptic ulcers, kidney stones, urinary tract **infections**, heart murmurs, or other health issues. Age, family history, and

previous medical history are also important. LBP in persons younger than 20 and older than 50 is apt to be associated with a more severe underlying condition or cause.

PHYSICAL EXAMINATION. The doctor will examine the patient's back and hips to check for conditions that require surgery or emergency treatment. The examination includes several tests that involve moving the patient's legs in specific positions to test for nerve root irritation or disc herniation. The flexibility of the lumbar vertebrae may be measured to rule out ankylosing spondylitis. Other physical tests include assessments of gait and posture, range of motion, and the ability to perform certain physical positions and coordinated movements. Reflex, sensory, and motor tests may help the clinician screen for referral to a specialist, as needed. Diagnostic tests may be used, especially with persisting, chronic pain. These tests may include x ray, CT scan, MRI, and electromyelographs (EMGs).

RED FLAGS. The presence of certain symptoms warrants a more rapid progress to deeper diagnostic examination as to cause. These serious symptoms include, but are not limited to the following:

- pain following violent injury, accident, or trauma
- constant pain that worsens
- upper spinal pain
- history of cancer
- being HIV positive
- history of steroid drug use or drug abuse
- development of an obvious structural deformity
- history of rapid weight loss
- unexplained fever or night sweats with back pain
- being under age 20 or over age 50

Treatment

A thorough differential diagnosis is important before any treatment is considered. There are times when alternative therapies may be most beneficial, and other times when more invasive treatments are needed.

Chiropractic

Chiropractic treats patients by manipulating or adjusting sections of the spine. It is one of the most popular forms of alternative treatment in the United States for relief of back pain caused by straining or lifting injuries and has been demonstrated through several rigorous randomized trials to be beneficial. Some osteopathic physicians, physical therapists, and naturopathic physicians also use spinal manipulation to treat patients with low back pain, along with work on soft tissue around the bones. Additional recommendations of shoe orthotics, exercise, cold packs to reduce and inhibit swelling immediately after injury, followed one to two days later by hot packs and cold packs to stimulate healing, **hydrotherapy**, and lifestyle adjustments may be recommended. Nutritional supplements known to be beneficial to joint repair and integrity, collagen support, and wound repair may also be recommended, including **glucosamine** sulfate, with or without **chondroitin**, methylsulfonylmethane(**MSM**), and a variety of mineral and vitamin cofactors.

Traditional Chinese medicine

Practitioners of **traditional Chinese medicine** treat low back pain with **acupuncture**, **acupressure**, massage, and the application of herbal poultices. They may also use a technique called **moxibustion**, which involves the use of glass cups, and heated air from a burning braid or stick of herb with a distinctive aroma.

Herbal medicine and anti-inflammatory enzymatic therapy

Herbal medicine uses a variety of antispasmodic and sedative herbs to help relieve low back pain due to spasm. For this purpose and easily available at a local health food store are herbs such as **chamomile** (*Matricaria recutita*), **hops** (*Humulus lupus*), passion flower (*Passiflora incarnata*), valerian (*Valeriana officinale*), and cramp bark (*Viburnum opulus*). **Bromelain** from pineapples has anti-inflammatory activity. Drinking fresh grape juice, preferably made from dark grapes, on a daily basis at a time other than mealtime, has also been found to be helpful. Minor backaches may be relieved with the application of a heating paste of **ginger** (*Zingiber officinale*) powder and water, allowed to sink in for 10 minutes and followed by an **eucalyptus** rub.

Aromatherapy with soothing **essential oils** of blue chamomile, birch, **rosemary**, and/or **lavender** can be effective when rubbed into the affected area after a hot bath.

Homeopathy

Homeopathic treatment for acute back pain consists of various applications of **Arnica** (*Arnica montana*); as an oil or gel applied topically to the sore area or oral doses alone or in prepackaged combination products, including other homeopathic remedies such as St. John's wort (*Hypericum perforatum*), Rhus tox (*Rhus toxicodendron*) and **Ruta** (*Ruta graveolens*). *Bellis perennis* may be recommended for deep muscle injuries.

Other remedies may be recommended based on the symptoms presented by the patient.

Body work and yoga

Massage and numerous other body work techniques can be very effective in treating low back pain. **Yoga**, practiced regularly and done properly, can be combined with **meditation** or imagery to both treat present and prevent future episodes of low back pain.

Allopathic treatment

All forms of treatment of low back pain are aimed either at symptom relief or to prevent interference with the processes of healing. None of these methods appears to speed up healing.

Acute pain

Acute back pain is treated with muscle relaxants or nonsteroidal anti-inflammatory drugs (NSAIDs), such as ibuprofen or aspirin. Applications of compresses using heat or cold also can be helpful to some patients. Acute LBP often resolves within a short time. Some patients may be prescribed opioid analgesics (pain relievers with codeine or codeine similars); however, statistics demonstrate no shortening of the healing period, as noted above. The use of muscle relaxants may increase risk of further damage, but they have been shown to be more effective than placebo (though no better than NSAIDS alone) in relieving acute pain. If the patient has not experienced some improvement after several weeks of treatment, the doctor will reinvestigate the cause of the pain.

Chronic pain

Patients with chronic back pain are treated with a combination of medications, physical therapy, and occupational or lifestyle modification. The medications given are usually NSAIDs, although patients with **hypertension**, kidney problems, or stomach ulcers are advised not take these drugs. Patients who take NSAIDs for longer than six weeks are advised to be monitored periodically for complications. Chronic pain, by definition longer than three months in duration, may also prompt a more thorough diagnostic analysis.

Physical therapy for chronic low back pain usually includes regular exercise for fitness and flexibility and massage or application of heat if necessary. Lifestyle modifications include quitting smoking, losing weight (if necessary), and evaluation of the patient's occupation or other customary activities. Good lift and bend mechanics may also be reviewed and counseled.

Patients with herniated discs may be treated surgically if the pain does not respond to medication. Vertebral fusion surgery may stiffen the spine; however, engineers of skyscrapers recognize the need of flexibility with height to preserve wind resistance: a fused spine may reduce capacity. Another surgical procedure known as kyphoplasty, involving guided penetration of the back and cemented repair, may be indicated in pain due to vertebral fracture. Patients with chronic low back pain sometimes benefit from pain management techniques, including **biofeedback**, acupuncture, and chiropractic manipulation of the spine. **Psychotherapy** is recommended for patients whose back pain is associated with a somatoform, **anxiety**, or depressive disorder.

Low back pain with leg involvement

Treatment of sciatica and other disorders that involve the legs may include NSAIDs. Patients with long-standing sciatica or spinal stenosis that do not respond to NSAIDs may be treated surgically. Although some doctors use cortisone injections in trigger points and vertebral facet joints to relieve the pain, this form of treatment is controversial. Also debated are benefits due to spinal traction and transcutaneous (through the skin) electrical nerve stimulation.

Expected results

The prognosis for most patients with acute low back pain is excellent. About 80% of patients recover completely in four to six weeks. The prognosis for recovery from chronic pain depends on the underlying cause.

Prevention

Low back pain due to muscle strain can be prevented by lifestyle choices, including regular physical exercise, weight control, avoiding smoking, and learning the proper techniques for lifting and moving heavy objects. Exercises designed to strengthen the muscles of the lower back and the opposing abdominals are also recommended. Simple actions can also help prevent low back pain, such as putting a small, firm cushion behind the lower back when sitting for long intervals; using a soft pillow for sleep that supports the lower neck without creating an unnatural angle for the head and shoulders; using a swiveling desk chair with a postural support or stool that maintains the knees at a higher level than the hips; standing on flexible rubber mats to avoid the impact of concrete floors at places of employment; and wearing supportive, soft-soled shoes and avoiding the use of high heels.

KEY TERMS

Ankylosing spondylitis—A type of arthritis that causes gradual loss of flexibility in the spinal column. It occurs most commonly in males between the ages of 16 and 35 and may be initiated by a food allergy component, such as an allergy to wheat.

Cauda equina—The nerve roots in the final portion of the spine, controlling movement and sensation in the legs. These nerve roots resemble a horse's tail.

Chiropractic—A method of treatment based on the interactions of the spine and the nervous system. Chiropractors adjust or manipulate segments of the patient's spinal column in order to relieve pain and increase the healthy flow of nerve energy.

Lumbar spine—The segment of the human spine above the pelvis that is involved in low back pain. There are five vertebrae, or bones, in the lumbar spine.

Osteoporosis—A condition found in older individuals in which bones decrease in density and become fragile and more likely to break. It can be caused by lack of vitamin D and/or calcium in the diet.

Placebo—A pill or liquid given during the study of a drug or dietary supplement that contains no medication or active ingredient. Usually study participants do not know if they are receiving a pill containing the drug or an identical-appearing placebo.

Radicular—Pain that is caused by compression or impingement at the root of a nerve.

Referred pain—Pain that is experienced in one part of the body but originates in another organ or area. The pain is referred because the nerves that supply the damaged organ enter the spine in the same segment as the nerves that supply the area where the pain is felt.

Sciatica—Pain caused by irritation of the sciatic nerve. Sciatica is felt in the lower back, the buttocks, the backs and sides of the upper legs, and sometimes the calves.

Spinal stenosis—Usually the result of arthritis of the spine, causing narrowing of the spinal canal in the lumbar vertebrae. The narrowing puts pressure on the roots of the sciatic nerve. It may cause sciatica, but not necessarily.

Lung cancer

Definition

Lung **cancer** is a disease in which abnormal cells in the lung grow uncontrollably and form tumors. Cells from these tumors can enter the circulatory system and travel through the body to form tumors in new sites. Lung cancer is often fatal; only four in ten people with lung cancer live one year beyond the time of their diagnosis.

Cross section of a human lung with cancer. *(Science Source / Photo Researchers, Inc.)*

Description

There are two types of lung cancer, primary and secondary. Primary lung cancer originates in the lung. Primary lung cancer can further be divided into small cell lung cancer and non-small cell lung cancer, depending on how the cells look under the microscope. Secondary lung cancer is cancer that starts somewhere else in the body (for example, the breast or colon) and spreads (metastasizes) to the lungs.

Small cell lung cancer was formerly called oat cell cancer because the cells resemble oats in their shape. About one-fourth of all lung cancers are small cell cancers. This type of cancer is aggressive and spreads to other organs within a short time. It is found most often in people who are heavy smokers. Its treatment is different from the treatment of non-small cell lung cancers.

Non-small cell lung cancers account for 75% of lung cancers. There are three types of non-small cell lung cancers. Although the cells of the non-small cell cancers look different, treatment of all three types is the same.

Incidence of lung cancer

Since 1987, lung cancer has been the leading cause of cancer death in both men and women in the United States. The American Cancer Society (ACS) estimated that in 2008 about 215,000 new cases of lung cancer would be diagnosed in the United States and approximately 162,000 Americans would die of the disease that year. Worldwide, more than one million new cases of lung cancer are diagnosed each year, 58% of which are in the developing world.

Lung cancer is usually diagnosed in people age 50 and older, with an average age at diagnosis being 60. Most lung cancer is not diagnosed until it is in an advanced stage. While in the United States the incidence of lung cancer has decreased among white men, it has steadily risen among African American men, and among both white and African American women. This change appears to be directly related to changes in the number of smokers in these groups.

Causes and symptoms

Lung cancer is most often caused by pollutants inhaled into the lungs over a long period. There are indications that genetic inheritance also plays a role in how susceptible different people are to these pollutants.

Smoking

Tobacco **smoking** (cigarettes, pipes, cigars) is the leading cause of lung cancer. Ninety percent of lung cancers can be prevented by completely avoiding tobacco use. Smoking **marijuana** cigarettes also is thought to be a risk factor for lung cancer, although it is difficult to obtain accurate information on marijuana use. Marijuana cigarettes have higher tar content than tobacco cigarettes. In addition, they are inhaled very deeply and the smoke is held in the lungs for a longer period than tobacco smoke.

Breathing in smoke from the environment (secondhand smoke) also increases the risk of lung cancer. In the twenty-first century many states have passed laws mandating smoke-free workplaces and public environments in order to protect non-smokers from secondhand smoke.

Exposure to asbestos and toxic chemicals

Repeated exposure to asbestos fibers, either at home or in the workplace, also is considered a risk factor for developing a specific type of rare lung cancer

called mesothelioma. Studies show that compared to the general population, asbestos workers are seven times more likely to die from lung cancer. Asbestos workers who smoke increase their risk of developing lung cancer by 50 to 100 times. Besides asbestos, miners who are exposed to coal products or radioactive ores, such as uranium, and workers exposed to chemicals, such as arsenic, vinyl chloride, mustard gas, and other carcinogens, have a higher than average risk of contracting lung cancer.

Environmental contamination

Exposure to high levels of radon gas increases the risk of developing lung cancer. Radon is a naturally occurring radioactive gas that cannot be seen or smelled. It is produced by the breakdown of uranium. Outdoors, the tiny amounts of radon produced mix with the air and do not present a cancer risk. However, in the basements of some houses that are built over soil containing natural uranium deposits, radon may accumulate and reach dangerous levels. An inexpensive test can detect the presence of indoor radon. Having one's house tested for the presence of radon gas when buying or renting is a good idea and is required by law in some states to be done when a house is sold.

Manmade environmental pollution (e.g., auto exhaust fumes, industrial air pollution) also increases the risk of developing lung cancer. Studies have conclusively linked long-term exposure to fine-particle air pollution with lung cancer deaths. The risk of death from lung cancer is increased substantially for people living in heavily polluted metropolitan areas, particularly in the developing world where the rate of cigarette smoking also is high.

Other causes

Inflammation and scar tissue sometimes are produced in the lung by diseases such as silicosis and berylliosis. These diseases result from inhaling certain minerals, **tuberculosis**, and certain types of **pneumonia**. This scarring may increase the risk of developing lung cancer. Radiation therapy to the chest also increases the risk of lung cancer, especially in people who smoke.

Symptoms

Lung cancers tend to spread very early, but only about 15% are detected in early stages when they are most treatable. Many symptoms of lung cancer are similar to those caused by other diseases. The chance of early detection is improved by promptly seeking medical care if any of the following symptoms appear:

- a cough that does not go away
- chest pain
- shortness of breath
- persistent hoarseness
- swelling of the neck and face
- unintentional significant weight loss
- fatigue and loss of appetite
- bloody or brown-colored spit or phlegm (sputum)
- unexplained fever
- recurrent lung infections, such as bronchitis or pneumonia

If the lung cancer has spread to other organs, the patient may have other symptoms, such as headaches, bone **fractures**, **pain**, bleeding, or **blood clots**.

Diagnosis

Diagnosis begins with a detailed medical and lifestyle history to determine symptoms and assess risk factors. This assessment is followed by a complete physical examination. Among other checks, the doctor will examine the patient's throat to look for other possible causes of hoarseness or coughing and listen to the patient's breathing and the sounds made when the patient's chest and upper back are thumped (percussed). The physical examination usually is inconclusive.

Imaging tests

Based on symptoms and risk factors that give the doctor reason to suspect lung cancer, imaging tests are performed. These usually begin with a chest x ray that can show the presence of any masses in the lungs. Special imaging techniques, such as computed tomography (CT) scans or magnetic resonance imaging (MRI) scans, can provide more precise information about the size, shape, and location of any masses. A special type of computed tomography called spiral CT can detect lung cancer when tumors are smaller than a dime. Routine screening using spiral CT remains controversial because it produces a high number of false positives (detection of an abnormality that turns out not to be cancer). This results in additional unneeded tests and procedures. The National Lung Screening Trial, a large-scale trial of spiral CT technology to detect lung cancer in 50,000 smokers, was conducted between 2002 and 2008. Results, which were expected to be available by 2009, were anticipated to help to clarify whether using this CT spiral technology to routinely screen high-risk individuals produces accurate and cost effective results.

Positron emission tomography (PET) is a diagnostic tool that uses small amounts of radioactive glucose (sugar) to detect where cells are rapidly growing. Cancer cells grow faster than healthy cells and thus use more glucose. Radioactive glucose becomes concentrated in cancer cells and can be detected by special imaging techniques. This procedure is especially helpful in locating very early lung cancers and in determining where more advanced cancers have spread. Some facilities have equipment that performs a simultaneous PET and CT scan.

Sputum analysis

Sputum analysis involves microscopic examination of the cells that are either coughed up from the lungs or are collected through a special instrument called a bronchoscope. Sputum analyses can diagnose at least 30% of lung cancers, some of which are in the very earliest stages and do not show up on chest x rays. The sputum test does not, however, provide any information about the location of the tumor and must be followed by additional tests.

Lung biopsy

Lung biopsy is the definitive diagnostic tool for cancer. It can be performed in several different ways. The doctor can perform a bronchoscopy, which involves the insertion of a slender, lighted tube, called a bronchoscope, down the patient's throat and into the lungs. In addition to viewing the passageways of the lungs, the doctor can use the bronchoscope to obtain samples of the lung tissue. In another procedure known as a needle biopsy, the location of the tumor first is identified using a CT scan or MRI. The doctor then inserts a needle through the chest wall and collects a sample of tissue from the tumor. In a third procedure, known as surgical biopsy, the chest wall is opened and a part of or the entire tumor is removed. A doctor who specializes in the study of diseased tissue (a pathologist) examines the tumor samples to identify the cancer's type and stage.

Treatment

Alternative therapies do not replace conventional treatment but may complement it and improve the patient's quality of life. Before beginning any alternative therapy, lung cancer patients should consult their doctors concerning the appropriateness if treatment and its role in an overall cancer treatment plan. Appropriate alternative treatments may help prolong a patient's life, improve the quality of life, reduce the recurrence of tumors, prolong time in remission, or reduce adverse reactions to chemotherapy and radiation.

Dietary guidelines

The following dietary changes may help improve a patient's quality of life, as well as boost the immune function to better fight the disease. In general, these dietary guidelines are accepted by both alternative and conventional medical practitioners.

- Avoid fatty and spicy foods. A high-fat diet may be associated with increased risk of lung and other cancers. Also, lung cancer patients may have a hard time digesting greasy foods.
- Eat new and interesting foods. Tasty foods stimulate appetite so that patients can eat more and have the energy to fight cancer.
- Increase consumption of fresh fruits and vegetables. They are the best sources of antioxidants, vitamins, and minerals. Especially helpful are the yellow and orange fruits (orange, cantaloupes) and dark green vegetables.
- Eat more broccoli sprouts. These young sprouts are a good source of sulforaphane, a substance thought to help fight lung cancer.
- Eat many (5–6) small meals per day. Small meals are easier to digest.
- Establish a regular eating time and avoid eating around bedtime.
- Avoid foods containing preservatives or artificial coloring.
- Monitor weight and intake of adequate calories and protein.

Nutritional supplements

Many cancer-fighting claims are made for nutritional supplements. However, the effectiveness of some conventional anticancer drugs used to treat lung cancer can be reduced when patients take megadoses of **antioxidants** or other supplements. Free radicals damage DNA, and sometimes this damage leads to the development of cancer. In laboratory cell cultures and animal studies, antioxidants appear to slow the development of cancer. The results have been mixed in studies in which humans took antioxidant dietary supplements. In a large study of 29,000 men, when a beta-carotene dietary supplement, which the body converts into **vitamin A**, was taken by men who smoked, they developed lung cancer at a rate 18% higher and died at a rate 8% higher than men who were taking a placebo.

Another study that gave men dietary supplements of beta-carotene and vitamin A was stopped when researchers found the men receiving the beta-carotene had a 46% greater chance of dying from lung cancer

than those who were given a placebo. Other large studies have shown either no or only slight protective effects against cancer. The position of the American Cancer Society, the National Cancer Institute, and several international health organizations is that antioxidants should come from a healthy diet high in fruits and vegetables and low in fat and not from dietary supplements. Cancer patients should check with their physicians before beginning any herbal or megadose vitamin or mineral therapy.

Most dietary supplements claim to help fight cancer by boosting the function of the immune system. A naturopath may recommend some of the following nutritional supplements to boost immune function and help fight tumor progression:

- Vitamins and minerals. Vitamins that are considered particularly beneficial to cancer patients include B-complex vitamins, especially vitamins B_6, along with vitamins C, D, E, and K. The most important minerals are calcium, chromium, copper, iodine, molybdenum, germanium, selenium, tellurium, and zinc. Many of these vitamins and minerals are strong antioxidants or cofactors for antioxidant enzymes. However, patients should not take megadoses of these supplements without first consulting their doctors. Significant adverse or toxic effects may occur at high dosages, which is especially true for the minerals.
- Other nutritional supplements may help fight cancer and support the body. They include essential fatty acids (fish or flaxseed oil), flavonoids, pancreatic enzymes (to help digest foods), hormones such as DHEA, melatonin, or phytoestrogens. Again, some of these supplements may interfere with specific conventional cancer treatments and should not be taken without consulting a physician knowledgeable about both conventional and alternative therapies.

Traditional Chinese medicine

Conventional treatment for lung cancer is associated with significant side effects. These adverse effects (such as **nausea**, **vomiting**, and **fatigue**) can be reduced with Chinese herbal preparations. Patients should consult an experienced herbalist who will prescribe remedies to treat specific symptoms that are caused by conventional cancer treatments.

Daily consumption of a soup used in **traditional Chinese medicine** is reported to have helped slow the progression of non-small cell lung cancer for patients with advanced stages of the disease. The soup consisted of herbs and vegetables containing natural ingredients that boost immunity and help fight tumors. Patients should check with their doctors and with a licensed traditional Chine medicine specialist for more information. The soup does not prevent or reverse the disease, but may prolong survival.

Juice therapy

Juice therapy involves the consumption of the juice of raw fruit or vegetables. A person may drink juice preventively to stay healthy or to treat a medical condition such as cancer. Juice therapy may be helpful for patients with cancer. Advocates of **juice therapies** maintain that refraining from eating solid food boosts the body's ability to heal itself. Since the body is not spending time and energy on digesting complex high-fat food, it can concentrate on healing instead. Advocates also believe that all-juice **diets** can help the body eliminate toxins (poisons).

The most extreme form of juice therapy for cancer is the Gerson juice therapy diet. The **Gerson therapy** treatment is based on drinking freshly pressed vegetable and fruit juice every hour. During a typical day at a Gerson clinic, a person would drink 13 glasses of raw carrot/apple and green-leaf vegetable juices. Vegetarian meals of organically grown food are served. During treatment, the patient receives coffee enemas during the evening to detoxify the blood and tissues. This treatment is administered in only two clinics, one in California and the other in Mexico. Critics of the Gerson diet say that it has many dangerous side effects, including dehydration, electrolyte imbalance, **constipation**, infection, poor resistance to disease, excessive weight loss, inflammation of the colon, and in some cases even death and that it does not cure cancer.

Homeopathy

There is conflicting evidence regarding the effectiveness of **homeopathy** in cancer treatment. Because cancer chemotherapy may suppress the body's response to homeopathic treatment, homeopathy may not be effective during chemotherapy. Therefore, patients should wait until after chemotherapy to try this relatively safe alternative treatment.

Acupuncture

Acupuncture uses needles inserted into the body to stimulate or direct the meridians (channels) of energy flow. Acupuncture has not been shown to have any anticancer effects. However, for some individuals it is an effective treatment for nausea and other unpleasant side effects of chemotherapy and radiation.

Other treatments

Other alternative treatments include **stress** reduction, **meditation**, **yoga**, t'ai chi, and the use of **guided imagery**. These techniques help the individual cope with cancer and improve quality of life, but do not have any curative effects.

Allopathic treatment

Treatment for lung cancer depends on the type of cancer, its location, and its stage. Treating the cancer early is key. The most commonly used modes of treatment are surgery, radiation therapy, and chemotherapy. Often these treatments are used in combination.

Surgery

Surgery is not usually an option for small cell lung cancers because most have spread beyond the lung by the time they are diagnosed. Because non-small cell lung cancers are less aggressive, however; surgery sometimes can be used to treat them. The surgeon decides on the type of surgery depending on how much of the lung is affected. Surgery may be the primary method of treatment, or radiation therapy and/or chemotherapy may be used to shrink the tumor before surgery is attempted.

There are three different types of surgical operations:

- Wedge resection. This procedure involves removing a small part of the lung.
- Lobectomy. A lobectomy is the removal of one lobe of the lung. If the cancer is limited to one part of the lung, the surgeon will perform a lobectomy.
- Pneumonectomy. A pneumonectomy is the removal of an entire lung. If the surgeon feels that removal of the entire lung is the best option for curing the cancer, a pneumonectomy is performed.

The pain that follows surgery can be relieved by medications. A more serious side effect of surgery is the patient's increased vulnerability to bacterial and viral **infections**. Preventative antibiotics and sometimes antiviral medications are given after surgery.

Radiation therapy

Radiation therapy involves the use of high-energy rays to kill cancer cells. It is used either by itself or in combination with surgery or chemotherapy. There are two types of radiation treatments: external beam radiation therapy and internal (or interstitial) radiotherapy. In external radiation therapy, the radiation is delivered from a machine positioned outside the body. Internal radiation therapy uses a small pellet of radioactive materials placed inside the body in the area of the cancer.

Radiation therapy may produce such side effects as tiredness, skin **rashes**, upset stomach, and **diarrhea**. Dry or sore throats, difficulty in swallowing, and loss of hair in the treated area are all minor side effects of radiation. These may disappear either during the course of the treatment or after the treatment is over. The side effects and ways to minimize them should be discussed with the doctor.

Chemotherapy

Chemotherapy uses anticancer medications that are either given intravenously or taken by mouth (orally). These drugs enter the bloodstream and travel to all parts of the body, killing cancer cells that have spread to different organs. Chemotherapy is used as the primary treatment for cancers that have spread beyond the lung and cannot be removed by surgery. It also can be used in addition to surgery or radiation therapy to kill any remaining cancer cells.

Chemotherapy is tailored to each patient's needs. Most patients are given a combination of several different drugs. Besides killing the cancer cells, these drugs also harm normal cells. Hence, the dose has to be carefully adjusted to minimize damage to normal cells. Chemotherapy often has severe side effects, including nausea, vomiting, **hair loss**, **anemia**, weakening of the immune system, and sometimes **infertility**. Most of these side effects end when the treatment is over. Other medications can be given to lessen the unpleasant side effects of chemotherapy.

Expected results

If the non-small lung cancer is detected and appropriately treated before it has had a chance to spread to other organs, about 47% of patients survive five years or longer after the initial diagnosis. Less than 15% of lung cancers, however, are found at this early stage. The one-year survival rate for all lung cancers in 2008 is about 40%.

Prevention

Overwhelmingly, the most effective way to prevent lung cancer is to not smoke or to quit smoking if one has already started. Secondhand smoke should be avoided as much as possible. Appropriate precautions should be taken when working with cancer-causing substances (carcinogens). Monitoring the diet and eating well-balanced meals that consist of whole foods, vegetables, and fruits; eliminating toxins, exercising routinely, and weight reduction; testing houses for the presence of radon gas; and removing asbestos from buildings also are useful preventive strategies.

KEY TERMS

Antioxidant—A molecule that prevents oxidation. In the body antioxidants attach to other molecules called free radicals and prevent the free radicals from causing damage to cell walls, DNA, and other parts of the cell.

Biopsy—The surgical removal and microscopic examination of living tissue for diagnostic purposes.

Bronchoscope—A thin, flexible, lighted tube that is used to view the air passages in the lungs.

Carcinogen—Any substance capable of causing cancer.

Chemotherapy—Treatment of cancer with synthetic drugs that destroy the tumor either by inhibiting the growth of cancerous cells or by killing them.

Electrolyte—Ions in the body that participate in metabolic reactions. The major human electrolytes are sodium (Na+), potassium (K+), calcium (Ca 2+), magnesium (Mg2+), chloride (Cl-), phosphate (HPO4 2-), bicarbonate (HCO3-), and sulfate (SO4 2-).

Free radical—A molecule with an unpaired electron that has a strong tendency to react with other molecules in DNA (genetic material), proteins, and lipids (fats), resulting in damage to cells. Free radicals are neutralized by antioxidants.

Lobectomy—Surgical removal of an entire lobe of the lung.

Pathologist—A doctor who specializes in the diagnosis of disease by studying cells and tissues under a microscope.

Placebo—A pill or liquid given during the study of a drug or dietary supplement that contains no medication or active ingredient. Usually study participants do not know if they are receiving a pill containing the drug or an identical-appearing placebo.

Pneumonectomy—Surgical removal of an entire lung.

Radiation therapy—Treatment using high energy radiation from x-ray machines, cobalt, radium, or other sources.

Sputum—Mucus or phlegm that is coughed up from the passageways of the lungs.

Stage—A term used to describe the size and extent of cancer.

Traditional Chinese medicine (TCM)—An ancient system of medicine based on maintaining a balance in vital energy or qi that controls emotions, spiritual, and physical wellbeing. Diseases and disorders result from imbalances in qi (the life force), and treatments such as massage, exercise, acupuncture, and nutritional and herbal therapy are designed to restore balance and harmony to the body

Wedge resection—Removal of only a small portion of a cancerous lung.

Lutein

Definition

Lutein is one of only two **carotenoids** (the other is zeaxanthin) that are found in the human eye. Lutein is thought to protect against certain eye diseases and possibly against some cancers.

Description

Found in spinach, kale, turnip, collard, and mustard greens, summer squash, peas, broccoli, brussels sprouts, and yellow corn, as well as egg yolks, lutein is a nutrient with a number of potentially beneficial effects. It is a member of the carotenoid family, a group of chemicals related to **vitamin A**. While beta-carotene, the precursor of vitamin A, may be the most familiar carotenoid, there are almost 600 others whose effects had as of 2008 not been extensively studied. Aside from lutein, these include alpha-carotene, **lycopene**, zeaxanthin, and beta-cryptoxanthin.

In plants, carotenoids such as lutein help to give color to sweet potatoes, carrots, and other fruits and vegetables. In humans, lutein and zeaxanthin make up much of the pigment in the center of the retina (the macula), where vision sensitivity is greatest. While lutein is not considered an essential nutrient, studies suggest that it plays an important role in maintaining healthy vision and preventing or slowing eye diseases such as age-related **macular degeneration** (ARMD), **cataracts**, and retinitis pigmentosa. Getting adequate amounts of lutein may also decrease the risk of developing certain types of **cancer**.

Carotenoids such as lutein are **antioxidants** that react with free radicals. Molecules called free radicals form during normal cell metabolism and with exposure to ultraviolet light or toxins such as cigarette smoke. Free radicals cause damage by reacting with fats and proteins in cell membranes and genetic material. This process is called oxidation. Antioxidants are compounds that attach themselves to free radicals so that it is impossible for the free radical to react with, or oxidize, other molecules. In this way, antioxidants may protect cells from damage. Although lutein and other carotenoids have antioxidant activity in the laboratory, it is not clear how much they function as antioxidants in the body. Concentrated mainly in the lens and retina of the eye, lutein is thought to protect vision by neutralizing free radicals and by increasing the density of eye pigment. Lutein may also shield the eyes from the destructive effects of ultraviolet rays in sunlight by absorbing light in the blue wavelength range.

General use

Several well-controlled clinical trials have produced strong indications that lutein plays an important role in maintaining vision and preventing ARMD and cataracts, the two leading causes of vision loss in adults. It also appears to slow the progress of retinitis pigmentosa. Research is ongoing, and a list of clinical trials currently enrolling volunteers in studies using lutein to treat various eye diseases can be found at http://www.clinicaltrials.gov. There is no charge to the patient to participate in these studies.

Research also indicates that getting adequate amounts of lutein may decrease the risk of endometrial cancer in women. As of 2008, research was underway that continues to investigate the relationship between lutein cancer prevention.

Preparations

Typically the United States Institute of Medicine (IOM) of the National Academy of Sciences develops values called Dietary Reference Intakes (DRIs) for vitamins and minerals. The DRIs define the amount of a nutrient a person needs to consume daily and the largest daily amount from food or dietary supplements that can be taken without harm. The IOM has not as of 2008 developed any DRIs for lutein or other carotenoids because not enough scientific information was available and because no diseases had been identified as being caused by inadequate intake of any carotenoid. The IOM, the American Cancer Society, and the American Heart Association all recommend that people meet their need for antioxidants, including lutein, from a diet high in fruits, vegetables, and whole grains rather than from dietary supplements.

Egg yolks are the richest source and also contain a large amount of zeaxanthin, another carotenoid found in the eye. Other sources of lutein include corn, red seedless grapes, kiwi fruit, squash, and green vegetables

KEY TERMS

Age-related macular degeneration (ARMD)—A chronic, painless eye disease occurring in people over age 50 that damages the macula, or central part of the retina, causing irreversible loss of central vision.

Antioxidant—An organic substance that is able to counteract the damaging effects of oxidation in human and animal tissue. Lutein is an antioxidant.

Carotenoid—Any of a group of red and yellow pigments that are chemically similar to carotene. They are contained in animal fat and some plants.

Cataracts—The clouding of the eye lens, which under normal circumstances is clear.

Free radical—A molecule with an unpaired electron that has a strong tendency to react with other molecules in DNA (genetic material), proteins, and lipids (fats), resulting in damage to cells. Free radicals are neutralized by antioxidants.

Retina—The layer of light-sensitive cells located at the back of the eye.

Retinitis pigmentosa—A group of inherited disorders that affect the rod cells of the retina. Retinitis pigmentosa begins with loss of night vision, followed by gradual loss of peripheral vision, the development of tunnel vision, and finally blindness.

such as zucchini, spinach, collard greens, kale, leaf lettuce, celery, peas, broccoli, and leeks. Oranges and orange juice, tomatoes, and carrots also prove good sources of lutein. Getting too much lutein through food and drink is not considered a significant risk because the nutrient is only present in relatively small amounts in plant and animal foods.

Despite the fact that the optimum daily dosage of lutein has not been established with certainty, indications suggest that therapeutic dosages range from 5 to 30 mg per day, although 6 mg daily is generally considered adequate for cancer prevention and 10 mg daily for ARMD treatment or prevention. As a dietary supplement, lutein is available in capsule form.

Precautions

Lutein is not known to be harmful when taken in recommended dosages, although the long-term effects of taking lutein supplements were unknown as of 2008. Due to lack of sufficient medical study, lutein should be used with caution in children, women who are pregnant or breast feeding, and people with liver or kidney disease.

Side effects

When taken in recommended dosages, lutein is not known to be associated with any significant side effects.

Interactions

Lutein is not known to interact adversely with any drugs or dietary supplements; however, as of 2008, few studies of interactions had been conducted.

Lycium fruit

Description

Lycium fruit, sometimes called lycium berry, is used extensively in Chinese herbalism. The fruit are the berries of *Lycium chinense* and more commonly *Lycium barbarum*. The roots also have healing properties. Lycium is a shrub that grows to about 12 ft (4 m) in height. It grows wild on hillsides in the cooler regions of northern China and Tibet. However, it is also cultivated in almost all parts of China and in some other regions of Asia.

Lycium fruit is rich in carotene, vitamins B_1 and B_{12}, and **vitamin C**. The fruit also contains **amino acids** (the building blocks of proteins), **iron**, and trace elements essential to the body, including **zinc**, **copper**, **selenium**, **calcium**, and **phosphorus**. The bright red berries are usually harvested in late summer or early autumn. The roots are usually harvested in the spring, although they can be dug any time of the year. Berries and roots can be used either fresh or dried. Lycium is also called Chinese wolfberry. Its Chinese name is *Gou Qi Zi*.

General use

The first recorded use of lycium fruit as a medicinal herb is from the first century A.D. For thousands of years it has been used in China to promote a long, vigorous, and happy life. It is used as both a *jing* (yin) tonic for liver and kidney, and as a blood tonic. In the Chinese system of health, *jing* is an essential life substance. To remain healthy, yin aspects must be kept in balance with yang aspects. Ill health occurs when the energies and elements of the body are out of balance or in disharmony. Health is restored by taking herbs and treatments that restore this balance.

Lycium fruit is traditionally believed to have many different effects upon the body. In addition to being a general longevity herb, it is said to raise the spirits, fight **depression**, and increase cheerfulness. Berries are made into a blood tonic that is given for general weakness, to improve circulation, and increase the cells' ability to absorb nutrients. When blended with more yang herbs, lycium is used as a sexual tonic.

In Chinese medicine, the liver is associated with the function of the eyes. Lycium berries are used as a liver tonic to brighten the eyes, improve poor eyesight, treat blurred vision, sensitivity to light, and other general eye weaknesses.

One of the qualities ascribed to lycium root is that it said to cool the blood. It is used to reduce **fever** and to treat other conditions of what is referred to as excess heat. These include traditional uses to relieve excess sweating, stop **nosebleeds**, reduce **vomiting**, and treat **dizziness**. Some herbalists use a tea made of lycium root and *Scutellaria* (**skullcap** or *Huang Qin*) to treat **morning sickness** in pregnant women. Lycium is also used to treat certain types of coughs and **asthma**.

Modern herbalists use lycium roots to treat high blood pressure. There is some scientific basis for this treatment, since extracts from the root have been shown in laboratory experiments to relax the involuntary muscles, including artery muscles. This **relaxation** lowers blood pressure.

Other modern scientific studies have shown that extracts of lycium root can reduce fever, including fever associated with **malaria**. One Korean study looked at the effect extracts from the berries and roots had on the blood of mice that were exposed to whole body x rays. They concluded that the mice that received doses of root extract replaced leukocytes, erythrocytes, and thrombocytes faster than those that did not receive the extract. This effect may account for lycium's reputation for creating good health, vigor, and long life.

Since the mid 1990s, claims have been made by some researchers, mainly in China, that lycium extracts can inhibit the growth of **cancer** cells. As of 2007, according to Memorial Sloan-Kettering Cancer Center, "Despite claims by several marketers, the efficacy and safety of lycium products for cancer treatment in humans have not been established." Nevertheless, research continued on this herb.

Preparations

High-quality, fresh lycium fruit has thick flesh, few seeds, and a delicious sweet taste. It can be eaten raw on a daily basis to promote general health and happiness. Dried berries can be used just as raisins are in cooking. Herbalists also make a decoction from dried, chopped lycium berries. To treat eye problems, about 0.5 cup (100 ml) of decoction is consumed daily.

Roots are used either fresh or dried. About 0.5 cup (100 ml) of root decoction daily is given to reduce fevers. A tincture can also be made of the root. About 0.5 teaspoon (3 ml) diluted with water three times a day is taken for coughs.

Combinations

Lycium is regularly used in tonics and herbal formulas that treat blood deficiencies, poor kidney function, and liver depletion. Among these are lycium formula, a blood tonic that is intended to strengthen

KEY TERMS

Decoction—The liquid made from boiling an herb, then straining out the solid material.

Erythrocytes—Known as red blood cells, the ones that carry oxygen to every part of the body.

Leukocytes—Also called white blood cells, the ones that fight infection and boost the immune system.

Thrombocytes—Also called platelets, these help the blood to clot so that wounds can heal.

Tincture—An alcohol-based extract prepared by soaking plant parts.

Yang aspects—Qualities such as warmth, activity, and light, the opposite of yin aspects.

Yin aspects—Qualities such as cold, stillness, darkness, and passiveness, the opposite of yang aspects.

the entire body and brain. Lycium is an ingredient in rehmannia eight combination, a common *jing* tonic for older men and women that is said to regulate blood sugar and control diabetes, and a vision formula with the Chinese name of *Qi Ju Di Huang Wan* is made of lycium, chrysanthemum, and rehmannia.

Precautions

Chinese herbalists do not recommend lycium for people who have a fever due to infection or who have **diarrhea** or bloating. The safety of lycium during **pregnancy** has not been established.

Side effects

There are no reported side effects from taking lycium. Lycium has been used for centuries, both as a healing herb and as a food.

Interactions

Lycium is often used in conjunction with other herbs with no reported interactions. Lycium has also been found to enhance the action of the blood-thinning drug warfarin (Coumadin).

Lycopene

Description

Lycopene is a red, fat-soluble pigment found in vegetables, and most commonly found in tomatoes. It is one of a family of pigments called **carotenoids**. Carotenoids are naturally occurring pigments responsible for the brightly colored fall leaves and the vivid colors of flowers, fruits, and vegetables. In fruits and vegetables, these pigments range in hue from bright yellow in squash, to orange in carrots, to bright red in tomatoes and peppers.

Although the human body does not produce lycopene, it is readily available through the diet. Minor sources include guava, rosehip, watermelon, and pink grapefruit. However, about 85% of lycopene in the U.S. diet comes from tomatoes and tomato products such as juice, soup, sauce, paste, and ketchup. A diet rich in carotenoid-containing foods is associated with a variety of health benefits.

Once lycopene is absorbed in the body, it is deposited widely in the liver, lungs, prostate gland, colon, and skin. Its concentration in body tissues tends to be higher than most other carotenoids. Working as a powerful antioxidant, lycopene fights free radicals—highly reactive molecules that damage cell membranes, attack DNA, and cause disease. Studies have found that patients with HIV infection, inflammatory diseases, and high cholesterol levels (with and without lipid-lowering treatment) may have depleted lycopene serum (blood) levels. In contrast to other carotenoids, serum levels of lycopene are not usually reduced by

Tomatoes are a good source of lycopene. *(© Sorin Alexandru / Alamy)*

smoking or alcohol consumption but rather by increasing age.

General use

A number of studies have indicated that a lycopene-rich diet lowers the risk of certain chronic diseases such as cardiovascular disease, **cancer**, and age-related macular degeneration .

Cardiovascular disease

In its role as an antioxidant, lycopene prevents the oxidation of low-density liproprotein (LDH), the "bad" **cholesterol** that leads to **atherosclerosis** (hardening of the arteries) and coronary artery disease.

As serum lycopene levels rise, the levels of oxidized lipoprotein, protein, and DNA compounds go down, thus lowering the risk of heart disease. Individuals with high levels of lycopene are half as likely to have a **heart attack** than those with low levels, according to one study.

Cancer

Researchers have found a strong relationship between lycopene intake and reduced risk of cancers of the prostate and pancreas. In several studies of these cancers, lycopene was the only carotenoid associated with risk reduction. In late 2001, the first clinical intervention trial of **prostate cancer** patients showed that supplementation with lycopene helped slow growth of prostate cancer. In fact, the spread of prostate cancer was reduced by 73%.

Consuming tomato products twice a week, as opposed to not at all, was associated with a reduced risk of prostate cancer of up to 34%, according to a study conducted by the Dana-Farber Cancer Institute. Of the 46 fruits and vegetables investigated, only tomato products showed a measurable association with reduced risk of prostate cancer. There is also medical evidence to suggest that a high intake of lycopene-rich tomato products is associated with a reduced risk of developing cancers of the lung, breast, cervix, and gastrointestinal tract.

Macular degeneration

Lycopene (as well as other carotenoids such as lutein and beta-carotene) may also help prevent macular degenerative disease, the leading cause of blindness in people over the age of 65. Lycopene is the only micronutrient whose serum level was shown to be inversely related to the risk of age-related **macular degeneration**.

In late 2001, a study showed that lycopene may also help relieve exercise-induced **asthma** symptoms.

Preparations

Although the major sources of lycopene for humans are tomatoes and tomato products, bioavailability from

KEY TERMS

Antioxidant—Agent that prevents or inhibits oxidation, which is the process of creating unstable molecules.

Bioavailability—The rate and extent to which a drug or other substance enters the general circulation.

Carotenoid—A pigment that gives color to plants.

Macular degeneration—Deterioration of the macula of the eye (a part of the retina).

different food items varies considerably. Cooking fresh tomatoes with a source of fat, such as olive oil in spaghetti sauce, enhances the body's absorption of lycopene, since lycopene is fat-soluble. By heating the tomatoes, the bound chemical form of lycopene is converted into a form that is more easily digested. In fact, one study showed that lycopene is absorbed 2.5 times better from tomato paste than from fresh tomatoes.

Although no dietary guidelines have been established, research shows that drinking two cups (about 540 ml) of tomato juice per day provides about 40 mg of lycopene. This is the amount recommended to significantly reduce the oxidation of LDL cholesterol, according to one human dietary intervention study.

The approximate lycopene content of tomatoes and tomato products, based on an analysis by a number of laboratories (mg/100 g wet weight) are listed below.

- tomatoes, fresh (0.9–4.2)
- tomatoes, cooked (3.7)
- tomato sauce (6.2)
- tomato paste (5.4–150)
- tomato soup, condensed (8.0)
- tomato juice (5.0–11.6)
- sun-dried tomato in oil (46.5)
- pizza sauce, canned (12.7)
- ketchup (9.9–13.4)

Although lycopene is available in concentrated capsule form and in combination with other vitamins, such as **vitamin E** or multivitamin preparations, there is inadequate evidence to conclude that supplements are more beneficial than the lycopene consumed in foods. Since most of the health benefits of lycopene have been ascertained from studies of estimated dietary intake or blood concentrations, as of the year 2000, researchers recommend that individuals consume a diet rich in carotenoids and an array of fruits and vegetables rather than turning to lycopene supplements. The United States Department of Agriculture reported in 2001 that people intake an average of 10.9mg per day.

Precautions

There are no known precautions regarding lycopene itself. However, there are a number of indirect problems that may result from consuming excessive amounts of tomatoes or commercially prepared tomato products.

Although processed tomato products are the richest source of lycopene in the diet, ingesting tomatoes may aggravate certain health conditions. As a member of the nightshade variety of plants—which includes eggplants, potatoes, peppers, paprika, and tobacco—tomatoes have been strongly and consistently linked with certain forms of arthritis, particularly rheumatoid and **osteoarthritis**.

One theory maintains that the alkaloids (alkaline chemicals) in the nightshades are deposited in the connective tissue, stimulate inflammation, and then inhibit the formation of normal cartilage. As a result, joint cartilage continues to break down and is not replaced by new, healthy cartilage cells.

Another indirect precaution is that processed tomato products usually contain large amounts of **sodium**, unless the product is labeled low-sodium or salt-free. An excess amount of sodium in the diet can exacerbate high blood pressure.

Side effects

Although extensive research has not been conducted, there have been no reported side effects or toxicity associated with lycopene intake.

Interactions

Research into the interactions of lycopene with food, drugs, or diseases has not been conducted as of the year 2000.

Lycopodium

Description

Lycopodium (*Lycopodium clavatum*) is a perennial evergreen plant that grows in pastures, woodlands, heaths, and moors of Great Britain, Northern Europe, and North America. It has a slender stem that trails along the ground and vertical branches that grow to 3 to 4 in (7.5–10 cm). The plant belongs to the (*Lycopodiaceae* family and is related to mosses and ferns. It is often called **club moss**. Other names include wolf's claw, stag horn, witch meal, and vegetable sulfur.

The pale yellow pollen collected from the spores is used to make the homeopathic remedy called lycopodium. The pollen is odorless, water resistant, and highly flammable. For this reason, it used to be a component of fireworks. It was also formerly used to create a coating for pills and as a powder for medical gloves.

Early physicians used the plant to stimulate the appetite and to promote urination and the excretion of other body fluids. Lycopodium was also used in the treatment of flatulence, rheumatism, **gout**, lung ailments, and diseases of children and young girls. In the seventeenth century the pollen was used as an internal remedy for **diarrhea**, dysentery, and rheumatism. Externally, the pollen was a treatment for **wounds** and diseases of the skin such as **eczema**. The whole plant was used to heal kidney ailments.

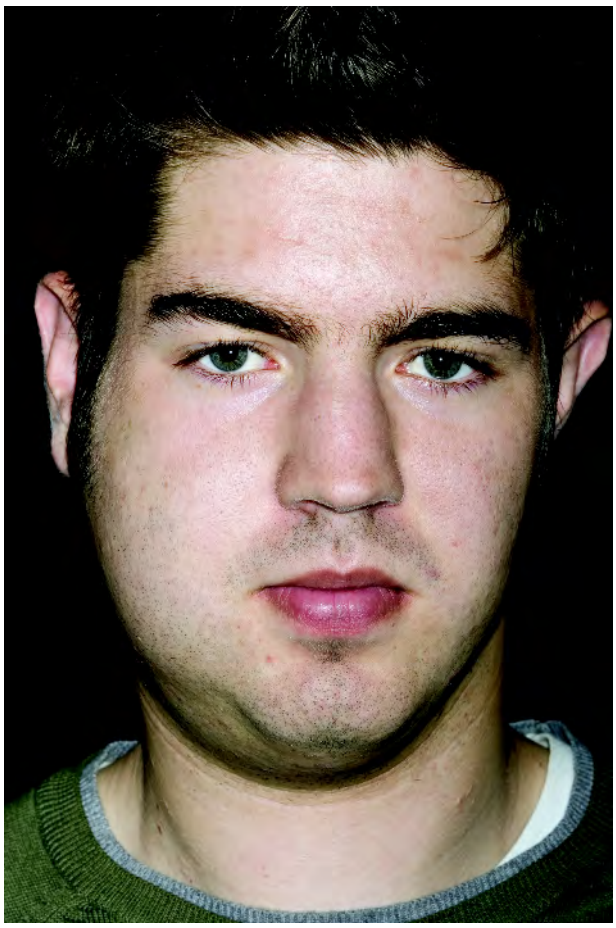
General use

Lycopodium is prescribed by homeopaths for both acute and chronic ailments such as earaches, sore throats, digestive disorders, urinary tract difficulties, prostatitis, and eye conditions. The remedy acts on soft tissues, blood vessels, bones, joints, the liver, and the heart. This polychrest is also recommended in the treatment of back **pain**, **bedwetting**, fevers, **food poisoning**, mouth ulcers, **mumps**, colds, **muscle cramps**, **constipation**, coughs, cystitis, **gas**, **sciatica**, gout, skin conditions, and joint pain. It is often indicated in the early stages of **pneumonia**. The levo-tetrahydropalmatine in lycopodium serratum preparations (also known as *Jin bu haun*) has sedative and analgesic properties.

***Lycopodium clavatum* is a perennial evergreen plant that grows in pastures, woodlands, heaths, and moors of Great Britain, Northern Europe, and North America.** *(Gregory K. Scott / Photo Researchers, Inc.)*

According to homeopaths, lycopodium ailments are frequently the result of anger, horror, chagrin, disappointment, grief, fright, mental exertion, sexual excesses, overeating, or alcohol consumption. Typical lycopodium patients are alcoholic, timid, and fearful adults, irritable and domineering children, or intellectuals who are strong in mind but weak in body. The latter generally look older than they are and their hair becomes gray prematurely. Children who require lycopodium are prone to **tonsillitis**, gas, and bronchial **infections**. They have tantrums if they do not get their way and dislike naps, often kicking and screaming beforehand or upon waking.

Homeopaths may believe that patients likely to use lycopodium are predisposed to lung ailments, gas, and



Lycopodium can aid in the treatment of mumps, pictured above. *(Dr. P. Marazzi / Photo Researchers, Inc.)*

gallstones. They have weak digestive systems and often suffer from dyspepsia, **colitis**, or gastro-enteritis. They become full soon after beginning a meal or have no appetite until eating, whereupon they become ravenous. They may crave sweets and dislike oysters, onions, cabbage, and milk. Their stomachs are often bloated, gassy, acidic, and sour, and are worse from cold drinks, beer, coffee, or fruit. They may become sleepy after eating.

Mentally these persons are irritable, restless, quarrelsome, sensitive, weepy, melancholy, and depressed. Other mental symptoms include dullness, confusion, poor memory, amnesia, anger, hypersensitivity to noise, sadness, and **anxiety** upon waking. They frequently suffer from performance anxiety and are nervous in social situations. They do not prefer the company of others and although they dread the presence of new persons, friends, or visitors, they are afraid to be alone.

Ailments are generally worse on the right side of the body, often traveling from right to left or from above downward. Symptoms are worse between 4:00 and 8:00 p.m. and worsen with cold food and drinks. Exhaustion and illness may set in after much physical exertion. Symptoms are generally worse from cold conditions with the exception of head and spine symptoms, which are worse from warmth. Symptoms are better from open air, warm drinks, and motion.

Specific indications

Physical indications are hunger with sudden fullness, urine with a red sandy color, gas, **fatigue**, numbness of fingers or toes, and a trembling of the limbs. Liver ailments such as **cirrhosis**, **hepatitis**, fatty degeneration of the liver, and liver **cancer** warrant the use of this remedy.

Periodic headaches result from digestive disturbances. If lycopodium patients miss a meal, they may get a **headache**, which is relieved upon eating.

The **sore throat** that typically warrants using this remedy is sore on the right side, with swollen tonsils. The throat feels dusty and is better after swallowing warm drinks.

The cold indicative of lycopodium is accompanied by a headache, yellow mucous, and a stuffed, dry nose. The patient often has to breathe out of his mouth. The lycopodium **cough** is constant, deep and hollow. The chest is tight and the mucus that is expelled is salty, thick, and gray. The cough is worse in the evening.

Eye conditions may develop in which the eyes are inflamed and red and the eyelids are grainy.

When abdominal pains are present they are of a cutting, griping, clutching, or squeezing nature. Gas is accompanied by a bloated abdomen that relieved after passing gas and by wearing loose clothing. The gas is worse after eating.

Joint pains are typically tearing pains that start on the right side and move to the left side. The knee and finger joints are especially stiff. Pains are better from continued movement or warmth and worsened during **fever**, sitting still, and initial movement.

The typical lycopodium patient has a pale, sickly face that is often covered with skin eruptions. Eczema, **psoriasis**, **rashes**, herpetic eruptions, and brown and yellow spots on the skin are common.

Men may be impotent. Women often suffer from inflammation and pain of the ovaries and uterus. The pain generally affects the right ovary more than the left.

Preparations

The spores of the plant are gathered at the end of the summer. The pollen is extracted from the spores and diluted with milk sugar.

KEY TERMS

Polychrest—A homeopathic remedy that is used in the treatment of many ailments.

Lycopodium is available at health food and drug stores in various potencies in the form of tinctures, tablets, and pellets.

Precautions

If symptoms do not improve after the recommended time period, a homeopath or healthcare practitioner should be consulted. The recommended dose of lycopodium should not be exceeded.

In the United States, herbal remedies are considered dietary supplements, which are not standardized. Although it was regulated under the 1994 Dietary Supplement Health and Education Act (DSHEA), there are no safety reviews or FDA approved therapeutic uses for lycopodium. In addition, herbal remedies are not standardized and preparations of lycopodium can vary greatly. Therefore, it is important to read labels carefully and consult a physician before taking this or any other herbal supplement.

Side effects

Liver toxicity and hepatitis have been reported in several studies, with associated symptoms, including liver enlargement, **jaundice**, fever, fatigue, **nausea**, abdominal pain, and **itching**. Therefore, patients should consult their doctor before using this supplement, particularly if they have known or suspected liver disease.

Interactions

When taking any homeopathic remedy, it is advised to avoid **peppermint** products, coffee, or alcohol. These products may cause the remedy to be ineffective.

Lycopodium is incompatible with the remedy coffea. These remedies should not be taken simultaneously.

Lycopus

Defintion

Lycopus is a genus within the family *Lamiaceae* consisting of about a dozen species. The plant is also known by a number of common names, primarily bugleweed and gypsywort.

Description

Lycopus is somewhat similar in appearance to mint, although lacking in mint's characteristic taste and odor. It is a perennial herb that may grow to about two feet in height. It produces small white or pale purple flowers at the base of leaves. Leaves are bright green, lobed, and pointed. Its prefer habitat is moist soil or wetlands. The primary chemical components of lycopus include tannins, lithospermic acid, lycopine, flavone–glycosides, phenolic derivatives, essential oil, **magnesium** and resin. These components are responsible for the plant's somewhat bitter and astringent taste.

Humans have used lycopus since ancient times for a variety of purposes. Its common name of gypsywort is said to have come from an ancient practice by members of the Roma culture in Eastern Europe in which extracts of the plant were used to dye the skin in order to produce a shade similar to that of the Egyptians. Interest in the use of lycopus for medical purposes in the United States was apparently sparked by an article written in 1822 by J. Smyth Rogers and James M. Pendleton, "Observations on the Lycopus Virginicus, or *Bugleweed*."

Herbalists and other practitioners use the leaves, stems, and flowers for their medicinal preparations.

Uses

The medicinal uses of lycopus have changed substantially over time. Traditionally it was used for a variety of purposes, including:

- treatment for coughs and sore throat
- as an astringent
- as a sedative or mild narcotic
- treatment of tuberculosis (consumption)
- treatment for heavy menstrual bleeding
- treatment for nosebleeds
- relief from anxiety

Modern medicinal applications of lycopus differ significantly from these traditional uses. Today, the plant is probably recommended most commonly for treatment of thyroid problems and palpitations. The herb is thought to be effective for these purposes because some of its components may reduce the activity of thyroid–stimulating hormone (TSH) and thyroxine, one of the primary hormones produced by the thyroid. Reduction of these hormones, in turn, is thought to relieve conditions of **hyperthyroidism**, which may be manifested in shaking and palpitations. The herb is also recommended, for this reason, for the treatment of Grave's disease, which is characterized by palpitations, shaking, and shortness of breath. The effectiveness of lycopus in the treatment of thyroid problems is less than that of synthetic drugs, but may be adequate to treat mild forms of the disorders.

Herbalists also suggest the use of lycopus for the treatment of a number of other diseases and disorders, including:

- cardiac problems
- dandruff
- as a sedative or mild narcotic
- excessive menstrual flow
- diuretic
- treatment for liver disorders
- breast and chest pain

As of 2008, the Natural Standard has found that "there is a lack of high–quality clinical trials investigating the safety and efficacy of bugleweed." The Natural Standard is an international research collaborative that collects and analyzes data on the safety and efficacy of complementary and alternative therapies.

KEY TERMS

Astringent—A substance that dries tissue, producing a "puckered" appearance and feeling.

Diuretic—A substance that tends to increase urine flow.

Grave's disease—A condition produced by excessive production of thyroid hormones, characterized by and enlarged thyroid gland and protruding eyeballs.

Hyperthyroidism—A condition resulting from overproduction of thyroid hormones.

Hypothyroidism—A condition resulting from underproduction of thyroid hormones.

Side effects

Although lycopus may be safely used by people with hyperthyroidism, it should not be ingested by individuals with normal thyroid function or **hypothyroidism**. In such cases, reduction in thyroid function could result in serious health problems and, possibly, death. The herb should also not be used by pregnant women or women who are breast feeding. Since there are no long–term studies on the overall safety of lycopus preparations, the product should be taken only under the advice and care of a health care professional.

Interactions

Preparations of lycopus may interact with drugs used for the treatment of thyroid problems since they may magnify or diminish the effects of the allopathic treatment. In general, there has been relatively little research on the interaction among herbal products or between herbs and allopathic drugs. For this reason, care should be taken in combining the use of lycopus products with other herbal and allopathic remedies.

Lyme disease

Definition

Lyme disease, which is also known as Lyme borreliosis, is an infection transmitted by the bite of ticks carrying the spiral-shaped bacterium (spirochete) *Borrelia burgdorferi* (Bb). The disease was named for Old Lyme, Connecticut, the town where it was first diagnosed in 1975, after a puzzling outbreak of arthritis. The spiral-shaped bacterium was named for its discoverer, Willy Burgdorfer. The effects of this disease can be long-term and disabling, unless it is recognized and treated properly with antibiotics.

Description

Lyme disease is a vector-borne disease, which means it is delivered from one host to another. It is also classified as a zoonosis, which means that it is a disease of animals that can be transmitted to humans under natural conditions. In this case, a tick bearing the Bb organism literally inserts it into a host's bloodstream when it bites the host to feed on its blood. It is important, however, to note that neither Bb nor Lyme disease can be transmitted directly from one person to another.

This Erythema migrans rash is one of the symptoms of Lyme disease, a common chronic disease in the United States and Europe. *(Adam Hart-Davis / Photo Researchers, Inc.)*

In the United States, Lyme disease accounts for more than 90% of all reported vector-borne illnesses. It is a significant public health problem and continues in the late 2000s to be diagnosed in increasing numbers. The Centers for Disease Control and Prevention (CDC) attributes this increase to the growing size of the deer herd and the geographical spread of infected ticks rather than to improved diagnosis. In addition, some epidemiologists believe that the actual incidence of Lyme disease in the United States may be 5–10 times greater than that reported by the CDC. The reasons for this difference include the narrowness of the CDC's case definition as well as frequent misdiagnoses of the disease.

Controversy clouds the true incidence of Lyme disease because no test is definitively diagnostic for the disease, and many of its symptoms mimic those of so many other diseases. Cases of Lyme disease have been reported in 49 of the 50 states; however, 92% of the 17,730 cases reported to the CDC in 2000 were from only nine states (Connecticut, Rhode Island, New York, Pennsylvania, Delaware, New Jersey, Maryland, Massachusetts, and Wisconsin). The disease is also found in Scandinavia, continental Europe, the countries of the former Soviet Union, Japan, and China; in addition, it is possible that it has spread to Australia.

The risk for acquiring Lyme disease varies, depending on what stage in its life cycle a tick has reached. A tick passes through three stages of development—larva, nymph, and adult—each of which is dependent on a live host for food. In the United States, Bb is borne by ticks

of several species in the genus *Ixodes*, which usually feed on the white-footed mouse and deer (and are often called deer ticks). In the summer, the larval ticks hatch from eggs laid in the ground and feed by attaching themselves to small animals and birds. At this stage they are not a problem for humans. It is the next stage—the nymph—that causes most cases of Lyme disease. Nymphs are very active from spring through early summer, at the height of outdoor activity for most people. Because they are still quite small (less than 2 mm in length), they are difficult to spot, giving them ample opportunity to transmit Bb while feeding. Although far more adult ticks than nymphs carry Bb, the adult ticks are much larger, more easily noticed, and more likely to be removed before the 24 hours or more of continuous feeding needed to transmit Bb.

Causes and symptoms

Lyme disease is a collection of effects caused by Bb. Once Bb gains entry to the body through a tick bite, it can move through the bloodstream quickly. Only 12 hours after entering the bloodstream, Bb can be found in cerebrospinal fluid (which means it can affect the nervous system). Treating Lyme disease early and thoroughly is important because Bb can hide for long periods within the body in a clinically latent state. That ability explains why symptoms can recur in cycles and can flare up after months or years, even over decades. It is important to note, however, that not everyone exposed to Bb develops the disease.

Lyme disease is usually described in terms of length of infection (time since the person was bitten by a tick infected with Bb) and whether Bb is localized or disseminated (spread through the body by fluids and cells carrying Bb). Furthermore, when and how symptoms of Lyme disease appear can vary widely from patient to patient. People who experience recurrent bouts of symptoms over time are said to have chronic Lyme disease.

Early localized Lyme disease

The most recognizable indicator of Lyme disease is a rash around the site of the tick bite. Often, the tick exposure has not been recognized. The area of rash eruption might be warm or itch. The rash—erythema migrans (EM)—generally develops within 3–30 days and usually begins as a round, red patch that expands. Clearing may take place from the center out, leaving a bull's-eye effect; in some cases, the center gets redder instead of clearing. The rash may look like a bruise on individuals with dark skin. Of those who develop Lyme disease, about 50% notice the rash; about 50% notice flu-like symptoms, including **fatigue**, **headache**, **chills** and **fever**, muscle and joint **pain**, and lymph node swelling. However, a rash at the site can also be an allergic reaction to the tick saliva rather than an indicator of Lyme disease, particularly if the rash appears in *less* than three days and disappears only days later.

Late disseminated disease and chronic Lyme disease

Weeks, months, or even years after an untreated tick bite, symptoms can appear in several forms:

- fatigue, forgetfulness, confusion, mood swings, irritability, numbness
- neurologic problems, such as pain (unexplained and not triggered by an injury), Bell's palsy (facial paralysis, usually one-sided but may be on both sides), and a mimicking of the inflammation of brain membranes known as meningitis (fever, severe headache, stiff neck)
- arthritis (short episodes of pain and swelling in joints) and other musculoskeletal complaints

In the past, Lyme arthritis occurred in 60% of patients with Lyme disease, but as of 2006, this number dropped to 10%.

Less common effects of Lyme disease are heart abnormalities (such as irregular rhythm or cardiac block) and eye abnormalities (such as swelling of the cornea, tissue, or eye muscles and nerves).

Diagnosis

A clear diagnosis of Lyme disease can be difficult and relies on information the patient provides and the doctor's clinical judgment, particularly through elimination of other possible causes of the symptoms. Lyme disease may mimic other conditions, including **chronic fatigue syndrome** (CFS), **multiple sclerosis** (MS), and other diseases with many symptoms involving multiple body systems. Differential diagnosis (distinguishing Lyme disease from other diseases) is based on clinical evaluation with laboratory tests used for clarification, when necessary. A two-test approach is common to confirm the results. Because of the potential for misleading results (false-positive and false-negative), laboratory tests alone cannot establish the diagnosis.

Doctors generally know which disease-causing organisms are common in their geographic area. The most helpful piece of information is whether a tick bite or rash was noticed and whether it happened locally or while traveling. Doctors may not consider Lyme disease if it is rare locally, but will take it into account if a

patient mentions vacationing in an area where the disease is commonly found.

Treatment

While antibiotics are essential in treating Lyme disease, many alternative therapies may minimize symptoms, improve the immune response, and help treat late disseminated or chronic disease. General nutritional guidelines include drinking plenty of fluids and eating cooked whole grains and fresh vegetables. The intake of sugar, fat, refined carbohydrates, and dairy products should be reduced. Alternative therapies used in treating Lyme disease include:

- Chinese medicine. Formulae used to treat systemic bacterial infections include Wu Wei Xiao Du Yin (Five-Ingredient Decoction to Eliminate Toxin), Yin Hua Jie Du Tang (Honeysuckle Decoction to Relieve Toxicity), and Huang Lian Jie Du Tang (Coptis Decoction to Relieve Toxicity). Inflammation at the site of infection may be treated externally with Yu Lu San (Jade Dew Extract) or Jin Huang San (Golden Yellow Powder). Specific Chinese herbs and treatments can be used for specific symptoms. For examples, for systemic bacterial infection, one may use honeysuckle flower, forsythia, isatidis, scutellaria, and phellodendron. Acupuncture and ear acupuncture treatments are also used.
- Herbals. Botanical remedies include Echinacea (*Echinacea* species) to clear infection and boost the immune system, goldenseal (*Hydrastis canadensis*) to clear infection and boost the immune system, garlic to clear bacterial infection, and spilanthes (*Spilanthes* species) for spirochete infections.
- Hydrotherapy. The joint pain associated with Lyme disease can be treated with hydrotherapy. Dull, penetrating pain may be relieved by applying a warm compress to the affected area. Sharp, intense pain may be relieved by applying an ice pack to the affected area.
- Imagery. The patient may treat Lyme disease by visualizing Bb as looking like ticks swimming in the bloodstream being killed by the flame of a candle.
- Probiotics. Probiotics is treatment with beneficial microbes either by ingestion or through a suppository. Probiotics can restore a healthy balance of bacteria to the body in cases in which long-term antibiotic use has caused diarrhea or yeast infection. Yogurt or *Lactobacillus acidophilus* preparations may be ingested.
- Supplements. Calcium and magnesium can be used for aches, chlorophyll to aide healing, vitamin C for bacterial infection and inflammation, bioflavonoids for joint inflammation and to boost the immune system, digestive enzyme for digestive problems, vitamin B complex to boost overall health, bromelain for inflammation, and zinc to boost the immune system and promote healing.

Allopathic treatment

For most patients, oral antibiotics (doxycycline or amoxicillin) are prescribed for 21 days. The doctor may have to adjust the treatment regimen or change medications based on the patient's response. Antibiotics can kill Bb while it is active, but not when it is dormant. When symptoms indicate nervous system involvement or a severe episode of Lyme disease, intravenous antibiotic (ceftriaxone) may be given for 14–30 days. Adults with late neurologic Lyme disease are often treated with intravenous ceftriaxone for a period of two to four weeks. Alternative treatments are intravenous cefotaxime or penicillin G.

Treatment for Lyme disease is a source of controversy. Some scientists believe that it is cured after a four-antibiotic regime and that further antibiotic treatment could result in drug allergy. Other researchers, however, believe that the B. burgdorferi may remain in a dormant state within human cells, necessitating another course of treatment.

Expected results

If aggressive antibiotic therapy is given early and the patient cooperates fully and sticks to the medication schedule, recovery should be complete. Only a small percentage of Lyme disease patients fail to respond or relapse (have recurring episodes). Most long-term effects of the disease result when diagnosis and treatment is delayed or missed. Co-infection with other infectious organisms spread by ticks in the same areas as Bb (babesiosis and ehrlichiosis, for instance) may be responsible for treatment failures or more severe symptoms. In certain cases, Lyme disease has been responsible for deaths, but that is rare. Most fatalities reported with Lyme disease involved patients co-infected with babesiosis.

Prevention

Vaccination withdrawn

A vaccine for Lyme disease known as LYMErix was available from 1998 to 2002, when it was removed from the U.S. market. The decision was influenced by reports that LYMErix may be responsible for neurologic complications in vaccinated patients. Researchers from Cornell-New York Hospital presented a

paper at the annual meeting of the American Neurological Association in October 2002 that identified nine patients with neuropathies linked to vaccination with LYMErix. In April 2003, the National Institute of Allergy and Infectious Diseases (NIAID) awarded a federal grant to researchers at Yale University School of Medicine to develop a new vaccine against Lyme disease. As of 2008, the best prevention strategy was through minimizing risk of exposure to ticks and using personal protection precautions.

Minimizing risk of exposure

Precautions to avoid contact with ticks include moving leaves and brush away from living quarters. In highly tick-populated areas, each individual should be inspected at the end of the day to look for ticks. Most important are personal protection techniques when outdoors:

- Avoid walking through woods, shrubbery, or tall grasses.
- Use repellents containing DEET.
- Wear light-colored clothing to maximize ability to see ticks.
- Tuck pant legs into socks or boot top.
- Check children and pets frequently for ticks.

Minimizing risk of disease transmission

The two most important factors are removing the tick quickly and carefully, and seeking a doctor's evaluation at the first sign of Lyme disease. When in an area that may be tick-populated, follow these precautions:

- Although ticks are quite small, check for them, particularly in the area of the groin, underarm, behind ears, and on the scalp.
- Stay calm and grasp the tick as near to the skin as possible, using tweezers.
- To minimize the risk of squeezing more bacteria into the site of the bite, pull straight back steadily and slowly.
- Do not use petroleum jelly, alcohol, or a lit match to remove the tick.
- Place the tick in a closed container (for species identification later, should symptoms develop) or dispose of it by flushing it in a toilet.
- See a physician for any sort of rash or patchy discoloration that appears 3–30 days after a tick bite.

KEY TERMS

Babesiosis—A disease caused by protozoa of the genus *Babesia* characterized by a malaria-like fever, anemia, vomiting, muscle pain, and enlargement of the spleen. Babesiosis, like Lyme disease, is carried by a tick.

Bell's palsy—Facial paralysis or weakness with a sudden onset, caused by swelling or inflammation of the seventh cranial nerve, which controls the facial muscles. Disseminated Lyme disease sometimes causes Bell's palsy.

Blood-brain barrier—A blockade of cells separating the circulating blood from elements of the central nervous system (CNS); it acts as a filter, preventing many substances from entering the central nervous system.

Cerebrospinal fluid—Clear fluid found around the brain and spinal cord and in the ventricles of the brain.

Disseminated—Scattered or distributed throughout the body. Lyme disease that has progressed beyond the stage of localized EM is said to be disseminated.

Erythema migrans (EM)—A red skin rash that is one of the first signs of Lyme disease in about 75% of patients.

Lyme borreliosis—Another name for Lyme disease.

Probiotics—Treatment with beneficial microbes, either by ingestion or through a rectal or vaginal suppository, to restore a healthy balance of bacteria to the body.

Spirochete—A spiral-shaped bacterium. The bacteria that cause Lyme disease and syphilis, for example, are spirochetes.

Vector—An animal carrier that transfers an infectious organism from one host to another. The vector that transmits Lyme disease from wildlife to humans is the deer tick or black-legged tick.

Zoonosis (plural, zoonoses)—Any disease of animals that can be transmitted to humans under natural conditions. Lyme disease and babesiosis are examples of zoonoses.

Lymphatic drainage

Definition

Lymphatic drainage is a therapeutic method that uses massage-like manipulations to stimulate lymph movement. Lymph is the plasma-like fluid that maintains the body's fluid balance and removes bacteria. Combined with other techniques of complete decongestive physiotherapy, it is used to treat lymphedema, swelling in the limbs caused by lymph accumulation.

Origins

The use of massage and compression techniques to treat swollen arms and legs was pioneered by Alexander Von Winiwarter, a nineteenth-century surgeon from Belgium. These techniques were refined during the 1930s by Danish massage practitioner Emil Vodder into what is now known as manual lymph drainage. During the 1980s, German physician Michael Foldi combined lymph drainage with other techniques to develop complete decongestive physiotherapy, widely used in the treatment of lymphedema.

Benefits

Lymphatic drainage is said to beneficially effect the nervous, immune and muscular systems. Its primary purpose is the treatment of lymphedema, a condition that causes unattractive swelling of arms and legs and creates an environment ripe for infection.

Description

Lymphatic drainage is accomplished by gentle, rhythmic massage following the direction of lymph flow. Mild stretching movements are used on the walls of lymph collectors to redirect the flow away from blocked areas into other vessels that drain into the veins. This massage action is often combined with other elements of complex decongestive therapy, which include:

- bandages
- dietary changes
- skin and nail care to prevent infection
- therapeutic exercise
- special compression sleeves, stockings, and other garments
- patient-applied lymphatic drainage and bandaging techniques
- light-beam generators to stimulate lymphatic drainage

Precautions

Any patient who has undergone **cancer** surgery and experiences sudden swelling after lymphatic drainage should stop treatment and be examined by a medical doctor. Treatment should also be stopped if infection of the lymphatic vessels occurs. The U.S. National Lymphedema Network recommends that patients taking anticoagulants for vascular disease be first checked for **blood clots** using ultrasound or other technology, and followed closely during the treatment. Congestive heart failure patients who may not be able to tolerate excessive movement of lymph need close monitoring also. If any **pain** is associated with lymphatic drainage, the treatment should stop until either the source is discovered or the pain goes away.

Side effects

There are concerns that lymphatic drainage and associated techniques could cause cancer to spread in patients with recurrent or metastatic disease.

A therapist performs lymphatic drainage on a woman. *(© Arco Images / Alamy)*

Research and general acceptance

Lymphatic drainage has enjoyed widespread acceptance in Europe for several decades, and is gaining acceptance within the North American medical establishment.

Training and certification

Lymphatic drainage therapy procedures are most commonly done by osteopaths, chiropractors, physical therapists, occupational therapists, massage therapists, and nurses. Training is available from a number of institutions, and typically involves about 30–130 hours. The Florida-based Academy of Lymphatic Studies offers certification in manual lymph drainage and complete decongestive therapy.

Lysimachia

Description

Several different species of the plant known as lysimachia (genus *Lythrum*) exist. Lysimachia is in the Primulae family. The various species are known by a variety of common names, such as willow herb, purple willow herb, long purples, moneywort, rainbows, soldiers, creeping Jenny, and purple and yellow loosestrife. Other common names include flowering Sally and soldanella, trientalis, and alvet. It is also known through out the world as salicaire, braune, and rother. Lysimachia has no smell but a slightly bitter taste, with astringent properties.

Lysimachia is a perennial found throughout Europe, Russia, central Asia, Australia, and North America. It is an attractive, mainly low-growing plant, with a creeping habit, and deep taproots. Some species can grow to about 4 ft (1.2 m) high. It primarily grows in a damp habitat, preferring riversides and swamps. It flowers from June to August.

Lysimachia punctata. *(© Arco Images / Alamy)*

The flowers, which can be either yellow or purple, are quite eye-catching, and are generally about 1 in (2.54 cm) across, arranged in cone shaped clusters. The leaves of the loosestrife species are downy, yellowish, and about 1 in (2.54 cm) long, although in some species they can be 3-6 in (7.62-15.24 cm). The stems are square and hairy.

All species of lysimachia are commonly used as ornamental plants. They prefer shade, but all grow and multiply readily. Purple loosestrife is successful to such an extent that in parts of the United States, it has been declared a danger to wetlands, as it tends to quickly dominate and force out other species of local flora.

General use

Loosestrife was once widely employed as a medicinal herb, but it has become less popular in modern times. The different species have various medicinal uses, many of which are related to the plants' flavonoids, saponins and phenolic acids.

Yellow loosestrife

Lysimachia vulgaris is the largest of the lysimachia varieties, and is also known as willow herb, willow wort, and wood pimpernel. Its yellow flowers have red stems. Yellow loosestrife is generally larger than purple loosestrife. Yellow loosestrife has been recommended as an antidote to hemorrhage and excess **menstruation**. The smoke created by burning the plant can be used as an insect repellent. In other parts of the world, its smoke is also used to keep snakes away. In addition, it is credited with having a sedative effect, which may explain why some folk customs recommend its use for banishing discord. Loosestrife means "to tame strife." Yellow loosestrife is also used to make a yellow hair dye.

Purple loosestrife

Like other species of lysimachia, the whole herb of purple loosestrife is said to have astringent and demulcent properties. Herbalists say that it is unusual to find both these properties in any one herb.

Purple loosestrife has been used as a lymphatic cleanser. Many of its other properties are similar to those attributed to other species. It may be particularly valuable as a remedy for many of today's gastrointestinal (GI) tract diseases, such as Crohn's disease, **irritable bowel syndrome**, leaky gut syndrome, and others, as it is an effective cure for **diarrhea** and is also an effective anti-inflammatory, with healing properties.

It also has properties that enable it to lower blood-glucose levels, so herbalists consider it valuable as an adjunct to diabetes treatment.

Creeping jenny

Creeping jenny (*Lysimachia numularia*) is one of the smaller species of lysimachia, reaching only about 4 in (10.16 cm) in height. It is also known as moneywort, herb tuppence, string of sovereigns, wandering jenny, wandering sally, creeping charlie, and creeping john. Its leaves are smooth, and it is a leafy trailing plant. The stems may grow to about 4 ft (1.2 m) long. It has small bright yellow flowers that will last all summer if conditions are right.

Like yellow and purple loosestrife, it is known as a deterrent to vermin and insects when burned. In common folklore, it symbolizes peace.

It may be used as a decoction, ointment, or as a poultice for infected **wounds**.

Irish folklore

The various species of lysimachia are common to the British Isles, and are well known to folk medicine. In Irish folklore, lysimachia was known as *lus na s'iochana, earball cait'in,* and *cr'eachtach*. It was believed that its use would discourage bad feeling and discord between the inhabitants of a house. It was also used as a dye and as a medicinal tonic.

Herbalists consider lysimachia to be an effective antidote to diarrhea and have used it effectively to counter outbreaks of dysentery in Switzerland. It is said to be particularly suitable for treating diarrhea in infants. Other medicinal uses include leucorrhea, **tuberculosis**, fevers, liver disease, and even cholera and typhoid. It can also be used as an antiseptic, healing wash for wounds and sores. Made up into an ointment, it is said to be useful for fading scars.

Lysimachia has a reputation for healing eye ailments, and is said to be able to restore sight in certain conditions. Some practitioners say it is superior to **eyebright** for these purposes. It is recommended as a treatment for **macular degeneration**.

It can also be used as an antiseptic gargle to cure throat **infections** and is said to be good for quinsy, which is an infected and very painful throat condition. Loosestrife has astringent properties, and has been used in the leather-tanning process.

It is said to be useful for the treatment of **whooping cough** when boiled with wine or honey.

Preparations

The dried herb may be used as an infusion or decoction. Generally, the whole herb is used. It was once commonly made up into an ointment for the treatment of **cuts** and **bruises**.

To make a useful gargle or eyewash, herbalists recommend mixing half a teaspoon of salt into two cups of boiling water, adding 1-2 tsp of the dried herb or 1-2 tbsp if fresh. Once the mixture has steeped for 10–15 minutes, it is allowed to cool before use. The mixture should be kept covered if used as an eyewash, to avoid contamination.

Precautions

Purple loosestrife may be taken up to three times daily for short periods.

Side effects

Lysimachia tends to have a high tannin content, and because of this, it should not be used as a remedy over long periods of time, as it may lead to deficiencies in valuable minerals.

KEY TERMS

Decoction—An infusion allowed to boil to obtain a more concentrated liquid.

Demulcent—Soothing to the skin.

Infusion—Made up in the form of a tea.

Leukorrhea—Also known as yeast infection, a fungal infection of the vagina producing a thick white discharge.

Macular degeneration—Degeneration of the area of the eye that is responsible for vision, often comes with aging.

Poultice—A mixture of herbs or other substances applied to wounds and inflammations to draw out impurities and inflammation.

Quinsy—Acute inflammation of the tonsils and throat area that often results in abscesses.

Interactions

Lysimachia is not known for its toxicity, and no records of any interaction have been found.

Lysine

Description

Lysine is an amino acid not produced by the body, but essential to the synthesis of protein molecules in the body. It is necessary for tissue repair and growth, and for producing antibodies, enzymes, and hormones.

Lysine is found in other protein sources, such as red meats, chicken, and turkey. Most individuals have an adequate intake of lysine from their normal diet. However, lysine levels may be low in vegetarians and low-fat dieters. Without enough lysine or any other of the eight essential **amino acids**, the body cannot build protein to sustain muscle tissue and carry out other essential body functions.

General use

The body uses L-lysine to synthesize protein. Since amino acid molecules are asymmetrical, each amino acid exists as both a right- and left-handed form, distinguished as D (for dextro, or right) and L (for levo, or left). As a supplement, L-lysine is used to treat the herpes simplex virus, help prevent **osteoporosis** and **cataracts**, and boost the immune system.

Herpes simplex virus remedy

In the 1950s, scientists discovered that foods containing certain amino acids could encourage or discourage the growth of the herpes virus. When added to the herpes virus, the amino acid **arginine** increases the growth of the virus. Lysine, by contrast, suppresses growth. Since the virus can cause cold sores, **canker sores**, and genital sores, L-lysine supplements increase the ratio of lysine to arginine in the body, preventing outbreak of the virus. Avoiding foods with arginine and eating foods with a higher lysine content helps alleviate the symptoms of the virus.

Foods containing arginine:

- legumes, especially soy
- fish and shellfish
- poultry
- spinach and seaweed
- nut and seed products

Foods containing lysine:

- fish and shellfish
- poultry
- red meats, especially game products
- eggs

Other uses

Lysine also promotes the body's absorption of **calcium**, helping to prevent osteoporosis. It slows the damage to the eyes caused by diabetes, and it may help prevent **atherosclerosis**. Since it is used to slow the growth of the herpes simplex virus, its antiviral properties may help treat **chronic fatigue syndrome**, **hepatitis**, and HIV.

KEY TERMS

Amino acid—An organic compound that contains both an amino ($-NH_2$) and carboxyl (-COOH) group. They are the constituents from which proteins are made.

Osteoporosis—A medical condition characterized by loss of bone mass, often leading to a greater risk for broken bones, especially in older women.

Preparations

L-lysine is best taken as a single supplement and not in combination with other amino acids. Such combinations are touted as nutritional supplements that build more muscle and are often used by athletes and bodybuilders. However, too much protein **strains** the functions of the liver and kidneys and can cause other health problems. The single supplement should be taken on an empty stomach because larger amounts of the amino acid can build up in the blood and brain, enhancing its health benefits. Supplements are best used by individuals suffering from a herpes outbreak or by vegetarians and low-fat dieters. Postmenopausal women can take lysine to encourage absorption of calcium by the body.

Precautions

Supplemental combinations of amino acids are not recommended to build muscle. Excessive build-up of protein in the body can cause kidney and liver problems.

Some consumers are sensitive or allergic to soybeans, a popular food used by vegetarians to replace the natural supply of lysine found in many meats. However, researchers have made progress in creating soybeans that are tolerated by consumers with those sensitivities by shutting off a gene in soybean seeds believed responsible for causing the **allergies**.

Side effects and interactions

As of 2008, no side effects or interactions had been identified.

Macrobiotic diet

Definition

A macrobiotic diet is part of a philosophy of life that incorporates the ancient Oriental concept of yin and yang. The diet itself consists mainly of brown rice, other whole grains, and vegetables. It requires foods to be cooked over a flame, rather than by electricity or microwave.

Origins

The term macrobiotics comes from two Greek words; *macro* (great) and *bios* (life). The macrobiotic diet is believed to have originated in nineteenth century Japan, with the teachings of Sagen Ishizuka, a natural healer. George Ohsawa (1893–1966), a Japanese teacher and writer, introduced macrobiotics to Europeans in the 1920s. Ohsawa claims to have cured himself of **tuberculosis** by eating Ishizuka's diet of brown rice, soup, and vegetables. The diet did not attract much attention in the United States until the mid-1960s, when Ohsawa's book *Zen Macrobiotics* was published and became a best seller, especially among the 1960s counterculture. The diet's popularity heightened when the macrobiotic philosophy was embraced by former Beatle John Lennon (1940–1980) and his wife, Yoko Ono (1933–). The macrobiotic diet has changed somewhat over the past forty years. Originally it recommended moving through stages of food elimination to achieve a diet that consisted almost solely of brown rice and water. These nutritionally unsafe dietary guidelines have mostly been replaced with a more moderate and balanced approach to eating.

Benefits

In the macrobiotic diet, foods are selected for their metaphysical qualities rather than their nutritional value. The regime, which is high in whole grains, vegetables, beans, and **soy protein**, has many of the same benefits as a vegetarian or vegan diet. Numerous scientific studies have shown that a diet of this type can significantly reduce the risk of diabetes, **heart disease**, **stroke**, and various cancers. The macrobiotic diet is rich in vitamins, high in dietary fiber, and low in fatty foods.

Description

In addition to its holistic approach to **nutrition**, macrobiotics applies these beliefs to life in general. Its philosophy recommends the following behaviors:

- eating two or three meals a day
- chewing each mouthful of food approximately 50 times to aid digestion and absorption of nutrients
- avoiding food for at least three hours before bedtime
- taking short baths or showers as needed, with warm or cool water
- consuming only organic foods
- using cast iron, clay pots, or stainless steel cookware
- cooking frequently with methods that use liquids (e.g. pressure cooking, boiling, steaming, soups, stews) instead of dry cooking methods (baking, broiling)
- eating nothing that is commercially processed and contains food additives
- taking no dietary supplements
- using grooming, cosmetic, and household products made from natural, non-toxic ingredients

Macrobiotic food. *(© isifa Image Service s .r.o.)*

- wearing only cotton clothing and avoiding metallic jewelry
- spending as much time as possible in natural outdoor settings and walking at least 30 minutes daily
- doing such aerobic or stretching exercises as yoga, dance, or martial arts on a regular basis
- placing large green plants throughout the house to enrich the oxygen content of the air, and keeping windows open as much as possible to allow fresh air circulation
- avoiding food preparation with electricity or microwaves; using gas or wood stoves; and using only cast iron, stainless steel, or clay cookware
- avoiding television viewing and computer use as much as possible

The macrobiotic diet assigns yin and yang energies to foods. Yin represents female or cool, dark, inwardly focused energy. Yang represents male or warm, light, outwardly focused energy. In this ancient Asian philosophy, everything in the universe is assigned a yin or yang quality. For good mental and physical health and a harmonious life, yin and yang forces must be balanced. This balance must be reflected in the food the individual eats. Because environmental yin and yang forces change with the seasons, with climate, and time of day, the diet must also change with them.

Meat, fish, poultry, eggs, and hard cheeses are considered yang, while milk, cream, fruit juice, alcohol, and sugar are yin. The macrobiotic diet consists mainly of foods in the middle, such as brown rice and other whole grains, beans, vegetables, fruit, and nuts. The diet is flexible, and allows fish on occasion. Its flexibility enhances its appeal. The macrobiotic diet allows people to design their own food regimens based on their personal requirements, environment, and medical conditions.

One of the principles of the macrobiotic diet is that people should primarily eat organically grown foods native to their climate and area. The theory is that human health depends on the ability to adapt to changes in the environment. When people eat foods

from a climate that differs from where they live, they lose that adaptability. Proponents of the macrobiotic diet claim that as society has moved away from its traditional ecologically based diet, there has been a corresponding rise in chronic illness. Therefore, for optimal health, the belief is that people need to return to a way of eating based on foods produced in their local environment, or at least grown in a climate that is similar to where they live.

Foods considered yang (contracted energy) last longer and can originate from a wide geographic area. Sea salt and sea vegetables are examples of yang foods. They can come from anywhere within the same hemisphere. Whole grains and legumes are also yang, and can originate anywhere within the same continent since they keep for a long time. Fresh fruits and vegetables are considered yin (expansive energy). Since they have a relatively short shelf life, they should be chosen only from those types that grow naturally within one's immediate area. According to macrobiotic beliefs, balance between yin and yang in diet and food helps achieve inner peace and harmony with one's self and the surrounding world.

Another aspect of the macrobiotic diet is that the type of foods eaten should change with the seasons. In the spring and summer, the food should be lighter, cooler, and require less cooking. This change is necessary because —according to the macrobiotic philosophy—the energy of fire is abundant in the form of sunlight and does not need to be drawn from cooked food. In the autumn and winter, the opposite is true.

The time of day also plays an important role in the macrobiotic diet since it relates to atmospheric energy levels. In the morning, when upward energy is stronger, breakfast should include light foods, such as a whole grain cooked in water. In the evening, when downward energy is stronger, the meal can be larger. Lunch should be quick and light, since afternoon energy is active and expansive.

In macrobiotics, it is believed that the dietary standards that are effective for one person may not work for another. These standards may change from day to day. Therefore, this diet requires a change in thinking from a static view of life to a dynamic one.

Many people are attracted to the diet because of claims that it can prevent or cure **cancer**. While no scientific studies support these claims, there are many people who believe the diet helped rid them of the disease when such conventional treatments as chemotherapy and radiation failed. Others use the diet to help treat diabetes, **hypertension**, arteriosclerosis, and other forms of heart disease. Many of the diet's supporters believe that these and other degenerative diseases occur because the body's yin and yang are out of balance, and that a macrobiotic diet helps restore this balance.

Macrobiotic foods

The primary food in the standard macrobiotic diet is whole cereal grains, including brown rice, barley, millet, rolled oats, wheat, corn, rye, and buckwheat. A small amount of whole grain pasta and breads is allowed. Grains should comprise about 50% of the food consumed.

Fresh vegetables should account for 20–30% of the diet. The most highly recommended vegetables include green cabbage, kale, broccoli, cauliflower, collard greens, carrots, parsnips, winter squash, bok choy, onions, **parsley**, daikon radishes, and watercress. Vegetables that should be eaten only occasionally include cucumber, celery, lettuce, and most herbs. Vegetables that should be avoided include tomatoes, peppers, potatoes, eggplant, spinach, beets, and summer squash.

About 10% of the diet should consist of beans and sea vegetables. The most suitable beans are azuki, chickpeas, and lentils. Tofu and tempeh are also allowed. Other beans can be eaten several times a week. Sea vegetables include nori, wakame, kombu, hiziki, arame, and agar-agar. Another 10% of the diet should include soups made with regular or sea vegetables.

Other permitted items include sweeteners such as barley malt, rice syrup, and apple juice; such seasonings as miso, tamari, soy sauce, rice or cider vinegar, **sesame oil**, tahini, and sea salt; occasional small amounts of seeds and nuts (pumpkin, sesame, sunflower, and almonds); and white-meat fish once or twice a week. Beverages allowed include tea made from twigs, stems, brown rice, and **dandelion** root, apple juice, and good-quality water without ice.

Items not allowed include meat, dairy products, fruits, refined grains, anything with preservatives, artificial flavorings and colorings or chemicals, all canned, frozen, processed, and irradiated foods, hot spices, **caffeine**, alcohol, refined sugar, honey, molasses, and chocolate.

Preparations

There are no specific procedures involved in preparing for the diet, except to change from a diet based on meat, sugars, dairy products, and processed foods, to one based primarily on whole grains, vegetables, and unprocessed foods. Some advocates of the macrobiotic diet recommend making the switch gradually rather than all at once.

Precautions

The macrobiotic diet does not include many fruits and vegetables that are important sources of nutrients and **antioxidants**, such as **vitamin C** and **beta carotene**. If followed rigidly, the diet can also be deficient in protein, **calcium**, **vitamin B_{12}**, folate, and **iron**. Individuals accustomed to a diet high in fat can experience sudden and drastic weight loss if they switch to a rigid macrobiotic diet. In its original form, the macrobiotic diet required foods to be slowly eliminated from the diet until only rice and beans were consumed. Carried to this extreme, the diet lacks significantly in necessary vitamins and nutrients.

A macrobiotic diet may worsen cachexia (malnutrition, wasting) in cancer patients. It is not recommended for people who have intestinal blockages, gluten-sensitive enteropathy (**celiac disease**), or cereal grain **allergies**. Children, pregnant women, and individuals with intestinal disorders, hypertension (high blood pressure), kidney disease, or malnutrition should consult their physician before starting a macrobiotic diet. A diet should never be a substitute for receiving appropriate medical treatment.

Side effects

There are no negative side effects associated with a macrobiotic diet in adults, other than such minor problems as **dizziness** in some people who experience rapid weight loss. Other, sometimes serious, side effects are possible if the diet is deficient in one or more vitamins or minerals.

Research and general acceptance

Like many alternative therapies, the macrobiotic diet is controversial and not generally embraced by allopathic medicine. Most of the controversy surrounds claims that the diet can cure cancer. These claims stem from anecdotal reports and are not substantiated by scientific research. The American Medical Association opposes the macrobiotic diet. The allopathic medical community is also concerned that people with such serious diseases as cancer may use the diet as a substitute for conventional treatment.

Scientific studies in the United States and Europe have shown that a strict traditional macrobiotic diet can lead to a variety of nutritional deficiencies, especially in protein, **amino acids**, calcium, iron, **zinc**, and ascorbic acid. These deficiencies can result in drastic weight loss, **anemia**, scurvy, and hypocalcemia. In children, a strict macrobiotic diet can cause stunted growth, protein and calorie malnutrition, and bone age retardation.

KEY TERMS

Cachexia—General physical wasting and malnutrition, usually associated with such chronic diseases as cancer and AIDS.

Celiac disease—An intestinal disorder characterized by intolerance of gluten, a protein present in the grains of wheat, rye, oats, and barley.

Enteropathy—A disease of the intestinal tract.

Hypertension—Abnormally high blood pressure.

Hypocalcemia—Calcium deficiency in the blood.

Legumes—The fruit or seed of a family of plants, including beans and peas.

Scurvy—A disease characterized by loose teeth, and bleeding gums and mouth, caused by a lack of ascorbic acid (vitamin C) in the diet.

Tempeh—A dense high-fiber food product made from fermented soybeans.

Tofu—A high-protein curd made from soybeans, used in meat and dairy replacement products.

Training and certification

No special training or certification is required. There are, however, several institutes in the United States that offer courses in the macrobiotic philosophy and diet.

Ken R. Wells

Macular degeneration

Definition

Macular degeneration (MD) is the progressive deterioration of the macula, the light-sensitive cells of the central retina, at the back of the eye. The retina is the sensitive membrane (soft layer) of the eye that receives the image formed by the lens and is connected with the brain by the optic nerve. As these macular cells malfunction and die, central vision becomes gray, hazy, or distorted, and eventually is lost. Peripheral (away from the center) vision is unaffected.

Description

Millions of people suffer from MD and it accounts for about 12% of all blindness in the United States. The macula contains the highest concentration of photo-sensitive cells in the retina. These cells transform light into electrical signals that are sent to the brain for processing into vision. Fine detail vision and critical color vision are located in the macula. The macula depend on nutrient diffusion from the choroid layer, a region of several delicate vascular (pertaining to blood vessels) membranes or structures behind the retina and under the macula. Anything that interferes with this nutrient supply can lead to MD.

Age-related macular degeneration (AMD or ARMD) is by far the most common type of MD. One in six Americans develops AMD between the

Macular degeneration. *(Jean-Luc Kokel / Photo Researchers, Inc.)*

ages of 55 and 64 and one in three Americans over 75 has AMD. About 10% of those with AMD eventually suffer severe vision loss. The incidence of AMD is expected to triple by 2025, as the population ages. Whites and Asians are more susceptible than blacks. Women and those with lighter-colored eyes are somewhat more susceptible. AMD may occur in only one eye. However there is a very high likelihood that the other eye will be affected eventually.

About 90% of AMD is the dry form. Over time, the macula thins and the pigmented retinal epithelium, a dark-colored cell layer that supports the retina, is gradually lost. About 10% of dry AMD cases progress to the wet form. In a process called choroidal neovascularization (CNV), new blood vessels proliferate in the choroid and may invade the retina. These fragile vessels can leak blood and fluid into the retina, damaging or killing macular cells and resulting in scar tissue that interferes with vision. If untreated, the macula may be destroyed. Wet AMD progresses more rapidly than dry AMD and severe vision loss typically occurs within two years.

Less common forms of MD include:

- juvenile macular degeneration (JMD), a group of inherited disorders affecting children and younger adults
- cystoid macular degeneration, the development of fluid-filled cysts (sacs) in the macular region, associated with aging, inflammation, or severe myopia (near-sightedness)
- diabetic macular degeneration
- retinal pigment epithelial detachment, a rare form of wet MD in which fluid leakage from the choroid causes the detachment or disappearance of the pigmented retinal epithelium

Causes and symptoms

Causes

Age-related macular degeneration (AMD) appears to result from a combination of hereditary,

KEY TERMS

Age-related macular degeneration (AMD, ARMD)—Macular degeneration that accompanies aging. The most common form of MD.

Amsler grid—A checkerboard pattern with a dot in the center that is used to diagnose MD.

Anthocyanosides—Flavonoid antioxidants from plant pigments that are particularly active in the eye.

Antioxidant—A substance that prevents oxidative damage, such as cellular damage caused by free radicals.

Carotenoid—A large class of red and yellow pigments found in some plants and in animal fat.

Choroid—The middle vascular layer of the eyeball, behind the retina.

Choroidal neovascularization (CNV)—The proliferation of new, fragile blood vessels in the choroid layer. Leakage from these vessels causes wet AMD.

Drusen—Yellowish-white fatty deposits on the retina, including the macula.

Electroretinogram—An instrument for measuring electrical signals from a point in the macula.

Fluorescein angiography—A method that uses a fluorescent dye for photographing blood vessels of the retina.

Free radical—A reactive atom or molecule with an unpaired electron. Oxygen free radicals can damage cells and their constituents.

Flavonoids—A group of chemical compounds naturally found in certain fruits, vegetables, teas, wines, nuts, seeds, and roots. Though not considered vitamins, they function nutritionally as biological response modifiers.

Indocyanin green angiography—A sensitive method for examining retinal blood vessels.

Lutein—An antioxidant carotenoid found in large quantities in dark-green, leafy vegetables such as spinach and kale. Lutein is deposited on the lens and macula of the eye where it protects cells from damage caused by ultraviolet and blue light.

Macula—An area of 0.1 0.2 in (3 5 mm) at the center of the retina that is responsible for sharp, central vision.

Omega-3 fatty acids.—Fatty acids from fish and vegetable oils that appear to protect against blood clots.

Ophthalmologist—A physician who specializes in eye diseases and disorders.

Ophthalmoscope—An instrument for examining the interior of the eyeball.

Optical coherence tomography (OCT) —A diagnostic method for imaging eye tissue.

Optometrist—A professional who examines eyes for visual acuity and prescribes eyeglasses or other visual aids.

Peripheral vision—Vision outside of the central vision.

Pigmented retinal epithelium—The dark-colored cell layer that supports the retina. It may thin or become detached with MD.

Photodynamic therapy (PDT)—A therapy that uses light-activated drugs to destroy rapidly-dividing cells or new blood vessels in the eye.

Retina—The nervous tissue membrane at the back of the eye, opposite the lens, that receives visual images and sends them to the brain via the optic nerve.

Visual acuity—Visual sharpness and resolving ability, usually measured by the ability to read numbers and letters.

Zeaxanthin—An antioxidant carotenoid that is the mirror image of lutein.

environmental, and metabolic factors. Over time, highly reactive free-oxygen radicals damage and destroy macular cells. Free radicals are produced by:

- bombardment of light on the macula, particularly long-term exposure to ultraviolet and blue light, including sunlight and sunlamps
- smoking, which increases the risk of AMD two- to four-fold
- a high-fat diet

The body's antioxidant systems that destroy free radicals become less effective with **aging**.

Factors that contribute to the hardening and blocking of the capillaries supplying the retina and lead to AMD include:

- smoking
- diets high in saturated fat and cholesterol
- low dietary consumption of antioxidants

The cause of choroidal neovascularization (CNV) in wet AMD is unknown. However many people with

AMD also have **cataracts** and cataract surgery increases the risk of dry AMD progressing to wet AMD.

Symptoms

AMD is painless, and in the early stages, the brain easily compensates for vision loss, particularly if AMD is restricted to one eye. Symptoms of AMD include:

- requiring more light for reading
- reduction, blurring, a blank spot, or loss of central vision while peripheral vision is unaffected
- difficulty recognizing faces
- visual distortions such as the bending of straight lines
- images appearing smaller
- changes in color perception or abnormal light sensations
- a decline of at least two lines in visual acuity as measured on a standard eye chart. For example, 20/20 vision declining to 20/80
- phantom visions, called "Charles Bonnet syndrome"

Diagnosis

Although vision loss is irreversible, early detection may halt or slow the progression of dry to wet AMD. However AMD is often fairly advanced by the time an ophthalmologist (a physician specializing in eye defects and diseases) is consulted. Tests for MD include:

- An Amsler grid, a checkerboard pattern with a black dot at the center. While staring at the dot with one eye, MD causes the straight lines to appear wavy or disappear or some areas to appear blank.
- A dilated eye exam whereby drops are used to dilate the pupils and a special magnifier called an ophthalmoscope shines a very bright light on the back of the lens to examine the retina. Gross macular changes, including scarring, thinning, or atrophy, may indicate MD. Numerous mid-sized yellow bumps called drusen, or one or more large drusen, can indicate intermediate-stage AMD. However, most people over age 42 have drusen in one or both eyes.
- Fluorescein or eye angiography, or retinal photography. An indicator dye is injected and photographs are taken to detect dye leakage from retinal blood vessels.
- Indocyanine green angiography examines choroid blood vessels that cannot be seen with fluorescein.
- Optical coherence tomography. Light waves are used to obtain cross-sectional views of eye tissue. This is easier and quicker than fluorescein angiography.
- An electroretinogram, whereby a weak or missing electrical signal from an illuminated point in the macula indicates MD.
- In a family history of MD suggesting hereditary juvenile macular degeneration (JMD), molecular genetic screening can reveal the presence of JMD-causing genes, facilitating early detection.

Treatment

Those with dry AMD should have a complete dilated eye examination at least once a year and use an Amsler grid daily to check for signs of wet AMD.

Diet

Dietary factors that can speed the progression from early-stage to advanced MD include:

- high fat consumption (70 gm versus 24 gm daily) triples the risk of advancement
- trans-fats consumption (4 gm versus 0.5 gm daily) doubles the risk
- consumption of commercial baked goods (two or more servings weekly) doubles the risk
- obesity doubles the risk of advancement

Foods containing omega-3 fats, such as nuts and fish, lower the risk of progression to advanced MD.

One study found that those with the highest dietary intake of **lutein** had a 57% lower risk for AMD. Foods high in lutein and zeaxanthin include:

- kale
- spinach
- mustard greens
- collard greens
- romaine lettuce
- leeks
- celery
- broccoli (cooked)
- peas
- corn
- zucchini
- yellow squash
- cucumbers
- orange bell peppers
- red grapes
- mangoes
- oranges

Many multi-vitamins also contain lutein.

Other factors for preventing AMD include:

- the use of sunglasses with UV protection
- maintaining normal blood pressure
- avoiding the risk factors, including smoking and secondhand smoke
- the use of supplemental estrogen by postmenopausal women is associated with a lower risk for AMD

Magnesium

Description

The chemical element magnesium (Mg) has an atomic mass of 24.31 and atomic number 12. In its elemental form, magnesium is a silver-white metal with a density of 1.738 g/cm^3. In solution, it occurs as *cations* (positively charge ions). Magnesium is the fourth most abundant cation in the human body by weight, after **calcium**, **potassium**, and **sodium**. Ninety-nine percent of the body's magnesium is contained within its cells: about 60% in the bones, 20% in the muscles, 19% to 20% in the soft tissue, and 1% in the blood. Important to both **nutrition** and medicine, magnesium, like calcium and **phosphorus**, is considered a major mineral. Magnesium carbonate and magnesium sulfate have been used for centuries as a laxative. The name of the element comes from Magnesia, a city in Greece where large deposits of magnesium carbonate were discovered in ancient times.

Magnesium is an important element in the body because it activates or is involved in many basic processes or functions, including the following:

- as cofactor for over 300 enzymes
- oxidation of fatty acids
- activation of amino acids
- synthesis and breakdown of DNA
- neurotransmission

Recommended dietary allowance of magnesium

Age	mg/day
Children 0-6 mos.	30 (AI)
Children 7-12 mos.	75 (AI)
Children 1-3 yrs.	80
Children 4-8 yrs.	130
Children 9-13 yrs.	240
Boys 14-18 yrs.	410
Girls 14-18 yrs.	360
Men 19-30 yrs.	400
Women 19-30 yrs.	310
Men ≥ 31 yrs.	420
Women ≥ 31 yrs.	320
Pregnant women ≤ 18 yrs.	400
Pregnant women 19-30 yrs.	350
Pregnant women ≥ 31 yrs.	360
Breast feeding women ≤ 18 yrs.	360
Breast feeding women 19-30 yrs.	310
Breast feeding women ≥ 31 yrs.	320

Foods that contain magnesium

	mg
Cereal, 100% bran, 1/2 cup	129
Oat bran, 1/2 cup, dry	96
Halibut, cooked, 3 oz.	90
Almonds, roasted, 1 oz.	80
Cashew nuts, roasted, 1 oz.	75
Spinach, cooked, 1/2 cup	75
Swiss chard, cooked, 1/2 cup	75
Beans, lima, cooked, 1/2 cup	63
Shredded wheat, 2 biscuits	54
Peanuts, roasted, 1 oz.	50
Black-eyed peas, cooked, 1/2 cup	43
Brown rice, cooked, 1/2 cup	40
Beans, pinto, cooked, 1/2 cup	35

AI = Adequate Intake
mg = milligram

(Illustration by GGS Information Services. Cengage Learning, Gale)

- immune function
- interactions with other nutrients, including potassium, vitamin B_6, and boron

General use

Compounds of magnesium have a number of general uses, primarily in standard allopathic medicine, but also in some alternative therapies.

Nutrition

Good dietary sources of magnesium include nuts; dried peas and beans; whole grain cereals such as oatmeal, millet, and brown rice; dark green vegetables; bone meal; blackstrap molasses; **brewer's yeast**; and soy products. Dark green vegetables are important sources of magnesium because it is the central atom in the structure of chlorophyll. Drinking hard water or mineral water can also add magnesium to a person's diet.

Severe magnesium deficiency in a healthy person is unusual because normal kidneys are very efficient in keeping magnesium levels balanced. This condition, called *hypomagnesemia*, is usually caused either by disease (kidney disease, severe malabsorption, chronic **diarrhea**, **hyperparathyroidism**, or chronic **alcoholism**) or as a side effect of certain medications, most commonly diuretics, cisplatin (a **cancer** medication), and a few antibiotics. The symptoms of hypomagnesemia include disturbances of the heart rhythm, muscle tremors or twitches, seizures, hyperactive reflexes, and occasional personality changes (**depression** or agitation). A patient with hypomagnesemia may also produce Chvostek's sign, which is a facial spasm caused when the doctor taps gently over the facial nerve. This condition of painful intermittent muscle contractions and spasms is known as *tetany*. Hypomagnesemia can be treated with either oral or intravenous preparations containing magnesium.

Magnesium toxicity (hypermagnesemia) is rare because excessive amounts are usually excreted in the urine and feces. Most cases of hypermagnesemia are caused by overuse of dietary supplements containing magnesium. The symptoms of magnesium toxicity include central nervous system depression, muscle weakness, **fatigue**, and sleepiness. In extreme cases, hypermagnesemia can cause death. It can be treated with intravenous calcium gluconate along with respiratory support. Severe hypermagnesemia can be treated by hemodialysis or peritoneal dialysis.

Standard medical practice

DIAGNOSIS. The levels of magnesium in a patient's blood or body fluids can help diagnose several illnesses. A high magnesium level in the blood may indicate kidney failure, **hypothyroidism**, severe dehydration, Addison's disease, or overingestion of antacids containing magnesium. A low blood level of magnesium may indicate hypomagnesemia. Because 99% of the body's magnesium is contained in its cells, blood tests can measure only the approximately 1% of magnesium that is extra-cellular (circulating in the

bloodstream), which makes it difficult to diagnose low magnesium levels in the body overall.

Fortunately, magnesium levels in urine can also aid diagnosis. High levels of urinary magnesium may indicate overconsumption of supplemental magnesium, overuse of diuretics, hypercalcemia (too much calcium in the body), hypophosphatemia (too little phosphate in the body), or metabolic acidosis (high blood acid levels). Low levels of magnesium in the urine may point to hypomagnesemia or hypocalcemia (too little magnesium or calcium in the body), an underactive parathyroid gland, or metabolic alkalosis (high blood alkaline levels).

TREATMENT. Compounds of magnesium are used to treat tachycardia (excessively rapid heartbeat) and low levels of electrolytes (chloride, potassium, and sodium). They help manage premature labor and can be given prophylactically to prevent seizures in toxemia of **pregnancy**. Magnesium sulfate is also effective in the treatment of eclampsia, a potentially fatal seizure condition in pregnant women.

Magnesium compounds help control seizures resulting from hypomagnesemia associated with alcoholism, **Crohn's disease**, or **hyperthyroidism**. Magnesium injections are also used to treat acute **asthma** attacks.

Magnesium preparations may be given as antacids in the treatment of peptic ulcers and hyperacidity. They are also given as laxatives for the short-term relief of **constipation** or to empty the patient's bowel prior to surgery or certain diagnostic procedures. Magnesium hydroxide is used to treat patients who have been poisoned by mineral acids or arsenic.

Magnesium in the form of magnesium sulfate is known as *Epsom salts*. It can be taken by mouth as a laxative but is also used externally to reduce tissue swelling, inflammation, and **itching** from insect **bites**, heat rash, or other minor skin irritations. Epsom salts can be applied to the affected skin or body part in moist compresses or dissolved in warm bath water.

Some research indicates that magnesium deficiency may contribute to **atherosclerosis** (hardening of the arteries), as well as to necrotizing enterocolitis (NEC), a sometimes-deadly inflammation that destroys the bowel in premature infants. Magnesium may also be useful in treating **attention-deficit hyperactivity disorder** (ADHD) and migraine headaches.

Alternative medicine

HOMEOPATHY. Phosphate of magnesia is a staple homeopathic remedy, called *Magnesia phosphorica (Mag. phos.)* It is recommended for symptoms that are relieved by the application of warmth and gentle pressure, such as **hiccups** accompanied by **colic** in infants, menstrual cramps that are relieved when the woman bends forward, and abdominal **pain** without **nausea** and **vomiting**. Patients who benefit from *Mag. phos.* are supposedly less irritable or angry in temperament than those who need *Colocynthis* or *Chamomilla*.

NATUROPATHY. Naturopaths emphasize the importance of proper food selection and preparation to obtain an adequate supply of nutrients in the diet. They maintain that modern methods of agriculture promote overcropping and soil depletion, which they believe reduces the amount of magnesium (and other minerals) available from food grown in that soil. The processing and refining of wheat and rice, which discards the magnesium contained in the bran, **wheat germ**, or rice husks, also reduces the amount of magnesium in these foods. For these reasons naturopaths often recommend organic produce, which they believe contains higher levels of minerals, and suggest that they not be overcooked or boiled in too much water. In addition, this water, or "pot liquor," is often rich in magnesium that cooks out of the vegetables. It should not be discarded but saved for use in soups or stews.

Many naturopaths believe that the official government recommended daily allowance (RDA) of magnesium is too low. They think that it should be doubled to about 600 or 700 mg daily for adults. Many recommend the use of dietary supplements containing magnesium to make up the difference.

Naturopathic practitioners regard magnesium to be important in the relief or cure of the following conditions:

- Mitral valve prolapse: Magnesium deficiency may lower the body's ability to repair defective connective tissue, including defective mitral valves.
- Atherosclerosis.
- Certain psychological conditions, including apathy, decreased ability to learn, memory loss, and confusion.
- Kidney stones: Magnesium increases the solubility of certain calcium compounds that form kidney stones if they are not excreted in the urine.
- Hypertension: Hypertensive people often have lower levels of magnesium within their cells than people with normal blood pressure.
- Angina pectoris: Magnesium is thought to relax spastic arteries and help prevent arrhythmias.

- Osteoporosis: Many osteoporosis patients have low levels of magnesium in their bodies.
- Premenstrual syndrome (PMS) and menstrual cramps: Some women report relief from the symptoms of PMS when taking magnesium supplements.
- Naturopaths also treat asthma, epilepsy, autism, hyperactivity, chronic fatigue syndrome, noise-induced hearing loss, insomnia, and stress-related anxiety with supplemental magnesium.

Preparations

Dietary supplements

Naturopaths generally recommend supplemental magnesium for people with high blood **cholesterol**, postmenopausal women, women taking birth control pills, diabetics, people who eat a lot of fast food or other highly processed food, and people who drink alcohol. Many nutrition experts recommend supplements that contain a balanced ratio of calcium to magnesium, usually two parts of calcium to one of magnesium. People who increase their calcium intake should increase their dose of magnesium (and phosphate) as well because these supplements work together and complement each other.

Some naturopaths recommend taking magnesium in the form of magnesium aspartate or magnesium citrate, arguing that these compounds are more easily absorbed by the body than magnesium carbonate or magnesium oxide. Others prefer magnesium chelated with **amino acids**. Magnesium can also be obtained from herbal sources, such as red raspberries.

Standard medical preparations

Magnesium hydroxide is a common over-the-counter antacid, available as either a tablet or liquid. Most antacid tablets contain about 200 mg of magnesium hydroxide. Liquid magnesium hydroxide is sometimes called *milk of magnesia*. Magnesium carbonate works as a cathartic or laxative when combined with citric acid to produce magnesium citrate. It is often flavored with lemon or cherry to make it more pleasant to swallow. Magnesium sulfate (in the form of Epsom salts) is available over the counter, usually in half-pound or pound boxes. Epsom salts are small whitish or colorless crystals that dissolve easily in water and have a bitter or salty taste.

Magnesium for intravenous dosage is prepared as the sulfate in a 50% solution. In general, intravenous administration of magnesium is reserved for patients with such serious symptoms as seizures, preeclampsia or eclampsia of pregnancy, acute asthma attacks, or severe cardiac arrhythmias. Magnesium sulfate can also be given by intramuscular injection.

KEY TERMS

Chvostek's sign—A facial spasm caused when a doctor taps lightly on a patient's facial nerve. A positive Chvostek's sign may indicate that the patient has hypomagnesemia.

Electrolyte—A substance, such as potassium or sodium, that has an electrical charge when dissolved in a fluid, such as blood.

Epsom salts—A preparation of magnesium sulfate, used internally as a laxative or externally in compresses or warm baths to reduce swelling, inflammation, and itching from minor skin problems.

Hypermagnesemia—A condition in which the levels of magnesium in body fluids are too high, almost always caused by a combination of low calcium levels and taking too much magnesium as a dietary supplement. Patients with hypermagnesemia may have central nervous system depression, muscle weakness, fatigue, or sleepiness.

Hypomagnesemia—A condition of magnesium deficiency, the symptoms of which include heart arrhythmias, muscle tremors or twitches, seizures, hyperactive reflexes, and psychiatric symptoms.

Major mineral—One of three important inorganic elements in human nutrition, distinguished from trace elements (minor minerals) and electrolytes. Magnesium is a major mineral, along with calcium and phosphorus.

Naturopathy—A type of alternative medicine that does not use surgery or synthetic drugs to treat disease but relies on fasting and special diets to assist the body's healing processes.

Tetany—A disorder of the nervous system characterized by muscle cramps, spasms of the arms and legs, and numbness of the extremities. It is a symptom of an abnormality in calcium metabolism.

Precautions

Preparations containing magnesium should not be given as laxatives to patients with kidney disease, nausea and vomiting, diarrhea, abdominal pain, rectal bleeding, symptoms of appendicitis, or symptoms of intestinal obstruction or perforation. In addition, these preparations should not be used routinely to relieve constipation, as individuals may become

dehydrated, lose calcium from the body, or develop a dependence on them. Antacids containing magnesium should be used with caution in patients with kidney disease.

Side effects

Magnesium preparations taken internally may cause hypermagnesemia, especially with prolonged use; electrolyte imbalance; and abdominal cramps when taken as a laxative. Milk of magnesia occasionally produces nausea or diarrhea. There are no known side effects of Epsom salts when used externally.

Interactions

Milk of magnesia decrease the patient's absorption of chlordiazepoxide, digoxin, isoniazid, quinolones, and tetracycline antibiotics. Because it increases the gastrointestinal tract's mobility, magnesium can also decrease the absorption (and thereby the effectiveness) of many other drugs and supplements as well. Magnesium sulfate, if given intravenously, is incompatible with calcium gluceptate, clindamycin, dobutamine, polymyxin B sulfate, procaine, and sodium bicarbonate.

Magnetic therapy

Definition

Magnetic therapy is the use of magnets to relieve **pain** in various areas of the body.

Origins

Magnetic therapy dates as far back as the ancient Egyptians. Magnets have long been believed to have healing powers associated with muscle pain and stiffness. Chinese healers as early as 200 B.C. were said to use magnetic lodestones on the body to correct unhealthy imbalances in the flow of *qi,* or energy. The ancient Chinese medical text known as *The Yellow Emperor's Canon of Internal Medicine* describes this procedure. The *Vedas*, or ancient Hindu scriptures, also mention the treatment of diseases with lodestones. The word "lodestone" or leading stone, came from the use of these stones as compasses. The word "magnet" probably stems from the Greek *Magnes lithos*, or "stone from Magnesia," a region of Greece rich in magnetic stones. The Greek phrase later became *magneta* in Latin.

Physiological reactions to positive and negative magnetic fields

Positive (stressful)

Increase in acid production

Depletes oxygen production

Cellular edema (water retention)

Produces insomnia, restlessness, wakefulness

Increases free radicals

Negative (anti-stressful)

Normalizes pH

Inhibits growth of microorganisms

Negates free radicals

Produces relaxation, rest, sleep

Increases oxygen production

(Illustration by Corey Light. Cengage Learning, Gale)

KEY TERMS

Fibromyalgia—A chronic syndrome characterized by fatigue, widespread muscular pain, and pain at specific points on the body.

Lodestone—A variety of magnetite that possesses magnetic polarity.

Transcranial magnetic stimulation—A procedure used to treat patients with depression.

Sir William Gilbert's 1600 treatise, *De Magnete*, was the first scholarly attempt to explain the nature of magnetism and how it differed from the attractive force of static electricity. Gilbert allegedly used magnets to relieve the arthritic pains of Queen Elizabeth I. Contemporary American interest in magnetic therapy began in the 1990s, as several professional golfers and football players offered testimony that the devices seemed to cure their nagging aches and injuries.

Many centuries ago, the earth was surrounded by a much stronger magnetic field than it is today. Over the past 155 years, scientists have been studying the decline of this magnetic field and the effects it has had on human health. When the first cosmonauts and astronauts were going into space, physicians noted that they experienced bone **calcium** loss and **muscle cramps** when they were out of the Earth's magnetic field for any extended period of time. After this discovery was made, artifical magnetic fields were placed in the space capsules.

Benefits

Some of the benefits that magnetic therapy claims to provide include:

- pain relief
- reduction of swelling
- improved tissue alkalinization
- more restful sleep
- increased tissue oxygenation
- relief of stress
- increased levels of cellular oxygen
- improved blood circulation
- anti-infective activity

Description

There are two theories that are used to explain magnetic therapy. One theory maintains that magnets produce a slight electrical current. When magnets are applied to a painful area of the body, the nerves in that area are stimulated, thus releasing the body's natural painkillers. The other theory maintains that when magnets are applied to a painful area of the body, all the cells in that area react to increase blood circulation, ion exchange, and oxygen flow to the area. Magnetic fields attract and repel charged particles in the bloodstream, increasing blood flow and producing heat. Increased oxygen in the tissues and blood stream is thought to make a considerable difference in the speed of healing.

Preparations

There are no special preparations for using magnetic therapy other than purchasing a product that is specific for the painful area being treated. Products available in a range of prices include necklaces and bracelets; knee, back, shoulder and wrist braces; mattress pads; gloves; shoe inserts; and more.

Precautions

The primary precaution involved with magnetic therapy is to recognize the expense of this therapy. Magnets have become big business; they can be found in mail-order catalogs and stores ranging from upscale department stores to specialty stores. As is the case with many popular self-administered therapies, many far-fetched claims are being made about the effectiveness of magnetic therapy. Consumers should adopt a "let the buyer beware" approach to magnetic therapy. Persons who are interested in this form of treatment should try out a small, inexpensive item to see if it works for them before investing in the more expensive products.

Side effects

There are very few side effects from using magnetic therapy. Generally, patients using this therapy find that it either works for them or it does not. Patients using transcranial magnetic stimulation for the treatment of **depression** reported mild **headache** as their only side effect.

Research and general acceptance

Magnetic therapy is becoming more and more widely accepted as an alternative method of pain relief. Since the late 1950s, hundreds of studies have demonstrated the effectiveness of magnetic therapy. In 1997, a group of physicians at Baylor College of Medicine in Houston, Texas studied the use of magnetic therapy in 50 patients who had developed polio earlier in life. These patients had muscle and joint pain that standard

treatments failed to manage. In this study, 29 of the patients wore a magnet taped over a trouble spot, and 21 others wore a nonmagnetic device. Neither the researchers nor the patients were told which treatment they were receiving (magnetic or nonmagnetic). As is the case with most studies involving a placebo, some of the patients responded to the nonmagnetic therapy, but 75% of those using the magnetic therapy reported feeling much better.

In another study at New York Medical College in Valhalla, New York, a neurologist tested magnetic therapy on a group of 19 men and women complaining of moderate to severe burning, tingling, or numbness in their feet. Their problems were caused by diabetes or other conditions present such as **alcoholism**. This group of patients wore a magnetic insole inside one of their socks or shoes for 24 hours a day over a two-month period, except while bathing. They wore a non-magnetic insert in their other sock or shoe. Then for two months they wore magnetic inserts on both feet. By the end of the study, nine out of ten of the diabetic patients reported relief, while only three of nine non-diabetic patients reported relief. The neurologist in charge of the study believes that this study opens the door to additional research into magnetic therapy for diabetic patients. He plans a larger follow-up study in the near future.

In 2000, a federally funded study began at the University of Virginia. This study evaluated the effectiveness of magnetic mattress pads in easing the muscle pain, stiffness and **fatigue** associated with **fibromyalgia**.

Magnetic therapy is also being studied in the treatment of depression and for patients with **bipolar disorder**. A procedure called repeated transcranial magnetic stimulation has shown promise in treating this condition. In one study, patients with depression had a lower relapse rate than did those using electroconvulsive therapy. Unlike electroconvulsive therapy, patients using magnetic therapy did not suffer from seizures, memory lapses, or impaired thinking.

Progress continues on the study of magnets and the brain. In 2002, more than 2,000 patients had undergone transcranial magnetic stimulation (TMS) for treatment of depression at the University of South Carolina with promising preliminary results. TMS is less shocking to the brain than electroconvulsive therapy. Another study was testing the use of magnets for therapy of essential tremors. By using a control group with sham repetitive TMS, the researchers noted **tremor** improvement and no adverse effects from the magnet therapy. These applications of magnet therapy are still under study and are not approved by the Food and Drug Administration (FDA) but look promising.

Training and certification

There is no training or certification required for administering magnetic therapy. Magnetic therapy can be self-administered.

Magnolia

Description

Many species of magnolia are used in both Eastern and Western herbalism. The Chinese have used the bark of *Magnolia officinalis*, called in Chinese *hou po* since the first century A.D. *M. officinalis* is a deciduous tree that grows to a height of 75 ft (22 m). It has large leaves surrounding a creamy white fragrant flower. The pungent aromatic bark is used in healing. Originally native to China where it grows wild in the mountains, *M. officinalis* is now grown as an ornamental for use in landscaping around the world.

Chinese herbalists also use the bud of *Magnolia liliflora* in healing. The Chinese name for magnolia flower is *xin yi hua*. In Chinese herbalism, magnolia bark and magnolia flower are considered different herbs with different properties and uses.

Western herbalists use other species of magnolia. These include *Magnolia virginiana, M. glauca, M. acuminate* and *M. tripetata*. Other names for magnolia

Magnolia vine. *(© Organica / Alamy)*

include white bay, beaver tree, swamp **sassafras** (not to be confused with other forms of sassafras used in the West), and Indian bark. The New World species of magnolia are smaller than their Asian counterparts, ranging in height from 6–30 ft (2–10 m). Both the bark and the root are used in **Western herbalism**.

General use

In Chinese herbalism, magnolia bark, *hou po*, is associated with the stomach, lungs, spleen, and large intestine. It is used to treat menstrual cramps, abdominal **pain**, abdominal bloating and **gas**, **nausea**, **diarrhea**, and **indigestion**. Injections of magnolia bark extract are said to cause muscle **relaxation**. It is also used in formulas to treat coughing and **asthma**. The bark is said to make the *qi* descend and is used for symptoms of disorders thought to move upward in the body.

Research suggests that compounds found in magnolia bark may have mild antibacterial and antifungal properties. These studies are in their preliminary stages, however, and have been limited to test tube research.

Magnolia flower, *xin yi hua*, is associated with the lungs. It is used to treat chronic respiratory **infections**, sinus infections, and lung congestion. Its main function is to open the airway. Little scientific research has been done on the magnolia flower.

Magnolia bark and root are also used occasionally in Western herbalism, although they are not major healing herbs. At one time, magnolia root was used to treat rheumatism, and was thought to be superior to quinine in treating **chills** and **fever**. It is not used much today. Russian herbalists use an oil extracted from the flowers and young leaves to treat **hair loss** and as an antiseptic on skin **wounds**. In homeopathic medicine a tincture of magnolia flower is a minor remedy for asthma and fainting.

Little recent scientific research has been done on magnolia in the West; however, Asian researchers have isolated a compound from *M. officinalis* known as honokiol. Honkiol is being studied for its ability to induce apoptosis, or cell self-destruction, in **cancer** cells. In Japan, honokiol is considered a useful in reducing **anxiety**; herbal preparations containing honokiol are prescribed as mild tranquilizers. Chinese researchers reported in 2007 that a mixture of honkiol and magnolol, another active ingredient in magnolia, acted as an antidepressant in rats.

Preparations

Magnolia bark is most commonly used with the following herbs:

- Agastache: for treatment of stomach flu and gastrointestinal upset
- Apricot seed and linum: for treatment of chronic constipation and hemorrhoids
- Bupleurum, inula and cyperus: for treatment of stress-related gastrointestinal disturbances All these formulas can be made into teas or are commercially available as pills or capsules.

Magnolia flower is most commonly used in xanthium and magnolia formula. It is used to relieve sinus congestion associated with a yellow discharge and to treat allergy symptoms such as runny nose. This formula can be made into a tea or is available in commercially produced capsules.

American herbalists dry magnolia bark and root and pound it into a powder or make a tincture that is taken several times daily. Russian herbalists soak the bark in vodka.

Magnolia flower. *(© D. Hurst / Alamy)*

KEY TERMS

Apoptosis—Cell self-destruction. Magnolia is thought to contain certain chemicals that cause the apoptosis of cancer cells.

Honokiol—A compound derived from magnolia that is used in some Japanese herbal preparations as a mild tranquilizer. Honokiol may also be useful in treating lung cancer.

Qi—The Chinese term for life force or vital energy.

Tincture—An alcohol-based extract prepared by soaking plant parts.

Precautions

Chinese herbalists recommend that magnolia bark not be used by pregnant women and that magnolia flower be used with caution if the patient is dehydrated.

Side effects

There are no unwanted side effects reported with normal doses of any of the different uses of magnolia. Large quantities of magnolia preparations, however, have been reported to cause **dizziness**. In addition, allergic reactions to the pollen from magnolia trees are not unusual.

Interactions

In Chinese herbalism, both magnolia bark and flowers are often used in conjunction with other herbs with no reported interactions. There are no formal studies of its interactions with Western pharmaceuticals; however, there are anecdotal reports of harmful interactions between magnolia bark and prescription weight-loss medications. In addition, magnolia should not be taken together with any medications given to lower blood pressure, as it increases their effects.

Maitake

Description

Maitake, *Grifola frondosa*, is a mushroom found growing wild in Japan and in forests in the eastern part of North America, where it grows on dying or already dead hardwood trees. The word *maitake* means "dancing mushroom" in Japanese; the mushroom was given this name because people were supposed to have danced for joy when they found it. It is also called "hen-in-the-woods" and can reach the size of a head of lettuce. Because maitake comes from the polypores group, it produces a bunch of leaf-like clumps that are intertwined. During Japan's feudal era, maitake was used as currency; the daimyo, or provincial nobles, would exchange maitake for its weight in silver from the shogun, the military ruler of Japan.

The mushroom is also cultivated in laboratories by growing a small amount of it on a sterile medium in a Petri dish. This culture is used to make what is called a spawn, which is then inoculated into production logs made from sawdust and grain. During the next 30 days, the spawn settles in and binds to the log. Then the logs are placed in temperature- and humidity-controlled mushroom houses until the mushrooms begin forming. They are then moved to a mushroom fruiting house. The entire procedure requires a period of 10–14 weeks.

Maitake's main ingredient is the polysaccharide beta-1.6-glucan, a complex carbohydrate substance high in sugar components bound together. The patented extracted form of this glucan is called the Maitake D-Fraction. Both terms can be used interchangeably. Two other components of maitake, named *fraction X* and *fraction ES*, were discovered by Harry Preuss, a medicine and pathology professor at Georgetown University Medical Center in Washington, DC.

General use

Although the Chinese and Japanese have used maitake in cooking and healing for many centuries, it is only in the last 20 years that studies have been conducted concerning its functions. Maitake's main functions are activating the immune system and acting as an antitumor agent. Maitake is known as an adaptogen and tonic, and as such it aids healthy people to keep their levels of blood sugar, blood pressure, **cholesterol**, and weight normal. The beta glucan in maitake is a *cell-surface carbohydrate*. This means that beta glucan aids cell communication in specific circumstances. As a polysaccharide, this glucan activates

Maitake mushroom (Grifola frondosa). *(MIXA Co., Ltd. / Alamy)*

the white blood cells, called *macrophages*, which in turn devour microorganisms that produce disease, as well as tumors.

A 1995 study at Japan's Kobe Pharmaceutical University investigated the effects of maitake's D-fraction on **cancer** in mice. Results showed 73.3-45.5% reduction in breast, lung, liver and prostrate cancer growth, 25% reduction in **leukemia**, 33.3% reduction in stomach cancer and 0–16% in bone cancer. These benefits increased 4–13% when combined with traditional chemotherapy treatment, as well as reducing chemotherapy's side effects and making it work better in treating cancer. Researchers attribute this latter result to the X and ES fractions of the mushroom. More recent studies of the use of MD-fraction in treating cancer patients have also found that its effectiveness varies somewhat depending on the type of cancer; a higher proportion of patients with cancers of the breast, lung, or liver showed improvement than patients with leukemia or brain cancers.

Another study by the same group of researchers looked at maitake's D-fraction function of activating memory T-cells. In turn, these T-cells remember the cells that started the tumor growth and nail them for destruction. The study found that maitake both decreases cancer cells and prevents them from occurring elsewhere in the body. In addition to its antitumor effects, maitake extract appears to increase cellular immunity to cancer.

KEY TERMS

Adaptogen—A herb or herbal product that helps the body adapt to a broad range of life stresses.

Glucan—A complex sugar molecule consisting of smaller units of glucose.

Spawn—Grain, often rye or millet, that has been inoculated with mushroom spores and is used to grow mushrooms commercially.

Spore—The asexual reproductive body of a mushroom or other nonflowering plant.

Tonic—A medicine or herbal preparation that is given to strengthen and invigorate the body.

Cancer research on apoptosis is one of the main areas of study. This process of programmed cell death is found to kill not only cancer cells, but all cells. At the Department of Urology, New York Medical College, *in vitro* research by Hiroshi Tazaki and his team shows that the D-fraction can kill **prostate cancer** cells.

Preuss, who discovered the fraction X (anti-diabetic) and fraction ES (anti-hypertensive) components of maitake, conducted studies based on the hypothesis that such chronic diseases of **aging** as diabetes, **hypertension** and **obesity** are connected partly to glucose/insulin disorders. From his 1998 study, Preuss concluded that maitake could positively affect the glucose/insulin balance and prevent these age-related diseases. A study done at Georgetown University in 2002 found that an extract of maitake does indeed improve glucose/insulin metabolism in insulin-resistant mice.

Maitake's affect on liver and cholesterol were discovered in two more studies at Kobe Pharmaceutical University. A 1996 study on rats with hyperlipidemia were fed either cholesterol or dried powder containing 20% maitake mushroom. Results showed that maitake altered the metabolism of fatty acids by stopping fatty acid from increasing in the liver and fatty acid levels from rising in the blood serum.

Maitake can also decrease high blood pressure. In 1994, a study at New York's Ayurvedic Medical Center, hypertensive patients took maitake concentrate two times daily for a month. Results showed their blood pressure decreased from 5–20%.

Studies have also shown maitake can help **AIDS** patients. In *Mushrooms as Medicine*, two 1992 *in vitro* studies, one in Japan and one at the United States National Cancer Institute, showed that maitake both improves T-cell activity and kills HIV. One study, using a sulfated maitake extract, stopped HIV killing T-cells by 97%. Another study, in 1996 at Memorial Sloan-Kettering Cancer Center in New York, looked at the functions of a variety of edible mushrooms, including maitake. Although the study showed that the information for mushrooms wasn't as strong as for vegetables, such as broccoli and cauliflower, the study also recommended that more research should be done regarding the use of mushrooms to treat serious diseases, such as cancer and AIDS.

In 1999, the U. S. Food and Drug Administration (FDA) granted Maitake Products approval to conduct a clinical study using maitake (in its patented D-fraction form) in people with advanced **breast cancer** and prostate cancer. The American Cancer Society (ACS) is less supportive of the claims made for maitake, stating in its guide to complementary and alternative treatments that "There is no scientific evidence that the maitake mushroom is effective in treating or preventing cancer in humans." The ACS points out that the Japanese studies of maitake have been done on mice, and that further research is necessary to show that the benefits also apply to humans.

Preparations

Maitake mushroom may be eaten fresh, made into a tea, taken as capsules, or taken as an alcohol extract.

When maitake mushroom is cooked, the taste is woodsy. The mushroom must be washed and soaked in water until it turns soft. It is sautéed in oil and used as a side dish, in stews, sauces, or in soups. Maitake mushrooms will keep from five to 10 days if properly stored in a paper bag in the refrigerator.

Dried maitake pieces may be made into a tea by using two to four grams per day, split into two preparations of tea. It is best to drink the tea between the morning and evening. To make the tea, it is first required to grind the dried maitake in a coffee grinder, then it is added to water, boiled and simmered from 20 minutes to four hours. Tea should be filtered before drinking. Grounds can be reused as long as they retain their color. Maitake can also be mixed with other tonic herbs, such as **green tea** or ginseng.

Capsules are available in 150-500 mg with a standardized D-fraction powder extract of 10 mg. They may be taken twice a day between meals or first thing in the morning. Dosage varies from one capsule of 150 mg to six capsules of 500 mg. It is best to consult with a health care provider for therapeutic doses. Taking maitake with **vitamin C** helps to increase maitake's absorption. Capsules should be stored in a cool dry place.

The FDA approved-for-clinical-study maitake products are available in D-fraction extracts of two to four ounce bottles, as well as capsules.

Precautions

Maitake is not recommended for children. Pregnant women and nursing women should consult a health care provider before taking maitake. People with such autoimmune diseases as lupus should avoid maitake. The mushroom stimulates the immune system, and their immune systems are already in overdrive.

Side effects

Side effects are rare and the only known one is possible loose bowels and stomach upset if the whole mushroom is eaten. To avoid this, take in capsule form.

Interactions

No interactions between maitake and prescription medications have been reported.

Malaria

Definition

Malaria is a serious infectious disease spread by certain mosquitoes. It is most common in tropical climates. It is characterized by recurrent symptoms of **chills**, **fever**, and an enlarged spleen. The disease can be treated with medication, but it often recurs. Malaria is endemic (occurs frequently in a particular locality) in many third world countries. Isolated, small outbreaks sometimes occur within the boundaries of the United States, with most of the cases reported as having been imported from other locations.

Description

Malaria is a growing problem in the United States. Although only about 1400 new cases were reported in the United States and its territories in 2000, many involved returning travelers. In addition, locally transmitted malaria has occurred in California, Florida, Texas, Michigan, New Jersey, and New York City. While malaria can be transmitted in blood, the American blood supply is not screened for malaria. Widespread malarial epidemics are far less likely to occur in the United States, but small localized epidemics could return to the Western world. As of late 2002, primary care physicians are being advised to screen returning travelers with fever for malaria, and a team of public health doctors in Minnesota is recommending screening immigrants, refugees, and international adoptees for the disease—particularly those from high-risk areas.

The picture is far more bleak, however, outside the territorial boundaries of the United States. A recent government panel warned that disaster looms over Africa from the disease. Malaria infects between 300 and 500 million people every year in Africa, India, southeast Asia, the Middle East, Oceania, and Central and South America. A 2002 report stated that malaria kills 2.7 million people each year, more than 75 percent of them African children under

the age of five. It is predicted that within five years, malaria will kill about as many people as does **AIDS**. As many as half a billion people worldwide are left with chronic **anemia** due to malaria infection. In some parts of Africa, people battle up to 40 or more separate episodes of malaria in their lifetimes. The spread of malaria is becoming even more serious as the parasites that cause malaria develop resistance to the drugs used to treat the condition. In late 2002, a group of public health researchers in Thailand reported that a combination treatment regimen involving two drugs known as dihydroartemisinin and azithromycin shows promises in treating multidrug-resistant malaria in southeast Asia.

Causes and symptoms

Human malaria is caused by four different species of a parasite belonging to genus *Plasmodium*: *Plasmodium falciparum* (the most deadly), *Plasmodium vivax*, *Plasmodium malariae*, and *Plasmodium ovale*. The last two are fairly uncommon. Many animals can get malaria, but human malaria does not spread to animals. In turn, animal malaria does not spread to humans.

A person gets malaria when bitten by a female mosquito seeking a blood meal that is infected with the malaria parasite. The parasites enter the blood stream and travel to the liver, where they multiply. When they reemerge into the blood, symptoms appear. By the time a patient shows symptoms, the parasites have reproduced very rapidly, clogging blood vessels and rupturing blood cells.

Malaria cannot be casually transmitted directly from one person to another. Instead, a mosquito **bites** an infected person and then passes the infection on to the next human it bites. It is also possible to spread malaria via contaminated needles or in blood transfusions. This is why all blood donors are carefully screened with questionnaires for possible exposure to malaria.

It is possible to contract malaria in non-endemic areas, although such cases are rare. Nevertheless, at least 89 cases of so-called airport malaria, in which travelers contract malaria while passing through crowded airport terminals, have been identified since 1969.

The amount of time between the mosquito bite and the appearance of symptoms varies, depending on the strain of parasite involved. The incubation period is usually between eight and 12 days for falciparum malaria, but it can be as long as a month for the other types. Symptoms from some strains of *P. vivax* may not appear until eight to 10 months after the mosquito bite occurred.

KEY TERMS

Arteminisinins—A family of antimalarial products derived from an ancient Chinese herbal remedy. Two of the most popular varieties are artemether and artesunate, used mainly in southeast Asia in combination with mefloquine.

Chloroquine—An antimalarial drug that was first used in the 1940s, until the first evidence of quinine resistance appeared in the 1960s. It is now ineffective against falciparum malaria almost everywhere. However, because it is inexpensive, it is still the antimalarial drug most widely used in Africa. Native individuals with partial immunity may have better results with chloroquine than a traveler with no previous exposure.

Mefloquine—An antimalarial drug that was developed by the United States Army in the early 1980s. Today, malaria resistance to this drug has become a problem in some parts of Asia (especially Thailand and Cambodia).

Quinine—One of the first treatments for malaria, quinine is a natural product made from the bark of the Cinchona tree. It was popular until being superseded by the development of chloroquine in the 1940s. In the wake of widespread chloroquine resistance, however, it has become popular again. Quinine, or its close relative quinidine, can be given intravenously to treat severe *Falciparum* malaria.

Sulfadoxone/pyrimethamine (Fansidar)—An antimalarial drug developed in the 1960s. It is the first drug tried in some parts of the world where chloroquine resistance is widespread. It has been associated with severe allergic reactions due to its sulfa component.

The primary symptom of all types of malaria is the "malaria ague" (chills and fever), which corresponds to the "birth" of the new generation of the parasite. In most cases, the fever has three stages, beginning with uncontrollable shivering for an hour or two, followed by a rapid spike in temperature (as high as 106°F [41.4°C]), which lasts three to six hours. Then, just as suddenly, the patient begins to sweat profusely, which will quickly bring down the fever. Other symptoms may include **fatigue**, severe **headache**, or **nausea** and **vomiting**. As the sweating subsides, the patient typically feels exhausted and falls asleep. In many cases,

this cycle of chills, fever, and sweating occurs every other day, or every third day, and may last for between a week and a month. Those with the chronic form of malaria may have a relapse as long as 50 years after the initial infection.

Falciparum malaria is far more severe than other types of malaria because the parasite attacks all red blood cells, not just the young or old cells, as do other types. It causes the red blood cells to become very "sticky." A patient with this type of malaria can die within hours of the first symptoms. The fever is prolonged. So many red blood cells are destroyed that they block the blood vessels in vital organs (especially the brain and kidneys), and the spleen becomes enlarged. There may be brain damage, leading to coma and convulsions. The kidneys and liver may fail.

Malaria in **pregnancy** can lead to premature delivery, miscarriage, or stillbirth.

Certain kinds of mosquitoes belonging to the genus *Anopheles* can pick up the parasite by biting an infected human. (The more common kinds of mosquitoes in the United States do not transmit the infection.) This is true for as long as that human has parasites in his/her blood. Since strains of malaria do not protect against each other, it is possible to be reinfected with the parasites again and again. It is also possible to develop a chronic infection without developing an effective immune response.

Diagnosis

Malaria is diagnosed by examining blood under a microscope. The parasite can be seen in the blood smears on a slide. These blood smears may need to be repeated over a 72-hour period in order to make a diagnosis. Antibody tests are not usually helpful because many people developed antibodies from past **infections**, and the tests may not be readily available. A new laser test to detect the presence of malaria parasites in the blood was developed in 2002, but is still under clinical study.

Two new techniques to speed the laboratory diagnosis of malaria show promise. The first is acridine orange (AO), a staining agent that works much faster (3–10 min) than the traditional Giemsa stain (45–60 min) in making the malaria parasites visible under a microscope. The second is a bioassay technique that measures the amount of a substance called histadine-rich protein II (HRP2) in the patient's blood. It allows for a very accurate estimation of parasite development. A dip strip that tests for the presence of HRP2 in blood samples appears to be more accurate in diagnosing malaria than standard microscopic analysis.

Anyone who becomes ill with chills and fever after being in an area where malaria exists must see a doctor and mention their recent travel to endemic areas. A person with the above symptoms who has been in a high-risk area should insist on a blood test for malaria. The doctor may believe the symptoms are just the common flu virus. Malaria is often misdiagnosed by North American doctors who are not used to seeing the disease. Delaying treatment of falciparum malaria can be fatal.

Treatment

Traditional Chinese medicine

The Chinese herb qiinghaosu (the Western name is artemisinin) has been used in China and southeast Asia to fight severe malaria, and became available in Europe in 1994. It is usually combined with another antimalarial drug (mefloquine) to prevent relapse and drug resistance. It is not available in the United States and other parts of the developed world due to fears of its toxicity, in addition to licensing and other issues.

Western herbal medicine

A Western herb called **wormwood** (*Artemesia annua*) that is taken as a daily dose may be effective against malaria. Protecting the liver with herbs like **goldenseal** (*Hydrastis canadensis*), Chinese goldenthread (*Coptis chinensis*), and **milk thistle** (*Silybum marianum*) can be used as preventive treatment. These herbs should only be used as complementary to conventional treatment and not to replace it. Patients should consult their doctors before trying any of these medications.

Traditional African herbal medicine

As of late 2002, researchers were studying a traditional African herbal remedy against malaria. Extracts from *Microglossa pyrifolia*, a trailing shrub belonging to the daisy family (Asteraceae), show promise in treating drug-resistent strains of *P. falciparum*.

Allopathic treatment

Falciparum malaria is a medical emergency that must be treated in the hospital. The type of drugs, the method of giving them, and the length of the treatment depend on where the malaria was contracted and the severity of the patient's illness.

For all strains except falciparum, the treatment for malaria is usually chloroquine (Aralen) by mouth for three days. Those falciparum strains suspected to

be resistant to chloroquine are usually treated with a combination of quinine and tetracycline. In countries where quinine resistance is developing, other treatments may include clindamycin (Cleocin), mefloquin (Lariam), or sulfadoxone/pyrimethamine (Fansidar). Most patients receive an antibiotic for seven days. Those who are very ill may need intensive care and intravenous (IV) malaria treatment for the first three days.

A patient with falciparum malaria needs to be hospitalized and given antimalarial drugs in different combinations and doses depending on the resistance of the strain. The patient may need IV fluids, red blood cell transfusions, kidney dialysis, and assistance breathing.

A drug called primaquine may prevent relapses after recovery from *P. vivax* or *P. ovale*. These relapses are caused by a form of the parasite that remains in the liver and can reactivate months or years later.

Another new drug, halofantrine, is available abroad. While it is licensed in the United States, it is not marketed in this country and it is not recommended by the Centers for Disease Control and Prevention in Atlanta.

Expected results

If treated in the early stages, malaria can be cured. Those who live in areas where malaria is epidemic, however, can contract the disease repeatedly, never fully recovering between bouts of acute infection.

Prevention

Preventing mosquito bites while in the tropics is one possible way to avoid malaria. Several researchers are currently working on a malarial vaccine, but the complex life cycle of the malaria parasite makes it difficult. A parasite has much more genetic material than a virus or bacterium. For this reason, a successful vaccine has not yet been developed. A new longer-lasting vaccine shows promise, attacking the toxin of the parasite and therefore lasts longer than the few weeks of those vaccines currently used for malaria prevention. However, as of late 2002, the vaccine had been tested only in animals, not in humans, and could be several years from use.

A newer strategy involves the development of genetically modified non-biting mosquitoes. A research team in Italy is studying the feasibility of this means of controlling malaria.

Malaria is an especially difficult disease to prevent by vaccination because the parasite goes through several life stages. One recent, promising vaccine appears to have protected up to 60% of people exposed to malaria. This was evident during field trials for the drug that were conducted in South America and Africa. It is not yet commercially available.

The World Health Organization has been trying to eliminate malaria for the past 30 years by controlling mosquitoes. Their efforts were successful as long as the pesticide DDT killed mosquitoes and antimalarial drugs cured those who were infected. Today, however, the problem has returned a hundredfold, especially in Africa. Because both the mosquito and parasite are now extremely resistant to the insecticides designed to kill them, governments are now trying to teach people to take antimalarial drugs as a preventive medicine and avoid getting bitten by mosquitoes.

Travelers to high-risk areas should use insect repellant containing DEET for exposed skin. Because DEET is toxic in large amounts, children should not use a concentration higher than 35%. DEET should not be inhaled. It should not be rubbed onto the eye area, on any broken or irritated skin, or on children's hands. It should be thoroughly washed off after coming indoors.

Those who use the following preventive measures get fewer infections than those who do not:

- Between dusk and dawn, remaining indoors in well-screened areas.
- Sleep inside pyrethrin or permethrin repellent-soaked mosquito nets.
- Wearing clothes over the entire body.

Anyone visiting areas where malaria is endemic should take antimalarial drugs starting one week before they leave the United States. The drugs used are usually chloroquine or mefloquine. This treatment is continued through at least four weeks after leaving the endemic area. However, even those who take antimalarial drugs and are careful to avoid mosquito bites can still contract malaria.

International travelers are at risk for becoming infected. Most Americans who have acquired falciparum malaria were visiting sub-Saharan Africa; travelers in Asia and South America are less at risk. Travelers who stay in air conditioned hotels on tourist itineraries in urban or resort areas are at lower risk than those who travel outside these areas, such as backpackers, missionaries, and Peace Corps volunteers. Some people in Western cities where malaria does not usually exist may acquire the infection from a mosquito carried onto a jet. This is called airport or runway malaria.

A 2002 report showed how efforts in a Vietnamese village to approach prevention from multiple angles resulted in a significant drop in malaria cases. Health workers distributed bednets treated with permethrin throughout the village and also made sure they were re-sprayed every six months. They also worked to ensure early diagnosis, early treatment, and annual surveys of villagers to bring malaria under control.

Malignant lymphoma

Definition

Lymphomas are a group of cancers in which cells of the lymphatic system become abnormal and start to grow uncontrollably. Because there is lymph tissue in many parts of the body, lymphomas can start in almost any organ of the body.

Description

The lymphatic system is made up of ducts or tubules that carry lymph to all parts of the body. Lymph is a milky fluid that contains lymphocytes. These, along with monocytes and granulocytes make

Swelling in the neck of a 70-year old woman with non-Hodgkin's type lymphoma, cancer of the lymph nodes. *(Dr. P. Marazzi / Photo Researchers, Inc.)*

up the leukocytes, or white blood cells, the infection-fighting and reparative bodies in the blood. Small pea-shaped organs found along the network of lymph vessels are called lymph nodes; their main function is to make and store lymphocytes. Clusters of lymph nodes are found in the pelvic region, underarm, neck, chest, and abdomen. The spleen (an organ in the upper abdomen), the tonsils, and the thymus (a small organ beneath the breastbone) are also part of the lymphatic system. Lymphocytes are held within the lymphoid tissue until they join the flow of lymph through the node. There are two main types of lymphocytes: the T cell and the B cell. Lymphomas develop from these two types. B-cell lymphomas are more common among adults, while among children, the incidence of T- and B-cell lymphomas are almost equal.

The T and the B cells perform different jobs within the immune system. When an infectious bacterium enters the body, the B cells make proteins called *antibodies,* which attach themselves to the bacteria, and flag them for destruction by other immune cells. The T cells help protect the body against viruses. When a virus enters a cell, it generally produces certain proteins that it projects onto the surface of the infected cell. T cells recognize these proteins and produce *cytokines* to destroy the infected cells. Some cytokines attract other cell types, which can digest the virus-infected cell. T cells can also destroy some types of **cancer** cells.

Lymphomas can be divided into two main types: Hodgkin's and non-Hodgkin's. There are at least 10 types of non-Hodgkin's lymphomas that are grouped (staged) by how aggressively they grow: slow growing (low grade), intermediate growing, and rapidly growing (high grade); and how far they spread.

KEY TERMS

Antibodies—Proteins made by the B lymphocytes in response to the presence of infectious agents such as bacteria or viruses in the body.

Biopsy—The surgical removal and microscopic examination of living tissue for diagnostic purposes.

Cytokines—Chemicals made by T cells that act on other cells to stimulate or inhibit their function.

Most non-Hodgkin's lymphomas begin in the lymph nodes; about 20% start in other organs, such as the lungs, liver or gastrointestinal tract. When lymphomas begin, malignant lymphocytes multiply uncontrollably and do not perform their normal functions, which affects the body's ability to fight **infections**. In addition, malignant cells may crowd the bone marrow, and, depending on the stage, prevent the production of normal red blood cells, white blood cells, and platelets. A low red blood cell count causes **anemia**, while a reduction in the number of platelets makes the person susceptible to excessive bleeding. Cancerous cells can also invade other organs through the circulatory system of the lymph, causing those organs to malfunction.

Causes and symptoms

The exact cause of non-Hodgkin's lymphomas is unknown. In general, males are at a higher risk than females, and the risk increases with age. Though it can strike people as young as 40, people between the ages of 60 and 69 are at the highest risk. In addition, the number of non-Hodgkin's cases has increased significantly in recent years, many of them due to the **AIDS** epidemic. (For reasons that are still poorly understood, AIDS patients have a higher likelihood of developing non-Hodgkin's lymphomas.)

People exposed to certain pesticides and ionizing radiation have a higher-than-average chance of developing this disease. For example, an increased incidence of lymphomas has been seen in survivors of the atomic bomb explosion in Hiroshima, and in people who have undergone aggressive radiation therapy. People who suffer from immune-deficient disorders, as well as those who have been treated with immune-suppressive drugs for heart or kidney transplants, and for conditions such as **rheumatoid arthritis** and autoimmune diseases, are at an increased risk for this disease. Some studies have shown a loose association between retroviruses, such as HTLV-I, and some rare forms of lymphoma. The Epstein-Barr virus has been

linked to Burkitt's lymphoma in African countries. However, a direct cause-and-effect relationship has not been established.

The symptoms of lymphomas are often vague and nonspecific. Patients may experience loss of appetite, weight loss, **nausea**, **vomiting**, abdominal discomfort, and **indigestion**. The patient may complain of a feeling of fullness, which is a result of enlarged lymph nodes in the abdomen. Pressure or **pain** in the lower back is another symptom. In the advanced stages, the patient may have bone pain, headaches, constant coughing, and abnormal pressure and congestion in the face, neck, and upper chest. Some may have fevers and night sweats. In most cases, patients go to the doctor because of the presence of swollen glands in the neck, armpits, or groin area. Since all the symptoms are common to many other illnesses, it is essential to seek medical attention if any of the conditions persist for two weeks or more. Only a qualified physician can correctly diagnose if the symptoms are due to lymphoma or some other ailment.

Diagnosis

Like all cancers, lymphomas are best treated when found early. However, they are often difficult to diagnose. There are no screening tests available, and, since the symptoms are nonspecific, lymphomas are rarely recognized in their early stages. Detection often occurs by chance during a routine physical examination.

When the doctor suspects lymphoma, a thorough physical examination is performed and a complete medical history taken. Enlarged liver, spleen, or lymph nodes may suggest lymphomas. Blood tests will determine the cell counts and obtain information on how well the organs, such as the kidney and liver, are functioning.

A biopsy (microscopic tissue analysis) of the enlarged lymph node is the most definitive way to diagnose a lymphoma. Once the exact form of lymphoma is known, it is then staged to determine how aggressive it is, and how far it has spread. This information helps determine the appropriate treatment. The doctor may also perform a bone marrow biopsy. During this procedure, a cylindrical piece of bone—generally from the hip—and marrow fluid are removed. These samples are sent to the laboratory for examination. Biopsies may also be repeated during treatment to see how the lymphoma is responding to therapy.

Conventional imaging tests, such as x rays, computed tomography scans (CT scans), magnetic resonance imaging, and abdominal sonograms, are used to determine the extent of spread of the disease. *Lymphangiograms* are x rays of the lymphatic system. In this procedure, a special dye, called contrast medium, is injected into the lymphatic channels through a small incision (cut) made in each foot. The dye is injected slowly over a period of three to four hours. This dye clearly outlines the lymphatic system and allows it to stand out. Multiple x rays are then taken and any abnormality, if present, is revealed.

In rare cases a lumbar puncture (spinal tap) is performed to see if malignant cells are in the fluid that surrounds the brain. In this test, the physician inserts a needle into the epidural space at the base of the spine and collects a small amount of spinal fluid for microscopic examination.

Treatment

Non-Hodgkin's lymphoma is a life-threatening disease, and a correct diagnosis and appropriate treatment with surgery, chemotherapy, and/or radiation are critical to controlling the illness.

Acupuncture, **hypnotherapy**, and **guided imagery** may be useful tools in treating the pain of lymphomas. Acupuncture uses a series of thin needles placed in the skin at targeted locations known as *acupoints;* in theory, this harmonizes the energy flow within the body, and may help improve immune system function.

In guided imagery, patients create pleasant and soothing mental images that promote **relaxation** and improve their ability to cope with discomfort and pain. Another guided-imagery technique involves creating a mental picture of pain. Once the pain is visualized, patients can adjust the image to make it more pleasing, and thus more manageable.

Herbal remedies, such as Chinese herbs and mushroom extracts, may also lessen pain and promote relaxation and healing. Some herbs, such as **ginger**, are effective in the treatment of nausea caused by chemotherapy, and others, such as **astragalus**, help build the immune system. Check with an herbal practitioner before deciding on treatment. Depending on the preparation and the type of herb, the remedies may interfere with other prescribed medications. Naturally, any other activities that promote well-being, such as **exercise**, **stress** reduction, **meditation**, **yoga**, **t'ai chi**, and **qigong** will also benefit the patient. Proper **nutrition** and some specialized **diets** may help in recovering from lymphomas.

Allopathic treatment

Treatment options for lymphomas depend on the type of lymphoma and its stage. In most cases,

treatment consists of chemotherapy, radiation therapy, or a combination of the two.

Chemotherapy uses anticancer drugs to kill cancer cells. In non-Hodgkin's lymphomas, combination therapy, which uses several drugs, has been found more effective than single-drug use. Treatment usually lasts about six months, but in some cases may be as long as a year. The drugs are administered intravenously (through a vein) or given orally. If cancer cells have invaded the central nervous system, then chemotherapeutic drugs may be instilled, through a needle in the brain or back, into the fluid that surrounds the brain. This procedure is known as intrathecal chemotherapy.

Radiation therapy, where high-energy ionizing rays are directed at specific portions of the body, such as the upper chest, abdomen, pelvis, or neck, is often used for treatment of lymphomas. External radiation therapy, where the rays are directed from a source outside the body, is the most common mode of radiation treatment.

Bone marrow transplantation is being tested as a treatment option when lymphomas do not respond to conventional therapy, or when the patient has had a relapse or suffers from recurrent lymphomas. There are two ways of doing bone marrow transplantation. In a procedure called *allogeneic* bone marrow transplant, the donor's marrow must match that of the patient. The donor can be a twin (best match), sibling, or not related at all. High-dose chemotherapy or radiation therapy is given to eradicate the lymphoma. The donor marrow is then given to replace the marrow destroyed by the therapy. In *autologous* bone marrow transplantation some of the patient's own marrow is harvested, chemically purged, and frozen. High-dose chemotherapy and radiation therapy are administered. The marrow that was harvested, purged, and frozen is then thawed and put back into the patient's body to replace the destroyed marrow.

A new option for lymphoma patients is *peripheral stem cell transplantation*. In this treatment, stem cells (immature cells from which all blood cells develop), that normally circulate in the blood are collected, treated to remove cancer cells, then returned to the patient in a process called *leukapheresis*. Researchers are exploring whether these cells can be used to restore the normal function and development of blood cells, rather than using a bone marrow transplant.

Expected results

Like all cancers, the prognosis for lymphoma patients depends on the stage of the cancer, and the patient's age and general health. When all the different types and stages of lymphoma are considered together, only 50% of patients survive five years or more after initial diagnosis. This is because some types of lymphoma are more aggressive than other types. The survival rate among children is definitely better than among older people. About 90% of children diagnosed with early-stage disease survive five years or more, while only 60-70% of adults diagnosed with low-grade lymphomas survive for five years or more. The survival rate for children with the more advanced stages is about 75-85%, while among adults it is 40-60%.

Prevention

Although the risk of developing cancer can be reduced by making wise diet and lifestyle choices, there is currently no known way to prevent lymphomas, nor are there special tests that allow early detection. Paying prompt attention to the signs and symptoms of this disease, and seeing a doctor if the symptoms persist, are the best strategies for an early diagnosis, which affords the best chance for a cure.

Manganese

Description

The chemical element manganese (Mn) has the atomic mass 54.938 and atomic number 25. Manganese is not to be confused with the somewhat better known element **magnesium**. Manganese is a trace mineral used by some people to help prevent bone loss and alleviate symptoms associated with **premenstrual syndrome** (PMS). It may have a number of other beneficial effects as well. While most of the body's mineral content is composed of such macrominerals as **calcium**, magnesium, and **potassium**, certain trace minerals are also considered essential in very tiny amounts to maintain health and ensure proper functioning of the body. They usually act as coenzymes, working in conjunction with proteins to facilitate important chemical reactions. Even without taking manganese supplements, people with an average diet consume somewhere between 2 and 3 mg of the mineral through food and drink. While most authorities agree that manganese is a vital micronutrient, it is not known for certain if taking extra amounts can be helpful in treating **osteoporosis**, menstrual symptoms, or other problems.

Manganese, which is concentrated mainly in the liver, skeleton, pancreas, and brain, is considered important because it is used to make several key enzymes in the body and activates others. One of the enzymes made from manganese is superoxide dismutase (SOD), an antioxidant facilitator. **Antioxidants** help to protect cells from damage caused by free radicals, the destructive fragments of oxygen produced as a byproduct during normal metabolic processes. As these rogue particles travel through the body, they cause damage to cells and genes by stealing electrons from other molecules, a process referred to as oxidation. Manganese may also have some anticancer activity as well as a number of other important functions. It is believed to play a role in **cholesterol** and carbohydrate metabolism, thyroid function, blood sugar control, and the formation of bone, cartilage, and skin. While the effects of a manganese-free diet had not been thoroughly studied in people as of 2008, animal experiments suggest that a lack of manganese can be unhealthy. Manganese deficiency in animals appears to have an adverse effect on the growth of bone and cartilage, brain function, blood sugar control, and reproduction. One study of dietary supplementation with manganese and other micronutrients in Mexican infants found that children who received the supplements grew faster and taller than a control group given a placebo. The authors concluded that growth retardation in children in developing countries is linked to manganese and other micronutrient deficiencies in the diet, among other factors.

Manganese nodule. *(© blickwinkel / Alamy)*

General use

While considered necessary for general good health, manganese is also used for specific health concerns. Health food advocates have touted a number of possible benefits from using manganese supplements. Some conditions for which it has been recommended are:

- Alzheimer's disease
- anemia
- arthritis
- asthma
- cancers
- carpal tunnel syndrome
- chronic fatigue syndrome
- Chron's disease
- emphysema
- epilepsy
- Lyme's disease
- osteoporosis

As of 2008, research had produced only very limited evidence to support most of these claims. The strongest evidence appeared to involve the role of manganese in the development of strong bones. In a 2004 summary of scientific research on this point, the National Institute of Arthritis and Musculoskeletal and Skin Diseases concluded that manganese "helps certain enzymes and local regulators function properly" for optimal bone development and strength. Based on this conclusion, manganese is sometimes suggested as a possible treatment for osteoporosis, usually in combination with other trace minerals.

Recommended dietary allowance of manganese

Age	mg/day
Children 0-6 mos.	0.3 (AI)
Children 7-12 mos.	0.6 (AI)
Children 1-3 yrs.	1.2
Children 4-8 yrs.	1.5
Boys 9-13 yrs.	1.9
Girls 9-13 yrs.	1.6
Boys 14-18 yrs.	2.2
Girls 14-18 yrs.	1.6
Men ≥ 19 yrs.	2.3
Women ≥ 19 yrs.	1.8
Pregnant women	2.0
Breastfeeding women	2.6

Foods that contain manganese

	mg
Tea, green, 1 cup	1.58
Pineapple, raw, 1/2 cup	1.28
Pecans, 1 oz.	1.12
Cereal, raisin bran, 1/2 cup	.94
Brown rice, cooked, 1/2 cup	.88
Spinach, cooked, 1/2 cup	.84
Tea, black, 1 cup	.77
Almonds, 1 oz.	.74
Bread, whole wheat, 1 slice	.65
Peanuts, 1 oz.	.59
Sweet potato, mashed, 1/2 cup	.55
Beans, navy, cooked, 1/2 cup	.51
Beans, lima, cooked, 1/2 cup	.48
Beans, pinto, cooked, 1/2 cup	.48

AI = Adequate Intake
mg = milligram

(Illustration by GGS Information Services. Cengage Learning, Gale)

A single, very small study conducted in 1993 suggested that manganese and calcium may be a potent team in alleviating menstrual symptoms and premenstrual syndrome (PMS). Researchers from the Grand Forks Human **Nutrition** Research Center, which is affiliated with the U. S. Department of Agriculture, examined how calcium and manganese affect menstrual symptoms in women in good health. Ten women with normal menstrual cycles were studied for about 170 days. The women received 587 or 1,336 mg of calcium a day with 1.0 or 5.6 mg a day of manganese. They filled out a Menstrual Distress Questionnaire during each cycle and the results were analyzed. Getting more calcium improved mood, concentration, and behavior, and also reduced menstrual **pain** and the water retention associated with the premenstrual phase. The role of manganese appeared to be important. Despite getting higher amounts of calcium, women who received lower amounts of manganese experienced more moodiness and pain prior to their periods. This study suggested that getting adequate amounts of calcium and manganese can help to reduce the pain and other symptoms associated with menstrual periods. The results of this study had not been confirmed, however, as of 2008.

Manganese may also be important for people with other diseases. Those with **epilepsy**, diabetes, and Perthes disease tend to have low levels of the mineral, which has led to suggestions that manganese may help to prevent or treat these disorders. Almost no research exists to support these contentions, however. A handful of animal studies have indicated that manganese may play a role in controlling seizures and blood sugar levels. Manganese may also decrease the risk of colon **cancer** by raising levels of the SOD enzyme, which has antioxidant effects.

Some people take manganese to help treat muscle **strains** or **sprains**, as well as **rheumatoid arthritis**, though there was as of 2008 no convincing scientific evidence to support these uses. Theoretically, manganese may act as an anti-inflammatory agent by boosting the activity of SOD.

Preparations

The optimum daily dosage of manganese has not been established with certainty. While there is no recommended daily allowance (RDA) or daily value (DV) for manganese, the U.S. government has established what is called an adequate intake level (AI) for certain nutrients. In adults over the age of 19, the AI for manganese is 2.3 mg/day for men and 1.8 mg/day for women. Adequate intake for children and adolescents varies with age and sex. Daily dosage ranges from 0.6 mg/day for both sexes from ages 7 to 12 months; 1.2 mg/day from age 1 to 3 years; 1.5 mg/day for ages 4 to 8; 1.9 mg/day for boys and 1.6 mg/day for girls age 9 to 13; and 2.2 mg/day for males and 1.6 mg/day for females age 14 to 18.

Even without taking supplements, most women get about 2.2 mg a day of manganese through their **diets**, while men consume about 2.8 mg. Vegetarians and people who consume large amounts of wholegrain foods may get as much as 10 to 18 mg a day. Some authorities believe it is better for people to avoid manganese supplements altogether and increase their intake of foods known to contain significant amounts of the mineral. Manganese-rich foods and drinks

KEY TERMS

Calcium—A mineral necessary for strong bones and proper functioning of organs and muscles.

Osteoporosis—An age-related disease in which bones become fragile and prone to debilitating fractures.

Pancreas—An organ behind the stomach that produces digestive enzymes and hormones such as insulin.

include peanuts, pecans, pineapples and pineapple juice, shredded wheat and raisin bran cereals, and oatmeal. Other good sources are rice; sweet potatoes; spinach; whole wheat bread; and lima, pinto, and navy beans. Meat, poultry, fish, and dairy products are considered poor sources. Getting too much manganese through food and drink is not considered a significant risk because the mineral is present only in small amounts in plants and animals.

Some people take as much as 50 to 200 mg of manganese for several weeks to help treat muscle sprains or strains, but the safety and effectiveness of taking dosages this high were unknown in the late 2000s.

Precautions

Manganese is not known to be harmful when taken in recommended dosages. Extremely high intake of the mineral, however, has resulted in cases of idiopathic **Parkinson's disease**. Some studies indicate that high levels of manganese alter the blood-brain barrier, lowering the **iron** content of blood plasma while allowing the iron content of cerebrospinal fluid to rise. These cases of manganese-induced parkinsonism are usually limited to miners who inadvertently breathe manganese-rich dust or people who drink contaminated water from wells. People who eat a manganese-rich diet are not considered at risk for these types of side effects. In fact, most foods high in manganese are believed to contribute to good health.

Side effects

When taken in recommended dosages, manganese is not associated with any bothersome or significant side effects.

Interactions

Manganese interacts with certain drugs and dietary supplements. People who take oral contraceptives or antacids may require higher intake of manganese. More of the mineral may be needed in people who also take **phosphorus**, fiber, **copper**, iron, **zinc**, magnesium, or calcium.

Mangosteen

Description

The mangosteen is the tree *Garcinia mangostana L.*. The tree is native to tropical Asia and is thought to have been first grown as a crop in Thailand or Burma. In the 2000s, mangosteens are cultivated mainly in Thailand, Burma, Kampuchea (Cambodia), Vietnam, Malaysia, and a few places in India and the Philippines.

Mangosteens are not hardy trees, and compared to many other species, they have a short lifespan. To survive, they need a tropical continuously warm, humid climate. Young trees die at temperatures below 45°F (7.2°C), and older trees do not survive temperatures above 100°F (37.8°C) or below 40°F (4.4°C). Mangosteens also require substantial amounts of water. They do best in areas with an annual rainfall of 50 inches (130 cm) or more and can survive in swampy conditions where their roots remain constantly wet. In dry spells they need daily irrigation. As a result of their environmental requirements, mangosteens have not done well as a commercial crop when introduced in such places as Hawaii, California, Florida, tropical Africa, the islands of the Caribbean, and tropical Central America.

Mangosteens grow slowly. It can take a tree 10–20 years to reach its full height of 20–80 feet (6–25 m). Trees have an outside layer of dark brown, flaky bark and an inside layer of bark that contains bitter latex. They produce thick, largish dark green leaves in the shape of elongated ovals. The fruit of the mangosteen is the only part of the plant used for food or in healing. Under the best conditions, trees do not bear fruit until they are six years old, and often they reach the age of 10–12 years before fruiting. Mangosteen fruit is produced asexually. There is no fertilization involved, and all fruit that comes from a single tree is genetically identical. This lack of genetic variation may explain why the tree has such rigorous environmental requirements and has not been successful when introduced outside its native range.

Mangosteen fruit is uniformly dark purple, round, and slightly smaller than a tennis ball. It has a hard rind (pericarp) that can be as much as 1 inch (2.5 cm) thick. The rind makes up about two-thirds of the weight of the fruit. Inside the rind are four to eight segments of soft, moist, white fruit. The taste is both acidic and sweet. Mangosteen fruit is considered highly desirable in the areas of Asia where it grows. The fresh fruit does not keep or travel well. U.S. law forbids the importation of fresh mangosteens from Asia into the continental United States because of concerns about contamination by insect pests. Small amounts of fruit from other locations are very sporadically available in some gourmet grocery stores. Some canned mangosteen fruit may be available in the United States, most often in grocery stores specializing in products from Southeast Asia. Despite having a name that sounds like the mango fruit, mangosteens and mangos are not closely related. In the areas where it grows, the mangosteen is also called mangostan, mangouste, mangostao, manggis, mang cut, mesetor, mangis, semtah, and sementah.

General use

Mangosteen fruit has two general uses, as food and as an herbal remedy. As food, mangosteens are usually eaten raw. They can also be canned or made into jam, but processing changes their flavor. Raw fruits are high in both acids and sugars, giving them their distinctive sweet-tart flavor. A 3.5 ounce (100 g) portion of flesh provides about 60 calories and is a good source of **potassium**.

Traditionally the rind of the mangosteen fruit has been used medicinally in Southeast Asia for several thousand years as part of both Ayurvedic and **traditional Chinese medicine**. Mangosteen is used to treat dysentery, **diarrhea**, cystitis (bladder inflammation), and **gonorrhea** (a sexually transmitted disease). Made into a lotion or paste, it is applied to the skin to treat skin **wounds** and diseases such as **eczema**. In the Philippines, the bark is used to treat **fever**, and in Malaysia the root is used to regulate **menstruation**.

In 2002, a Utah company began a mangosteen craze in the United States when it promoted a mangosteen-containing drink called XanGo. XanGo is a pasteurized dietary supplement beverage that promoters claim provides the nutritional value and health benefits of mangosteens. The contents of the beverage are proprietary and are not revealed, but the company has claimed the drink provides benefits against specific diseases.

As a dietary supplement, the production of XanGo is regulate in the United States under the 1994 Dietary Supplement Health and Education Act (DSHEA). At the time the act was passed, legislators believed that because many dietary supplements come from natural sources such as plants and have been used for hundreds of years by practitioners of complementary and alternative medicine(CAM), these products did not need to be as rigorously regulated as prescription and over-the-counter drugs used in conventional medicine. DSHEA regulates dietary supplements such as XanGo in the same way that food is regulated. Like food manufacturers, manufacturers of dietary supplements do not have to prove that a supplement is either safe or effective before it can be sold to the public. Nevertheless, dietary supplement manufacturers cannot claim that their products treat or cure specific diseases. In September 2006, the United States Food and Drug Administration (FDA) sent a letter of warning to the manufacturers of XanGo to stop making claims that XanGo treated or prevented

specific diseases. The complete FDA letter can be found at the FDA Web site.

After the introduction of XanGo, dozens of health-promoting products claiming to contain mangosteen appeared on the market. These products claimed to treat bacterial **infections**, **fungal infections**, and skin infections; to promote wound healing; cure diarrhea; and prevent or cure **cancer** by killing cancer cells and acting as **antioxidants**. The basis for these claims was the presence of a group of compounds called xanthones that are found in the mangosteen fruit and the rind. Xanthone extracts have been shown in test tube and a few animal studies to have antibacterial, antifungal, and anti-inflammatory actions. In some laboratory experiments specific xanthones extracted from the mangosteen rind have killed certain cancer cells or slowed their growth. Extracts of the rind also have antioxidant properties.

Although xanthones, such as those found in mangosteen, seem to show potential health benefits in test-tube and animal studies, there is no evidence as of 2008 that these same effects will be carry over into humans, nor is there any indication of what dosage a human might need. There is also no evidence that any dietary supplements containing mangosteen offer any specific health benefits beyond their food value. Memorial Sloan-Kettering Cancer Center issued a statement in August 2007 saying that "There is no conclusive evidence regarding the efficacy and safety of mangosteen in treating cancer." This statement can be found at the center's Web site.

KEY TERMS

Antioxidant—A molecule that prevents oxidation. In the body antioxidants attach to other molecules called free radicals and prevent the free radicals from causing damage to cell walls, DNA, and other parts of the cell.

Ayurvedic medicine—A 5,000-year old system of holistic medicine developed on the Indian subcontinent. Ayurvedic medicine is based on the idea that illness results from a personal imbalance or lack of physical, spiritual, social, or mental harmony.

Decoction—A preparation made by boiling an herb, then straining the solid material out. The liquid is then taken internally as a drink.

Dietary supplement—A product, such as a vitamin, mineral, herb, amino acid, or enzyme, that is intended to be consumed in addition to an individual's diet with the expectation that it will improve health.

Traditional Chinese medicine (TCM)—An ancient system of medicine based on maintaining a balance in vital energy or qi that controls emotions, spiritual, and physical well being. Diseases and disorders result from imbalances in qi (the life force), and treatments such as massage, exercise, acupuncture, and nutritional and herbal therapy are designed to restore balance and harmony to the body.

Preparations

Traditionally, mangosteen fruits are dried and the rind is ground into a powder that is used medicinally. Mixed with water mangosteen rind can be taken internally for diarrhea, or it can be made into a paste and applied to the skin. A decoction of the bark is taken internally to treat fever, and a decoction of the root is used to treat menstrual disorders.

As a dietary supplement, mangosteen is available primarily as a health beverage. These beverages are heat-treated (pasteurized) and usually contain other ingredients besides mangosteen juice. They are not equivalent to fresh mangosteen. Dried mangosteen is also incorporated into some lotions for external use. The mangosteen content of dietary supplements is not standardized, and as of the early 2000s there was no agreed-upon standard dosage of mangosteen. Because of the difficulty in cultivating and obtaining mangosteen, mangosteen dietary supplements tend to be expensive.

Precautions

Individuals with diabetes should be careful when drinking mangosteen juice products because of their high sugar content.

Side effects

There are no known side effects of mangosteen. The fruit has been eaten for centuries and used medicinally without ill effects.

Interactions

Very little is known about how mangosteen products interact with pharmaceutical drugs or other herbal remedies. Nevertheless, because of their sugar content, mangosteen juice products may adversely affect individuals who take medication to control their blood sugar level. Mangosteen products also may interfere with the action of chemotherapy drugs.

Manuka honey

Description

Manuka honey is the natural product of honeybees who gather nectar from the blossoms of the manuka bush *(Leptospermum scoparium)*, also known as tea tree. The manuka bush is a tropical evergreen shrub in the Myrtle family native to New Zealand and southeast Australia, and grows wild and abundantly throughout New Zealand. The honey it yields is darker and richer in taste than clover honey and has been found to contain unique antibiotic properties.

General use

From ancient times honey has been a valued folk remedy throughout the world. Honey has long been used in the diet and as a potent means of fighting infection. Honey is an effective anti-inflammatory and antioxidant. The Aboriginal Maori people, indigenous to New Zealand, used honey produced from the manuka bush as a medicinal treatment for stomach ailments and **wounds**. Manuka is a word from the Mauri language, and in Mauri traditional medicine, manuka honey has a reputation as a powerful antiseptic and healing salve.

Honey has been widely available and in continual use for thousands of years. The ancient physicians Dioscorides and Aristotle distinguished from various types of honey to find those best suited for treatment of specific ailments. Honey is in common use in modern times as a home-remedy for sore throats and coughs, as a treatment for **burns** and other external injuries, and in the diet as an immune boosting, infection preventative.

All honey has healing properties due primarily to the action of glucose oxidase, an enzyme secreted by worker bees into the nectar. When the honey is exposed to oxygen and applied to a damp surface, such as when applied to a wound, a chemical interaction releases hydrogen peroxide, which acts as a disinfectant. In addition, Honey is acidic with a high sugar but low water content, a combination that limits growth of micro-organisms that become dehydrated and unable to survive in the presence of honey. Although most bacteria and other microorganisms cannot grow or reproduce in honey, honey varies widely in its antibacterial and antimicrobial properties. This bioactivity of honey depends on many factors including the type of plant pollinated, and its location. Manuka honey from New Zealand is considered one of the most medicinally potent of the hundreds of types of honey available.

The particular healing qualities of manuka honey, and its very broad spectrum of antibiotic action, has been brought to wider attention due to the work of Professor Peter Molan, a New Zealand biochemist whose extensive investigations at Waikato University and the Waikato Honey Research Unit have demonstrated what he has termed "a unique manuka factor, or UMF." This factor works independently of and synergistically with the glucose oxidase action present in all honey to impart a higher level of antibiotic action. According to Molan, writing in 2008 on the blog site *Apitherapy News* "The currently used rating system, UMF, measures the actual antibacterial activity of each batch of honey, tested against Staphylococcus aureus, the species of bacteria that is the most common cause of wound infections.". Manuka honey is stable, and its healing properties are not diminished when exposed to light, heat, or air, or when stored for long periods of time.

Anecdotal evidence and reports from clinical practice of the healing qualities and therapeutic effectiveness of manuka honey include its success in the treatment of:

- abscesses
- Burns
- Conjunctivitis
- Dyspepsia
- Gastgroenteritis
- Periodontal disease
- Persistent wounds
- Pressure sores
- Stomach ulcers
- Strep throat
- Virus

Research

German researchers have identified the natural compound Methylglyoxal (MGO) as responsible for manuka honey's unique health-giving properties. Manuka honey has a significantly higher level of antibacterial activity when compared to other honeys, according to the researchers at the Institute of Food Chemistry in Dresden, Germany, who tested samples of New Zealand manuka honey compared with other commercially available honey. They found up to 100-fold higher amounts of MGO in the New Zealand manuka honey, with amounts ranging from 38 to 761 mg/kg. The antibacterial activity of manuka honey was detected even when the honey was diluted to 15-30 percent.

In 2006, the journal *Palative Medicine* reported on the success of daily applications of topical manuka honey applied to ulcers in three hospice patients whose sores were contaminated with the so-called superbug, *methicillin-resistant Staphylococcus aureus* (MRSA) that has been a significant health problem in hospitals and schools. Research at the University of Dresden shows that a minimum of 100mg/kg methylglyoxal (MGO) must be present in the manuka honey to inhibit *Staphylococcus aureus* and other harmful bacteria.

Manuka honey has demonstrated effectiveness against the streptococci bacterium present in **strep throat infections**. It is also effective against fungi, protozoa and other infectious organisms. It is useful as a topical antimicrobial for both chronic and acute wounds and burns, and has been shown effective for athelete's foot infections and ringworm.

Manuka honey has been found to be about twice as effective as other honey against *Eschericihia coli* and *Staphylococcus aureus*, the most common causes of infected wounds.

When taken internally, manuka honey gives a boost to the immune system and helps combat infections. Its dietary use may promote the rehydration of the body and reduce the duration of **diarrhea**, **vomiting** and upset stomach. Relief from stomach ulcers is possible through manuka honey's action against the *Helicobacter pylori* microbe found in stomach ulcers. Manuka honey has been demonstrated as beneficial in treatment of **acne**, cracked skin, sore gums, **indigestion**, and eye infections.

The acid-producing bacteria *Streptococcus mitis, Streptococcus sobrinus*, and *Lactobacillus caseii* found in the mouth, have demonstrated sharp reduction of acid production in laboratory tests, when antibacterial honey is present. Results of a 2004 pilot study of the effects of manuka honey on periodontal diseases such as gingivitis and plaque indicated that there were statistically "highly significant reductions" in plaque scores and the percentage of bleeding sites in the manuka honey group. Researchers reported no significant changes in the control group, and concluded that manuaka honey could be of therapeutic value in treatment of gingivitis and periodontal disease.

Though research on manuka honey has been going forward in New Zealand and elsewhere for the past two decades, more research needs to be done with randomized controlled trials to further substantiate the qualitative differences between manuka honey and other honey, and to provide further scientific confirmation of the anecdotal and clincical practice reports of the benefits of manuka honey.

Most of the available scientific evidence substantiates the wound healing properties of honey. According to biochemist Peter C. Molan of the University of Waikato in New Zealand, honey, and in particular manuka honey, acts effectively as a wound dressing in the following ways:

- Honey provides a protective barrier preventing cross-infections
- Honey maintains a moist healing environment
- Honey produces and provides controlled delivery of hydrogen peroxide
- Honey provides a rapid healing effect
- Honey saturated dressings do not stick to wounds
- Honey reduces scarring
- Honey inhibits the odor in healing wounds
- Honey facilitates the uptake of serum into the wound
- Honey has beneficial anti-inflammatory and antioxidant properties

Preparations

Wound healing

In 2007, the U.S. Food and Drug Administration approved a honey-impregnated wound-dressing product for wound and burn care. The "medical device" Medihoney is the trademarked brand marketed by the New Zealand based natural health company Comvita. Comvita controls a large share of production of New Zealand's manuka honey.

Manuka honey dressings can also be prepared at home. Wound treatment with sterilized manuka honey should begin first by cleansing the wound with a saline solution. Apply about one tablespoon of Manuka Honey to a sterile gauze and apply to the wound, covering with a few more layers of gauze on top of the first layer. Secure with paper tape to keep the dressing in place. The dressing should be changed every 24 hours until the wound is completely healed.

Internal use

Manuka honey can be introduced into the diet as a nutritious food, with anti-inflammatory and immune boosting benefits. For stomach or peptic ulcers, a more concentrated manuaka honey product can be taken a spoon at a time on an empty stomach, or spread on a small piece of bread about twenty minutes prior to a meal. Honey can be administered in spoon size doses to soothe sore throats and cold symptoms. In clinical settings, manuka honey has been used effectively as an ointment-like dressing beneath the eyelid to treat **conjunctivitis**.

Manuka honey is available commercially in various concentrations of the trade-marked UMF or "Unique Manuka Factor," as described by New Zealand researcher Professor Peter Molan. The more concentrated product is called "active manuka honey," and is available commercially from distributers throughout the world. Strengths range from UMF 5, said to be equivalent to a 5% solution of a standard antiseptic, to UMF 20, equivalent to a 20% solution.

Precautions

Researchers warn that untreated honey may carry a risk of botulism, and if applied to a wound may introduce the rare but deadly infection. Commercially available manuka honey is sterilized by gamma irradiation to eliminate the possible risk of introducing infection. The irradiation does not bring about loss of any of manuka honey's antibacterial activity, researchers say. Increasingly, sterilized honey dressings are now among the first line of treatment for early wound infections, and no adverse reactions have been noted, even in diabetic patients. There may be a mild stinging or burning sensation with topical application of honey due to its acidic content.

Marijuana

Description

Marijuana (marihuana), *Cannabis sativa L.*, also known as Indian hemp, is a member of the Cannabaceae or hemp family, thought to have originated in the mountainous districts of India, north of the Himalayan mountains. The herb was referred to as "hempe" in A.D. 1000 and listed in a dictionary under that English name. Supporters of Pancho Villa (1878–1923) first called the mood-altering herb they smoked marijuana in 1895 in Sonora, Mexico. The term hashish is derived from the name for the Saracen soldiers, called *hashashins*, who ingested the highly potent cannabis resin before being sent out to assassinate enemies.

Two related species of cannabis are *C. ruderalis* and *C. indica*, a variety known as Indian hemp. Indian hemp grows to a height of about 4 ft (1.2 m) and the seed coats have a marbled appearance.

The species *C. sativa L.* has many variations, depending on the origin of the parent seed and the soil, temperature, and light conditions. These factors also affect the relative amounts of 9-tetrahydrocannabinol (THC) and cannabidiol, the chemicals present in varying amounts in cannabis that determine if the plant is primarily a fiber type or an intoxicant. Generally, the species grown at higher elevations and in hotter climates exude more resin and are more medicinally potent.

Marijuana is a somewhat weedy plant and may grow as high as 18 ft (5.4 m). The hairy leaves are arranged opposite one another on the erect and branching stem. Leaves are palmate and compound, deeply divided into five to seven narrow, toothed, and pointed leaflets. Male and female flowers are small and greenish in color and grow on separate plants. Male flowers grow in the leaf axils in elongated clusters. The female flowers grow in spike-like clusters. The resinous blossoms have five sepals and five petals. The male and female blossoms can be distinguished at maturity. The male plant matures first, shedding its pollen and dying after flowering. Female plants die after dropping the mature seeds. Marijuana produces an abundance of quickly germinating seeds. This hardy annual is wind pollinated and has escaped from cultivation to grow wild along roadsides, trails, stream banks, and in wayside places throughout the world. The plant matures within three to five months after the seed has been sown.

History

Marijuana has been cultivated for thousands of years. Cannabis was first described for its therapeutic use in the first known Chinese pharmacopoeia, the *Pen Ts'ao*. Cannabis was called a "superior" herb by the Emperor Shen-Nung (2737–2697 B.C.), who is believed to have authored the work. Cannabis was recommended as a treatment for many common ailments. Around that same period in Egypt, cannabis was used as a treatment for sore eyes. The herb was used in India in cultural and religious ceremonies and recorded in Sanskrit scriptural texts around 1400 B.C. Cannabis was considered a holy herb, and it was characterized as the "soother of grief," "the sky flyer," and "the poor man's heaven." Centuries later, around 700 B.C., the Assyrian people used the herb they called *Qunnabu* for incense. The ancient Greeks used cannabis as a remedy to treat inflammation, **earache**, and **edema**. Shortly after 500 B.C., the historian and geographer Herodotus recorded that the people known as Scythians used cannabis to produce fine linens. They called the herb *kannabis* and inhaled the "intoxicating vapor" that resulted when it was burned. By the year 100 B.C. the Chinese were using cannabis to make paper.

Cannabis use and cultivation migrated with the movement of traders and travelers, and knowledge of the herb's value spread throughout the Middle East,

Eastern Europe, and Africa. Around A.D. 100, Dioscorides, a surgeon in the Roman Legions under the Emperor Nero, named the herb *Cannabis sativa* and recorded numerous medicinal uses. In the second century, the Chinese physician Hoa-Tho used cannabis in surgical procedures, relying on its analgesic properties. In ancient India, around 600, Sanskrit writers recorded a recipe for "pills of gaiety," a combination of hemp and sugar. By 1150, Moslems were using cannabis fiber in Europe's first paper production. This use of cannabis as a durable and renewable source of paper fiber continued for the next 750 years.

By the 1300s, government and religious authorities, concerned about the psychoactive effects on citizens consuming the herb, were placing harsh restrictions on its use. The Emir Soudon Sheikhouni of Joneima outlawed cannabis use among the poor. He destroyed the crops and ordered that offenders' teeth be pulled out. In 1484, Pope Innocent VIII outlawed the use of hashish, a concentrated form of cannabis resin. Cannabis cultivation continued, however, because of its economic value. A little more than a century later, Queen Elizabeth I issued a decree in England commanding that landowners holding 60 acres (24 ha) or more must grow hemp or pay a fine. Commerce in hemp, which was primarily valued for the strength and versatility of its fibers, was profitable and thriving. Hemp ropes and sails crossed the sea to North America with the explorers. By 1621, the British were growing cannabis in Virginia where cultivation of hemp was mandatory. In 1776, the Declaration of Independence was drafted on hemp paper. As president, both George Washington and Thomas Jefferson advocated hemp as a valuable cash crop. Jefferson urged farmers to grow the crop in place of tobacco. By the 1850s, hemp had become the third largest agricultural crop grown in North America. The United States Census of that year recorded 8,327 hemp plantations, each with 2,000 or more acres in cultivation. But the invention of the cotton gin was already bringing many changes, and cotton was becoming a prime and profitable textile fiber. More change came with the introduction of the sulfite and chlorine processes used to turn trees into paper. Restrictions on the personal use of cannabis as a mood-altering, psychoactive herb, were soon to come.

Controversy

The 1856 edition of the *Encyclopedia Britannica*, in its lengthy entry on hemp, noted that the herb "produces inebriation and delirium of decidedly hilarious character, inducing violent laughter, jumping and dancing." This inebriating effect of marijuana use has fueled controversy and led to restrictions that have surrounded marijuana use throughout history in many cultures and regions of the world. Cannabis use has been criminalized in some parts of the United States since 1915. Utah was the first state to criminalize it, followed by California and Texas. By 1923, Louisiana, Nevada, Oregon, and Washington had legal restrictions on the herb. New York prohibited cannabis use in 1927.

In 1937, the federal government passed the Marijuana Tax Act, prohibiting the cultivation and farming of marijuana. This bill was introduced to Congress by then-secretary of the Treasury Andrew Mellon, who was also a banker for the DuPont Corporation. That same year, the DuPont Chemical Company filed a patent for nylon, plastics, and a new bleaching process for paper. The 1937 Marijuana Transfer Tax Bill prohibited industrial and medical use of marijuana and classified the flowering tops as a narcotic. Restrictions on the cultivation and use of cannabis continued. Marijuana was categorized as an illegal narcotic, in the company of LSD, heroin, cocaine, and morphine. Nevertheless, illegal use continued. The FBI 1966 publication, *Uniform Crime Reports for the United States* reported that 641,642 Americans were arrested for marijuana offenses that year, with as many as 85% of these arrests for simple possession, rather than cultivation or commerce.

In a reversal of the state-by-state progression of criminalizing marijuana that led to the 1937 Marijuana Transfer Tax Bill, there is a movement underway, state by state, to endorse the legalized use of medical marijuana. By 1992, 35 states in the United States had endorsed referenda for medical marijuana. A growing body of scientific research and many thousands of years of folk use supported the importance of medical marijuana in treatment of a variety of illnesses, and the economic value of hemp in the textile, paper, and cordage industries has a long history.

Controversy and misinformation persists around this relatively safe and non-toxic herb. The World Health Organization, in a 1998 study, stated that the risks from cannabis use were unlikely to seriously compare to the public health risks of the legal drugs, alcohol and tobacco. Despite thousands of years of human marijuana use, not one death has been directly attributed to cannabis. The chief legitimate concern is the effect of **smoking** on the lungs. Cannabis smoke carries even more tars and other particulate matter than tobacco smoke, but the amount smoked is much less, especially in medical use.

General use

Every part of the cannabis plant, including buds, leaves, seeds, and root, has been used throughout the long history of this controversial herb. Despite persistent legal restrictions and criminal penalties for illicit use, marijuana continues to be widely used in the United States and throughout the world, both for its mood-altering properties and its proven medicinal applications. The conflicting opinions on the safety and effectiveness of cannabis in a climate of prohibition make any discussion of its beneficial uses politically charged.
